E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 121
Emergency radiology I

A-001 08:30
A. Acute aortic syndrome
H. Alkadhi; *Zurich/CH (hatem.alkadhi@usz.ch)*

Computed tomography (CT) imaging - often preceded by conventional radiography - represents the major imaging modality for the diagnosis of acute aortic syndromes. This lecture will review the various underlying diseases of acute aortic syndrome, demonstrate typical imaging features enabling the diagnosis and discuss management options depending on the type, extent, and location of the disease. Clinical examples will be shown.
Learning Objectives:
1. To understand the different types of acute aortic syndrome.
2. To learn about imaging findings and management options.

A-002 09:15
B. Abdominal trauma
R. Basilico; *Chieti/IT (rbasilic@unich.it)*

Abdominal traumas can be classified into two categories: penetrating and blunt traumas. Abdominal injuries are more often observed in the setting of polytrauma; in fact, they are present in about 10% of patients admitted to level 1 trauma. However, only 11% of patients with abdominal trauma require laparotomy when a correct imaging-guide approach is performed. In fact, because the management of trauma patients mainly depends on the mechanism and severity of the trauma, it is crucial to choose the correct imaging modality and/or technique when evaluating a trauma patient on the basis of these two parameters. For example, an ultrasound examination, possibly integrated by contrast-enhanced ultrasonography, may be adequate to image a minor blunt abdominal trauma. This modality, however, is not appropriate when evaluating a severe blunt or penetrating abdominal trauma or even a polytrauma patient with a minor mechanism of injury. Multidetector CT is actually the modality of choice for evaluating severe trauma patients, accompanied by an appropriate CT protocol to image these patients so as to avoid missed injuries and to correctly detect abdominal solid organ injuries, mesenteric and intestinal injuries and abdominal vascular traumatic lesions. Moreover, due to the fact that during the past decades there has been a major change from operative to increasingly conservative management of abdominal traumatic injuries, even in patients with higher grades of injuries or those with older age, imaging features together with hemodynamic considerations play an essential role in the treatment choice: surgery, conservative management, and endovascular treatment.
Learning Objectives:
1. To identify the signs of trauma.
2. To provide an indication of their clinical significance.

08:30 - 10:00 **Room B**

GI Tract

RC 101
GI bleeding: how to solve the problem?

A-003 08:30
Chairperson's introduction
S. Wirth; *Munich/DE (stefan.wirth@med.uni-muenchen.de)*

Sometimes, things may become more difficult and easier at the same time. On one hand advances in imaging allow for very precise and also fast diagnoses in a continuous increasing number of cases. Consequently, even the bleeding of the GI-tract comes even more into radiological play. On the other hand, radiologists have to be more and more aware of clinical entities, pathological patterns, and interdisciplinary networks to quickly and precisely provide our clinical partners with the information they need. Besides that, more and more cases can be managed by minimal-invasive interventional procedures, i.e., by radiologists themselves.

Session Objectives:
1. To define acute, overt and occult GI bleeding.
2. To learn about different imaging modalities that can be utilised in the work-up of GI bleeding.
3. To define the role of the interventional radiologist in the management of the GI bleeding.

A-004 08:35
A. Acute GI bleeding
G.H. Mostbeck; *Vienna/AT (gerhard.mostbeck@wienkav.at)*

Acute gastrointestinal (GI) bleeding is a common medical problem associated with high morbidity and mortality. The clinical presentation of acute GI bleeding varies with the location of the bleeding site, the cause, the amount of blood loss, and the presence of comorbidities. Anatomically, the ligament of Treitz is the border between upper (mouth to Treitz) and lower (Treitz to anus) GI bleeding. However, it is not always possible to differentiate between upper and lower GI bleeding clinically, despite the fact that clinical presentation is different, as is the etiology. In decreasing order, erosions and ulcer, variceal bleeding, Mallory-Weiss tears, vascular lesions, and neoplasms are responsible for upper GI bleeding. In contrast, lower GI bleeding occurs in the elder population, with diverticular disease, angiodysplasia, neoplasms, colitis and benign anorectal lesions being the major etiologies. The main diagnostic objective is the identification of the etiology and site of bleeding. Endoscopy is the initial diagnostic step in upper GI bleeding, but limited in lower GI bleeding due to difficulties in colonic cleansing in an emergency situation. Accordingly, CT is the imaging method of choice [technique: no positive oral contrast, high dose /iodine content/flow of contrast material (e.g.,100-150 ml, 350 mg/ml, 4-6 ml/sec), plain, arterial and parenchymal phases, dual-energy CT with iodine maps if available, multiplanar reformation, high anatomic resolution]. We search for high-attenuation (> 80HU) luminal or wall lesions not seen on unenhanced CT data. Detection rates vary, and an amount of bleeding > 0.35-0.5 ml/min is required. As bleeding might be intermittent, CT should be performed when active bleeding is present.
Learning Objectives:
1. To learn about the common causes of the acute upper and lower GI bleeding.
2. To understand the rationale for different investigative pathways depending on the likely site of bleeding.
3. To appreciate how best to optimise imaging protocols to identify the site and cause of bleeding, and assist with treatment planning.

A-005 08:58
B. Occult and overt GI bleeding: the role of radiology
J. Brito; *Portimão/PT (jbmbrito@gmail.com)*

The term obscure gastrointestinal bleeding (OGIB) was traditionally used to include patients with gastrointestinal bleeding who underwent normal upper and lower endoscopic examinations in addition to a small bowel series that did not reveal a source of bleeding. This definition was a sign of the difficulties experienced in small bowel exploration in the past. Given to recent advances in small bowel investigative methods, including endoscopic (video capsule endoscopy, deep enteroscopy) and radiological (CT and MR enterography, CT angiography) techniques, the cause of bleeding is no longer obscure and can now be reached in majority of the patients. For this reason, the term OGIB has been reclassified as “small bowel bleeding”, which corresponds to ~5-10% of all patients presenting with gastrointestinal bleeding. “OGIB” is now reserved for patients in whom a source of bleeding cannot be identified anywhere in the gastrointestinal tract after a comprehensive investigation. Small bowel bleeding can be overt, if patient presents with melena or hematochezia, or occult for patients presenting with iron-deficiency anaemia. Causes of small bowel bleeding are varied and the likelihood to be due to a vascular, inflammatory or mass lesion is related to the patient’s age. Algorithms for investigation of suspected small bowel bleeding include endoscopic and radiological methods, frequently with a complementary role, indicating that an adequate interaction is required among the elements of a multidisciplinary team.
Learning Objectives:
1. To learn about the differences between obscure, occult and overt GI bleeding, and the most common causes of each.
2. To understand when imaging is indicated which tests to perform, and the most important diagnoses to look for.
3. To appreciate the interaction between endoscopic and radiologic investigations in managing patients with obscure GI bleeding.

A-006 09:21

C. When is the interventional radiologist needed?

D.K. Tsetis; *Iraklion, Crete/GR (tsetis@med.uoc.gr)*

Acute significant gastrointestinal bleeding is generally defined as a bleeding requiring transfusion of at least 4 units of blood within 24 hours or showing signs of hemodynamic instability (hypotension, tachycardia, signs of hypovolemic shock). Most cases are resolved endoscopically, pharmacologically, or by correction of coagulation parameters. Due to its minimally invasive nature, the endovascular solution is currently in most cases, after the previous methods fail, considered the method of choice. The most often used access to undergo embolisation is percutaneous access via common femoral or brachial artery. After reaching the appropriate visceral artery with a diagnostic 4 or 5F catheter, and verification of the source of bleeding, microcatheres are introduced coaxially. The most commonly used embolic materials are microcoils , PVA microspheres and gelatin foam. In the case of more massive bleeding, using of tissue glue (Histoacryl, etc.) may be considered . Upper gastrointestinal tract is characterised by a rich network of collateral supply with lower risk of ischemia. In the risk of rebleeding via collaterals, it is necessary to perform embolisation proximally and distally from the site of bleeding (so-called sandwich method). In the lower gastrointestinal tract, and in particular in the colon, due to the higher portion of terminal branches, ischemia risk is higher and embolisation should be as selective as possible.

Learning Objectives:

1. To learn about the role of interventional radiology in the management of acute and chronic GI bleeding.
2. To learn about the variety of techniques available to the interventional radiologist to evaluate obscure GI bleeding and control acute GI bleeding.
3. To understand when interventional radiology is clearly indicated, when it should be considered, and when it should be avoided if possible.

09:44

Panel discussion: Guidelines for management of GI bleeding and real life: why are they different?

08:30 - 10:00 **Room C**

Chest

RC 104

When and how to use perfusion imaging in pulmonary vascular and airway disease?

Moderator:
C.J. Herold; Vienna/AT

A-007 08:30

A. CT

M. Rémy-Jardin; *Lille/FR (martine.remy@chru-lille.fr)*

Since the introduction of dual-energy CT (DECT) in clinical practice, great interest has been directed toward analysis of the distribution of iodine in the most distal parts of the pulmonary circulation, often referred to as perfusion imaging. Initially only available with dual-source CT, dual-energy CT has become accessible to single-source CT, with the introduction of rapid kV switching and more recently, dual-layer (sandwich) detectors. Regardless of the difference in the technological approach, perfusion images are generated from the same data set as that used for morphological evaluation, offering the possibility of a simultaneous approach of structure and function in respiratory patients. This combined information provided with CT is a major advantage over scintigraphy and MRI, not only in the field of primary disorders of the pulmonary circulation, like acute pulmonary embolism, but also in the context of bronchopulmonary diseases where perfusion alterations can be interpreted with precise knowledge of the underlying morphologic changes. More recently, this complementarity has also been extended in the field of chronic thromboembolic disease and pulmonary hypertension while a growing interest is reported in oncologic indications. The purpose of this presentation is to make radiologists familiar with the use of CT lung perfusion in clinical practice.

Learning Objectives:

1. To learn about the creation of CT perfusion images.
2. To understand the complementarity between morphological and functional information.
3. To learn the various causes of perfusion defects.

Author Disclosure:

M. Rémy-Jardin: Research/Grant Support; Resaerch grant support from Siemens Heathcare.

A-008 09:00

B. MRI

M.O. Wielpütz; *Heidelberg/DE (wielpuetz@uni-heidelberg.de)*

Among functional lung magnetic resonance imaging (MRI) techniques, dynamic contrast-enhanced (4D) perfusion MRI is probably the most robust and widely used method that has entered the clinical arena of routine patient management. Because it delivers temporally resolved datasets, perfusion parameters such as time-to-peak or pulmonary blood flow may be directly quantified by dedicated post-processing. In pulmonary vascular disease it may help to identify arterio-venous-malformations, pulmonary shunts or anomalous venous return. In combination with contrast-enhanced and non-constrast enhanced lung MR angiography, 4D perfusion MRI is now considered an alternative for computed tomography angiography for pulmonary embolism. In case of airways disease such as cystic fibrosis or chronic obstructive pulmonary disease, 4D perfusion imaging exploits the physiological mechanism of hypoxic pulmonary vasoconstriction. This effects a downregulation of perfusion to functional lung units with reduced ventilation, i.e. airway obstruction. Thus, 4D perfusion MRI can directly visualize functional lung impairment associated with airways disease, even when small airways are affected that cannot be otherwise captured with structural imaging. The lecture will summarise technical aspects of performing 4D perfusion imaging with clinical MRI scanners, discuss the most important routine indications incl. implementation into routine workflow, and discuss most relevant imaging findings in vascular and airways disease. Further, future developments and non-contrast-dependent techniques will be reviewed.

Learning Objectives:

1. To become familiar with the technical aspects of MRI perfusion.
2. To learn key imaging features.
3. To discuss the most relevant clinical indications.

Author Disclosure:

M.O. Wielpütz: Advisory Board; Boehringer Ingelheim. Investigator; Boehringer Ingelheim, Vertex.

A-009 09:30

C. Nuclear medicine and hybrid imaging

E.J.R. van Beek; *Edinburgh/UK (edwin-vanbeek@ed.ac.uk)*

Initial management of pulmonary vascular and lung diseases has consisted of lung scintigraphy, enabling the study of both lung perfusion and ventilation. The advent of CT and CTPA has replaced many of the acute indications. Nevertheless, there remains an important role for the use of both lung scintigraphy and the combined use of new hybrid systems (SPECT/CT) to study these disease and facilitate in their management. This presentation will evaluate the historical and current state-of-the-art capabilities of lung scintigraphy to study lung perfusion and ventilation. It will also evaluate the potential best applications in the current diagnostic management, as well as demonstrate some of the pitfalls of this technology.

Learning Objectives:

1. To learn about the specificities of perfusion scintigraphy.
2. To understand the advantages of hybrid imaging.
3. To appreciate potential pitfalls of nuclear medicine techniques.

Author Disclosure:

E.J.R. van Beek: Advisory Board; Aidence BV. Equipment Support Recipient; Siemens Healthineers. Founder; QCTIS Ltd. Owner; QCTIS Ltd.

08:30 - 10:00 **Room O**

Paediatric

RC 112

Paediatric musculoskeletal imaging

Moderator:
A.C. Offiah; Sheffield/UK

A-010 08:30

A. How to distinguish normal variants from pathology on musculoskeletal MRI in children

D. Avenarius; *Tromsø/NO (Derk.Avenarius@unn.no)*

Normal variations of development of the skeleton are well documented when it comes to radiographs; with the introduction of MRI there are many more features to consider that are often less known. Normal variations are common and these can simulate disease. It is important for radiologist to be aware of this and an overview of cases will be presented. Protocols for MRI imaging in paediatric MSK imaging will be discussed.

Learning Objectives:
1. To discuss MRI protocols for MSK-imaging in children.
2. To give an overview of normal development and variations in MR anatomy and signal patterns.
3. To provide an understanding of features indicative of pathology.

A-011 09:00

B. MRI of the temporomandibular joints: findings that can mimic arthritis

T. von Kalle; *Stuttgart/DE (t.vonkalle@klinikum-stuttgart.de)*

Arthritis of the temporomandibular joint (TMJ) is common in children and adolescents with juvenile idiopathic arthritis (JIA). Early treatment is warranted to prevent severe growth disturbances and joint deformities. As TMJ arthritis is often clinically silent, MRI with contrast-enhancement has been considered to be the most reliable method to assess signs of inflammation. To reliably guide therapeutic decisions and monitor outcomes, it would be of utmost importance to clearly define the MR characteristics of a normal TMJ as a basis for the assessment of minor pathologies. However, similar to other small joints in children, we are just beginning to understand its developmental, physiological and anatomical characteristics as well as its reaction to inflammatory diseases and their treatment. Recent studies on normal TMJ in children have revealed age dependent changes in shape and angulation of the mandibular condyle as well as typical time-intensity curves of contrast-enhancement in the soft joint tissue and the condyle. To date, the differentiation between normal synovial findings and mild signs of synovitis remains challenging. This lecture presents typical MR images of normal and inflamed TMJs in children and adolescents, including age dependent anatomical variations. It discusses the available data on possible cut-offs between normality and pathology, the impact of the temporal dynamics of contrast-enhancement, and presents findings that can mimic arthritis. It summarizes the minimum requirements of image quality and spatial resolution, the best image orientation, as well as the advantages of fat suppression and subtraction analysis in contrast-enhanced imaging.

Learning Objectives:
1. To discuss MRI protocols for imaging of the temporomandibular joints (TMJ).
2. To give an overview of MR imaging finding in arthritis of the TMJ.
3. To highlight the major differential diagnoses of TMJ arthritis and its MR imaging characteristics.

A-012 09:30

C. Skeletal trauma in children

I. Barber; *Esplugues de Llobregat/ES (ibarber@hsjdbcn.org)*

Musculoskeletal injuries are common in children. They account for 15-20% of admissions to the ED. Children have an immature skeleton with unique biomechanical features and a stronger, thicker and richly vascularized periosteum. Paediatric fractures may present with unique patterns including plastic deformation, buckled fractures, and greenstick fractures. Fractures in children include the ones involving the physis (epiphysiolysis) and we will review their classification and prognosis after treatment. We will review these injuries making special remarks on the imaging techniques used for their correct diagnosis and treatment planning.

Learning Objectives:
1. To become familiar with the types of injuries seen in children.
2. To understand the basic mechanisms.
3. To learn about the diagnostic imaging approach.

08:30 - 10:00 **Room N**

Head and Neck

RC 108

Differential diagnoses you don't want to miss

Moderator:
M.R. Eriksen; Stavanger/NO

A-013 08:30

A. Differential diagnoses of orbital masses

V. Chong; *Singapore/SG (vincent_chong@nuhs.edu.sg)*

The approach to orbital mass analysis follows two basic rules. The first rule emphasizes the general fact that diseases arise from pre-existing tissues or structures unique to different spaces in the orbit. The second rule highlights exceptions to the general rule. For example, metastatic or other systemic diseases may involve the orbit, while trans-spatial pathological processes such as infiltrative lesions may affect multiple compartments simultaneously or metachronously. The orbit can be divided (by the muscle cone) into an intra-conal and an extra-conal compartment. Structures in the intra-conal compartment include the optic nerve/sheath complex and the surrounding fibro-fatty tissues, small vessels and small nerve branches. The contents of the extra-conal space include the lacrimal gland, cranial nerves (V1 and V2) and the periosteum of the orbit. Hence, knowledge of the applied anatomy of the orbit with a working knowledge of commonly seen diseases is a prerequisite for generating lists of differential diagnoses. The analysis of orbital masses should always be carried out in the clinical context of the patient. Tentative as well as definitive diagnosis can often be made with reference to the clinical information. For example, a lesion with unusual morphology or location can be tentatively diagnosed as metastatic disease in the presence of a history of malignancy elsewhere. In conclusion, the integration of knowledge of orbital anatomy, pathology and clinical information provides the basis of sound radiological differential diagnoses for further patient management.

Learning Objectives:
1. To become familiar with the anatomy of the orbit.
2. To learn which imaging technique to use.
3. To understand the typical imaging appearance of orbital masses.

A-014 09:00

B. Differential diagnoses of the jaw masses

C. Czerny; *Vienna/AT (christian.czerny@meduniwien.ac.at)*

Cystic and tumorous pathologies of the jaws can be imaged with cone-beam CT, CT and MRI. These pathologies include, e.g. in most cases inflammation or tumours. PET-CT or PET-MR may also be used. CT may be used without or with the i.v. application of iodinated contrast material dependent on the pathology. The images can be documented in soft-tissue- and/or bone-window-level setting. Imaging planes are usually axial, coronal or sagittal depending on the pathology. MRI has the advantage of higher soft tissue contrast and the possibility of using different sequences. Depending on the pathology, e.g. fat-suppressed T2-weighted, diffusion-weighted, T1-weighted sequences before and after the i.v. use of gadolinium and T1-weighted contrast-enhanced sequences with fat suppression are used. The imaging planes may be axial, coronal or sagittal. In this refresher course, the normal anatomy of the jaw, variants mimicking osteolytic or osteoblastic lesions, and cystic and tumorous pathologies of the jaws will be shown, and the imaging characteristics will be explained.

Learning Objectives:
1. To become familiar with the anatomy of the jaw.
2. To learn which imaging technique to use.
3. To understand the typical imaging appearance of jaw lesions.

A-015 09:30

C. Differential diagnoses of soft tissue masses

D. Farina; *Brescia/IT (nappaje@yahoo.it)*

Soft tissue masses of the supra and infrahyoid neck are a rather heterogeneous group of tumours, classified by WHO in nine categories, based on their histologic differentiation: adipocytic, fibroblastic or myofibroblastic, fibrohistiocytic, smooth muscle, skeletal muscle, vascular, pericytic, and chondro-osseous tumours, and tumours of uncertain differentiation. Based on their clinical behavior and history such tumours may be described as benign, malignant or intermediate, the latter further subclassified as locally invasive or metastatising at distant sites. US is generally the first imaging step in infrahyoid neck lesions; MDCT or MRI are mandatory in suprahyoid masses, but are also needed to better define the deep extent and anatomic relationships of infrahyoid tumours. In many cases, imaging findings are overlapping and insufficient for tumour characterisation; nonetheless, some specific clues may orient the differential diagnosis. Site of origin of the lesion is probably the first brick in the wall; therefore, knowledge of the space-based neck anatomy is essential prerequisite. Patient's age, size and number of lesions, presence and pattern of calcifications are useful additional details. Some specific density or signal intensity patterns may cut the list of differentials, whereas the potential role of the additional information provided by DWI-MRI or dual-energy CT is far from being fully elucidated. However, it is clearly assumed that imaging diagnosis does not replace pathologic assessment, which in a significant number of cases can be accurately obtained with FNA.

Learning Objectives:
1. To become familiar with the anatomy.
2. To learn which imaging technique to use.
3. To understand the typical imaging appearance of soft tissue masses.

08:30 - 10:00 **Room E1**

Special Focus Session

SF 1

Hepatocellular carcinoma: diagnosis, staging and current guidelines

A-016 08:30

Chairperson's introduction

G. Brancatelli; *Palermo/IT (gbranca@yahoo.com)*

Hepatocellular carcinoma (HCC) is the second leading cause of cancer death worldwide. In this session, the rationale behind the need for screening for HCC will be discussed, and the geographic differences in screening programs will be highlighted. The benefits of using LI-RADS terminology, interpretation, and reporting for both clinical care and research will be presented. Typical and atypical appearance of HCC will be shown, along with common mimickers and useful tips of differentiation of focal hepatic nodules in cirrhotic liver. Finally, the speakers will be exposed to challenging cases in the form of unknown, will share their reasoning with each other, and engage in discussions with the chairperson and the audience.

Session Objectives:

1. To become familiar with the international guidelines for HCC screening.
2. To understand why a standardised report facilitates patient management.
3. To learn about the key concepts of diagnosis of typical and atypical HCC with CT and MRI.

Author Disclosure:

G. Brancatelli: Speaker; Bayer, Guerbet.

A-017 08:35

Screening for HCC, American, Asian and European guidelines: why are they different?

V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Hepatocellular carcinoma (HCC) is the most common type of liver cancer, accounting for 80-90% of all cases of liver cancer. It is the fifth most common cancer and the third leading cause of cancer-related deaths around the world. As HCC occurs in 90% of the cases in patients with chronic liver disease, screening is indicated in those patients having compensated cirrhosis. Several guidelines have been implemented to help the practitioner to manage the patients during the screening, when a nodule is detected and to decide the optimal treatment in patients with HCC. Among the HCC guidelines which are the most used: AASLD, EASL, Japanese, Korean, and Asia-Pacific ones, there are common features. All agree : (i) on the noninvasive diagnosis of HCC using contrast-enhanced CT or MR imaging with two hallmarks: hypervascularisation on arterial-phase and wash-out on portal and/or delayed phase in lesions larger than one centimeter; (ii) on the role of liver biopsy when diagnosis cannot be achieved with imaging. Yet they differ in many other issues: stratification according to lesion size, first-line imaging modality, role of hepatobiliary MR contrast agents, and role of contrast-enhanced ultrasound. These differences are explained by the different prevalence of HCC worldwide and the different goals of diagnostic performance (high specificity or high sensitivity).

Learning Objectives:

1. To be aware of the different guidelines in HCC screening.
2. To know the most striking differences.
3. To understand the consequences in patient management.

A-018 08:58

Diagnosis of HCC, LI-RADS 2017: why we need it?

C.B. Sirlin; *San Diego, CA/US (csirlin@ucsd.edu)*

LI-RADS is a comprehensive system for imaging HCC in adults with cirrhosis or other risk factors for HCC. It provides standardized terminology with precise definitions and illustrations for screening and surveillance using US, diagnosis and staging using CT, MRI, and CEUS, and treatment response assessment using CT and MRI. It addresses the entire spectrum of lesions and pseudo lesions encountered in the cirrhotic liver as well as the full range of malignant neoplasms associated with chronic liver disease. This lecture will review LI-RADS terminology, interpretation, and reporting and explain why standardization is needed for clinical care, research, and education.

Learning Objectives:

1. To understand the need for standardised terminology, interpretation, and reporting for clinical care.
2. To understand the need for standardised terminology, interpretation, and reporting for research.
3. To become familiar with LI-RADS terminology, interpretation, and reporting.

Author Disclosure:

C.B. Sirlin: Advisory Board; Bayer. Grant Recipient; Bayer, GE, Siemens, Philips, ACR.

A-019 09:21

Atypical appearance of HCC and mimics: how to solve the challenging cases

J.M. Lee; *Seoul/KR (jmsh@snu.ac.kr)*

Hepatocellular carcinoma (HCC) poses a burden on global health. As HCC typically has a poor prognosis with a 5-year survival rate of only 28.6%, it is of paramount importance to achieve the earliest possible diagnosis of HCC and to recommend the most up-to-date optimal treatment strategy in order to increase the survival rate of patients who develop this disease. HCC is commonly diagnosed using dynamic CT and/or dynamic MRI without histological confirmation, on the basis of a characteristic arterial enhancement and portal venous or delayed phase washout. Indeed, the noninvasive diagnosis of HCC in high-risk patients by typical imaging findings alone is widely adopted in major practice guidelines for HCC. HCC usually presents with typical imaging characteristics but at times can present with a wide spectrum of atypical appearances. Familiarity with unusual presentations and their imaging findings is critical to ensuring prompt, accurate diagnosis and treatment. Moreover, while imaging techniques have markedly improved in detecting small liver lesions, they often detect incidental benign liver lesions and non-hepatocellular malignancy that can be misdiagnosed as HCC. The common mimickers of HCC in the cirrhotic liver include nontumorous arterioportal shunts, rapidly enhancing hemangiomas, intrahepatic mass-forming type cholangiocarcinoma (CC), angiomyolipomas, focal inflammatory liver lesions and focal nodular hyperplasia-like nodules. Among them, it is important to recognize the suggestive imaging findings for intrahepatic CC as the management of CC is largely different from that of HCC. Recognition of the typical imaging findings of common HCC mimickers can reduce false-positive HCC diagnosis.

Learning Objectives:

1. To demonstrate imaging spectrum of hepatocellular carcinoma including typical and atypical appearance.
2. To illustrate common mimickers of hepatocellular carcinoma in cirrhotic liver.
3. To provide useful tips of differentiation of focal hepatic nodules in cirrhotic liver.

Panel discussion: At the plateau of the learning curve: how do experts reason?

08:30 - 10:00 **Room E2**

Neuro

RC 111

The degenerative cervical spine

Moderator:
A. Cianfoni; Lugano/CH

A-020 08:30

A. Degenerative uncovertebral and facet disease
J. Van Goethem; *Antwerp/BE (johan.vangoethem@uantwerpen.be)*

Neck pain is a common problem with many possible causes. The facet joint and the uncovertebral joint are frequently involved in degenerative cervical spine disease. It is important to learn how to differentiate normal and asymptomatic changes that occur with age from abnormal findings that are causing neck and/or arm pain. I will demonstrate the use of plain film, CT, SPECT, and MRI in diagnosing an offending uncovertebral or facet joint. Many of these offending joints can be targeted specifically, leading to easy and fast pain reduction in many patients with aspecific neck pain.
Learning Objectives:
1. To learn about the physiological and pathophysiological degeneration of the cervical spine.
2. To understand the role of imaging in the diagnosis and clinical decision making in the degenerative cervical spine.
3. To appreciate the clinical relevance of imaging findings in the degenerative cervical spine.

A-021 09:00

B. Cervical spinal stenosis and cervical spondylotic myelopathy
A.S. Gersing; *Munich/DE (alexandra.gersing@ucsf.edu)*

Degenerative changes of the cervical spine occur during the aging process or are caused by segmental mechanical overload. Among the degenerative processes leading to spinal stenosis are marginal osteophytes of the vertebral bodies and joints, intervertebral disc degeneration with herniation and hypertrophy of the ligaments. CT, CT-myelography, and MR imaging are essential in assessing the extent and severity of spinal canal stenosis, especially with a view to guiding conservative or surgical treatment. Next to the assessment of the osseous and soft tissue structures of the vertebral column as well as spinal canal stenoses, T2-weighted MRI imaging is crucial for the assessment of signal changes within the myelon. The differentiation between signs of an acute myelopathy and myelomalacia, caused by an irreversible damage of the spinal cord, is essential to select the appropriate treatment option. Moreover, patients present with a broad spectrum of clinical symptoms ranging from neck pain to spastic paraparesis; therefore, it is crucial to put imaging findings in context with clinical symptoms to assess the potential benefit of different conservative and surgical treatment options.
Learning Objectives:
1. To learn about the pathophysiology and imaging findings in spinal stenosis and cervical spondylotic myelopathy.
2. To understand the relation between imaging findings and clinical presentation.
3. To appreciate the importance of imaging findings and the clinical presentation with respect to possible treatment options.

A-022 09:30

C. The postoperative cervical spine
I. Herrera; *Madrid/ES (isabel.herherrera@gmail.com)*

Cervical spine surgery is common, so it is important for radiologists to know what the normal imaging findings are to avoid pitfalls. This is not easy as there are substantial imaging overlaps between normal early postoperative findings and surgical complications. Because there are a vast variety of surgical approaches and hardware that can be applied to the spine, it is a challenge for the radiologists to know their anatomical implications and possible complications. The use of a particular imaging technique is dictated by multiple factors including the underlying pathology, surgical approach, device or instrumentation used, and suspected complications. The postoperative imaging should be able to assess progression of osseous fusion, confirm correct positioning and integrity of instrumentation, and detect suspected complications such as new disease or disease progression. Radiographs are most commonly used for assessment of fusion. CT is the modality of choice for the evaluation of graft position, hardware, bone integrity, and fractures. It also provides imaging of bone detail to accurately assess the degree of osseous fusion. MRI is the best option for evaluation of endplates, paraspinal soft tissues, epidural spaces, and intrathecal structures, making it useful for detecting and monitoring infection or postoperative collections.
Learning Objectives:
1. To learn about the imaging findings and pitfalls of postoperative cervical spine imaging.
2. To understand the heterogeneity of imaging findings and their clinical relevance.
3. To appreciate the importance of standardised imaging, interpretation and reporting of postoperative imaging findings in the cervical spine.

08:30 - 10:00 **Room F1**

E³ - Rising Stars Programme: Basic Session

BS 1

Head and neck: inflammation, tumour or something else?

Moderator:
B. Verbist; Leiden/NL

A-023 08:30

Sinuses
R. Maroldi; *Brescia/IT*

"no abstract submitted"
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe common imaging manifestations of inflammatory diseases.
3. To review tumour and tumour-like lesions.

A-024 08:53

Thyroid and parathyroid
H. Imhof; *Vienna/AT*

The thyroid gland consists of two lobes which are interconnected by the isthmus. The gland is directly attached to the larynx and trachea. The standard view is axial, visualising the main overlying (strap) muscles, the great vessels and lymphnodes and the oesophagus, as well. The main congenital abnormalities are thyroglossal duct cyst, lingual thyroid gland and aberrant thyroid tissue. Diagnosis of the thyroid masses/nodules is done by sonography using the TI-RADS classification and colour-doppler, lesion size suspicion grade, and fine needle aspiration biopsy (FNAB) reaching an accuracy of 94%. Very important is to differentiate malignancy (papillary / follicular / anaplastic / medullary carcinoma) and inflammatory changes (Hashimoto and DeQuervain thyroiditis). Standard imaging procedures for the parathyroidea are sonography and Sesta-MIBI-SPECT reaching an accuracy of 97%. In unclear cases 4D-CT and/or MRI + contrast may be used additionally.
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe common imaging manifestations of inflammatory diseases.
3. To identify and describe the imaging appearance of malignant pathologies.

A-025 09:15

Salivary glands
S.J. Golding; *Oxford/UK (stephen.golding@nds.ox.ac.uk)*

This presentation offers a clinically orientated approach to imaging salivary gland disease in which the alignment between findings and further management is defined. Salivary imaging has been changed dramatically by the development of cross-sectional imaging. Ultrasound, CT and MRI have consigned radiographs and sialograms to a subsidiary role. Scintigraphy offers the best measure of global salivary gland function, but currently is not widely used in practice. Today investigation is closely related to the underlying pathology of salivary disorders and to provide reliable guide to surgical or medical treatment. Masses are well detected by cross-sectional imaging, which provides accurate guidance on appropriate approaches for surgical management. Differential diagnosis cannot always be achieved, but this is rarely a clinical problem because biopsy or resection are usually indicated. Sialography remains a reliable method of showing calculi and ductal changes in sialadenitis, but cross-sectional techniques, especially ultrasound and MRI, have advantages in inflammatory disease and complete sensitivity in detecting ductal disease may not be necessary in practice because patients may be treated symptomatically. A strong case can be made for using MRI as a sole investigation as this has been shown to be sensitive to both surgical and medical conditions. On this basis, the radiologist may be well placed to offer a primary referral service with triage, directing clinical management of patients or

further referral on the basis of findings on MRI. Salivary interventional techniques have more recently extended the role of the radiologist.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe common imaging manifestations of inflammatory diseases.
3. To identify and describe the imaging appearance of malignant pathologies.

A-026 09:38

Lymph nodes

S.S. Özbek; *Izmir/TR (sureyya.ozbek@ege.edu.tr)*

In case of a visible or palpated neck mass, lymph node enlargement is routinely included in the differential diagnosis list. Medical imaging can be effectively used to distinguish other causes of cervical swelling, as well as characterizing enlarged lymph nodes. Although commonly used as a criterion, nodal size is not reliable in characterization. Imaging parameters including internal structure, vascularity pattern, degree of enhancement, and perinodal tissue changes may shed light on the etiology of any lymphadenopathy, which may be reactive hyperplasia, infection, inflammation or neoplastic infiltration. Characteristically, reactive hyperplastic lymph nodes have well-defined borders, reniform shape and central fatty hilum contiguous with adjacent cervical fat tissue. In children, and in most of the adult cases with a low risk of malignancy, ultrasound is the first choice of imaging modality owing to its radiation-free nature, and due to practical reasons. However, when further characterization of nodal abnormality or evaluation of sonographically inaccessible anatomic locations is required, use of other cross-sectional techniques, like CT and MRI are mandatory. They provide not only more detailed information including anatomic localization, size, number, internal structure, and enhancement characteristics of lymph nodes, but also important data about perinodal soft tissue and other associated pathologic processes in the region. Although the choice of imaging modalities to be used in the evaluation of cervical lymph nodes changes according to the means, experience, and preferences of institutions, the role of medical imaging remains pivotal and decisive in this common indication.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features of infectious and inflammatory disorders.
3. To describe the imaging appearance of neoplastic disorders.

E³ - ECR Master Class (Oncologic Imaging)

E³ 126

Novelties in oncologic imaging

Moderator:
C.J. Zech; Basle/CH

A-027 08:30

A. Imaging and response assessment of immune-related therapies

P. Brader; *Graz/AT (peter.brader@diagnostikum-graz.at)*

The immune system is capable of preventing the development of tumour diseases and stimulation of cytotoxic T-lymphocytes can repress existing tumours. A new class of antibody-based medication, the immune checkpoint inhibitors, influences the activation of T-lymphocytes. Immune checkpoint inhibitors are active against a number of tumours. In some cases, such as malignant melanoma and non-small cell lung cancer, the response rates are impressive and exceed those achieved with conventional chemotherapies. Modern immunotherapies in oncology show tumour response patterns differing from conventional chemotherapies including initial pseudo-progression which can occur in up to 10% of cases depending on the immunomodulating drug and tumour entity. Response Evaluation Criteria in Solid Tumours (RECIST 1.1) represent the currently most used response criteria for conventional chemotherapy of solid tumours. However, atypical response patterns of immunotherapies are not correctly classified using RECIST 1.1 so that the effectiveness is also incorrectly interpreted. To correctly interpret these atypical response patterns, special Immune-Related Response Criteria in Solid Tumours (iRECIST) have been published. iRECIST was developed only for usage in trials testing modern immunotherapeutics. In contrast to RECIST 1.1, according to iRECIST an initially unconfirmed progressive disease (iUPD) requires confirmation (iCPD) in clinically stable patients by subsequent control imaging after 4-8 weeks. New lesions are separately assessed within iRECIST.

Learning Objectives:

1. To understand the basic principle of immune related therapies.
2. To learn how tumour morphology and functional parameters change with therapy.
3. To appreciate the existing evidence for immune therapy follow-up strategies.

A-028 09:00

B. Radiomics: the role of imaging

S. Rizzo; *Milan/IT (stefania.rizzo@ieo.it)*

Radiomics is an emerging translational field of research, aiming to extract data from clinical images, containing information that may reflect the underlying pathophysiology of tumoural tissue. The extracted information may be associated with clinical data, and can be used to assess prognosis and to support clinical decision. Specific softwares allow the extraction of radiomic features, representative of the entire tumors or defined subvolumes within tumors, from digital images (CT, MR, PET), and convert them into mineable high dimensional data for hypothesis generation, testing, or both. The steps necessary for a radiomic approach to digital radiological examinations include: acquisition of the images; identification of volumes of interest that may contain prognostic value; segmentation of volumes; extraction of radiomic features from the volume; clustering of the features; creation of a database; inclusion of the extracted data to develop models to predict outcomes, possibly in combination with demographic, clinical, comorbidity, or genomic data. Imaging is used in routine practice for oncological patients worldwide, at many stages of diagnosis and treatment. In the current era of targeted therapies, radiomics guarantees a nearly limitless supply of imaging biomarkers over time during and after therapy, to quantify and monitor phenotypic changes many times during treatment. The power of a predictive classifier model is dependent on the amount of data; hence, it is desirable that the radiomic studies will consider sharing of data between different centers, with the creation of databases including radiomics data and covariates, such as genomic profiles, histology, serum markers, patient histories, and biomarkers.

Learning Objectives:

1. To learn about the concept of radiomics and individualised medicine.
2. To learn how radiomics can be extracted from standard clinical examinations.
3. To appreciate the consequences of radiomics for radiologists in the future.

A-029 09:30

C. Imaging-guided liver interventions in oncology

B. Gebauer; *Berlin/DE (bernhard.gebauer@charite.de)*

Oncologic liver interventions play an important role in patients management, specially in HCC, colorectal cancer, and neuroendocrine tumors. Percutaneous, ablative techniques (thermal ablation (RFA, MWA, brachytherapy) and transarterial techniques (TACE, TAE, RE/SIRT) are available. Precise pre-interventional imaging is essential to select the correct patients for these techniques. In transarterial liver interventions enhanced intraprocedural imaging with ultrasound and cone-beam-CT increased technical opportunities for patients treatment and widened the opportunities for interventional oncology.

Learning Objectives:

1. To learn about new established treatment options in interventional oncology.
2. To understand the role of pre- and post-treatment imaging in increasing clinical outcome.
3. To appreciate potential future application of interventional oncology.

Author Disclosure:

B. Gebauer: Speaker; BARD, SIRTex Medical, St. Jude Medical, COOK, AngioDynamics, Pharmcept, Roche, Merck, 3M, Siemens, Philips, IPSEN, Bayer, Pfizer. Other; ICON Bioscience, PAREXEL, BAYER.

MRI of articular cartilage and bone: areas of imaging confusion and practical solutions

Moderator:
O. Papakonstantinou; Athens/GR

A-030 08:30

A. Bone oedema syndromes and avascular necrosis
B. Vande Berg; *Brussels/BE (bruno.vandeberg@uclouvain.be)*

Bone marrow edema is a pattern of marrow alteration frequently observed at MRI. It is defined by the presence of an ill-delimited area of moderate and homogeneous decrease in signal intensity on SE T1 images that converts to high signal intensity on fat-saturated proton density or T2-weighted images. It is non-specific and may be associated with almost any abnormal marrow, bone or joint conditions. Epiphyseal bone marrow edema can be associated with self-limited spontaneously resolutive conditions (overuse, stress insufficiency fractures, transient osteoporosis), or with evolutive disorders including chondropathy or spontaneous osteonecrosis. The main task of the radiologist is to assess the cause for bone marrow edema and to highlight imaging features that contribute to a specific diagnosis and subsequently a prognosis (resolutive versus non-resolutive). The current lecture aims at emphasizing imaging features indicative of bone marrow edema to avoid confusion with systemic osteonecrosis. We will also highlight imaging features of prognostic significance that enable the clinician to tailor the treatment to the patient's condition.
Learning Objectives:
1. To understand the aetiologies of bone marrow oedema syndromes.
2. To learn about the imaging characteristics of avascular necrosis of bone.

A-031 09:00

B. Osteochondral injury, subchondral fractures and traumatic bone oedema: what is important and how do I describe it
F.W. Roemer; *Erlangen/DE (frank.roemer@uk-erlangen.de)*

Bone marrow contusions are frequently identified at magnetic resonance imaging after an injury to the musculoskeletal system. These osseous injuries may result from a direct blow to the bone, from compressive forces of adjacent bones impacting one another, or from traction forces that occur during an avulsion injury. Commonly these injuries resolve without long term sequelae. However, they may also involve the cartilaginous surface with or without an associated fracture line defining these as osteochondral injuries, which may have a different prognostic relevance. Subchondral fractures have been implicated in the genesis of some well-known destructive articular conditions whose cause was previously undetermined, such as rapidly progressive osteoarthritis of the hip or spontaneous osteonecrosis of the knee. Subchondral fractures may ultimately lead to bone collapse, secondary osteonecrosis, and severe articular damage. It should be suspected in the appropriate clinical setting, as in early stages it is usually indistinct on initial plain radiographs and magnetic resonance imaging is required for a definitive diagnosis. The fracture line usually appears as a band of low signal intensity in the subchondral bone plate, adjacent to the articular surface, most often surrounded by bone marrow edema. As these injuries may be occult on radiographs, the differentiation of bone contusions from osteochondral injuries or subchondral fractures is possible only with MRI including fat-suppressed and non-fat suppressed sequences. While purely subchondral lesion may have a good prognosis if diagnosed early, disruption of the articular surface may lead to early degenerative alterations including focal cartilage loss and other features of osteoarthritis.
Learning Objectives:
1. To understand the pathomechanisms of osteochondral injury and subchondral fractures.
2. To learn about the imaging techniques and prognostic values.
Author Disclosure:
F.W. Roemer: Shareholder; Boston Imaging Core Lab (BICL), LLC.

A-032 09:30

C. Rheumatoid arthritis
I. Sudoł-Szopińska; *Warsaw/PL (sudolszopinska@gmail.com)*

Rheumatoid arthritis is the most common inflammatory rheumatic disease. The pathogenesis of RA is subject to ongoing discussion. The traditional concept of inflammatory pannus, in which fibroblast-like synoviocytes provoke cartilage and bone destruction through direct invasion and indirect triggering of catabolic cascades has been termed the outside-in hypothesis. There is also evidence supporting the inside-out hypothesis, in which joint inflammation and destruction originates from the bone marrow. Next to synovium and subchondral bone, another tissue involved in cartilage and bone damage in RA is extra- or intraarticular fat tissue which produces ca. 50 adipo(cyto)kines which may be involved in degradation of all components of the connective tissue, including cartilage. Finally, the hyaline cartilage autoantigens, activated by cartilage damage, may activate and maintain synovitis and lead to joint damage. In everyday practice, the clinical relevance of synovitis and bone marrow inflammation in terms of their role as an erosions precursors is known and ultrasound and MRI are used to detect synovitis, BME, inflammatory cysts, hyaline cartilage loss, and bone erosions. Less in known about inflammatory and destructive potential of intra- and extraarticular fat tissue which may also be evaluated in US and MRI. And only research centers use quantitative MR applications to cartilage to show glucosaminoglycans loss possibly preceeding visible cartilage damage. In this presentation pathomechanisms that result in articular cartilage and bone damage in RA will be presented, including the clinical relevance of synovitis and BME in terms of their role as an erosion precursors, as well as the role of imaging techniques to detect early cartilage damage and bone erosions.
Learning Objectives:
1. To understand the pathomechanisms that result in articular cartilage and bone damage in rheumatoid arthritis, including the clinical relevance of synovitis and BME in terms of their role as an erosion precursor.
2. To learn about the role of imaging techniques to detect early cartilage damage and bone erosions.

Physics in Medical Imaging

RC 113

Single-dual-multi-energy CT

A-033 08:30

Chairperson's introduction
A. Torresin; *Milan/IT (alberto.torresin@unimi.it)*

CT dual energy publications have heavily increased in the last years. The trend seems to be continuing since PubMed has found, from Jan 2015 until Nov 2017, around 1000 peer review abstracts. Publications on phantom simulation (for algorithm verification) and patient's study regarding the most important area of diagnostic have been published sourcing from CT imaging and Hybrid Imaging (PET CT for examples). Bone and high density tissue evaluation are one of the most important application with high density artifact reduction, materials analysis based on attenuation spectra observed, tumor analysis and no contrast imaging application. A lot of technological solutions have been introduced during the last years, but the technique has not yet seen widespread implementation in routine protocols. During the course, the basic principle of dual energy and some new trend of spectral imaging will be introduced both technologically and clinically. To compare image quality and radiation dose of single-energy CT and dual energy, it is very important to quantify the patient risk with the introduction of these new technologies. Quantitative evaluation studies (retrospective and prospective) will be more and more important. During the refresh-course, the basic principle of patient dose in spectral imaging will be presented and attention is paid to the quantitative method of image analysis.
Session Objectives:
1. To learn about the basics of dual-energy CT (DECT).
2. To understand today's photon counting detector technology.
3. To learn how DECT is applied in clinical practice.

A-034 08:35

A. Basics of dual- and multi-energy CT
K. Perisinakis; *Iraklion/GR (Kostas.Perisinakis@med.uoc.gr)*

Dual energy CT (DECT) refers to the use of two CT beams of different photon energy spectrum to collect two separate sets of projection data and provide two corresponding image datasets of the same anatomical body region to

exploit spectral information regarding attenuation ability of tissues for diagnostic purposes. Despite conceived during '70s soon after the first clinical CT, the clinical endorsement and widespread application of DECT was initiated with the advent of dual-source CT systems in 2006. Providing the potential to improve CT image quality through artifact suppression and extracting valuable information regarding tissue composition and function, DECT is the new exciting field for the radiology community and the main driving force for CT technology evolution over the last decade. Currently, all CT vendors put considerable efforts in developing CT systems capable of performing DECT studies, while novel clinical applications of DECT are continuously introduced. However, comprehension of the basic physics of DECT and familiarisation with the advanced technological features of modern DECT scanners is prerequisite to fully exploit the advantages of DECT imaging.

Learning Objectives:

1. To learn about the underlying physics and today's technology.
2. To see potential advantages compared to single-energy CT.
3. To appreciate the rationale behind clinical applications.

A-035 08:58

B. Photon counting detectors in diagnostic CT

A. Altman; *Haifa/IL (ami.altman@philips.com)*

Recent years' advances in room-temperature semi-conductors, especially CZT and CdTe, have enabled the transformation from energy-integrated (EI) detectors to photon-counting (PC) detectors in diagnostic CT, enhancing significantly its clinical benefits. The higher signal per x-ray photon (X10) and the short rise time of ~10 nanoseconds enable spectral analysis of each counted photon, use of adjustable multi-energy bins, K-edge imaging, and increased CNR through different energy weightings, while reducing the dose significantly. The continuous sensitivity of a pixelated sensor and the elimination of electronic noise through a threshold above it enable using much smaller detection pixels than in a conventional EI CT and contribute to further lowering of the dose. Consequently, spatial resolution is improved compared to EI CT (> 20 lp/cm). Reduction of the detection pixel size is essential also for lowering photon rates per pixel to avoid pile-up effects. However, charge sharing and Kα escapes of Te and Cd cause severe distortions to the recorded x-ray spectrum. A forward model of the detector response is used to address it and restore spectral capability, using a projection domain material decomposition. It will be shown that this can be accomplished as long as the peak-to-tail ratio is not too large, namely, detection pixel of about 0.5 mm. HW and SW methods of pile-up corrections will be shown too. Phantom and pre-clinical verifications on the PHILIPS Spectral Photon-Counting CT (SPCCT) in Lyon demonstrate the capability of such a system achieving spectral results superior to dual-energy CT, and the advantage of dual-contrast injection in a single scan.

Learning Objectives:

1. To learn about the underlying physics and technological solutions.
2. To understand the potential advantages compared to dual-energy CT.
3. To appreciate how mature today's photon counting technology is.

Author Disclosure:

A. Altman: Employee; PHILIPS Healthcare.

A-036 09:21

C. Clinical need of multi-energy CT

S.T. Schindera; *Aarau/CH (sschindera@aol.com)*

During the last decade, dual-energy CT has gained increasing attention in clinical routine due to improved diagnostic performance from the quantitative analysis of different tissue composition. Various clinical indications for a dual-energy CT scan will be reviewed with a focus on the added value. Potential future opportunities of dual-energy CT, which still are viewed as research tools, will be also discussed.

Learning Objectives:

1. To learn about medical applications and potential benefits.
2. To understand which single-energy applications could be replaced by dual-energy applications, and why.
3. To learn which additional multi-energy CT applications could be developed.

09:44

Panel discussion: Are there sufficient benefits of this technique?

08:30 - 10:00 **Room K**

Radiographers

RC 114

Forensic imaging

A-037 08:30

Chairpersons' introduction (part 1)

J. McNulty; *Dublin/IE (jonathan.mcnulty@ucd.ie)*

Radiographers play an essential role in the provision of high quality forensic imaging services. This is recognised in many countries and forensic imaging has been recognised by the European federation of radiographer societies (EFRS) as one of nine specialist areas of advanced practice for radiographers. While the concept of optimisation is at the heart of the profession, there remains room for improvement in further advancing optimisation for forensic applications. As with all specialist areas, or areas of advanced practice, appropriate education and training, and continuous professional development are fundamental. Through international organisations such as the international society for forensic radiology and imaging (ISFRI) and the international association of forensic radiographers (IAFR), together with national organisations and groups, forensic imaging continues to move in the right direction.

Session Objectives:

1. To provide insights into the role of imaging, and radiographers, in forensic imaging and mass fatality incidents.
2. To appreciate the key aspects of a quality forensic imaging service.
3. To understand the challenges associated with forensic imaging.

A-038 08:33

Chairpersons' introduction (part 2)

R.R. van Rijn; *Amsterdam/NL (r.r.vanrijn@amc.uva.nl)*

Forensic radiology and imaging is a relatively new field within the realm of forensic science and medicine. This introduction provides a short overview of the scientific challenges facing the forensic radiological technician radiologist.

Session Objectives:

1. To provide insights into the role of imaging, and radiographers, in forensic imaging and mass fatality incidents.
2. To appreciate the key aspects of a quality forensic imaging service.
3. To understand the challenges associated with forensic imaging.

Author Disclosure:

R.R. van Rijn: Author; Author books published by Thieme and Springer.

A-039 08:35

A. Disaster victim identification

J. Kroll; *Maastricht/NL (j.kroll@mumc.nl)*

Forensic radiology, mainly as a tool for forensic odontology, has long been an essential discipline in the post-mortem identification of human remains. Because forensic radiology is a rapidly developing field due to the fast technical developments of CT scanners, the possible applications are increasing. A whole body CT contains a wealth of identification information that can be used in an identification process. This presentation will highlight the contribution of forensic radiology within a DVI process, discussing its applications, equipment, advantages and positioning within a DVI-process. It will also discuss future developments, opportunities and challenges which futures DVI processes will face.

Learning Objectives:

1. To appreciate the role of forensic radiology in a disaster victim identification process.
2. To learn about the methods using forensic radiology in a disaster victim identification process.
3. To discuss added value of forensic radiology in a disaster victim identification process.

A-040 08:58

B. The role of CT angiography in forensic imaging

A. Dominguez; *Lausanne/CH (Alexandre.DOMINGUEZ@hesav.ch)*

Multiphase post-mortem CT angiography (MPMCTA) has been set up almost ten years ago at the University Center of Legal Medicine of Lausanne-Geneva, Switzerland (CURML). A research project allowed the creation of the Virtangio® device: a specific injection system for post-mortem angiography. Nowadays, this setting is regularly used as almost a third of the autopsies

benefit of this technique at the CURML. The indication to perform the MPMCTA is the suspicion of vascular lesions due to natural or traumatic origin, such as traffic accidents, homicides (stab wounds, ballistic), medical malpractice (especially in a post-surgery context), or unexpected adults death. This procedure allows examining vascular anatomy: analyses of the vascular lumen with potential stenosis or dilatation; analyse of the vascular walls with potential dissections or ruptures; characterization of the nature of an arterial and/or venous leakage. It also permits to obtain morphological information of the organs parenchyma. At the CURML, the MPMCTA is fully executed by the forensic radiographer. He is in charge of preparing the body, collecting samples before the angiography, denudating the arterial and venous vessels for the injections and proceeding the CT-scan acquisition. The duration of this technique lasting about 30 minutes won't disturb the investigation work flow. The MPMCTA is then interpreted by a team involving forensic pathologist and a radiologist. Limitations and pitfalls of this technique should be known to identify artefacts and pitfalls.

Learning Objectives:

1. To learn about the development of multiphase post-mortem CT angiography (MPMCTA).
2. To appreciate the benefits and limitations of MPMCTA examinations.
3. To understand the role of the radiographer in the MPMCTA.

A-041 09:21

C. The importance of the radiographer's role in forensic imaging

A.L. Brookes; *London/UK (amyleebrookes@outlook.com)*

Forensic imaging is an ever-expanding sub-speciality of both radiology and forensic medicine. The overall role of forensic imaging is to obtain evidence and answer legal questions associated with either living or deceased individuals. Forensic imaging can be utilised in a variety of cases including suspected physical abuse, medical negligence, drug trafficking and mass fatalities incidents. In forensic pathology, forensic imaging has established a role in the assessment of identification and establishment of cause of death, particularly in cases of severely decomposed or burnt remains. The role of radiographers within forensic imaging contrasts significantly with that of the routine clinical environment. Those individuals involved in forensic imaging must understand and be aware of the medico-legal features and professional guidelines that impact their practice.

Learning Objectives:

1. To appreciate the role of the radiographer in forensic imaging.
2. To learn about the importance of continuity of evidence and record keeping.
3. To discuss the various situations a radiographer can be exposed to during forensic imaging.

09:44

Panel discussion: Developing a service/getting involved in forensic imaging

Peripheral vascular malformations: what every radiologist should know

A-042 08:30

Chairperson's introduction

J.A. Reekers; *Amsterdam/NL (j.a.reekers@amc.uva.nl)*

Vascular malformations are rare and therefore the diagnosis is often unknown to a general radiologist. It is important to differentiate a congenital vascular malformation from an infantile hemangioma. Congential vascular malformations a have a specific anamnesis, which is often the major clue to the final diagnosis. There are 3 main types of congenital vascular malformations. Arterial (high flow with direct fistula), venous (low flow) and lymphatic. There are some related vascular tumours like capillary malformation and port-wine stains. There are several syndromes in relation to vascular malformations. The most known is Klippel-Trenaunay-Weber syndrome. For a general radiologists it is important to recognise a vascular malformation. Treatment and further work-up diagnosis should only be undertaken in centres of expertise. Only malformations that give complaints like pain, bleeding or cosmetic issues should be treated. Both embolisation (for high flow) and local sclerotherapy (for low flow) are used to treat vascular malformations.

Session Objectives:

1. To review classification and description.
2. To identify the role of imaging modalities.
3. To understand the role of interventional radiologist in management and treatment.

A-043 08:35

A. The diagnostic assessment

M. Köcher; *Olomouc/CZ (martin.kocher@seznam.cz)*

Vascular malformations are categorised into the low-flow malformations and high-flow malformations. From imaging methods is expected to distinguish between the low-flow lesions and high-flow lesions, localisation, volume and range of lesion and relationship to the surrounding tissues and organs. Color doppler ultrasonography (DUS) can offer good differentiation between high-flow and low-flow lesions. Magnetic resonance (MR) offers good differentiation between high-flow and low-flow lesions also, and moreover good evaluation of volume and extent of lesion, good interpretation of anatomical relationship to the surrounding tissues and organs. On DUS the low-flow malformations are demonstrated as hypoechogenic or heterogeneous lesions with minimal flow inside, flow during augmentation and normal arterial flow volumes and normal high arterial resistance flow. The high-flow malformations are heterogeneous lesions with tortuous feeding arteries, high velocity and low-resistance flow in feeding arteries, multiple arteriovenous shunts and pulsatile flow in draining veins. On MR the low-flow malformations typically have low signal intensity in T1 weighted images in abnormal vascular structures and high signal intensity in T2 weighted images, whereas the high-flow lesions usually demonstrate a signal voids in abnormal vascular structures on most sequences. At follow-up DUS demonstrates thrombosis and fibrosis of the low-flow lesion. In the high-flow lesion the waveform will be normalised and the resistive indexes and the flow volumes will become normalised as well. MR demonstrates thrombosis and fibrosis of low-flow malformation by the loss of high signal in T2 weighted images and loss of signal voids in high-flow lesions.

Learning Objectives:

1. To learn about classification and terminology.
2. To understand the role of US, CT and MRA in diagnostic assessment.
3. To learn the optimal imaging algorithm for diagnosis and follow-up.

A-044 08:58

B. Percutaneous or endovascular treatment: when and how?

B. Peynircioglu; *Ankara/TR (borapeynir@gmail.com)*

Vascular anomalies, are divided in two different categories which carry different prognosis and management: "Vascular tumors" and "Vascular malformations" (VM). Their precise identification is crucial and involves a good knowledge of the biological classification published by Mulliken and Glowacki and that has recently been updated by the International Society for the Study of Vascular Anomalies (ISSVA). Vascular malformations are always congenital and grow with the child. They can involve type of vessels solely or combined with others. A rheologic differentiation between low and high flow malformations is essential to characterise the seriousness of the lesion. Interventional radiology (IR) plays major role in both curative and palliative treatments of these VM. Once understanding the nature and high/low flow characteristics of VM, transcatheter/endovascular (transarterial or transvenous) or direct percutaneous puncture under imaging guidance are the 2 main techniques for treating these lesions. Depending on the type, nature, location and surroundings of the VM, one should decide the best strategy for treatment. Another key point is to decide whether to use embolisation or sclerotherapy. Again, the type, location of the VM is vital and the patient based decision is to be made carefully by a multidisciplinary team. Operator's experience is of most importance in determining all of the above variables, together with the local circumstances. There are many different types of embolic and sclerotherapy agents available around the world.

Learning Objectives:

1. To recognise the indications and the real need for treatment.
2. To learn about technical approach and how to plan the intervention.
3. To understand possible limitations and the final result prediction.

A-045 09:21

C. Paediatric vascular malformations: diagnosis and treatment

A. Barnacle; *London/UK (Alex.Barnacle@gosh.nhs.uk)*

Haemangiomas are by far the most common type of vascular anomaly that present in childhood. Haemangiomas are benign vascular tumours; several subtypes exist. Infantile haemangiomas are the commonest subtype and the vast majority of these require no intervention at all, because they involute spontaneously over the first few years of childhood. These well defined vascular masses have a highly characteristic growth pattern and typical

imaging features. They can be distinguished from the rarer congenital haemangiomas by their clinical presentation. Rarer benign childhood vascular tumours include kaposiform haemangioendotheliomas (KHEs) and tufted angiomas, both of which are associated with thrombocytopaenia and have characteristic imaging features to distinguish them from haemangiomas. Unlike vascular tumours, vascular malformations are present from birth and grow slowly in childhood. Lymphatic malformations (LMs) tend to present earlier and are encountered much more commonly in children than adults. Macrocystic LMs consist of thin-walled cysts containing lymph or clot and microcystic lesions appear more solid. Ultrasound is often sufficient to make a diagnosis but MRI may be required to determine the extent of deep-seated lesions. Small lesions may not require treatment; larger lesions are usually treated with percutaneous image-guided sclerotherapy, though surgery has an important adjunctive role in debulking larger lesions. Finally, some children present with complex overgrowth, often of just one limb, which is associated with a vascular malformation. These patients require expert input from a multidisciplinary team and imaging is key.

Learning Objectives:

1. To understand the specifics of vascular malformations in children.
2. To recognise when to observe and when to intervene.
3. To learn about interventional techniques used and results of treatment.

09:44

Panel discussion: How could we improve diagnosis and optimise the results of our interventions?

Computer Applications

RC 105

Everything you need to know about 3D post-processing

A-046 08:30

Chairperson's introduction

E. Sorantin; *Graz/AT (erich.sorantin@medunigraz.at)*

Progress in imaging technology equipment enables scanning patients in high geometrical and temporal resolution as well as in multidimensional space (e.g. 4D). The amount of resulting data cannot be read any more in 2D as done in the last millennium. Furthermore, advances in computational power enable the use of sophisticated processing algorithms in real time. Thus reading in 2D, as done in the previous millennium, will be gradually replaced by volumetric reading as well as extracting diagnostic information from parametric images. Moreover, for personalized medicine, radiology has to deliver more detailed information, especially to measure tumour volumes or characterize contrast uptake on perfusion imaging. To get familiar with those now really emerging techniques, three well-known speakers will cover essential subtopics and provide a road map on how to migrate from the reading style in the last millennium to that in the current millennium.

Session Objectives:

1. To learn about the state of the art in 3D post-processing.
2. To understand how 3D post-processing can most optimally be used in daily clinical practice.
3. To appreciate how automated 3D post-processing and quantification will lead to increased use of 3D visualisations for diagnostics and therapy planning, over 2D viewing.

A. 3D post-processing in 2018

A. Alberich-Bayarri; *Valencia/ES (alberich_ang@gva.es)*

One of the most important developments in radiological interpretation is the need for the incorporation of advanced tools to assist the specialist in the study evaluation. Automated segmentation of structures based on convolutional neural networks (CNN) in the frame of deep learning would allow to significantly increase the efficiency of the study evaluation by the radiologist. Although the detailed segmentation of organs is still intricate in the field of abdomen and modalities like MR, current technology allows for the automated detection of the organs' location and identification of most of the tissue using bounding boxes. These applications may be used today in clinics for the automated assessment of tissue properties. A clear example is the automated detection and identification of vertebrae centroids, which allows for the acceleration of the radiologist reading process in spine CT examinations while it also allows for the automated calculation of trabecular bone quality properties in each identified vertebrae, therefore providing a high value to perform osteoporosis population studies without the need for a user interaction. These algorithms have been recently labelled as zero-click solutions and will provide a paradigm shift in 3D post-processing for radiologists, having the results of the 3D assessment already generated in their PACS even before starting review of the study.

Learning Objectives:

1. To learn about recent advances in 3D post-processing techniques.
2. To understand how these techniques can be used in clinical practice now.
3. To learn new tips and tricks to use in your daily practice.

Author Disclosure:

A. Alberich-Bayarri: CEO; QUIBIM SL. Founder; QUIBIM SL.

A-048 08:58

B. Making better use of your 3D package: tips and tricks

P.M.A. van Ooijen; *Groningen/NL (p.m.a.van.ooijen@umcg.nl)*

Advanced visualization, simulation and planning software is increasingly used in clinical practice providing a shift from 2D to 3D visualization, processing and interpretation. With this ongoing trend the radiological profession should not only focus on the diagnosis to be made, but also on the utilization of our imaging data in patient simulation, planning, and treatment. Current functionality moves in this direction with providing extensive possibilities for support of surgical interventions and treatment planning in 3D including the advent of Virtual and Augmented Reality. With this 3D is also moving into the operating theater. Although these new possibilities are interesting and exiting one should be very aware of the pitfalls that come with 3D visualization and processing of data. This not only includes the technical but also the procedural pitfalls where image acquisition optimal for diagnosis is not always optimized for the intended use by the referring physician. To adequately use the new techniques and to provide optimal support from radiology to the referring physicians training is required and dedicated staff should be involved in this process.

Learning Objectives:

1. To learn about the functionality of state-of-the-art 3D packages.
2. To understand the pitfalls in use of 3D post-processing.
3. To appreciate the need for training in 3D post-processing techniques.

A-049 09:21

C. Interpretation of 3D processing results: from image to volume reading

T. Frauenfelder; *Zurich/CH (thomas.frauenfelder@usz.ch)*

The widespread introduction of multidetector computed tomography (MDCT) has revolutionized the field of computed tomography (CT). This revolution can be attributed to three primary properties of MDCT: its ability to produce a vast quantity of volumetric data in a reduced amount of time, the high resolution, and the ability to create isotropic voxel data and, consequently, reliable multiplanar and three-dimensional (3D) reconstructions. Diagnostic approaches that rely solely on axial reconstructions of MDCT data are often insufficient for formulating an accurate diagnosis or for documentation of clinical cases. Specialized 3D reconstruction techniques permit the visualization of anatomical details, which would be difficult to evaluate using axial reconstructions alone. Such details may require the use of oblique or curved reconstructions, or more complex methods, such as maximum intensity projection (MIP), minimum intensity projection (MinIP), surface-shaded volume rending (SS-VRT), and virtual endoscopy. For example, small pulmonary nodules can only be rapidly and reliably identified through the use of MIP Slab slices. The current trend is to merge the routine diagnostic console and 3D reconstruction workstation. The integration of 3D reconstruction utilities into the standard bi-dimensional diagnostic software has increased the number of operations possible on each exam data, greatly increasing the perceived complexity of CT diagnosis. Although many of us believe that the use of 3D reconstructions greatly increases total exam evaluation time, there are reports show how using 3D reconstruction techniques for examining volumetric data are effective and also improve the speed of interpretation, recognition, and description of specific clinical conditions. Many of these reconstruction techniques are of particular importance for the analysis of subspecialty exams, as for example the 3D depiction and quantification of lung emphysema.

Learning Objectives:

1. To learn about different developments in creating 3D anatomical and functional models for diagnostic and therapy planning purposes.
2. To understand the pros and cons of such technologies.
3. To appreciate that automated 3D image analysis will lead to new ways in which diagnosis and therapy planning will be performed.

Interventional Radiology

RC 109
Portal hypertension and interventional radiology (IR)

A-050 08:30
Chairperson's introduction
A. Mizzi; *Msida/MT (adrianmizzi@yahoo.co.uk)*

Portal hypertension is characterized by high pressure in the hepatic portal venous circulation. Clinically significant portal hypertension is diagnosed when the hepatic venous pressure gradient (HVPG) exceeds 10 mmHg. It may be caused by hepatic, pre-hepatic or post-hepatic aetiologies. Diagnostic radiology plays a crucial role in establishing the aetiology, identifying complications and in planning management. Interventional radiology (IR) plays a major role in both the diagnostic and therapeutic management of portal hypertension. HVPG measurement is a minimally invasive IR technique that establishes the diagnosis of portal hypertension. Different therapeutic IR procedures may be used in different clinical scenarios and have replaced more invasive open surgical techniques. The hepatobiliary radiologist is a key player in the multidisciplinary team caring for patients with portal hypertension. The imaging findings of portal hypertension and the different IR procedures used in this condition will be discussed during this session. Emphasis will be made on the practical aspects of interventional radiology procedures, including transjugular intrahepatic portosystemic shunt (TIPS), variceal embolization, splenic artery embolization and balloon-occluded retrograde transvenous obliteration (BRTO) - including their indications, methodology, complications, and clinical outcomes.
Session Objectives:
1. To appreciate the role of multidisciplinary treatment of portal hypertension.
2. To learn about imaging and intervention in portal hypertension.
3. To discuss outcomes of interventions in portal hypertension.

A-051 08:35
A. Imaging of portal hypertension
I. Bargellini; *Pisa/IT (irenebargellini@hotmail.com)*

Portal hypertension (PH) represents a fearful complication of several diseases (most frequently liver cirrhosis), associated with high morbidity and mortality. Definitive diagnosis of PH is based on the measurement of hepatic venous pressure gradient (HVPG). PH is diagnosed by measuring a HVPG higher than 5 mmHg, it is considered clinically significant when HVPG is higher than 10 mmHg and severe when HVPG is above 12 mmHg. A direct relation has been demonstrated between HVPG and risk of variceal bleeding, hepatic decompensation and liver related mortality, and HVPG has become a surrogate endpoint in the assessment of treatment response and reduction of risk of liver-related mortality. However, HVPG measurement is invasive, is not routinely available and it is reliably standardized only in expert centers. Thus, non-invasive methods, such as elastography, are under investigation, in the attempt to diagnose and grade PH, and to predict presence, extent and risk of variceal bleeding. Non-invasive imaging, such as ultrasound (US), computed tomography (CT) and magnetic resonance imaging (MR) may enable diagnosis of PH through the identification of complications (such as varices, splenomegaly, ascites). The anatomic information provided by these imaging modalities becomes essential to identify the causes of PH and when treatment planning is required (such as in patients indicated for TIPS or candidate for liver transplantation). Imaging plays a crucial role also to assess response to treatment and post-treatment complications.
Learning Objectives:
1. To appreciate imaging features of portal hypertension.
2. To discuss the appropriate choice and timing of imaging technique in investigation of portal hypertension
and its complications.
3. To learn about relevant findings that influence therapy choice in portal hypertension.

Author Disclosure:
I. Bargellini: Advisory Board; Bayer Spa. Speaker; GE Healthcare, BTG, Sirtex Medical.

A-052 08:58
B. Embolisation of varices and splenic artery in portal hypertension
I.E. Keussen; *Lund/SE (inger.keussen@med.lu.se)*

Portal hypertension is most common secondary to liver cirrhosis, however it can also be caused by portal/splenic vein thrombosis or occlusion. A bleeding secondary to portal hypertension, usually originates from esophageal or gastric varices, other sites may be duodenal, stomal or rectal varices. A bleeding from esophageal varices is primarily most often treated endoscopically with sclerotherapy or rubber banding. Gastric varices are less prevalent, but more difficult to treat endoscopically. If medical and endoscopic treatment methods fail, interventional treatment is the next option, which includes embolisation of varices, TIPS, BRTO and partial splenic arterial embolisation. Embolisation of varices may be performed by percutaneous or transjugular-transhepatic approach, but transsplenic route or direct puncture of the stomal varices are also reported. A BRTO may be applied in patients with a splenorenal shunt and secondary gastric varices. Partial splenic embolisation may decrease inflow of blood to the portal vein and secondary decrease the portal hypertension. In most cases a combination of different techniques is necessary to achieve good results.
Learning Objectives:
1. To discuss the rationale for embolisation.
2. To learn about the selection of technique and choice of material.
3. To understand outcomes from embolisation techniques.

A-053 09:21
C. Transjugular intrahepatic portosystemic shunt (TIPS): critical appraisal of techniques and guidelines for treatment
A. Krajina; *Hradec Králové/CZ (antonin.krajina@fnhk.cz)*

TIPS is a minimally invasive method of creating a portosystemic shunt for decompression of portal hypertension (PH). A side-to-side shunt of determined diameter is created to shunt blood flow from the portal vein (PV) to hepatic vein or inferior vena cava above the liver using transjugular approach, long needle, balloon angioplasty, and stent-graft. The most often indication for TIPS is cirrhotic ascites, which is sometimes combined with severe hydrothorax. However, TIPS is used in those patients who are intolerant of repeated large-volume paracenthesis. TIPS has been used as a rescue treatment in rare cases of endoscopically uncontrollable variceal bleeding, especially from gastric fundal varices. Emergent TIPS (in 72 hours) performed in patients with severe PH and high risk of early rebleeding, has been proved to have better bleeding control and survival in 1 year. Partial or complete PV thrombosis does not change usual technique of TIPS. TIPS is technically difficult in chronic extrahepatic PV obstruction, in children, and in patients with massive hepatic veins thrombosis (Budd-Chiari Syndrome - BCS). The absence of hepatic veins and distorted anatomy due to the caudate lobe hypertrophy requires sometimes direct transcaval approach to the PV in patients with BCS. Moreover, these patients must be anticoagulated life long due to underlying hypercoagulopathy. TIPS demonstrated good control of ascites and reversal of liver failure in large series of patients with BCS. All patients with TIPS must be followed regularly in specialized multidisciplinary center, and the surveillance of TIPS function is mandatory.
Learning Objectives:
1. To discuss the selection of patients for TIPS.
2. To learn about the techniques for TIPS formation.
3. To discuss outcomes of TIPS and role of imaging surveillance.

Lung cancer in the era of molecular oncology and immune therapy

A-054 08:30

Chairperson's introduction

H. Prosch; *Vienna/AT (helmut.prosch@meduniwien.ac.at)*

Lung cancer is the most common cause of cancer-related death in Western countries. In the last several years, a number of new drugs have revolutionized systemic therapy in lung cancer. These new therapies can be divided into two major groups, the targeted therapies and the immunotherapies. Targeted therapies, such as EGFR tyrosine kinase inhibitors, or ALK inhibitors, are a class of drugs that specifically target a well-defined molecular pathway. They have been shown to be more effective than classic chemotherapies in patients who harbor the specific mutation and are associated with fewer toxicities. As these drugs target molecules with a specific mutation, patients who harbor this specific mutation need to be identified. In addition to bronchoscopy, image-guided biopsies are the main modality for obtaining tissue for molecular analysis. Imaging may have a potential role in identifying tumors that harbor a specific mutation, and thus, in guiding further pathologic and genetic work-up. Immunotherapy, however, targets immunological pathways to induce an immunological response against tumors. Immunotherapy has been shown to be a very effective treatment in a subset of patients with non-small cell cancer. Imaging plays a major role in the follow-up evaluation of patients undergoing immunotherapy, as immune reactions must be differentiated from disease progression.

A-055 08:35

A. Lung adenocarcinomas with EGFR mutations

M. Lederlin; *Rennes/FR (Mathieu.LEDERLIN@chu-rennes.fr)*

Adenocarcinoma is the most prevalent type of lung cancer, showing a large spectrum of genetics, histologic subtype, CT appearance, clinical behavior and prognosis. Activating mutations of EGFR are found in 30%-50% of lung adenocarcinomas in East Asian patients and approximately 15% in Caucasian patients. EGFR mutation status is correlated with nonsmoking status, female sex, lepidic subtype, and high response rate to EGFR tyrosine kinase inhibitors (TKI). Some CT findings have shown to be associated with EGFR mutation such as nonsolid or mixed ground-glass opacity, air bronchogram, smaller and peripheral tumors, and pleural retraction. Furthermore, non-smoking patients presenting with diffuse miliary metastatic disease at diagnosis may be diagnosed with adenocarcinoma harboring EFGR mutation and may show dramatic response to EGFR-TKI. The most common resistance mechanism to EGFR-TKI is the T790M mutation, against which new irreversible TKIs have been found to be clinically effective, thus increasing demand for rebiopsy in progressive NSCLC to analyze mutational status. Rebiopsies are feasible and informative in most of patients with acceptable rates of complications. Furthermore, continued EGFR-TKI therapy may be indicated beyond RECIST progression, because these tumors grow slowly and some tumor cells remain sensitive to EGFR-TKI. Radiologists should also be aware of the risk of class-effect toxicity of EGFR-TKI, in particular pneumonitis with an incidence rate of 4-5% in the Japanese population. Finally, European radiologists should keep in mind that a majority of studies dealing with EGFR mutations in adenocarcinomas arise from Asian countries with results that might not be transposable to Caucasian populations.

Learning Objectives:

1. To be aware of the importance of detecting EFGR mutation.
2. To learn about demographic and CT features suggestive of EGFR mutation.
3. To learn about the various initial and follow-up CT features.

A-056 09:03

B. ALK-rearranged lung adenocarcinomas

M. Silva; *Parma/IT (mariosilvamed@gmail.com)*

The 2-7% of non-small cell lung cancers (NSCLC) harbor the rearrangement of anaplastic lymphoma kinase (ALK) - an oncogene related to a tyrosine kinase pathway - notably in adenocarcinoma histology and in non-smokers (about 60% of all ALK-rearranged NSCLC). Target therapy by tyrosine kinase inhibitors (TKI) is clinically available for ALK-positive advanced NSCLC and improves progression-free survival (PFS) compared with previous reference chemotherapy. Hence, testing for mutations is paramount for optimal planning of medical treatment of advanced NSCLC. In the face of a better disease control by TKI, however, it happens that ALK-positive tumors are prone to driver mutation with resistance to first-line TKI, in the first months of therapy. In clinical practice, diagnostic imaging, notably computed tomography (CT), has high yield in the management of patients under target therapy. The CT evidence of disease progression, either local or systemic (note: brain metastases are relatively common because first-line TKIs have low trespassing coefficient through emato-encephalic barrier) is paramount for timely adaptation of therapy. Rapid radiologic progression demands prompt TKI swap towards second-line (e.g., ceritinib, brigatinib, or alectinib) or third-line target therapy (e.g., lorlatinib) or otherwise. Re-biopsy is suggested to pitch the optimal second (or further) line therapy by continuous molecular testing. In clinical trials, again, diagnostic imaging has high yield in the assessment of target therapies, namely for definition of PFS. Adverse events occur in a minority of patients under TKI (1% incidence of lung toxicity). Therapy discontinuation is usually sufficient to reduce toxic effects, with only 3-6% of cases lingering after therapy withdrawal.

Learning Objectives:

1. To learn about clinicopathologic features characterising ALK-rearrangement.
2. To understand the impact of ALK rearrangement on the prognosis of non-small cell lung cancer.
3. To see some illustrative cases.

A-057 09:31

C. PD-L1 positive lung tumours

O.L. Sedlacek; *Heidelberg/DE (sedlaczek@web.de)*

Immune checkpoint inhibitors (ICI) are effective in the treatment of many cancers, blocking immunosuppressive pathways; they play a increasing role in the first-line treatment of lung-cancers. This is particularly true when there is evidence for a significant pretreatment tumor lymphocytic infiltration and/or tumors exhibit a positive staining for PD-L1. As ICIs work through a different mode of action there is good reason to use therapy response criteria other than RECIST. In contrast to cytotoxic agents anti-tumour response in immunotherapy may take longer and in the initial phase the response to immune therapies can manifest in a morphologic “progressive disease”, therefore, called “pseudoprogression”. In this situation a early discontinuation of the treatment would not be appropriate, unless PD is confirmed. “Clinically insignificant” PD may even include the detection of new lesions ("unconfirmed progression") that may not lead immediately to a discontinuation of the oncologic regiment and has to be reevaluated. As ICIs act through a different mechanism than cytotoxic agents or tyrosine inhibitors, deblocking the immune system a broad spectrum of auto immune diseases can be triggered. Imaging characteristics of frequent and serious immune-related adverse events (irAEs) will be discussed.

Learning Objectives:

1. To know about the impact of PD-L1 positivity.
2. To know how to evaluate the tumour response after immunotherapeutics.
3. To be aware of the imaging features of immune therapy complications.

08:30 - 10:00 **Room M 5**

Molecular Imaging

Merging the best: hybrid imaging

Moderator:
G. Antoch; Düsseldorf/DE

A-058 08:30

A. Hybrid imaging with SPECT/CT

A. Scarsbrook; *Leeds/UK (a.scarsbrook@nhs.net)*

Latest generation SPECT/CT cameras incorporate multi-detector CT and state-of-the-art gamma camera technology in tandem. These scanners improve the efficacy of a wide variety of nuclear medicine tests by providing more accurate localisation of lesions, exclusion of potentially misleading physiological uptake, characterisation of equivocal or indeterminate activity and detection of additional lesions. In addition, they offer the potential for a more efficient "one-stop-shop" imaging approach. Iterative reconstruction algorithms and faster processing power facilitate radiation dose reduction and increased image resolution. The clinical utility of SPECT/CT is diverse and a cross-spectrum of applications in musculoskeletal, oncological, cardiological, endocrine, hepato-biliary and GI tract imaging will be presented.

Learning Objectives:

1. To learn the basic principles of hybrid SPECT/CT imaging.
2. To understand what complementary information can be given by SPECT/CT.
3. To learn about clinical applications of SPECT/CT.

A-059 09:00

B. Hybrid imaging with MR/PET

F.M.A. Kiessling; *Aachen/DE (fkiessling@ukaachen.de)*

In this talk an overview on the technological state of the art in PET-MRI as well as an outlook on emerging new technologies will be provided. Concerning the latter in particular new PET-insert solutions will be highlighted that are tailored to specific medical applications and body parts. Besides this, there will be a brief overview on new detector setups providing higher sensitivity and spatial resolution as well as on the methods to improve absorption correction and quantification. In the final part of the talk the focus will be set on the medical applications of PET-MRI. In this context, it will be discussed, which applications inevitably demand for PET-MRI hybrid imaging. Thus, with this talk I will try to convince the audience of the high development potential and clinical value of PET-MRI and its future role in patient management.

Learning Objectives:

1. To learn the basic principles of hybrid MR/PET imaging.
2. To understand what new information can be given by MR/PET.
3. To learn about emerging clinical applications of MR/PET.

A-060 09:30

C. Hyperpolarised MRI

F.A. Gallagher; *Cambridge/UK (fag1000@cam.ac.uk)*

There is increasing evidence to support a role for metabolism in many diseases; for example, deregulation of cellular energetics is now considered to be one of the key hallmarks of cancer. There are a number of imaging methods that have been used to probe this metabolism: the most widely available is 18F-fluorodeoxyglucose (FDG), an analogue of glucose, used in PET. Hyperpolarised carbon-13 MRI (13C-MRI) is an emerging molecular imaging technique for studying cellular metabolism, particularly in the fields of oncology and cardiology. This method allows non-invasive measurements of tissue metabolism in real-time. To date, the most promising probe used in conjunction with hyperpolarised MRI has been 13C-labelled pyruvate: pyruvate is metabolised into lactate in normal tissue in the absence of oxygen, but in tumours this occurs very rapidly even in the presence of oxygen. Results from many animal models have shown that there is a reduction in the metabolism of pyruvate to lactate following successful treatment with chemotherapy. In the heart, pyruvate is also metabolised to carbon dioxide in addition to lactate and this balance between anaerobic and aerobic metabolism alters in many disease states. There are now a small number of sites performing human hyperpolarised carbon-13 MRI imaging. This talk will discuss the progress that has been made in this field within the areas of oncology and cardiology and potential clinical applications.

Learning Objectives:

1. To learn the basic principles of hyperpolarisation.
2. To understand what new information can be given by hyperpolarised MRI.
3. To learn about oncological and non-oncological applications of hyperpolarised MRI.

Musculoskeletal radiology: inflammation

A-061 10:30

A. Inflammatory and infections in the soft tissues

S. Martin; *Palma de Mallorca/ES (silvia.m.martin@gmail.com)*

The diagnosis of infections is based on the presence of clinical symptoms like erythema, swelling, and pain. Also the diagnosis is based on the presence of clinical signs such as fever, tachycardia, shock, and hypotension and laboratory test such as leukocytosis, C protein reactive and Erythrocyte sedimentation rate. However, the clinical symptoms and signs of infection may not be specific, especially in the early stages of the disease. In these cases, imaging tests play a fundamental role in the early diagnosis of infections and in the differential diagnosis. The most important radiological findings for inflammatory and infections soft tissue are: (1) intramuscular fluid collections; (2) soft tissue air; (3) fascial fluid collections; and (4) muscle edema. Potential causes of these radiological findings are diverse, including, infectious, autoimmune, inflammatory, neoplastic, neurologic, traumatic and iatrogenic conditions. Some of these conditions require prompt medical or surgical management, whereas others do not benefit from medical intervention. Necrotizing fasciitis is a rare, life-threatening soft-tissue infection and a medical and surgical emergency that radiologist must know. The presence of gas within the necrotized fascia is characteristic, but may be lacking. The main finding is thickening of the deep fascia due to fluid accumulation and reactive hyperemia. All these findings may be seen in other different conditions. The ability to accurately diagnose these conditions is therefore necessary, and biopsy may be required to establish the correct diagnosis. Clues to the correct diagnosis and whether biopsy is necessary or appropriate are often present on the images techniques, especially when they are correlated with clinical features.

Learning Objectives:

1. To learn the key signs for differential diagnosis.
2. To learn about imaging findings and management options.

A-062 11:15

B. Arthropathies

U. Aydingoz; *Ankara/TR (uaydingo@hacettepe.edu.tr)*

Arthritis is a common problem involving the joints in the axial and/or appendicular skeleton across all age groups. Imaging plays a key role in the diagnosis and management of arthropathies, which are generally divided into degenerative, inflammatory, and metabolic categories. Digital radiography is the main imaging tool for joint diseases. Magnetic resonance imaging (MRI), computed tomography and ultrasonography are also used along with digital radiographs in the initial diagnosis and follow-up of joint diseases. The multiplicity and distribution of the involved joints, the pattern of joint space narrowing, and periarticular bone and soft tissue changes are important considerations for radiological diagnosis. The involvement of a single joint with inflammatory arthritis requires the exclusion of infection, whereas c involvement with degenerative arthritis may be due to an identifiable remote trauma. Septic arthritis does not have a pathognomonic radiological finding and, in the presence of clinical suspicion for infection, imaging should not delay joint fluid aspiration for microbiological investigation. This interactive session will cover the radiographic clues of arthropathies and the use of cross-sectional imaging methods, especially MRI, for suggesting the likely diagnosis. Some conditions, such as rotator cuff arthropathy and degenerative disease of the medial compartment of the knee secondary to medial meniscus posterior root avulsion, that have typical MRI findings shedding light on the pathophysiology of arthropathies will also be addressed.

Learning Objectives:

1. To explain the key points in the differential diagnosis of common arthropathies.
2. To describe the imaging findings of common arthropathies as they relate to pathophysiology.

Oesophagus

S. Romano; *Naples/IT (stefromano@libero.it)*

In this presentation focused on the first segment of the alimentary tract, current imaging techniques for evaluation of normal anatomy will be considered and described. From conventional radiography to modern hybrid imaging, essential information regarding the methods will be included. The second part of the lecture will describe the imaging features in most common benign pathologies, to give the attending useful informations for the daily clinical practise. Elective and Emergency conditions for the evaluation of the oesophagus will be considered. Finally, a pictorial guided review of the imaging features of malignant pathologies will be done.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

A-064 10:53

Stomach

M. Laniado; *Dresden/DE (michael.laniado@uniklinikum-dresden.de)*

Today, the stomach is well accessible for endoscopic evaluation. Therefore, double-contrast barium studies of the stomach have almost completely disappeared from the armamentarium of imaging studies in radiology. However, abdominal computed tomography (CT) - not so much magnetic resonance imaging (MRI) - has become the number one procedure in many scenarios if ultrasonography fails to provide a conclusive diagnosis. As the stomach is always imaged when abdominal CT is performed knowledge of normal anatomy, incidental findings, and the most often benign and malignant gastric pathologies is mandatory. Depending on the clinical request, imaging techniques are slightly different. If the main focus is on a lesion of the stomach, maximum wall distention should be achieved by oral administration of up to 2 L of water shortly before the study and i.v. administration of a hypotonic agent. In addition, i.v. administration of iodinated contrast material is mandatory. The presentation will cover normal anatomy of the stomach including locoregional lymph nodes. Examples of common and uncommon gastric lesions (e.g., carcinoma, lymphoma, GIST, NET, metastases, ulcer, portal gastropathy, pneumatosis, ischemia, pseudocysts) will be shown and discussed. Also examples of postoperative anatomy and potential complications will be part of the presentation.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

Small bowel

N. Papanikolaou; *Lisbon/PT*
(nickolas.papanikolaou@research.fchampalimaud.org)

Magnetic resonance imaging (MRI) provides excellent soft-tissue contrast without radiation exposure and three-dimensional imaging capabilities, which are important when studying the small intestine. Various sequences and contrast agents have been proposed for MRI examination of the small bowel. The development of high performance gradient systems improved the performance of ultra fast sequences and allowed comfortable breath-hold acquisition times. For a more detailed evaluation of small bowel diseases, MRI examination should be performed in conjunction with duodenal intubation and administration of a suitable contrast agent, i.e., iso-osmotic water solution (PEG) for homogeneous lumen opacification and adequate distention. A comprehensive MR enteroclysis imaging protocol should comprise single shot turbo spin echo (SSTSE), diffusion weighted imaging, true FISP, HASTE and fat suppressed T1 FLASH sequences. SSTSE is utilized for monitoring the infusion process and performing MR fluoroscopy while true FISP and HASTE, classified as sequential ultra fast techniques insensitive to motion, are mainly used for anatomic demonstration and detection of the pathology. T1 FLASH sequences after intravenous gadolinium injection may aid tissue characterization. For the assessment of Crohn's disease activity other alternative techniques may be used including perfusion and calculation of the magnetization transfer ratio of the bowel wall. These techniques may be useful for differentiating edematous or inflammatory bowel thickening from fibrotic thickening, but a more extensive evaluation is required to determine the clinical utility of these methods.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

Colon

R.G.H. Beets-Tan; *Amsterdam/NL (r.beetstan@nki.nl)*

Ultrasound, CT and MRI has a role in the workup of diseases of the large bowel. Transabdominal US is accurate to detect appendicitis. Contrast enhanced CT identifies the causes of bowel obstruction and dilatation. CT shows postoperative complications such as leakage of surgical anastomosis, internal herniation, bowel strangulations ,and bowel ischemia. Inflammation of the bowel, diverticulitis, epiploic appendagitis are well detected on CT. While endorectal US and MRI have been widely adopted in the staging work up of rectal tumors, the role of imaging in Colon cancer is limited to preoperatively roadmap the extent of the tumor into surrounding structures and to identify distant disease. Nevertheless this role may increase in the near future. This lecture will deal with various diseases of the colon and its imaging features and highlights future direction in imaging of colon cancer.

Learning Objectives:

1. To discuss current imaging techniques for evaluation of normal anatomy.
2. To describe the imaging features in most common benign pathologies.
3. To review and illustrate the imaging features of malignant pathologies.

CT of vascular pulmonary diseases

A-067 10:30

Chairperson's introduction

J.D. Dodd; *Dublin/IE*

Pulmonary vascular disease includes a wide spectrum of disease entities, many of which have overlapping clinical and imaging features. CT of the pulmonary vasculature has become an integral part of the investigation of such entities. In this session we are going to evaluate three distinct disease sub-categories of pulmonary vascular disease: pulmonary arterial hypertension, pulmonary vasculitis and Rendu-Osler disease. The first talk will cover pulmonary hypertension, the current clinical classification of pulmonary vasculitis, CT signs suggestive of the diagnosis, and CT signs that help discriminate between different causes. The comprehensive nature of CTPA in evaluating the mediastinum, vasculature and lung parenchyma will be shown. The second talk covering pulmonary vasculitis will emphasise the importance of combining CT signs with the clinical features and laboratory results since vasculitis may mimic other disorders and sometimes the clinical features are the major clue. CT findings in granulomatosis with polyangiitis and eosinophilic granulomatosis with polyangiitis will be shown, particularly emphasising the imaging differences between the two entities. The imaging findings of pulmonary hemorrhage will also be shown alongside the commonest causes. Finally the association between interstitial lung disease and the ANCA associated vasculitis will be discussed. The third talk covering Rendu-Osler disease will show the typical imaging features of this disease with a particular emphasis on those imaging aspects that determine outcome and treatment strategies. The talk will also cover contemporary aspects of endovascular treatment modalities and their complications.

A-068 10:35

A. CT imaging of pulmonary hypertension

N.J. Screaton; *Cambridge/UK (Nicholas.Screaton@papworth.nhs.uk)*

Pulmonary hypertension (PH) typically presents insidiously with non-specific symptoms and is usually progressive with poor outcome independent of aetiology. CT plays a vital role both in suggesting the possibility of pulmonary hypertension, whether initially clinically suspected or not, and in identifying a specific cause of pulmonary hypertension. The causes of pulmonary hypertension can be broadly divided into those affecting primarily the small vessels, PH secondary to left heart disease or chronic lung disease / hypoxia (the most common causes), chronic thromboembolic PH, and multifactorial causes. CT is widely available, inexpensive, and permits comprehensive assessment of the heart, pulmonary vasculature and lung parenchyma. CT signs such as dilatation of the proximal pulmonary arteries and right heart chambers can be considered as generic features associated with PH of any cause. Signs of a specific cause may lie in the mediastinum (left heart disease, shunt, oesophageal varices, oesophageal dilatation), vasculature (signs of CTEPH, tumour, large vessel vasculitis, fibrosing mediastinitis) or lungs (parenchymal lung disease, mosaic perfusion in CTEPH, signs of a small vessel vasculopathy). CTEPH is a not uncommon sequela of previous acute embolism. If the distribution is proximal it is potentially cured by surgical pulmonary endarterectomy or by balloon pulmonary angioplasty. Imaging in general and CT in particular play fundamental roles in both identification of CTEPH, its differentiation from acute PE, and in characterising its distribution. Imaging signs in CTEPH can be subtle and systematic evaluation of a CTPA is essential.

Learning Objectives:

1. To learn about the CT signs of pulmonary hypertension (PHT).
2. To become familiar with the current classification of PHT.
3. To be aware of the imaging features suggesting a thromboembolic origin.

A-069 11:03

B. Evaluating the pulmonary vasculitis

E. Castañer; *Sabadell/ES (ecastaner@tauli.cat)*

We will emphasize the importance of combine CT signs with the clinical features and laboratory results as vasculitis may mimic other disorders and sometimes the clinical features rate the clue. We will describe the findings in granulomatosis with polyangiitis (GPA) and eosinophilic granulomatosis with polyangiitis, highlighting the differences. Diffuse alveolar hemorrhage (DAH) is one of the manifestations of primary pulmonary vasculitis, among other entities (idiopathic alveolar hemorrhage, collagen vascular diseases, drug reactions, anticoagulation disorders). GPA and microscopic polyangiitis are the most common causes of DAH. Radiologic signs of DAH are nonspecific and variable, but must be considered in patients with otherwise unexplained alveolar infiltrates, particularly when seen with new onset renal insufficiency or a connective tissue disease. Finally we will mention the association between interstitial lung disease and ANCA associated vasculitis.

Learning Objectives:

1. To learn the common imaging features of granulomatosis with polyangitis (GPA).
2. To learn how to differentiate between GPA and eosinophilic granulomatosis with polyangiitis (Churg-Strauss).
3. To learn about the imaging features and differential diagnosis of pulmonary haemorrhage.

A-070 11:31

C. Rendu-Osler disease

S.D. Qanadli; *Lausanne/CH (Salah.Qanadli@chuv.ch)*

Rendu Osler disease (ROD) is an autosomal dominant genetic disorders characterized by the presence of telangiectasias and/or arteriovenous malformations. Pulmonary arteriovenous malformations (PAVM) are observed in up to 80% in ROD patients and it is believed that up to 30% of ROD patients will develop PAVM. During the last decade CT became the standard of reference in assessing pulmonary and associated subphrenic anomalies in patients with ROD. This lecture will focus on current protocols and recommendations for CT depending on the objective of the examination (screening, diagnostic or follow-up). Typically, PAVM is a well circumscribed rounded lesion that is connected to an afferent feeding artery and an enlarged efferent vein. PAVMs can be focal, multiple or diffuse. Imaging features as well as a comprehensive classification is provided. In asymptomatic patients, the risk of complications was reported to be high in PAVMs with an afferent artery diameter of 3 mm or more. The role of CT is then not only crucial in diagnosis, but also in therapeutic decision making process even if the 3 mm threshold concept in matter of debate and controversies. Principles of endovascular management of PVAM are reviewed. The transarterial access is the most common procedure. The modern approach includes the use of coils and/or plugs. CT flow up studies aim diagnosis of early complications, PAVM reperfusion detection, surveillance of small PAVMs, and diagnosis of new PAVMs.

Learning Objectives:

1. To become familiar with the CT manifestations of this disease.
2. To identify imaging features determining outcome and treatment strategies.
3. To learn about endovascular treatment modalities and complications.

No time to lose: aortic dissection - revisited

Moderator:
M. Krokidis; Cambridge/UK

A-077 12:30

Acute diagnosis and imaging in aortic dissection

R. Iezzi; *Rome/IT (roberto.iezzi.md@gmail.com)*

Aortic dissection is the most common acute emergency condition of the aorta, often resulting in the death of the patient. The overall outcome is determined by the type and extent of dissection and the presence of associated complications; therefore, evaluation of the entire aorta, branch vessels, and iliac and proximal femoral arteries is recommended to aid in treatment planning. Early diagnosis and treatment are essential for improving the prognosis. Patients may present with the classic history of acute onset of tearing central chest pain that radiates to the back. Stanford type A dissection involves the ascending thoracic aorta, and the dissection flap may extend into the descending aorta. Type A dissections account for 60%-70% of cases, requiring urgent surgical intervention to prevent extension into the aortic root, pericardium, or coronary arteries. If untreated, type A dissections are associated with a mortality rate of over 50% within 48 hours. Stanford type B dissection involves the descending thoracic aorta distal to the left subclavian artery and accounts for 30%-40% of cases. Management takes the form of medical treatment of hypertension, unless there are complicazioni due to extension of the dissection. CT imaging of the aorta is fast and widely available, which are the important features in making an accurate diagnosis quickly in unstable patients. Multidetector CT allows imaging of the entire aorta with rapid acquisition and data reconstruction to provide prompt and accurate diagnosis and to help identify relevant complications that may have an impact on treatment and management.

Learning Objectives:

1. To learn about definition and classification of aortic dissections and subtypes.
2. To understand the importance of accurate diagnosis for appropriate treatment planning.
3. To appreciate the need for acute diagnosis and treatment indication.

A-078 13:00

Endovascular treatment in aortic dissection

J.P. Schäfer; *Kiel/DE*

Acute aortic dissection represents a life-threatening condition, which must be diagnosed immediately. CTA is considered the imaging modality of choice, offering all relevant information on the pathoanatomy with highest spatial resolution. Stanford classification is used to distinguish between type A- and B-dissections, whereas the left subclavian artery represents the border in between the two types. Actually, surgical repair is the method of choice and indicated in type Adissection, and endovascular repair is the method of choice in type B-dissection, if indicated. Type Bdissection may be uncomplicated or complicated. For uncomplicated type B, best medical treatment is the method of choice, and it is defined by no further symptoms, relief of symptoms and absence of additional dissection associated findings. For complicated type B, endovascular repair including a variety of interventions is the method of choice, and it is defined by mesenterial, renal, peripheral and spinal malperfusion, progressive dissection, aneurysm forming, uncontrollable hypertension, rupture, progressive periaortic and pleural haemorrhage, severe hypotension and shock. Regarding symptom onset and imaging based diagnosis, type B-dissection is classified as acute (<2 weeks), subacute (2-8 weeks), and chronic (>8 weeks). Endovascular repair usually includes prosthesis placement in the descending aorta, in order to seal the proximal entry tear. This excludes the perfusion of the false lumen along the covered aortic segment and restores the blood flow into the true lumen, maintaining and improving the visceral and peripheral perfusion. Additionally, target visceral artery stenting, membrane fenestrating or embolising may be indicated. Protocolled CTA follow-up is mandatory.

Learning Objectives:

1. To learn about endovascular treatment possibilities for aortic dissections.
2. To understand the role of radiology in modern treatment of aortic dissections.
3. To appreciate the need to combine the radiological information with the clinical situation.

Degenerative disorders

A. Cotten; *Lille/FR (anne.cotten@chru-lille.fr)*

Osteoarthritis is the most common joint disease worldwide. It is a major source of pain, disability, and socioeconomic cost. The epidemiology of the disorder is complex and multifactorial, with genetic, biological, and biomechanical components. Conventional X-ray is the standard diagnostic method to confirm the clinical diagnosis, to evaluate the degree of severity of osteoarthritis and to look for predisposing conditions. CT can be performed for the assessment of

bone stock, anatomic conditions and bone deformation. MRI can be used to confirm early forms and to clarify possible damage and/or wear and tear, which cannot be seen on X-rays. Finally, intraarticular administration of contrast will be performed in selected cases, when a precise assessment of the cartilage or fibrocartilage is required. This lecture will focus on the role of imaging in clinical practice, the typical and atypical imaging features of OA, the radiological features which should not be read as OA, and the main predisposing factors that have to be known and searched.

Learning Objectives:

1. To appreciate the musculoskeletal imaging manifestations of degenerative disorders.
2. To understand the underlying pathomechanisms involved in these imaging abnormalities.
3. To appreciate the strengths and weaknesses of imaging modalities in assessing these disorders.

Brain injury
J. Walecki; *Warsaw/PL*

Head injuries are one of the most frequent causes of death and disability. The following presentation will discuss the indications for imaging in patients with traumatic brain injury(TBI), review the role of X-ray examination, computed tomography (CT) and magnetic resonance imaging (MRI) in the management of TBI. CT still remains the method of choice in brain injury diagnosis and allows rapid assessment of the extent and type of brain pathology which ensures us which patients require urgent surgical intervention. There are many CT structural modalities such as MPR, volume rendering and CT angiography important in particular cases of traumatic patients. In addition to above, author will also discuss TBI diagnosis in MRI applications which are newly applied to clinical practice like TDI, fMRI and analyse potential applications of these imaging modalities. Using a complex variety of MR sequences, we can provide data concerning both structural and pathophysiological derangements. Future developments with such imaging techniques could improve understanding of the pathophysiology of brain injury and provide data that improve management and prediction of functional outcome. In this presentation all type of brain injury and its imaging features will be presented. Goals and objectives - to understand the mechanisms of traumatic brain injury - to learn about CT and MR imaging findings in different traumatic lesions of the brain - to be familiar with advantages and disadvantages of different imaging techniques in traumatic brain injury

Learning Objectives:

1. To review mechanisms of brain injury.
2. To present current imaging techniques for evaluation of brain injury.
3. To illustrate different types of traumatic intracranial lesions.

A-081 14:30

Subarachnoid haemorrhage
C. Calli; *Izmir/TR (cem.calli@gmail.com)*

Subarachnid hemorrhage (SAH) is a very common and life-threatining disease. It occurs most commonly secondary to trauma and intracranial vascular abnormalities. The early diagnosis is very important and imaging modalities have an important role. Non-contrast CT (NCCT) should be the first choice for imaging. It can provide the visualisation of hyperdense blood products in the cisterns and sulci. In cases of negative NCCT scan, MRI may be a choice, especially in patients in the subacute phase using FLAIR and SWI sequences. However, every case with non-traumatic SAH should be examined with digital substraction angiography (DSA) in order to exclude a vascular abnormality, particularly aneurysm. In this lecture both common and uncommon causes of SAH will be discussed and a multi-modality approach to the diagnosis will be reviewed.

Learning Objectives:

1. To review the most common pathologies leading to SAH.
2. To present current imaging techniques for evaluation of SAH.
3. To describe the radiological findings of SAH.

A-082 15:00

Ischaemic stroke
Z. Merhemic; *Sarajevo/BA (merhemic.zulejha@gmail.com)*

CT is primary imaging modality in patients with acute stroke. The early signs of brain infarction on non contrast CT are insular ribbon sign reflect cytotoxic edema and relates to specificity of of arterial anatomy.Disappearing basal ganglia sign is caused my MCA occlusion proximally to lenticulostriate artery. Early mass effect includes narrowing of Sylvian fissure or loss of cortical sulci. Hyperdense artery sign represent stasis of flow due to arterial thrombus and correlates positively with angiographic finding of occlusion. CTA is essential for evaluation of intra- and extracranial vessels and intravascular thrombi. Conventional MRI finding in acute stroke are hyperintense zones on T2 and FLAIR, mass effect, sulcal effacement, loss of arterial flow voids, and abnormal blooming and parenchymal black dots due to the hemorrhage on T2*GE and SWI. DWI with ADC maps is most sensitive for detection of hyperaute stroke at first 6 hours. In ischemic stroke, reduction of perfusion occurs, typically in an affected vascular territory. Regions with hypoperfusion are shown as decreased CBF, decreased CBV, prolonged MTT, and prolonged measures of contrast transit such as TTP, Tmax or DT. Since these parametric changes are detectable minutes after stroke onset, they are of great use for early diagnosis of ischemic stroke and to differentiate ischemic penumbra from infarct core. There are two perfusion approaches with good application in acute stroke, MR perfusion and CT perfusion. Compared the two methods, CT perfusion (CTP) has the advantage of rapidity and wide accessibility in emergency room together with CTA which may be used to guide thrombolytic treatment and may guide predictions of functional outcome and hemorrhagic complications.

Learning Objectives:

1. To become familiar with the most common aetiologies of stroke.
2. To present current imaging techniques for evaluation of stroke.
3. To recognise the imaging signs of stroke.

E³ 318

MR imaging of the lungs

A-083 14:00

Chairperson's introduction
E.J.R. van Beek; *Edinburgh/UK (edwin-vanbeek@ed.ac.uk)*

MRI of the lungs is increasingly used for a variety of reasons. In some diseases, it can be used as an escape from harmful radiation, such as in young or pregnant patients with suspected pulmonary embolism. This is being extended by short, focused protocols as a first line test in some centres. In other diseases, it is the "go to" modality; for instance, in patients with superior sulcus tumours or where difficult anatomical structures need to be evaluated before treatment decisions can be made. Lastly, airway imaging and evaluation of dynamics of breathing can be assessed using novel methods. This session will go into detail for the three areas described.

A-084 14:05

A. Diagnosing pulmonary embolism
B. Ghaye; *Brussels/BE (benoit.ghaye@uclouvain.be)*

Twenty-five% of patients suspected of PE may present with contraindication to iodinated CM which indicates a potential role for MR. Recent MR technical refinements have been substantial in this field with faster sequences, larger coverage, lung perfusion imaging and high-resolution pulmonary MR angiography (MRA). Basic sequences for PE include unenhanced SSFP and 3D GRE pulmonary MRA. Technically inadequate examinations are reported in 25-30%, mainly due to poor vascular opacification and artifacts. MR direct signs of acute PE are similar to those of CT, including partially occluding endoluminal filling defects and complete arterial obstruction showing a meniscus termination outlining the clot. Reported sensitivity and specificity of MRA in large series were around 80% and 95-100%, respectively. Sensitivity decreases from central to lobar level (close to 100%), segmental level (70-90%) and subsegmental level (30%). Unenhanced MRA has 82% sensitivity and 90% specificity in the 50% interpretable examinations, showing a similar decrease of sensitivity from proximal to distal level. Perfusion also showed 75% sensitivity and 90% specificity in the 50% interpretable examinations. Similar to CT, MR can provide alternative diagnoses or ancillary findings

altering the management of the patient. A comprehensive assessment of the venous thromboembolic disease may be achieved by the addition of a MR venous phase without further injection of Gadolinium CM. The sensitivity of the combined test may however be increased at the expense of a higher rate of technically inadequate examinations. It is expected that newer 3D MR angiography sequences will increase yield in the field of venous thromboembolism.

Learning Objectives:

1. To learn about the various MR sequences for pulmonary arteries imaging.
2. To become familiar with the MR signs of pulmonary embolism.
3. To understand the current limitations of MR for PE diagnosis.

A-085 14:33

B. Evaluating lung neoplasms

J. Dinkel; *Munich/DE*

The purpose of this presentation is to review the currently available MR techniques useful in thoracic oncology and to provide an overview of present and emerging clinical applications of oncologic thoracic MRI. Although many studies have advocated a valuable role for thoracic MRI, it has currently limited clinical utilization with the exception of cardiovascular imaging. However, new technical developments and MRI sequences have continuously improved the quality and broadened the clinical indications for thoracic MRI, especially in thoracic oncology. Furthermore, due to its high soft tissue contrast and the lack of radiation exposure, MRI allows for repeated measurements of the lung structures and, therefore, appears to be appropriate for functional investigation of lung.

Learning Objectives:

1. To review the role of MR for assessing the T status.
2. To learn about MR diffusion sequence performance for N staging.
3. To review the persisting limitations.

A-086 15:01

C. Evaluating the airways

G. Dournes; *Bordeaux/FR (gael.dournes@chu-bordeaux.fr)*

Due technical difficulties related to motions and susceptibility artifacts, MR imaging has long been considered out of the scope of routine application in the field of imaging of airways, except in a few expert centers. However, recent improve and simplification in MR acquisition techniques have enabled MRI to reach high resolution imaging for morphological evaluation of both large and small airways. In addition, acute and chronic airway diseases are largely misunderstood by far, so that the ability of MRI to combine both morphology and functional information in a single radiation-free examination will eventually make MRI a modality of choice for better understanding, improving patient care and long term follow up requiring iterative examinations. Finally, recent advances in treatment are also prone to make radiologist reconsider the role and place of imaging in chronic diseases (cystic fibrosis, idiopathic pulmonary fibrosis, etc) to assess sensitively and specifically response to treatment.

Learning Objectives:

1. To review the role of MR for evaluating the large and small airways.
2. To learn about the current state-of-the-art MR sequences.
3. To learn about the current role of MR in cystic fibrosis.

14:00 - 15:30 **Room M 5**

E³ - ECR Academies: Update on Hepatobiliary Imaging

E³ 320
Diffuse liver disease

A-087 14:00

Chairperson's introduction

C. Triantopoulou; *Athens/GR (ctriantopoulou@gmail.com)*

The session is focused on the different aspects of diffuse liver disease. An update in non-invasive imaging will be offered in detail, pointing mainly to fat, iron, and fibrosis deposition and the accuracy of quantitative methods in disease grading and severity assessment. Non-alcoholic fatty liver disease is the most common cause of chronic liver disease in Western countries. US, CT and MRI are used to evaluate the disease, to assess severity, and quantify the amount of fat deposition. Despite advances in imaging techniques accurate measurements are still challenging, and new evolving methods are applied on US and MRI. MRI remains the gold standard and the method of choice, answering the clinically important questions. Congenital diffuse liver diseases comprise some rather uncommon conditions, while iron overload is related to a variety of congenital and hereditary conditions. Differential diagnosis is of outmost importance for patients' management. MRI is the method of choice to evaluate and quantify iron overload provided that specific imaging protocols are used and the standardized techniques together with validated acquisitions are applied. Diagnosis and staging of liver fibrosis is one of the most challenging aspects of non-invasive imaging. Current application of US and MRI are nowadays able to provide accurate measurements based on US and MRI elasticity tools. "Virtual biopsy" refers to the possibility of imaging techniques to depict, map and measure fibrosis minimizing the need for liver biopsies in chronic diffuse liver diseases. MR allows an accurate determination of steatosis, iron overload and fibrosis, even if they coexist.

A-088 14:05

A. Assessment and quantification of fat in NAFLD

M. Ronot; *Clichy/FR (maxime.ronot@bjn.aphp.fr)*

The diagnosis of steatosis in patients with NAFLD is historically based on histological examination of a tissue specimen obtained by liver biopsy. However, liver biopsy has well-known limitations (invasiveness and sampling variability) and cannot be proposed for all patients, especially given the high prevalence of NAFLD worldwide. Several imaging techniques can be used for the non-invasive diagnosis and quantification of steatosis. Ultrasonography and computed tomography are useful for the detection of marked steatosis, but of limited use for precise quantification of mild to moderate fat deposition. MR proton spectroscopy (MRS) is the most accurate technique, but it is not feasible in routine use and is time consuming. Chemical shift sequences offer now an accurate alternative and have been shown to be very well correlated to MRS and liver biopsy. As a consequence, they are progressively accepted as a reference technique for detection and quantification of hepatic fat deposition. Recently, novel parameters, such as the controlled attenuation parameter (CAP), or the speed of sound estimation have been proposed and offer promising results. As for liver fibrosis, the diagnostic strategy should rely on the combination of several non-invasive techniques.

Learning Objectives:

1. To be familiar with the pathogenesis of NAFLD.
2. To recognise current non-invasive imaging methods used to evaluate hepatic steatosis.
3. To realise the clinical applications, diagnostic accuracy and limitations of each method.

A-089 14:33

B. Congenital diffuse liver diseases and iron overload

M.M. França; *Porto/PT (mariamanuela.franca@gmail.com)*

Congenital and inherited hepatic diseases, like congenital hepatic fibrosis, Wilson disease or hereditary hemochromatosis, are rare diffuse liver diseases that may progress to cirrhosis. Liver imaging, particularly magnetic resonance (MR) imaging, provides important information on diffuse parenchymal abnormalities, but may also reveal focal liver lesions. Iron overload is found in hereditary hemochromatosis, but also in transfusional hemosiderosis and iron loading anemias, and chronic liver diseases. Quantification of liver iron concentration by MR imaging is crucial for the diagnosis and treatment monitoring of iron overload diseases. MR quantification of liver iron can be performed with signal intensity ratio (SIR) methods or relaxometry techniques. Both R2 and R2* values are increasingly being used for quantification of liver iron concentration, but they must be performed with validated acquisition and analysis protocols. Hereditary hemochromatosis will be presented as an example of a clinical scenario, to emphasize the relevance of MR for detection and quantification of liver iron deposits and its role in patients' management and treatment monitoring.

Learning Objectives:

1. To recognise specific imaging findings in patients with congenital hepatic diseases such as Wilson's disease and congenital hepatic fibrosis.
2. To be able to determine iron content in liver by MRI.
3. To be able to differentiate common focal lesions found in storage disease of the liver.

A-090 15:01

C. Diagnosis and staging of liver fibrosis

L. Martí-Bonmatí; *Valencia/ES (marti_lui@gva.es)*

Chronic liver disease is a major public health problem with an increasing prevalence and an emergence clinical interest. Fat, inflammation and iron deposits induce an oxidative stress on the liver with synergistic effects in the progression of fibrosis and cirrhosis. In this sense, it is well known that around 7% of the adult population without known liver disease have liver fibrosis, mostly associated with NAFLD. The up-till-now gold standard biopsy is limited by sample size (≈1/50.000); sample quality; sampling variability errors (30-40%); inter- and intraobserver variability (>30%); morbidity (1%); and not being

feasible for follow-up and research studies. Therefore, radiologists need to understand the hallmarks and therapeutic implications of liver fibrosis. However, correlation with pathology is troublesome, unless digital pathological quantitation is achieved. In this way, radiologists need to depict, map and measure fibrosis in chronic liver disorders to initiate treatment and evaluate response. The fat-suppressed T2w, STIR, and equilibrium phase DCE T1w images show fine hyperintense reticular septa. These changes are late in the course of disease. Although diagnostic accuracy by texture analysis might be earlier (skewness, GLGM categories). T1ρ MR imaging is also able to detect early liver fibrosis as correlates with collagen content. Elasticity can be measured with US and MR elastography. IVIM elasticity measures can be also incorporated into the imaging armamentarium. All this radiomic and imaging biomarkers features have different reproducibility and accuracy, but can be excellent tools for the non-invasive diagnosis, follow-up, and treatment evaluation metrics in liver fibrosis.

Learning Objectives:

1. To be able to understand the clinical relevance of detection, characterisation and grading of liver fibrosis.
2. To recognise the imaging techniques that have an emerging role in non-invasive assessment of liver fibrosis.
3. To be able to detect portal hypertension.

16:00 - 17:30 **Room B**

Abdominal Viscera

RC 401

Imaging of the complicated postoperative abdomen

A-095 16:00

Chairperson's introduction

C.J. Zech; *Basle/CH (christoph.zech@usb.ch)*

Imaging of the postoperative abdomen is a crucial part in the evaluation of postoperative complications and will lead the clinician in the decision for treatment of postoperative complications with either re-laparotomy, interventional-radiology treatment or conservative/medical treatment. Knowledge of the performed surgical techniques and procedures, the normal imaging appearance postoperative and typical findings of frequent complications are inevitable to successfully treat patients with complications. A good interaction between the surgeon and the abdominal radiologist is needed. Nowadays, radiology should be able to diagnose most complications and minimise the number of mere diagnostic laparoscopies to evaluate a complicated postoperative clinical course.

Session Objectives:

1. To learn about the most common indications for abdominal surgery.
2. To understand the normal imaging findings in postoperative abdomen.
3. To describe and identify the most common postoperative complications.

Author Disclosure:

C.J. Zech: Speaker; Bayer HealthCare.

A-096 16:05

A. Liver

C. Ayuso; *Barcelona/ES (cayuso@clinic.ub.es)*

Liver resection is proven to achieve long term survival in selected patients with primary or secondary focal liver lesions. Advances in surgical techniques including robotic liver surgeries, systemic adjuvant chemotherapy and postoperative intensive care improved the outcome of liver resection. Adequate liver remnant is crucial to guarantee the correct liver function after radical potentially curative liver resection. In borderline cases, portal vein embolisation (PVE), or associating liver partition and portal vein ligation for staged hepatectomy (ALPPS) has been proposed before surgery to increase the liver remnant. Preoperative volumetric analysis of the liver based on imaging plays an essential role in the preoperative work-up previous to liver resection. Also the knowledge of the vascular hepatic anatomy and possible variants of the biliary system are also key aspects to avoid postoperative complications. Imaging tools based on multidetector computed tomography (MDCT) and magnetic resonance (MR) influencing preoperative decisions and surgical approaches will be discussed. The role of different imaging techniques as plain ultrasonography (US), contrast enhanced ultrasonound (CEUS), MDCT and MR for the detection and management of hepatic complications after liver resection or transplantation (infectious, vascular, biliar, parenchymatous (liver rejection) will be analysed.

Learning Objectives:

1. To learn about indications for liver interventions and different surgical approaches to focal liver lesions.
2. To understand the role for the different imaging techniques (US, CEUS, CT and MRI) in assessing different types of complications.
3. To appreciate the spectrum of parenchymal, biliary and vascular complications occurring after liver resection or transplantation.

A-097 16:28

B. Pancreas

R.M. Gore; *Evanston, IL/US (rgore@uchicago.edu)*

Both benign and malignant pancreatic disease carry significant morbidity and mortality. Because of the fastidious nature of the pancreas and its local and regional anatomy, treatment of these disorders also carries significant morbidity. Indeed, perioperative morbidity of pancreaticoduodenectomy is approximately 30-40%. Due to the diversity of pathology, detection, and characterisation of postoperative complications can be challenging. Familiarity with the normal imaging appearances of the spectrum of surgical procedures and their complications is vital. In this presentation the common pancreatic surgical procedures performed for tumour resection (i.e., the Whipple's operation, enucleation, central and distal pancreatectomy, spleen preserving distal pancreatectomy) and chronic pancreatitis (i.e., Puestow procedure, Beger procedure, Frey procedure) and their normal postoperative appearances are discussed. The common postsurgical complications including pancreatic fistulas and leaks, abscess formation, haemorrhage, and delayed gastric emptying are then described in detail.

Learning Objectives:

1. To learn about the various surgical approaches for acute and chronic pancreatitis, benign and malignant pancreatic neoplasms.
2. To understand profound impact that the partial and complete pancreatectomy have on the adjacent abdominal organs.
3. To appreciate the common postoperative complications of pancreatic surgery.

A-098 16:51

C. Bowel

D.J.M. Tolan; *Leeds/UK (djmtolan@doctors.org.uk)*

Post operative assessment of the luminal GI tract is very complex and relies heavily on CT. It presents a major challenge for interpretation and detection of abnormalities in the context of a very broad range of normal post operative appearances. In judging whether the imaging appearances are normal or not it is essential to consider the time that has elapsed since the operation and the complexity of the procedure that was performed, since a straight forward procedure or one performed laparosscopically with carbon dioxide insufflation should have very little residual fluid or gas, compared with a complex open surgical procedure. Anastomotic leak is the most important complication to detect, and in this regard positive luminal contrast is the most sensitive for evaluation and this can be administered orally or rectally depending on the position of the anastomosis. An 8% concentration of 300mg/ml concentration non ionic contrast is used by the author. Other complications such as abscess can be detected by CT but this must be differentiated from haemostatic surgical material which is left in situ deliberately.

Learning Objectives:

1. To learn about the most common types of major oesophago-gastric, small bowel and colorectal surgical procedures and the expected postoperative anatomy and imaging findings.
2. To understand how to optimise imaging protocols to maximise the opportunity to detect postoperative complications after enteric surgery.
3. To appreciate and identify early and late complications after bowel surgery.

CT - patterns in chest radiology: back to basics and beyond

A-099 16:00

Chairperson's introduction

M.A. Mazzei; *Siena/IT (mmazzei@sirm.org)*

Today the majority of diagnosis in chest radiology is accomplished by high-resolution computerised tomography (HRCT) and advanced HRCT imaging interpretation which have improved a lot the accuracy in diagnosing diffuse lung diseases, such as interstitial pneumonia, thus avoiding the need for a surgical biopsy in many patients. All this can be possible because of the anatomical distribution of the lesions often suggests the diagnosis in pulmonary diseases, owing to the close relationship between HRCT pattern and some diseases and also because of the exact depiction of pulmonary anatomy at HRCT imaging. For this reason the knowledge of anatomy in reading CT is essential for radiologists: recognising the anatomical distribution of lesions or a typical pattern at HRCT imaging is the key to a successfully correct diagnosis.

Session Objectives:

1. To emphasise the importance of anatomy in reading CT.
2. To appreciate the necessity of defining patterns to improve CT diagnoses.

A-100 16:05

A. Secondary pulmonary lobule anatomy: essential to tackle with the nodular pattern

T. Frauenfelder; *Zurich/CH (thomas.frauenfelder@usz.ch)*

The goal of this lecture is to provide information about the anatomy of the lung and to provide a structured approach to nodular pattern. High-resolution CT gives detailed morphologic information about lung structures. This allows distinguishing findings by their typical predominance in certain anatomical compartments. The secondary pulmonary lobule is the functional unit of the lung and is the key to HRCT terminology. The anatomy of secondary lobule, therefore, plays a key role. Based on the distribution of nodular lesions in relation to the bronchial, vascular and lymphatic structure of the secondary lobule the number of possible pathologies can be narrowed down. For example, centrilobular predominance of nodules is a frequent sign of bronchiolitis. Perilymphatic predominance in the periphery of the lobules is associated with sarcoidosis or lymphangitic spread of cancer. Random distribution of nodules is interpreted as a sign of haematogenic spread of disease. Therefore, a subtle interpretation can contribute substantially to clinical decision making. Nevertheless, these signs may not always replace biopsy and histologic workup. Sometimes is it can be difficult to determine the pattern of lung nodules within the secondary pulmonary lobule. By following a consistent approach it will minimise the difficulty in interpretation. During this lecture, a stepwise algorithm for differentiating nodular pattern will be provided that allows a pragmatic approach for a successful reading of HRCT.

Learning Objectives:

1. To become confident in recognising the anatomical compartments of the lung.
2. To describe typical nodular imaging patterns of lung disease using appropriate terminology.

Author Disclosure:

T. Frauenfelder: Other; Bayer.

A-101 16:28

B. Linear and reticular pattern

F. Molinari; *Lille/FR (francescomolinari.dr@gmail.com)*

The reticular pattern is one of the imaging findings that may suggest the presence of a diffuse parenchymal lung disease at HRCT. Reticulations are typically formed by a collection of innumerable small linear opacities that by summation produce an appearance resembling a "net". Lines may vary from smooth to nodular and irregular. The resulting "net" may alter the normal HRCT appearance of the lung and become suspected for an underling lung disease. Chest radiologists typically use a structured approach to interpret this finding and eventually to propose a diagnosis. The radiologic approach consists in identifying the dominant types of lines, in establishing what portion of the lung interstitium is predominantly involved, and in correctly classifying the type of reticulation (namely inter-lobular, peri-lobular, intra-lobular). When all the radiologic features are correctly interpreted, the radiologist can differentiate reticulations that represent an acute disease from those that indicate a chronic inflammatory or fibrotic change in the lung. In addition, by integrating clinical and laboratory data, it is possible to significantly narrow the final differential diagnosis.

Learning Objectives:

1. To recognise and interpret typical reticular imaging patterns.
2. To differentiate acute and chronic diseases which cause septal patterns.

A-102 16:51

C. Ground glass opacities (GGO) and consolidation

J. Vogel-Claussen; *Hannover/DE (vogel-claussen.jens@mh-hannover.de)*

Ground glass opacity (GGO) is a nonspecific finding on computed tomography (CT) scans of the chest that indicates a partial filling of air spaces in the lungs by exudate or transudate, as well as interstitial thickening or partial collapse of lung alveoli. The term derives from the similarity in appearance of the small objects to small chips of glass that are a by-product of glass grinding. The differential diagnosis of the many causes of GGO includes pulmonary oedema, infections (including cytomegalovirus and Pneumocystis jirovecii pneumonia), various noninfectious interstitial lung diseases (such as hypersensitivity pneumonitis, Hamman-Rich syndrome), diffuse alveolar haemorrhage, and cryptogenic organising pneumonia. Thus, clinical correlation and disease dynamics are important to narrow down the differential diagnosis. The aim of this refresher course is to distinguish ground glass opacities from consolidations on chest CT and give practical instructions for daily clinical routine.

Learning Objectives:

1. To appreciate different conditions which cause GGO pattern and consolidation.
2. To learn how to interpret GGO and consolidation in different clinical settings.

A-103 16:00

Thyroid US elastography: indications and limitations

V. Cantisani; *Rome/IT (vito.cantisani@uniroma1.it)*

Thyroid gland examination by palpation is a basic method in the assessment of thyroid nodules as firm and anelastic lesions should be suspected being of malignant nature. On the other hand, US, despite its high sensitivity for the detection of thyroid lesion, has limited accuracy to differentiate benign and malignant lesions. Indeed, to date, FNAC is still considered the gold standard for optimal characterisation of thyroid lesions, but still in 15% to 25% of cases FNAC findings can be suspicious and in 5% to 15% of cases inconclusive. Elastography is a new imaging modality where elastic tissue parameters related to the structural organisation of normal and pathological tissues are imaged. The relationship of tissue elasticity and hardness to Cy follows the basic principle that to be palpable, the object must be harder than the surrounding tissue. The evaluation of stiffness can be qualitative with a color coding system or semiquantitatively by means of strain ratio or ECI or quantitatively (sp-SWE or 2D-SWE) . Elastography has showed good diagnostic values both with qualitative and quantitative modalities. However, to date, still some issues may be answered. The main features,the diagnostic accuracy and the main recognised limitations of the different elastographic techniques, suggesting how we can improve accuracy, and reduce interobserver variability will be presented. Personal experience and review of the literature will be provided.

Learning Objectives:

1. To learn about updated status on thyroid nodule evaluation by using TIRADS and US-elastography.

2. To provide tips and tricks, guidelines established indications and limitation of thyroid US-elastography.
Author Disclosure:
V. Cantisani: Speaker; bracco, samsung, toshiba.

A-104 16:20

Elastography of the breast: when should we assess tumour stiffness?
J. Carlsen; *Copenhagen/DK (jonathan.carlsen@gmail.com)*

Elastography is an adjunct to B-mode imaging in breast tumour evaluation and has been included in the latest BIRADS atlas of 2013. Both quantitative and qualitative elastography methods can be used to assess breast tumour stiffness, which correlates with the risk of malignancy. Elastography is easily performed, and is implemented in most new ultrasound systems, but depending on the elastography method used, different diagnostic cut-offs or visual scoring systems are used. As a stand-alone examination elastography is inferior to B-mode imaging, but in combination with B-mode imaging, elastography may be used to determine weather or not to perform biopsies or do follow-up examinations in low-suspicion tumours. Different ways of combining the two diagnostic methods have been proposed, and the diagnostic algorithms will vary depending on the clinical practice and setting used. It is therefore important, to understand the different elastography methods, their pit-falls and limitations.
Learning Objectives:
1. To learn how to perform elastography of the breast with different US techniques.
2. To learn when breast elastography is a useful adjunct to the standard breast ultrasound examination.
3. To understand the potentials and limitations of breast elastography.

A-105 16:40

Is there any value in tendon and nerve assessment?
A. Klauser; *Innsbruck/AT*

The Achilles tendon has been the most studied musculoskeletal structure with strain and shear wave elastography (SWT). Alterations in strain elastograms of asymptomatic Achilles tendons mainly occur in the mid-portion, they do not always correspond to changes on conventional US. This has been correlated with histology, where the sensitivity of strain elastography was better than B-mode US in Achilles tendons, flexor and extensor tendon insertions of the elbow for the detection of tendinotic changes. SWT confirmed and quantified softening within the Achilles tendon in patients and in lateral epicondylosis significantly lower strain ratios in the common extensor tendon origins in terms of tendon softening can be observed. For peripheral nerves strain elastography has shown, that the diagnostic accuracy of ultrasonographic assessment can be improved. Furthermore the stiffness of the intracarpal tunnel contents in untreated CTS patients is higher than that of healthy volunteers but decreases after corticosteroid injection. Shear-wave elastography provides a further exciting tool for examining nerve biomechanics; however, longitudinal studies are needed to elucidate clinical relevance before they can be adopted into routine clinical practice. To summarize, elastography can be used as a supplementary tool to conventional US scanning to increase the diagnostic confidence in diagnosing tendinopathies.
Learning Objectives:
1. To learn about the value of sonoelastography in musculoskeletal disorders.
2. To understand the impact of sonoelastography in tendon and nerves.
3. To appreciate the meaning of sonoelastographic findings in tendon and nerve disorders.
4. To become familiar with sonoelastographic techniques used in tendons and nerves.

A-106 17:00

Scrotal elastography: hype or real?
M. Bertolotto; *Trieste/IT (bertolot@units.it)*

The testis is readily palpable, allowing a direct examination of masses. Hard lesions at palpation are considered likely malignant, until proved differently. Compared to palpation elastography provides a more objective evaluation of tissue consistency, but the information provided is basically the same. As a consequence, benign pathologies that are hard at palpation will display increased consistency at elastography as well. On contrary, malignant tumours may display soft areas, or appear globally soft. Correlation with histologic features helps explain these discrepancies, and changes in time of elastographic appearance of evolving lesions. Use of elastography in evaluation of diffuse testicular pathologies affecting endocrine function and spermatogenesis is undergoing investigation in an attempt to find new clinically useful independent parameters. A quantitative evaluation of testicular stiffness is feasible using shear-wave modes. In preliminary experience, the elasticity pattern of the testis seems to be related to the volume and function. Elastography, in particular, seems promising to differentiate azoospermia from different causes. The clinical impact of these findings in the current practice is, however, questionable and technical optimization is necessary.
Learning Objectives:
1. To learn about how to perform elastography of the testis with the different US equipment.
2. To become familiar with the appearance of normal testis at strain and at shear wave elastography.
3. To understand the potential and limitation of elastographic modes in imaging scrotal pathologies.

Paediatric

RC 412

Vascular and interventional radiology in children

Moderator:
E. Alexopoulou; Athens/GR

A-107 16:00

A. Common IR procedures in children: state-of-the-art
A. Barnacle; *London/UK (Alex.Barnacle@gosh.nhs.uk)*

Interventional radiology (IR) procedures are now a vital part of paediatric care for most complex diseases, providing reliable intravenous access and feeding tube support during intensive therapy such as chemotherapy and delivering innovative minimally invasive therapies for other conditions to avoid surgery. Central venous access in children can be technically challenging, but is quicker and less invasive than open surgical techniques and there is evidence to suggest that the central veins are preserved for longer, which is key in children with chronic disease. Looking beyond central venous access, paediatric IR delivers therapies such as sclerotherapy for vascular malformations, percutaneous nephrolithotomy (PCNL) for renal stone extraction, oesophageal dilatations to manage oesophageal structures and biopsy to safely and accurately stage childhood tumours.
Learning Objectives:
1. To learn about the most common causes for image-guided intervention in children.
2. To understand how the practical and technical approach to intervention in a child differs from that in adults.
3. To appreciate tips, tricks and pitfalls in the paediatric intervention.

A-108 16:30

B. Vascular malformations: diagnosis and interventions
N.N.

Learning Objectives:
1. To learn about the classification of paediatric vascular malformations.
2. To understand the diagnostic work-up and the indications for percutaneous treatment of paediatric vascular malformations.
3. To appreciate the treatment options for different vascular malformations.

A-109 17:00

C. Percutaneous treatment of osteoid osteoma
D. Filippiadis; *Athens/GR (dfilippiadis@yahoo.gr)*

Percutaneous treatment of osteoid osteoma. Osteoid osteoma is a benign inflammatory bone tumor encompassing 2-3% of all bone tumors and 10% of benign bone tumors; it is most common in males < 25 years of age with patients typically complaining of pain that worsens at night and is promptly relieved by salicylates. The tumor was first reported by Jaffe in 1953; osteoid osteoma is composed of the nidus which is bone at various maturity stages surrounded by highly vascular connective tissue stroma. Depending on the location and axial imaging findings, osteoid osteoma can be classified into subperiosteal, intracortical, endosteal or intramedullary, and intra-articular with the latter being the least common type and refers to lesions located within or near a joint. In the literature there are scarce studies with limited patient number reporting disappearance of the pain post conservative therapy even if the imaging findings remain with no change; however, the long term use of

NSAIDs can result in potential complications and additionally there is a chance of muscular atrophy and bone deformity in ages<5 years. The application of radiofrequency ablation (RFA) was introduced in clinical practice by Rosenthal in 1992 performing a percutaneous approach for the treatment of osteoid osteoma. Nowadays thermal ablation of osteoid osteoma constitutes a first line therapy. Numerous studies upon all ablation techniques, others with lesser and others with higher numbers of patients report high pain reduction rates (up to 96%) and low recurrence rates (~7% at 2 years). Comparing percutaneous ablation to the traditional surgical techniques for osteoid osteoma (wide excision removing a bone block, marginal resection of the entire nidus, curettage or high speed burr techniques) favors percutaneous approach in terms of minimum trauma, minimum functional restriction and significantly lower cost.

Learning Objectives:

1. To learn about the treatment options for osteoid osteomas.
2. To understand the techniques for percutaneous treatment of osteoid osteoma: preparations, procedure and follow-up.
3. To appreciate advantages and potential complications in percutaneous treatment of osteoid osteoma in children.

RC 408

Pathways for tumour spread

Moderator:
J. Huyskens; Antwerp/BE

A-110 16:00

A. Pathways for oral cavity and oropharynx tumour spread
A. Borges; *Lisbon/PT (borgalexandra@gmail.com)*

90% of oral cavity and oropharyngeal malignancies originate from the epithelial lining and spread superficially along the mucosa and deeply into the submucosa, adjacent muscles, bone, and along cranial nerves. As local tumour staging is based on size, depth of invasion and involvement of adjacent structures, imaging is crucial in this regard. There are 8 tumour subsites in the oral cavity each with different patterns of spread and different implications on management. Those with direct impact on surgical management are the midline raphe, extrinsic tongue muscles, bone and oropharyngeal spread. Tumours of the retromolar trigone disseminate in a complex pattern as they lay in the crossroad between the oral cavity, masticator space and oropharynx. Patients tend to present in late stages, often with trismus. Whereas tumours of the superior alveolar ridge can invade the maxilla and spread along the superior alveolar nerves and V2, tumours of the inferior alveolar ridge can invade the mandible, the inferior alveolar nerve and spread along V3. Invasion of the neurovascular tongue bundle prone tumours to spread along the lingual or hypoglossal nerves. There are 4 different oropharyngeal subsites. The palatine tonsil has the highest association with lymph node metastases. Local spread is through the palatoglossus muscle and transgression of the constrictor muscles and pterygomandibular raphe lead to tumour extent into the retromolar trigone and pterygoid plates. Tongue base tumours can spread anteriorly to the tongue root and floor of the mouth and posteriorly into the supraglottic larynx. Palatal tumours spread inferiorly into the palatine fossa, laterally into the parapharyngeal space and are prone to perineural spread along the greater and lesser palatine nerves.

Learning Objectives:

1. To become familiar with the anatomy of the oral cavity and oropharynx.
2. To learn which imaging technique to use.
3. To understand the typical local and remote spread of oral cavity and oropharynx tumours.

A-111 16:30

B. Pathways for nasopharyngeal tumour spread including perineural spread
M. Lell; *Nuremberg/DE*

The nasopharynx is the uppermost portion of the pharynx, extending from the skull base to the the soft palate. Its main connections are the nasal cavity anteriorly and the oropharynx inferiorly. The nasopharynx is best imaged by MRI to detect the primary tumour, lymph node metastases as well as intracranial and bone invasion and perineural tumour spread (PNS). Nasopharyngeal cancer (NPC) frequently arises in the fossa of Rosenmuller, invades or displaces the parapharyngeal fat laterally and can cause obstruction of the Eustachian tube, leading to fluid retention in the tympanon and mastoid cells. Often subtle and therefore more difficult to detect than direct invasion is PNS. PNS most commonly occurs in a contiguous retrograde fashion from the primary tumour toward the intracranial compartment. PNS in NPC most commonly involves branches of the trigeminal and facial nerves. These 2 nerves are responsible for most of the sensory and motor innervation of the face. The trigeminal nerve provides sensory information from the face and motor innervation to the muscles of mastication. Understanding the CN anatomy is critical in identifying PNS.

Learning Objectives:

1. To become familiar with the anatomy of the nasopharynx.
2. To learn which imaging technique to use.
3. To understand the typical local and remote spread of nasopharyngeal tumours, including perineural spread.

A-112 17:00

C. Pathway for laryngeal and hypopharyngeal tumour spread
R. Kohler; *Sion/CH (romain.kohler@hopitalvs.ch)*

Squamous cell carcinoma is by far the most frequent malignant neoplasm of the larynx and hypopharynx and imaging plays a critical role in its diagnosis and management as only its superficial part is accessible to endoscopic evaluation. The larynx and hypopharynx are both divided into three subsites (supraglottis, glottis, subglottis and piriform sinus, retro cricoarytenoid region and posterior wall, respectively). Other important landmarks are the cartilages (especially the thyroid and cricoid cartilages) and the paraglottic and preepiglottic spaces. After a short overview of the imaging techniques, we will discuss in detail the most important pathways of tumour dissemination of supraglottic, glottic, subglottic, piriform sinus, retro cricoarytenoid, and posterior wall cancer. Endolaryngea dissemination is from one anatomical structure to another in the same subsite, from one subsite to another, to the prepiglottic/paraglottic spaces or to the cartilages. Extralaryngeal dissemination means extension through the cartilages or laryngeal membranes into the soft parts of the neck. Criteria for cartilage invasion, dissemination to lymph nodes and distant metastases will also be discussed. The description of all invaded structures is of greatest importance for the planification of surgery or radiation therapy as invasion of some specific structures upstages the tumour. Finally, two non-epithelial malignancies with particular appearance and neoplastic extension are presented: lymphoma and chondrosarcoma.

Learning Objectives:

1. To become familiar with the anatomy of the larynx and hypopharynx.
2. To learn which imaging technique to use.
3. To understand the typical local and remote spread of laryngeal and hypopharyngeal tumours.

T. Leiner; Utrecht/NL

A-113 16:00

Modelling brain multicompartment microscopic diffusion
C. Poupon; *Gif-sur-Yvette/FR (cyril.poupon@cea.fr)*

Diffusion-weighted magnetic resonance imaging (dMRI), sensitised to the diffusive motion of water along the direction of an applied magnetic field gradient, has become a well established technique to non-invasively probe the cellular organisation of tissues, providing access, for instance, to the human brain structural connectivity in vivo. Because the contrast of results from restrictions of water molecule trajectories by cell membranes populating the tissue, it also embeds key information about the tissue at cellular scales than can be deciphered using advanced models. Such models rely on the use of several compartments corresponding to the numerous cell populations composing the tissue that can be modeled using analytical equations involving the key characteristics of the various populations, like their volume fraction or statistics of cell dimensions (eg axon diameter, size of neuron bodies, ...). The presentation will address the various models proposed in the literature to characterise brain white matter microstructure, including CHARMED, AxCaliber, ActiveAx, and how they are about to revolutionise the in vivo mapping of the human brain cytoarchitecture. The NODDI model also able to characterise the dendrite arborisation within the cortical ribbon will be presented too, as well as the Intra-Voxel-Incoherent-Motion model providing

insights about the microvascular compartment irrigating the brain parenchyma. Case studies will be presented during the whole presentation to illustrate the strengths and weaknesses of these novel tools that progressively turns diffusion MRI into a virtual microscope able to perform virtual biopsies in vivo.

Learning Objectives:

1. To learn about the basic principles of diffusion MRI used to turn MRI into a virtual microscope.
2. To understand the potential of diffusion MR microscopy to map in vivo the organisations of brain tissues at cellular scales.
3. To appreciate the potential of brain microstructure maps to provide more specific imaging biomarkers of brain disorders.

A-114 16:30

How quantitative MRI reveals brain microstructure

C. Granziera; *Basle/CH (cristina.granziera@usb.ch;)*

This lecture will first introduce the difference between quantitative and conventional MRI, underlying the advantages and disadvantages of both. Then, we will focus on the biological and pathological significance of quantitative and semi-quantitative MRI contrasts (q/sqMRI) such as T1,T2,T2* relaxometry, magnetization transfer imaging, quantitative susceptibility mapping, and diffusion MRI. In the second part of the lecture, several examples will be presented related to studies where multiple q/sq MRI metrics were applied to answer specific pathophysiological or clinical questions in patients affected by neurological diseases (i.e., multiple sclerosis, stroke, migraine and neurodegenerative diseases). Through these exemplary studies, we will present the advantages and disadvantages of q/sqMRI in clinical research and the potential perspectives for clinical routine applications. As well as, we will illustrate the potential gain derived by the combination of multiple q/sqMRI contrasts in comparison to single contrasts approaches. Finally, on-going developments will be presented in the field of quantitative MRI, especially regarding fast and robust qMRI acquisition schemes, multi-parametric qMRI protocols as well as personalized ways of quantifying brain damage and repair using multiple q/sq MRI metrics.

Learning Objectives:

1. To learn about the biological and pathological significance of quantitative and semi-quantitative MRI contrasts (q/sqMRI).
2. To understand the on-going methodological developments in the field of q/sqMRI.
3. To appreciate the potential perspectives of multiple q/sqMRI contrasts for clinical routine applications.

A-115 17:00

MRI of cardiac muscle microstructure

M. Froeling; *Utrecht/NL (M.froeling@umcutrecht.nl)*

Investigating microstructural changes in the heart using DWI is mostly done using the DTI model. However, other models are being explored, e.g. IVIM and DKI. DWI of the can be challenging due to its low T2 relaxation time of only 30 to 50 ms. DWI imaging is typically done using a spin echo - echo planar imaging sequence (SE-EPI). The diffusion of water in the heart is fast (MD ≈ 1.6 to 1.8 mm2/s) and the diffusion anisotropy is low (FA ≈ 0.20 to 0.4). DWI of the beating heart is challenging due to that the heart is always moving. Measuring the microscopic motion of water in the presence of macroscopic motion needs a different diffusion sequence design. To overcome this two different approaches are possible: (1) using a stimulated echo acquisition (STEAM) which applies the diffusion weighting over two consecutive heartbeats and (2) Designing the diffusion weighting wave form to become insensitive for macroscopic motion. Diffusion tensor imaging in the heart is of great interest since it allows to, next to diffusion parameters, obtain detailed information about the cardiac myocardial architecture. Myocytes are aligned in a left-handed helix in the epicardium, to circumferential in the mid wall, to a right handed-helix in the endocardium. The heart muscle fibers are arranged in a laminar structure, called sheetlets. Changes of myocardial architecture over the cardiac cycle during development and in pathology have been studied and can potentially give new insights in cardiac function and disease and monitory of cardiac therapy.

Learning Objectives:

1. To learn about the state-of-the-art quantitative diffusion MRI acquisition strategies to investigate cardiac and skeletal muscle.
2. To understand the limitations of such methods and cofounding factors, such as noise, inflammation, fat and other artefacts.
3. To appreciate the potential perspectives in a clinical setting.

16:00 - 17:30 **Room E1**

Breast

RC 402

Screening for breast cancer

A-116 16:00

Chairperson's introduction

F.J. Gilbert; *Cambridge/UK (fjg28@cam.ac.uk)*

In 2003 the European Council recommended implementation of screening according to best practice guidelines and that mammography is offered every two years to women between the ages of 50-70 years. Apart from the three yearly programme in the UK all countries offer two yearly mammography or digital breast tomosynthesis (DBT). Nine countries start at age 40 or 45 years with 18 at age 50 years. Three countries stop at 64 years, with the majority at stopping at age 69 years although 3 countries continue until age 74 years. Uptake varies between 37-85% with Latvia and Poland having the lowest uptakes and Finland, Ireland and Holland having the highest acceptance rates. Some countries offer supplemental screening with ultrasound to women with increased breast density. It is known that high breast density increases the likelihood of developing breast cancer by twofold in the over 50 year age group and that increased breast density increases the chance of a cancer being missed or not being detected until the tumour is of a larger size. Digital breast tomosynthesis has been shown to have increased cancer detection together with reduced recall rates. Some countries have adopted this technology while others are conducting large randomised controlled trials to establish the impact, costs and benefits of this more complex examination. It is important to ascertain that when changing an established population screening programme this will result in a survival benefit and not merely increase over diagnosis.

Session Objectives:

1. To learn about mammography screening and how it should be monitored.
2. To understand the value of supplementary techniques and how it should be used in practice.
3. To recognise that tomosynthesis presents significant advantages and disadvantages when used in a screening setting.

A-117 16:05

A. Screening with mammography only

R.M. Pijnappel; *Utrecht/NL (r.m.pijnappel@umcutrecht.nl)*

Screening with mammography has proven to save lives. The reduction in mortality is substantial. In Netherlands, woman who attend all biannual offered screening rounds from 50-75 years reduce their change of dying from breast cancer before the age of 80 with 50%. The basis for this positive effect from screening with mammography only is training and auditing. The shift from analogue form to digital between 2005-2010 has improved these results and showed that more high risk tumors were detected by mammography. The cost effectiveness of screening with mammography only is acceptable. The drawbacks of screening with mammography only, i.e., false positive and overdiagnosis will be discussed. So far, no other modality has proven to save lives and no information is available regarding the aggressiveness of the breast cancers detected by other modalities like ultrasound MRI and tomosynthesis. The positive predictive value of ultrasound is substantially lower and quality control (operator dependent) is difficult. Tomosynthesis is very promising, but at this moment there is very little information regarding detection in subsequent rounds and interval cancers. For these reasons screening with mammography only still is the gold standard for population based screening with an average risk.

Learning Objectives:

1. To learn about benefits and limitations of mammography screening.
2. To become familiar with common findings, recall rates and assessment outcomes.
3. To appreciate errors.

A-118 16:30

B. Screening with mammography and ultrasound

T.H. Helbich; *Vienna/AT (Thomas.Helbich@meduniwien.ac.at)*

The sensitivity and specificity of mammography are limited in highly fibroglandular /dense breasts. Digital mammography provides increased sensitivity in young women and those with moderately dense breasts, and digital three-dimensional mammography (tomosynthesis) promises further

improvement. For women with the densest breasts, however, radiography is unlikely to be the optimum solution. MRI, although not affected by breast density, is expensive and access is often limited. Ultrasonography is attractive for breast cancer screening because, likewise, it is not impaired by breast density, and it avoids the use of ionizing radiation and the need for breast compression. Nevertheless, enthusiasm for the use of ultrasonography has been limited because its specificity has been much lower than that of mammography, but technical developments have given rise to sharper, more informative images. These improvements foster the use of ultrasound particular in those women with higher breast density. Different trials have been preformed and promising results have been reported. This talk will focus on benefits, harms, and cost-effectiveness of supplemental ultrasonography screening for women with dense breasts.

Learning Objectives:

1. To learn about the added value of US in screening and its indication.
2. To become familiar with the common level of evidence.
3. To appreciate its role in clinical practice.

A-119 16:55

C. Screening with tomosynthesis

U. Bick; *Berlin/DE (Ulrich.Bick@charite.de)*

By eliminating ambiguity from superposition of normal breast parenchymal structures, digital breast tomosynthesis (DBT) holds the potential to improve cancer detection rates while at the same time reducing call-backs related to false-positive findings. The magnitude of these two effects will depend on the clinical setting. In European population-based screening programs, where recall rates are kept low, DBT will primarily increase detection rates. On the other hand, in screening practices with high recall rates such as North America, the main effect of DBT will be to lower recall rates by improving specificity. In screening, the advantages of DBT must be weighed against the potential disadvantages of DBT such as higher costs (higher equipment and image storage costs, longer reading times) and possible increases in radiation exposure, especially if DBT is used as an adjunct to 2D mammography. However, synthetic 2D views reconstructed from the DBT dataset can be used to replace 2D mammography in screening. Although depiction of subtle microcalcifications may be slightly inferior on synthetic 2D views, studies have shown no significant difference in terms of detection rates or recall frequency between 2D mammography and synthetic 2D views. Despite the very promising data from the available first DBT screening trials, which all showed a significant increase in detection rates with DBT, further studies are needed before DBT can replace 2D mammography in population-based screening programs. The key question still unanswered up to now is whether the additional cancers found by DBT are in the majority clinically relevant and contribute to a reduction in advanced-stage interval cancers.

Learning Objectives:

1. To learn about the role of tomosynthesis in the screening setting.
2. To become familiar with the different protocols.
3. To appreciate potential advantages of tomosynthesis in screening.

Professional Challenges Session

PC 4
Mass casualties

A-120 16:00

Chairperson's introduction

M. Scaglione; *Castel Volturno/IT*

Recent mass casualty incidents have raised many problems in the western world, requiring a wide revision of many aspects of the civil life, ranging from the public order to medical facilities. More specifically, this “new” emergency needs planning, governance, education and specifically, a new team work mentality. In this Session, not only the strength and limits of imaging in massive attacks from Paris to Brussels, Thai tsunami and migrant victims drowned in the Mediterranean sea will be discussed, but also the need for a plan and areas of improvements will be illustrated. Finally, the new roles and challenges for the radiologists in A&E will be pointed out.

Session Objectives:

1. To understand about the need of a new plan for emergency hospitals.
2. To became familiar with the range of imaging findings related to MCI.
3. To learn about new roles and challenges for radiologists in Europe.

A-121 16:05

Mass casualty incidents: the London framework for planning

S. Vaidya; *London/UK (Sujit.Vaidya@bartshealth.nhs.uk)*

Mass casualty events challenge and have a capacity to rapidly overwhelm healthcare systems. Over recent years, we have felt the need to have an organized response to major events, to effect better patient care and flow. Collaboration, co-operation, and meticulous planning eventually helps save lives and limbs. This talk will outline some of the guiding principles of this collaboration. There is a need for the imaging department to adapt to the altered demands in such situations. Our experiences, successes and inefficiencies will be shared with a view to understand the challenges.

Learning Objectives:

1. To understand the objectives of the plan.
2. To appreciate the role of imaging in mass casualty.
3. To provide an overview of the major incident planning in London.

A-122 16:23

Lesson learned from the Paris attacks

P.A. Grenier; *Paris/FR (philippe.grenier@aphp.fr)*

Following the multiple mass casualty terrorist attacks on November 13th, 2015 in Paris, several measures have been taken in France to improve our medical capacity to face the unexpected. French Military Medical Service was asked to transfer their expertise into the civilian setting, favouring the concept of prehospital damage control to the civilian prehospital phase. A teaching of civilian surgeons, anesthesiologists, and emergency physicians by their military colleagues about damage control resuscitation and surgery, triage and care “under fire” was organized at national and regional levels. An online course is now accessible on demand. Dedicated teaching for all medical students and dedicated course in trauma management during residency have been implemented. Mobilization of the other regions seems to be essential to activate rapidly distant additional means and to identify quickly additional preserved resources, according to a medical strategy coordinated by experience health care professionals. Hospital trauma teams have improved their ability to triage between absolute and relative emergencies. Some multidisciplinary simulation exercises particularly focused on triage were performed. Identification of the victims was clearly a deficiency during the Paris and Nice attacks particularly those left dead on scene. Priority is given to identification process with the collection of primary identifiers combined with external examinations of deceased victims. During and after the attacks, a large number of individuals required psychological care. It requires a large mobilization of psychiatrists and psychologists able to cope with acute stress and to take on a continuous flow of patients over weeks or months.

Learning Objectives:

1. To learn from the terrorist attacks in Paris and Nice.
2. To understand the planning for pre-hospital damage control, medical strategy for quick mobilisation of resources, training and multidisciplinary simulation exercises, and post-trauma psychological care.
3. To appreciate the role of imaging in case of massive attack.

A-123 16:41

Postmortem imaging of migrant victims drowned in the Mediterranean Sea

G. Lo Re; *Palermo/IT (giuseppe.lore12@gmail.com)*

Europe is involved in a large-scale migratory flow coming from Africa and Middle East, and Italy is often the first step towards European countries for migrants. This high number of people may determine some issues related to public security, financial aspects, and ethical issues. In the last years, and until now, we have assisted to numerous shipwrecks in the Sicilian Sea, and sometimes we had the opportunity to study, with radiological images, the dead corps recovered at sea. For example, in 2016, a large number of corpses, more than 150, were studied using a multislice CT scanner; the bodies came from a shipwreck of an overcrowded boat drowned off the Libyan coasts in April 2015. Other corpses were recovered at sea, and in particular near Trapani we recovered two child corpses drowned during transhipment operations. Radiology in these cases could be essential in helping forensic pathologists and police activities, speeding up and making more secure identification of people and diagnosis of eventual pathological events. Study of number, type, congruency, calluses, fractures and anthropometric measurements of bones, teeth, growth-cartilages and of internal/external genitals helped to identify sea victims. Furthermore, study of foreign objects

was useful for bodies identification and for a better knowledge of the travel conditions of migrants. Radiology has a pivotal role in mass disasters, especially in migrant victims, and can help in determining age of people died and alive.

Learning Objectives:

1. To describe typical findings and pitfalls of virtopsy in mass casualty emergency.
2. To understand the strength and limits of forensic radiological examination.
3. To become familiar with postmortem imaging.

A-124 16:59

High-end CT imaging in forensic medicine: experience after recent Brussels terror attacks

W. Develter; *Leuven/BE (wim.develter@uzleuven.be)*

The importance of radiology in the evolution of the ID-process. Experiences from former mass disasters revealed an evolution in the identification process. Digitalisation boosted logistics and the ongoing technical revolution made of radiology an indispensable versatile instrument. Radiology that was used for individual diagnostics is now applied for screening - triage and diverse documentation (identification, legal inquiry and reconciliation).

Learning Objectives:

1. To illustrate MC findings from the Thai Tsunami over the MH-17 to the Brussel attacks.
2. To became familiar with the imaging findings related to unidentified people and its medico-legal related issues.
3. To understand the importance of imaging in the reconciliation process with the relatives of the victims.

17:17

Panel discussion: How to be prepared accordingly?

16:00 - 17:30 **Room F1**

E³ - Rising Stars Programme: Basic Sessions

BS 4

Thoracic emergencies

Moderator:
K. Malagari; Athens/GR

A-125 16:00

Acute aortic syndrome

T. Jargiello; *Lublin/PL (tojarg@interia.pl)*

Acute aortic syndrome (AAS) describes symptoms relevant to severe chest or back pain caused by several aortic pathologies which can be potentially life threatening. The most common aetiology, compromises the majority of AAS is aortic dissection. Other causes of AAS with similar presentation include intramural haematoma, penetrating aortic ulcer (atherosclerotic), aneurysm formation (rupture, enlargement), and traumatic transection (pseudoaneurysm). Imaging plays a vital role in diagnosing AAS. The role of the plain chest radiograph is nowadays historic. Echocardiography (plain or transoesophageal) is an effective portable tool, but does not visualise the whole thoracic aorta. It may only suggest a certain AAS aetiology. Contrast enhanced CT is now considered as the diagnostic method of choice. It provides accurate aortic assessment as well as detailed evaluation of other thoracic structures. CT permits 3D reconstructions, essential for intervention planning and it is widely available. Its sensitivity for aortic disorders reaches 100%. MRI is another imaging modality to diagnose AAS. Although it provides greater anatomical detail than CT, it is seriously limited. The limitation involve procedure time, lesser availability, and the expense.

Learning Objectives:

1. To become familiar with the most common aetiologies of acute aortic diseases.
2. To present current imaging techniques for evaluation of acute aortic diseases.
3. To demonstrate the most important imaging findings.

A-126 16:30

Pulmonary embolism

C. Loewe; *Vienna/AT (christian.loewe@meduniwien.ac.at)*

Pulmonary embolism (PE) represent a daily clinical challenge at the emergency department: out of the patients admitted to an emergency room because of the very unspecific clinical symptom of chest pain and/or dyspnea, the early identification of patients with an high clinical likelihood for PE is a difficult task. The D-Dimer test is very sensitive, but unspecific for pulmonary embolism, and using this test without clinical assessment, a high number of false positive patients will result. On the other hand, PE is potentially life threatening; and early and safe diagnosis of this relevant disease is important to improve patient's outcome. CT angiography of the pulmonary arteries has been established as the first method of choice to accurately detect PE with an high PPV and PPV. This presentation will provide an overview about the diagnostic challenges in the chest pain unit will explain the need for accurate clinical assessment to select the right patient for the appropriate diagnostic test. Furthermore, the risks due to overdiagnosis or false-positive diagnosis will be exemplified. In the second part, this presentation will focus on the radiological view on this picture by explaining an optimized imaging technique and possible pitfalls and problems. Challenging situations in the daily clinical practice will be discussed by addressing the role of imaging in suspected PE in pregnancy and in the oncologic patients. Finally typical findings in acute and chronic pulmonary embolism will be reviewed.

Learning Objectives:

1. To review the most common pathologies leading to pulmonary embolism.
2. To present current imaging techniques for evaluation of pulmonary embolism.
3. To become familiar with the typical findings in acute and chronic pulmonary embolism.

Author Disclosure:

A-127 17:00

Acute coronary syndrome

R.M.M. Hinzpeter; *Zurich/CH (Ricarda.Hinzpeter@usz.ch)*

Normal anatomic conditions of the coronary arteries consists of two main coronary arteries, a left coronary artery and a right coronary artery arising from the coronary sinuses in the proximal ascending aorta immediately distal of the aortic valve. The right coronary artery descends in the right atrioventricular groove to the inferior surface of the heart, continuing as the posterior descending artery representing a right dominant circulation. After a short common stem the left coronary artery bifurcates into the left anterior descending, coursing in the anterior interventricular groove and the left circumflex artery coursing in the left atrioventricular groove. After the initial work-up of acute coronary syndrome in the emergency department, including laboratory values and ECG changes, coronary CT angiography (CCTA) as a non-invasive examination plays an important role besides invasive techniques. Especially in patients with low to intermediate risk CCTA is a quick and reliable method for ruling out coronary artery disease with a very high negative predictive value in the absence of coronary artery calcifications. Besides the detection of significant coronary artery stenosis, the presence, amount and composition of non-calcified plaques and the degree of coronary remodelling is substantial. In addition, information about structural changes of the myocardium and myocardial perfusion can be obtained by CCTA.

Learning Objectives:

1. To become familiar with segmental coronary anatomy.
2. To present different techniques for assessment of acute coronary syndrome.
3. To become familiar with the typical findings of acute coronary syndrome.

16:00 - 17:30 **Room F2**

Multidisciplinary Session

MS 4

The heart team: coronary imaging and treatment

A-128 16:00

Chairperson's introduction

E. Mershina; *Moscow/RU (elena_mershina@mail.ru)*

Due to the rapid technological progress of non-invasive methods of cardiac visualisation frequent updates on the clinical indications to perform coronary CT angiography (cCTA) and cardiac magnetic resonance (CMR) are required. The role of each method including invasive coronary angiography in diagnostic algorithm in the patients with different degree of coronary artery disease (CAD) probability will be underlined. Various challenges still exist in acquiring high-quality imaging in cardiac CT, such as artifacts due to calcification and metallic densities, motion, noise and poor contrast enhancement. Nevertheless cCTA is the first-line diagnostic tool for low-to-intermediate risk CAD patients. On the other hand an invasive angiography supported by FFR is the method of choice for the patients with high probability of CAD. CMR myocardial perfusion imaging produces accurate information on the presence of myocardial

ischemia. As a means of guiding the initial management of patients with stable angina and an intermediate-to-high risk of CAD, noninvasive CMR perfusion imaging is comparable to a strategy with invasive angiography supported by FFR. The implementation of different methods for coronary imaging will be illustrated by clinical examples.

Session Objectives:

1. To recognise the possibilities of modern coronary imaging modalities.
2. To explain possible discrepancies in the results of different diagnostic investigations and clinical picture.
3. To understand how to translate the results of coronary imaging into clinical practice.

A-129 16:05

Non-invasive cardiac imaging

V.E. Sinitsyn; *Moscow/RU (vsini@mail.ru)*

Major indications for cardiac CT angiography are imaging of coronary arteries in suspected coronary artery disease, visualization of pulmonary veins and planning of endovascular surgical procedures (such as TAVI). Modern types of CT scanners open up the opportunity to reach significant improvements of image quality of coronary arteries and heart structures even in "difficult" patients and to get high quality diagnostic images with very low radiation exposure and less volume of contrast media. The contemporary standard of coronary CTA (CCTA) is prospective-gated or high pitch wide detector or dual source acquisition with iterative image reconstruction. There are some new technologies for assessment of coronary or myocardial blood flow with the help of CCTA such as perfusion CT, CT-FFR, dual-energy CT. Major indications for cardiac MR (CMR) are cardiomyopathies, myocarditis or coronary artery disease (imaging of scars and perfusion). Selection of cardiac MR protocols is dependent on the main indication for examination. Cine-MR, black-blood sequences, perfusion and late gadolinium enhancement modules together with blood flow analysis are the most used ones. Today the tissue characterization modules (T1, T2 mapping) have become the essential part of CMR protocols. Recent changes in cardiological paradigms about approaches to diagnosis, treatment, and assessment of prognosis in patients with coronary artery disease (CAD) together with the technical development of CCTA and CMR and accumulation of scientific data proving the high diagnostic value of both imaging modalities have shown their high value in assessment of prognosis and selection of the optimal therapy.

Learning Objectives:

1. To get knowledge about modern technology and protocols used in coronary/cardiac CT and MRI in coronary artery disease (CAD).
2. To learn about scientific evidence (including results of major clinical trials) supporting use of these technologies in CAD.
3. To be aware about new developments in non-invasive cardiac imaging including studies of coronary flow, myocardial perfusion and hybrid imaging.
4. To understand the role of co-operation between radiologists and cardiologists in non-invasive cardiac imaging for benefit of CAD patients.

A-130 16:25

Interventional treatment/percutaneous

A. Osiev; *Moscow/RU (osiev_ag@mail.ru)*

The strategy of diagnosis of coronary artery disease (CAD) was changed since non-invasive multi-detector computed tomography (MDCT) had been introduced into the common clinical practice. However, in case of high coronary calcium score the invasive coronary angiography remains the “Gold standard” in CAD diagnostics. Randomised clinical studies demonstrated that primary PCI significantly improve the outcomes in pts with ACS especially presenting with STEMI, but influence of PCI on long-term prognosis in pts with stable CAD is still unclear. Today the most controversial issues are the management of the Left Main CAD and strategy selection of myocardial revascularisation in pts with multivessel disease (MVD). According to recent research data in these cases, we shouldn’t make a decision if not to consider SYNTAX Score and SYNTAX score II. As well, the questions of chronic total occlusion revascularisation remain unresolved and require meticulous preliminary non-invasive assessment of myocardial viability. The innovative methods of visualisation are helpful in decision-making in the presence of complex cases. Fractional flow reserve (FFR) measurement provides important information about lesion severity especially in the presence of MVD. Indications for stenting and result assessment can be evaluated by intravascular ultrasound imaging (IVUS) and optical coherent tomography (OCT). MDCT allows the physicians to verify the anatomical features of culprit lesion and key criteria of strategy definition and prediction of procedure success.

Learning Objectives:

1. To learn about the current indications for diagnostic coronary catheterisation and transluminal interventions.
2. To know about the latest innovations in percutaneous coronary revascularisation technique.
3. To understand difficulties in assessment of stenosis and occlusions during coronary interventions.
4. To be aware how combined analysis of coronary CTA and invasive coronary angiography could help in planning of interventional treatment of coronary lesions.

A-131 16:45

The role of coronary imaging in the coronary artery bypass and valve surgery

K. Mershin; *Moscow/RU*

Learning Objectives:

1. To learn about surgeon's opinion and the possibilities of different methods of coronary imaging.
2. To understand which coronary imaging modality should be the best in complicated cases.
3. To be aware of CT coronary angiography benefits in the redo procedures.

A-132 17:05

Multidisciplinary case presentation and discussion

Y. Ashikhmin; *Moscow/RU (ya.ashikhmin@gmail.com)*

At present time, non-invasive cardiac imaging tools intensively penetrate clinical guidelines. Nevertheless, use of modern imaging devices capabilities by majority of cardiologists are still scanty. On the other hand, some physicians have many footless expectations about potential of conventional scanners. The rational diagnostics pathways in typical clinical situations and difficult diagnostic cases will be highlighted within multidisciplinary discussion. An important place will be given to the discussion of implementation of the current guidelines in the real world clinical practice, mentioning the areas of uncertainty and discrepancies in the guidelines as well as evidence-based personalized diagnostic strategies. Furthermore, attention will be paid to cardiovascular prophylaxis, in particular, the usefulness of the coronary calcium scoring will be highlighted. It will be explained how to switch clinicians from invasive procedures to cardiac MRI and CT when it is the best bet. At last, the future of imaging technologies will be discussed, including the present transition from the technology-driven model to the unmet clinical need-driven progress in imagine tools.

Learning Objectives:

1. To outline the rational diagnostics pathways in typical situations: following the guidelines.
2. To learn how to manage the difficult diagnostic cases: beyond the guidelines.
3. To explain how to switch clinicians from invasive procedures to cardiac MRI and CT when it is the best bet.
4. To discuss the future in imaging technologies translation: from the technology-driven to the unmet clinical need-driven progress in imagine tools.

16:00 - 17:30 **Room D**

Musculoskeletal

RC 410

Bone, joint and soft tissue infection

Moderator:

T. Kaya; Eskisehir/TR

A-133 16:00

A. Osteomyelitis

K. Verstraete; *Ghent/BE (koenraad.verstraete@ugent.be)*

Osteomyelitis (OM) is an infection of the bone, and can present clinically in an acute, subacute or chronic form. Acute OM affects mostly children, just like subacute OM which predominantly presents as a Brodie’s abscess. Chronic OM is more prevalent in adults (vascular insufficiency, diabetes mellitus). Routes of contamination are hematogenous (predominantly in children), spread from a contiguous source (cutaneous, dental), or direct implantation (bites, open fractures, postoperative). One to 2 weeks after onset, when >50 % of trabecular bone is destroyed, radiography can detect OM as ill-defined radiolucencies; later findings include extensive osteolysis, periosteal reaction, sequestra, involucrum, sinus (cloaca) through the cortex, and permeative bone destruction, which may resemble a malignant bone tumor. Bone scintigraphy is

highly sensitive for OM and within 48 hours a focus of increased activity in the affected bone can be seen. Specificity is low however, as tumors, trauma, and neuropathic osteoarthropathy can result in hot spots. CT has a limited role in acute OM, but is useful to evaluate complex findings in chronic OM (e.g., sequestra). MRI is the modality of choice to detect acute OM in an early stage: it is highly sensitive and specific demonstrating bone marrow edema, periosteal reaction, soft-tissue edema, abscess formation and sequestra. Gadolinium administration demonstrates enhancement of granulation tissue in the abscess wall, along sinus tracts and around sequestra. Special manifestations are Garré's sclerosing OM, tuberculous OM, diabetic foot (may resemble neuropathic osteoarthropathy), spondylodiscitis, CRMO (chronic recurrent multifocal OM) and SAPHO.

Learning Objectives:

1. To understand the pathophysiology and disease spectrum of osteomyelitis.
2. To learn about the basic imaging criteria for diagnosis of acute and chronic osteomyelitis in children and adults.

A-134 16:30

B. Septic arthritis

M. Zanetti; *Zurich/CH (marco.zanetti@hirslanden.ch)*

Septic arthritis is often a clinical diagnosis based on physical examination and prompt arthrocentesis. Sampling at arthrocentesis can usually be achieved with needle aspiration imaging guided, such as fluoroscopy, ultrasound, MRI, or CT. Plain radiography and ultrasound have been suggested to be the preferred initial imaging method. If further imaging is required, MRI is the most accurate technique. FDG-PET is also used less commonly. Staphylococcus aureus infection is most commonly seen in acute bacterial arthritis in adults and in children older than 2 years. Most septic joints develop hematogenously. Rarely, acute septic arthritis may also occur as a result of joint aspiration or local corticosteroid joint injection. In addition, bacterial arthritis may arise secondary to trauma even without an obvious break in the skin. Bacterial arthritis, in association with arthroplasties is commonly seen in our areas. In infants, small capillaries cross the epiphyseal growth plate and permit extension of infection into the epiphysis and joint space. In children older than 1 year, osteomyelitis infection presumably starts in the metaphyseal sinusoidal veins and is usually contained by the growth plate. The joint is spared unless the metaphysis is intracapsular. In adults, the growth plate has resorbed and the infection may again extend to the joint spaces. Based on these considerations the basic imaging criteria for diagnosis of septic arthritis in adults will be shown.

Learning Objectives:

1. To understand the pathophysiology and disease spectrum of septic arthritis.
2. To learn about the basic imaging criteria for diagnosis of septic arthritis in children and adults.

A-135 17:00

C. Pyomyositis and other soft tissue infections

D.J. Wilson; *Oxford/UK (davidwilson.stlukes@btconnect.com)*

Soft tissue infection can range from a minor wound infection through cellulitis to pyomyositis and necrotising fasciitis. At one end of the spectrum the treatment may be limited to anti-sepsis and oral antibiotics whilst at the other many months of intravenous antibiotics and radical surgery may be necessary. Severe infection may be rapidly fatal. Imaging plays a crucial role in the detection of the extent of infection, the detection of abscesses and the planning of surgical procedures. It is also very useful in determining response to therapy. Ultrasound and MRI are the principal techniques. The strength of ultrasound has its rapid availability and discrimination of free fluid from oedematous solid tissue. It is also critically helpful in detecting foreign material which could be a source and irritant causing persisting infection. MRI gives us a much better overview showing bone involvement and extent of tissue damage or destruction. There is a role for both techniques and their often complementary. The first and perhaps most important lesson is to recognise the risk of infection. This is particularly true for patients who are immunosuppressed or diabetic. The symptoms may be relatively minor and these immune compromised individuals should be a low threshold for performing imaging investigations. Imaging may be used to guide aspiration of cavities and biopsy of tissue to identify organisms. On rare occasions the primary treatment of abscesses may be via sump drainage catheter is placed using ultrasound guidance. Normally these patients are treated with surgery to include excision of necrotic tissue, but there are occasions when patients are unfit for anaesthetic and ultrasound guided techniques assist.

Learning Objectives:

1. To understand the pathophysiology and disease spectrum of pyomyositis and other soft-tissue infections.
2. To learn about the basic imaging criteria for diagnosis of these conditions.

16:00 - 17:30 **Room G**

Special Focus Session

SF 4

Gadolinium deposition: is it harmful?

A-136 16:00

Chairperson's introduction

P.M. Parizel; *Antwerp/BE* (*paul.parizel@uantwerpen.be*)

Since the initial introduction of gadolinium-based contrast agents (GBCAs) in the late 1980's, this class of products has historically been considered safe and well tolerated. In a landmark article published in 2014, authors from Japan demonstrated that gadolinium is deposited in the brain, as evidenced by T1-shortening in the dentate nucleus, globus pallidus, and pulvinar of patients who had received repeated administrations of gadodiamide and/or gadopentetate dimeglumine. Subsequently, many other investigators have confirmed the finding that gadolinium deposition occurs, even in patients with normal renal function. In the brain, residual gadolinium is mostly discovered in the endothelial walls, although small quantities apparently cross the blood-brain barrier and accumulate within the neuronal interstitium. Moreover, we now know that residual gadolinium is not only deposited certain brain regions, but also in tissues such as liver, skin and bone. Today, although gadolinium accumulation in tissues is well documented, there is very limited clinical information regarding the potential risks and mechanisms of toxicity. In this special focus session, 3 of the world leading experts on this topic will explore WHERE gadolinium is deposited in the brain, HOW it gets there, what are the RISKS and COMPLICATIONS of possible gadolinium toxicity, WHICH AGENTS are associated with greater amounts of gadolinum deposition, and WHAT are the recommendations of the European Medicines Agency (EMA). The special focus session will conclude with a discussion about the future strategy to be adopted by the radiological community regarding GBCAs.

Session Objectives:

1. To review the evidence of intracranial gadolinium deposits after intravenous administration of gadolinium-based contrast agents (GBCAs).
2. To summarise current theories about why, how, and where gadolinium is deposited in the brain and other tissues.
3. To assess the clinical relevance of this finding for daily radiological practice.

Author Disclosure:

P.M. Parizel: Advisory Board; Bracco. Research/Grant Support; Bayer, Bracco, General Electric. Speaker; Bracco.

A-137 16:05

Gadolinium deposition in the brain: from preclinical studies to clinical implications

R.J. McDonald; *Rochester, MN/US*

"no abstract submitted"

Learning Objectives:

1. To understand how gadolinium is deposited in the brain (chemistry and pathophysiology).
2. To demonstrate where gadolinium is deposited in the brain (and other tissues) (neuropathology).
3. To assess the potential clinical implications of gadolinium deposition in the human body.

A-138 16:30

Assessing tissue integrity in the presence of gadolinium deposition in the brain

C. Olchowy; *Wroclaw/PL (cyprian.olchowy@gmail.com)*

A growing evidence of the accumulation of small amounts of gadolinium in the cerebellum structures after repeated administrations of selected gadolinium-based contrast agents (GBCAs) dictates the search for sensitive markers of brain tissue damage. Sodium (23Na) MRI can detect possible tissue abnormalities. It enables measuring intracellular sodium concentration, which is considered a useful marker of tissue viability and has been proved to be elevated in many brain disorders. In patients with multiple sclerosis, elevated sodium levels were detected in contrast-enhancing lesions to much greater extent than in non-enhancing T1 hypointense lesions. These findings may be linked to the increase in the blood -brain barrier permeability and signs of edema. Multiple sclerosis patients often present with signal hyperintensity within the dentate nucleus and globus pallidus as a possible result of multiple applications of GBCAs. However, the total sodium concentration within the hyperintense dentate nucleus of MS patients did not significantly differ from that of the dentate nucleus of MS patients without increased signal intensity and healthy controls. Gadolinium deposits have been detected in tissues from

autopsy samples of patients who had been exposed to GBCAs; however, until today, there has been no evidence of the direct harmful effect of GBCAs on brain tissues. One of the possible reasons is the lack of precise diagnostic methods and, the other, the lack of the knowledge of the type of damage resulting on using improper diagnostic methods. The hypotheses about the possible mechanism and signs of damage will be discussed.

Learning Objectives:

1. To detect possible tissue abnormalities with sodium (23Na) MRI in the brain of MS patients.
2. To measure total sodium concentrations in the brains of patients exposed to repeated gadolinium administrations.
3. To predict possible harmful effects of gadolinium deposition in the brain in view of the presence or absence of tissue abnormalities.

A-139 16:55

Clinical recommendations in consideration of the EMA's pharmacovigilance and risk assessment committee recommendation for suspension of linear agents

V. Runge; *Berne/CH (val.runge@mac.com)*

After a two year long consideration of the latest issue (gadolinium deposition in the brain and body), including many meetings, rounds of questions from the EMA to industry with responses, and two ad hoc expert group meetings, the pharmacovigilance and risk assessment committee (PRAC) concluded it's assessment of the gadolinium based agents and, on March 10, 2017, recommended the following regulatory action (further confirmed by the PRAC on July 7, 2017): suspension of the marketing authorization for body imaging of 4 linear GBCAs (gadodiamide - omniscan, gadoversetamide - optimark, gadopentetate dimeglumine - magnevist, and gadobenate dimeglumine - multiHance), which would leave—of the linear agents—only gadoxetic acid (primovist) and gadobenate dimeglumine on the market (for liver scans only) and a formulation of gadopentetic acid for joint injections. Approval for the macrocyclic agents was left unchanged; this recommendation was confirmed by the committee for medicinal products for human use of the EMA on July 21. The final stage of review is the adoption by the European Commission of a decision, applicable and legally binding, for all European Union Member States.

Learning Objectives:

1. To review the in vivo distribution, possible dechelation, and subsequent deposition of gadolinium.
2. To clarify this phenomenon and to stratify gadolinium-based contrast agents on this basis.
3. To provide clinical recommendations to radiologists on how to deal with gadolinium deposition in the brain and body.

Panel discussion: Strategies for the future

16:00 - 17:30 **Room K**

Radiographers

RC 414
Maximising outputs from research

A-140 16:00

Chairpersons' introduction (part 1)

F. Zarb; *Msida/MT (francis.zarb@um.edu.mt)*

The radiography profession has gone through numerous developments over the past decades. It is also important that we acknowledge these developments and the educational requirements to fulfill the developing roles of the radiographer. The radiography profession has been required to use and also generate quality research on which to develop evidence-based practice. The presenters of this session are active researchers within the field of radiography and we will be benefitting from their knowledge and experience of radiographic research.

Session Objectives:

1. To appreciate the importance of study design in enhancing research outcomes.
2. To become familiar with the benefits of collaboration in designing and disseminating research.
3. To understand current funding opportunities and strategies for success.

A-141 16:03

Chairpersons' introduction (part 2)

M. Raissaki; *Iraklion/GR*

The cornerstone of academic medicine has always been balanced on the concepts of teaching, research and clinical practice. The same concepts are interacting with each other in academic radiography. In the era of innovation and advancing technology, imaging biomarkers, evidence-based medicine and ALARA, radiographers have the opportunity to perceive research on a local, National and International level, as their opportunity to make a visible difference as health specialists, to better appreciate and understand aspects of their craft, to reduce dose and improve or maintain image quality in all imaging modalities. Radiographers can and should be aware of the role of research in optimization of clinical practice. Familiarization and a positive and attitude towards research are important for implementing the paradigm shift from the traditional model of practice to evidence-based practice. Research is a learning process both on an undergraduate and on a postgraduate level. Research can only be mastered through team work, careful design, trial and error, dedication, and appropriate funding. Collaboration among institutions can lead to enormous benefits for local, National, and International evidence and guidelines.

Session Objectives:

1. To appreciate the importance of study design in enhancing research outcomes.
2. To become familiar with the benefits of collaboration in designing and disseminating research.
3. To understand current funding opportunities and strategies for success.

A-142 16:05

A. Designing robust research projects

L.A. Rainford; *Dublin/IE (louise.rainford@ucd.ie)*

The presenter will provide the audience with a detailed discussion of the key steps required to be fulfilled in the design of research projects. The principles discussed will bear relevance to a range of research project types from local studies to research activity involving international collaborators. The information provided will be based on the presenter's personal experience and from referenced literature. The presentation will outline details of support mechanisms available to radiography researchers active or those interested in becoming research active. The scope of information will range from local academic institutions support, professional society support, national and international research agencies and European groups, in particular the European Federation of Radiography Societies (EFRS). The importance of understanding how careful project design is critical to a research project success and core considerations in the design process will be provided to the audience. Matters such as appropriate supervisory teams, understanding roles, maintenance of progress, meeting deadlines, appropriate ethical oversight, preparing for unforeseen issues, ensuring novel and innovative approaches, ensuring standards are maintained, and positive student development. Considerations required if planning multi-site studies either within one jurisdiction or internationally will be included in the presentation.

Learning Objectives:

1. To learn about the research design process.
2. To understand the mechanisms available to support the successful design of research studies in radiography.
3. To appreciate the importance of careful research design for successful projects.

A-143 16:28

B. Collaborating across Europe

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

Radiography profession is evolving in an exponential way, driven mostly by the technological development and the new models of delivering care to the patient. It's because these two main drivers that is essential to promote research, as a tool to develop the radiographer profession field of knowledge. Radiographers, as the guardians of the profession, have the obligation to improve the knowledge basis of professional work through research, which is only accepted and adopted by the peers, if published: "It doesn't exist if it isn't written down". The number of publications in one year is higher than all the publications until 1970, and this has a tremendous impact on our daily life. According to the European Research Area, Europe must increase the

efficiency and effectiveness of its public research system. This requires more cooperation so that the brightest minds work together to make greater impact on grand challenges. We have to bear in mind that research paradigm has changed. Changes came from a lonely scientist closed in his laboratory to a whole worldwide network of knowledge (as the common maxim states: “it’s not what you know, it’s who you know.”), reason why networking and integrating a multidisciplinary approach into research is essential, not only to avoid unnecessary duplication of research and infrastructure investment, but also to create knowledge and increase the visibility of radiographers in the patient clinical pathway.

Learning Objectives:

1. To learn about the importance of networking to promote research activities.
2. To understand the potential of research collaborations in a multinational approach.
3. To be aware about the importance of research in developing the professions' field of knowledge.

A-144 16:51

C. Winning research grants

C. Malamateniou; *London/UK (christina.malamateniou@kcl.ac.uk)*

Research in healthcare professions allied to Medicine has been traditionally seen as the "difficult to achieve", "challenging" and often "an additional, different to clinical practice" task, that was demanding more time from an already overloaded clinical schedule of the healthcare practitioners. Recent work has shown that research can increase quality of practice, improve patient outcomes and job satisfaction and make the service more efficient. Radiography research capacity and quality building has been identified as one of the key areas for development under the 2016-2021 Research strategy agenda of the Society and College of Radiographers. Research capacity building involves enhancing research awareness, facilitating research involvement but also and most importantly ensuring high quality research leadership. There are many different methods one can employ to achieve these outcomes, but in order to cement a research leadership role for Radiography, one needs to consider how to increase the research income and how to succeed in Research grant applications. There is not sadly a cookbook on how this can be achieved and it is recognised that one needs to travel through rough waters and often learn from constructive feedback and through failure, in order to become better in successful grant writing. This talk is about the challenges in securing grant funding in Radiography in the UK, some tips to help people increase their chances of securing a grant as well as to present the currently available research funding opportunities for radiographers.

Learning Objectives:

1. To learn about potential research funders for radiographers.
2. To understand challenges and opportunities in research grant applications.
3. To appreciate strategies for successful research bids.

17:14

Panel discussion: How to avoid strategic mistakes in research?

16:00 - 17:30 **Room M 1**

EuroSafe Imaging Session

EU 1

Euratom Basic Safety Standards Directive: a comprehensive approach for radiation protection

Moderator:
G. Frija; Paris/FR

A-145 16:00

Chairperson's introduction

S. Ebdon-Jackson; *Didcot/UK (steve.ebdon-jackson@phe.gov.uk)*

EC Directive 2013/59/Euratom lays down basic safety standards for protection against the dangers arising from exposure to ionising radiation. Previously, such directives have addressed occupational and public exposure and a separate directive considered medical exposures (EC Directive 97/43/Euratom). In contrast, this latest "Basic Safety Standards Directive" includes medical exposures and therefore, provides a comprehensive EC approach to radiation protection for radiology and other activities in medicine that utilise ionising radiation. For occupational exposure, new dose limits are introduced for the lens of the eye. For medical exposures, the directive extends requirements for justification, at generic and individual levels, and optimisation and gives greater detail regarding equipment and the role of the medical physics expert. It includes new requirements for non-medical imaging using medical radiological equipment and accidental and unintended medical exposures.

Session Objectives:

1. To become familiar with the new Basic Safety Standards Directive (Council Directive 2013/59/EURATOM).
2. To learn about the most important changes compared to the previous directive.
3. To understand the implications of the new directive for medical imaging.

A-146 16:05

The technical approach: achievements and future of dose reduction

W.A. Kalender; *Erlangen/DE (willi.kalender@imp.uni-erlangen.de)*

The introduction of spiral-CT in the 1990s followed by the development of multi-slice detector technology led to substantial increases in CT performance and in its use. In consequence, the cumulative patient exposure also increased. Fortunately, new efforts of developing intelligent dose reduction approaches, meanwhile helped reducing patient dose significantly. These comprise the following innovative approaches: Tube current modulation (TCM), automated exposure control (AEC), application-dependent optimal choice of X-ray spectra, elimination of z-overscanning effects, dose-efficient iterative image reconstruction, advanced detector technology. They all have in common that dose will be reduced, but not combined with compromising image quality, i.e., not by reducing the mAs product. The underlying principles and the resulting reduction of dose will be explained. The total effect has actually been very successful during the last two decades allowing for a reduction by a factor of 10 or higher and for sub-mSv CT imaging in many CT-applications.

Learning Objectives:

1. To learn about the technical perspective from the BSS.
2. To become familiar with dose reduction.
3. To become familiar with the achievements and future of dose reduction.

Author Disclosure:

W.A. Kalender: Consultant; Bayer Schering AG, Advanced Breast-CT GmbH. Shareholder; Advanced Breast-CT GmbH.

A-147 16:17

The clinical approach: the gap to be closed

G. Frija; *Paris/FR (guy.frija@aphp.fr)*

Several aspects of optimisation and justification are clearly relating to a clinical task and this will be introduced. The talk will focus for example on optimisation driven by the clinical indication and patient characteristics, and the report, which should include dose metrics. Examples will be taken for illustrating the importance of considering an integration of radiation protection into the clinical work, and thus increasing healthcare professionals’ awareness.

Learning Objectives:

1. To learn about the clinical perspective.
2. To become familiar with the concept of clinical DRLs.
3. To understand the need for DRLs based on clinical indications.

A-148 16:29

The clinical audit: the missing link

E.J. Adam; *London/UK (drjaneadam@gmail.com)*

Translating legislation into routine practice can be challenging. European legislation deadlines relating to radiation protection are looming. Regulatory agencies across Europe may take different approaches to assessing compliance, but there is no need to wait. Self audit within departments is easy to carry out, and will mean that departments will have evidence to show that they have high standards of safe practice in line with the legislation. The ESR audit system makes it straightforward to start, and bridges the gap between regulation and routine practice. It should be a continuous, multidisciplinary process which is professionally led and aims to improve the performance rather than be a pass or fail assessment. Ultimately, it can expand to cover all areas of practice and all parts of the patient journey.

Learning Objectives:

1. To understand what clinical audit is.
2. To learn how to implement clinical audit in practice.
3. To become familiar with the ESR audit pack.

A-149 16:41

The regulatory approach

S. Ebdon-Jackson; *Didcot/UK (steve.ebdon-jackson@phe.gov.uk)*

EC Directive 2013/59/Euratom is intended to provide basic safety standards for protection against the dangers arising from exposure to ionising radiation.

Member States are expected to transpose the Directive into national law. The Directive requires member states to have in place a competent authority which will undertake a range of activities including regulatory control through a graded approach, which includes notification, registration and licensing. Justification of new types or classes of practices provides a particular challenge for medical exposures and member states will be required to put in place meaningful and responsive processes. The principle of justification is extended to individual justification and the justification process will be subject to scrutiny. Member states are required to have in place inspection programmes that may be proactive. In addition, new requirements relating to accidental and unintended medical exposures mean reactive inspection processes must be available. The heads of the European Radiation protection Competent Authorities (HERCA) working group on medical applications has undertaken a range of activities to enhance common understanding of Directive requirements, including Multi-Stakeholder Meetings and Workshops which have informed position papers and statements on a range of topics included within 2013/59/Euratom. Regulators and professionals have the common goal of ensuring safe practice and common understanding of regulatory approaches and good medical practice will enable increased safety for patients, workers and the public.

Learning Objectives:

1. To understand the regulator's perspective on the BSS.
2. To learn about the regulator's role and tasks.
3. To become familiar with inspection.

A-150 16:53

The European Commission's perspective and update on the transposition in the European Member States

G. Simeonov; *Luxembourg/LU (georgi.simeonov@ec.europa.eu)*

The "Basic Safety Standards" (BSS) Directive 2013/59/Euratom was published in 2014 and has to be implemented in the EU Member States by 6 February 2018. The BSS Directive updates and consolidates previous pieces of European legislation and introduces some important changes, including in relation to protection of patients. The European Commission is empowered to monitor the implementation of the European BSS in the Member States and take corrective action, wherever necessary. The Commission implements also a series of 'soft measures' to support the implementation of the BSS Directive into practice, with recent examples on paediatric DRLs, MPE qualification framework and education and training of medical professionals. The main focus in the next years will be on ensuring full implementation of the BSS Directive. One specific area, where the Commission will focus further efforts, is the development and use of DRLs, where a European survey on clinically-specified DRLs has been recently launched.

Learning Objectives:

1. To learn about the Euratom Basic Safety Standards Directive.
2. To understand the European Commission's perspective.
3. To understand how the European Commission ensures implementation of the BSS Directive.

A-151 17:05

The industry's perspective and work needed to comply with the Basic Safety Standards

N. Denjoy; *Brussels/BE (denjoy@cocir.org)*

The medical technology sector in Europe represented by COCIR is highly technological and innovative, with around 28 billion € total turnover and 7-8% of annual revenues invested in research and development. COCIR Companies are working already to implement the new requirements, in particular article 60 and 78. Nonetheless companies have a few concerns in particular regarding a non-harmonized transposition with different requirements at national and local level regarding important topics such as justification and information on equipment. Manufacturers provide to undertakings manuals and accompanying documentation when selling a medical device, containing all the information required for safe use. The additional requirements on information in the BSS Directive, e.g., article 78, may end requiring a duplication of documentation, adding a significant burden on manufacturers and on undertakings as well.

Learning Objectives:

1. To learn about industry's perspective on the BSS.
2. To understand the work needed to comply with the BSS.
3. To identify regulatory hurdles for industry.

17:17

Panel discussion: Is the Basic Safety Standards Directive a step forward for patients, clinical professionals and regulators?

G. Frija[1], S. Ebdon-Jackson[2], W.A. Kalender[3], E.J. Adam[4], N. Denjoy[5], G. Simeonov[6]; *[1]Paris/FR, [2]Didcot/UK, [3]Erlangen/DE, [4]London/UK, [5]Brussels/BE, [6]Luxembourg/LU*

E³ - ECR Master Class (Paediatric)

E³ 426

Juvenile idiopathic arthritis (JIA)

Moderator:
K. Rosendahl; Bergen/NO

A-152 16:00

A. Conventional radiography, still a helpful method?

S.C. Shelmerdine; *London/UK*

Juvenile idiopathic arthritis (JIA) is a chronic, rheumatic illness that is associated with a high risk of long-term physical disabilities. Radiography can help identify changes related to JIA, which are primarily those of chronic, destructive changes seen in late disease, but it can also provide indirect information on soft tissue inflammation (such as peri-articular increased soft tissue density or the presence of a joint effusion). In the initial assessment of a child with joint pain, radiography is also useful to rule out other differential diagnoses such as neoplasms, posttraumatic changes and developmental defects. In this lecture, we will focus on the typical findings of joint inflammation and destruction seen in a variety of commonly affected joints and review the literature regarding the specificity and sensitivity of such radiographic signs. We will also touch upon common pitfalls and how such features may overlap with normal findings of a skeletal maturation. We conclude by reviewing the benefits and drawbacks of using radiography as a follow-up imaging tool and how this modality compares with other radiology techniques for JIA imaging.

Learning Objectives:

1. To learn about the features of joint inflammation on plain radiographs.
2. To understand the role of this technique in the diagnosis and follow-up of children with JIA.
3. To appreciate the strengths and limitations of conventional radiography compared to other modalities in JIA.

A-153 16:30

B. Ultrasound for detecting and grading of inflammation in JIA

L. Tanturri De Horatio; *Rome/IT (laura.tanturri@opbg.net)*

Musculoskeletal ultrasound (MSUS) is an attractive imaging technique in children; particularly, it is a useful tool for joint assessment and guidance of steroid injection therapy in JIA. The method is radiation free without any need for sedation and allows for a dynamic evaluation of several joints per session including assessment of the vasculature with Doppler. Moreover, the new high-resolution probes provide exquisite image quality. Caution should be taken when translating adult musculoskeletal sonographic findings to the paediatric joints, as age-related variations in thickness of cartilage and appearances of ossification centres can mimic pathology. Moreover in children it may be challenging to distinguish between synovial hypertrophy and the adjacent cartilage or joint fluid because all these structures may have a similar, hypoechoic appearance. Furthermore, the interpretation of intra-articular Doppler signals as a marker for synovitis is difficult due to physiologically enhanced blood flow which should not be misinterpreted as pathology. Over the past decades a great deal of effort has been done by the Outcome Measures in Rheumatology Clinical Trials (OMERACT) Ultrasound Task Forces to provide a definition of the normal age-dependent sonographic anatomy and to standardise an approach to MSUS scanning in children. The results from these studies provide the basis to develop definitions for pathology and to support the standardised use of MSUS in paediatric rheumatology. However, at present, very few studies have addressed the repeatability/reproducibility of MSUS finding. Moreover, validated definitions and scoring systems for ultrasound pathology in children with JIA are lacking.

Learning Objectives:

1. To learn about normal features vs pathology on ultrasound of joints in children.
2. To understand the role of ultrasound in diagnosing and grading of joint inflammation.
3. To appreciate the research-based evidence of ultrasound.

A-154 17:00

C. MRI and role of contrast in the assessment of synovitis

L.-S. Ording Müller; *Oslo/NO (lilsofie.ording@googlemail.com)*

MRI scanning is the current gold standard modality for imaging synovitis and tenosynovitis in patients with Juvenile idiopathic arthritis. Enhancement of the synovium after gadolinium injection is traditionally regarded as mandatory in the assessment of synovitis, both for diagnosis and grading, and to distinguish

between active and inactive disease. There have been huge advances in medical treatment of JIA over the last two decades and disease remission is now the ultimate goal for all patients. This increases the role of imaging to detect early signs of disease or relapse and to monitor subtle response to treatment. Several research groups work on establishing scoring systems to create objective imaging measures for disease activity in JIA. However it is challenging to reliably differentiate between normal synovial enhancement and inflammation and to grading contrast enhancement in early disease. Timing of imaging post contrast injection has shown to play an important role in the assessment and grading of synovitis and dynamic contrast-assessment might be a better method to improve quantification of synovitis. Focus on potential harmful effects of Gd-injection forces us to search for alternative methods in synovitis imaging. The diffusion weighted imaging (DWI)-derived apparent diffusion coefficient (ADC) seems to be higher in active JIA and may serve as a non-invasive imaging biomarker for JIA in the future. In this lecture current knowledge on the role of contrast in synovitis assessment, challenges in standardisation of imaging, and potential alternative methods for detection and grading of synovitis in JIA will be presented.

Learning Objectives:

1. To learn about the definition of synovitis on MRI.
2. To understand the appearances of synovitis and potential pitfalls on MRI.
3. To appreciate new techniques that may replace contrast-enhanced MRI in the assessment of synovitis.

16:00 - 17:30 **Room M 3**

Molecular Imaging

RC 406
Molecular imaging in oncology

A-155 16:00

Chairperson's introduction

K. Nikolaou; *Tübingen/DE (Konstantin.Nikolaou@med.uni-tuebingen.de)*

Radiology is playing a central role in the set-up of multidisciplinary cancer centers and in the comprehensive work-up of oncologic patients, integrating an ever increasing amount of qualitative and quantitative diagnostic information. Still, radiology is facing significant challenges, as “precision medicine” develops and matures. Integrating functional and molecular information in a quantitative fashion and adding complementary multimodality information is crucial. In detail, molecular imaging is regarded as the direct or indirect noninvasive monitoring and recording of the spatial and temporal distribution of *in vivo* molecular, genetic, and/or cellular processes for biochemical, biological, diagnostic, or therapeutic applications. Molecular and functional image information that indicate the presence of malignancy can be acquired using an abundance of modalities, including optical, ultrasonic, radiologic, radionuclide, and magnetic resonance techniques. In this session, multimodality imaging of oncologic processes will be reviewed with respect to their physical basics and imaging characteristics, including attributes of hypoxia, proliferation, and metabolism. Also, the role of prognostic, predictive and therapy response oncologic imaging biomarkers will be discussed and current and future clinical applications in oncologic diagnosis will be reviewed.

Session Objectives:

1. To understand the basics of molecular imaging.
2. To appreciate the unmet needs of oncological imaging.
3. To learn the role of molecular imaging in oncology.

A-156 16:05

A. Imaging of hypoxia

V.J. Goh; *London/UK (vicky.goh@kcl.ac.uk)*

Tumour hypoxia is present in up to 60% of locally advanced solid tumours. Tumour hypoxia is a significant challenge to successful therapy, contributing to treatment resistance and a poor prognosis. Intra-tumoural hypoxia may be assessed by molecular markers including hypoxia inducible factor 1 (HIF-1) and carbonic anhydrase isoenzyme IX (CA-IX). However, hypoxia is a dynamic process and alters depending on perfusion and oxygenation status. Noninvasive imaging of intra-tumoral hypoxia provides an opportunity to better stratify patients to improve local control. Tumour hypoxia may be assessed in vivo by direct and indirect imaging techniques. Positron emission tomography (PET) imaging targets hypoxic cells with tracers including 18F fluoromisonidazole (18F-MISO), 18F-fluoroazomycin arabinofuranoside (18FFAZA) and 64Cu-diacetyl-bis(N4-methylthiosemicarbazone (64Cu-ATSM). Hypoxia imaging may also be undertaken by magnetic resonance imaging (MRI) with techniques such as blood oxygenation level-dependent (BOLD) MRI and oxygen enhanced MRI measuring R2* and R1 changes, respectively. This lecture will review the biological basis and fundamentals of hypoxia imaging and potential clinical applications including radiotherapy.

Learning Objectives:

1. To review the fundamentals of hypoxia imaging.
2. To review the advantages and disadvantages of hypoxia imaging and its relation to perfusion.
3. To learn about hypoxia imaging in radiation treatment.

Author Disclosure:

V.J. Goh: Research/Grant Support; Siemens Healthineers. Speaker; Bayer, Siemens Healthineers.

A-157 16:23

B. Imaging of proliferation

A. Kjaer; *Copenhagen/DK (akjaer@sund.ku.dk)*

Uncontrolled proliferation is a hallmark of cancer and may be imaged both at the DNA level with 18F-FLT and at the protein level through amino acid PET tracers, e.g., 18F-FET. The value of proliferation imaging with PET in oncology will be reviewed with particular focus on use for tumor delineation, prognostication and therapy monitoring. Additionally, the relative value compared to that of 18F-FDG for the same applications will critically be discussed.

Learning Objectives:

1. To understand basic principles of proliferation imaging.
2. To become familiar with imaging of proliferation.
3. To learn about difficulties in liver proliferation imaging.

A-158 16:41

C. Imaging of metabolism

C. Nanni; *Bologna/IT (cristina.nanni@aosp.bo.it)*

18F-FDG PET/CT is an imaging technique that is aimed to evaluate glucose metabolism of tissues and organs. PET/CT scanners consist of a combination of a PET scanner and a CT scanner providing both morphological and functional images that can be fused to accurately localize any pathological finding. The procedure is standard and includes several steps. Patients are not allowed to consume any food or sugar for at least 6 h prior to the start of the PET study. Injection should be fully intravenous. Optimal uptake time is 60 min. In general, for a 3D system and 3 MBq/Kg of FDG, 2 min/bed position is enough, leading to an average overall acquisition time of 14 minutes. Low dose CT (120 kV, 80 mA) is necessary both for attenuation correction and for image interpretation. Once reconstructed, images must be interpreted on a dedicated workstation. SUV max based on body weight is the standard semi-quantitative index. FDG PET/CT was proved to be accurate for several malignancies for the definition of TNM at staging and in the suspect of relapse. Furthermore, changing in SUV max are related to the response to systemic therapies, both during and after treatment. This parameter is considered a non invasive surrogate for therapy assessment. Some particular kinds of malignant tumors are not detectable at FDG PET. In particular mucinous ca, transitional cell cancers, clear cell cancers, indolent HCC and some adenocarcinomas fail to significantly concentrate FDG. Low accuracy can also be found in some particular areas of the body where FDG is physiologically concentrated such the brain and the urinary tract.

Learning Objectives:

1. To learn the clinical indications for FDG imaging.
2. To become familiar with imaging protocol.
3. To learn about difficulties in FDG imaging.

A-159 16:59

D. Biomarker imaging with MR

M.E. Mayerhöfer; *Vienna/AT (marius.mayerhoefer@meduniwien.ac.at)*

Originally regarded as a purely morphological imaging technique with excellent soft-tissue contrast, MRI today is recognised as a technique that can also provide functional biomarkers through different approaches. For treatment response assessment, diffusion-weighted imaging (DWI), which indirectly provides information on cell density in tumours, is already well-established, and for some tumors (e.g., lymphoma), is has even been proposed as a radiation-free alternative to [18F]FDG-PET for staging and treatment response assessment. Nevertheless, limitations for DWI include artefacts and standardisation of apparent diffusion coefficients between different DWI pulse sequences, and between MR scanners of different vendors. Perfusion-weighted imaging (PWI) is another technique that is increasingly being used in the response evaluation of hypervascular tumours, such as hepatocellular carcinoma. In the body, PWI is most commonly performed on the basis of dynamic contrast-enhanced sequences, with k-trans, a measure of capillary permeability, being the best-known parameter. Alternatively, PWI may be performed using arterial spin labeling, without contrast media. MR

spectroscopy (MRS), which today is most frequently based on protons, is another technique that can be used to assess biomarkers in the form of metabolites, such as lactate and choline. While several studies reported encouraging data, for instance, in breast cancer and prostate cancer, limitations such as, long acquisition times and difficulties in terms of standardisation and quantification have prevented MRS from being introduced into routine clinical imaging. Cutting-edge techniques, such as chemical exchange saturation transfer (CEST) imaging, may overcome the limitations of MRS.

Learning Objectives:

1. To learn the clinical indications for biomarker imaging.
2. To become familiar with quantification.
3. To learn about difficulties in quantification.

17:17

Panel discussion: The pros and cons of molecular imaging in oncology

16:00 - 17:30 **Room M 4**

E³ - ECR Academies: Chest Imaging

E³ 418

Cavitary and cystic diseases of the lung

A-160 16:00

Chairperson's introduction

N. Howarth; *Chêne-Bougeries/CH (nigel.howarth@grangettes.ch)*

The session will provide an overview of cavitary and cystic diseases of the lung. Diagnostic criteria for cavitary lesions and cysts will be explained and the differential diagnosis will be explored in a variety of clinical situations. The pathogenesis of different forms of cavitary and cystic lesions will be explained. Key CT features will be reviewed. Attendees will learn a practical and logical approach for CT interpretation based on clinical setting, of value in everyday work.

A-161 16:05

A. Cavitary lung lesions

A.P. Parkar; *Bergen/NO (apparkar@gmail.com)*

A cavity is defined as “a gas-filled space, seen as a lucency or low-attenuation area, within pulmonary consolidation, a mass, or a nodule”. The wall thickness may vary considerably. There is a continuous transition from cavities to cysts. Cysts are usually thin walled (i.e., < 2 mm). A wall thickness < 7 mm is highly specific for benign disease, a thickness >24 mm is highly specific for malignant disease. However, this is not absolute, as thin-walled carcinomas do exist. An additional indicator for malignancy is the lack of perilesional centrilobular nodules around a cavity. The cavity content is unhelpful in differentiating benign and malignant lesions. Wall rim enhancement on contrast-enhanced CT is common in abscesses. A connecting pulmonary artery may be seen in smaller metastases, but not in larger ones, as the larger nodules tend to compress the vessels, so no feeding artery does not always imply benign nodules. The acute onset of symptoms is sometimes helpful to distinguish malignant and non-malignant disease. Hemoptysis is not a useful symptom to differentiate between benign and malignant cavities. Benign diseases may also cause fatigue and weight loss similar to malignancies. Acute onset of fever is usually helpful to distinguish benign disorders from malignant, but a pulmonary cancer may cause a super-infection secondary to the tumor. However, the combination of symptoms, laboratory results, past clinical history, and imaging findings leads to recognition of the correct diagnosis. This presentation will guide you through the most commonly encountered cavitary lung in adults.

Learning Objectives:

1. To review the diagnostic criteria and differentials of cavitary lung lesions.
2. To learn about the most common causes.
3. To learn about an algorithmic approach to narrow the differential diagnosis.

A-162 16:33

B. Langerhans cell histiocytosis (LCH)

A. Devaraj; *London/UK*

This presentation will review the characteristic and atypical CT appearances of Langerhans. The challenges in establishing a confirmed diagnosis in atypical cases will be reviewed as well as a discussion of the differential diagnoses when faced with cystic lung disease. The role of CT beyond diagnosis will be highlighted, including a review of complications and outcomes of the disease.

Learning Objectives:

1. To understand the pathophysiology of LCH.
2. To review key features on CT.
3. To learn about the various stages of the disease.

A-163 17:01

C. Lymphangioleiomyomatosis

A. Oikonomou; *Toronto, ON/CA (anastasia.oikonomou@sunnybrook.ca)*

Lymphangioleiomyomatosis (LAM) is a rare cystic lung disease caused by infiltration of the lung with smooth muscle cells. It occurs in patients with tuberous sclerosis complex (TSC-LAM) and in a “sporadic” form in patients without tuberous sclerosis (S-LAM). S-LAM is seen exclusively in women of reproductive age while TSC-LAM may also be seen in men. Parenchymal lesions in LAM mainly include cysts, which are thin-walled, well-defined, rounded, usually small in size up to 2 cm and may reach large numbers. They have no zonal lung predominance. Nodules are extremely rare in S-LAM and are more commonly seen in TSC-LAM. They may either be solid or ground-glass and usually tiny. They represent multifocal micronodular pneumocyte hyperplasia. Pleural manifestations include chylothorax and pneumothorax. Chylous pericardial effusions may be seen. Recent guidelines for the diagnosis of LAM from the European Respiratory Society LAM task force classify LAM as definite, probable and possible. LAM is differentiated by other cystic lung diseases such as Langerhans histiocytocis (PLCH), Birt-Hogg-Dube (BHD), lymphocytic interstitial pneumonia (LIP) and amyloidosis. In PLCH the cysts have a bizarre shape, are variable in number and are upper and middle lobe predominant. In LIP the cysts are round and variable in size but usually small and random in distribution surrounded by ground glass opacity. In BHD the cysts are elliptical in shape and have a subpleural, lower zone predominance adjacent to vessels. In amyloid the cysts are variable in size but usually large and diffusely distributed. Nodules are seen in PLCH and amyloid.

Learning Objectives:

1. To learn about the current concepts on pathogenesis.
2. To review the typical and atypical CT features.
3. To learn about the tuberous sclerosis complex.

16:00 - 17:30 **Room M 5**

E³ - ECR Academies: Update on Hepatobiliary Imaging

E³ 420

Advanced MR techniques and imaging biomarkers

A-164 16:00

Chairperson's introduction

D.-M. Koh; *Sutton/UK (dowmu.koh@icr.ac.uk)*

Advanced MR imaging is being applied to the hepatobiliary system to improve disease diagnosis and patient management. These include diffusion-weighted MRI, MR and US elastography, as well as liver selective contrast media. These techniques enhance the diagnostic potential of MR imaging for focal and liver diseases, and have impacted on imaging pathways and patient management. This session will demonstrate the application of these techniques for patient care.

A-165 16:05

A. Diffusion-weighted imaging

N. Papanikolaou; *Lisbon/PT*
(nickolas.papanikolaou@research.fchampalimaud.org)

Diffusion-weighted MR imaging (DWI), based on the thermally driven random motion of water molecules (otherwise called Brownian motion) has been increasingly applied in the evaluation of a wide variety of oncological diseases not only in the brain, but in the body during recent years. Promising results for improved detection and treatment evaluation, in terms of prediction and early response assessment, have been reported. DWI is probing water mobility propelled by thermal energy, and since water molecules are interacting with cellular membranes or other structures, DWI has the potential to provide us with information regarding the cellular architecture in a non-invasive manner. The apparent diffusion coefficient (ADC) is a property of tissue that reflects local water mobility. In the presence of pathology, ADC, has been correlated with important histologic properties, including the tumor proliferation index, tumor grade, the presence of necrosis, and tumor cell apoptosis. The model that is used to calculate the ADC value is based on a mono-exponential function that generally works well. However, in the presence of increased

vascularity, there is a second component that is called microperfusion and needs to be taken into consideration. In that case the use of a bi-exponential function where ADC is decomposed into D and D*, the true diffusion coefficient and the microperfusion coefficient is providing more accurate modeling of diffusion signals. In the presence of increased tissue heterogeneity a non-Gaussian diffusion model should be considered to take into account the interactions between water molecules and local tissue architecture components.

Learning Objectives:

1. To recognise the general principles of liver DW MRI.
2. To be familiar with the clinical applications of DW imaging in diffuse and focal liver diseases.
3. To be aware of the evolving developments in liver DW imaging.

Author Disclosure:

N. Papanikolaou: Advisory Board; Advantis. Founder; MRIcons.

A-166 16:33

B. MR and US elastography

D.J. Lomas; *Cambridge/UK*

Elastography is the measurement of tissue stiffness which is routinely assessed by subjective clinical palpation. Non-invasive in vivo imaging methods for quantitative elastography have been developed over the last few decades using ultrasound and MRI. These involve vibrating the tissue of interest and measuring the speed of the generated acoustic waves as they pass through the tissue. Essentially waves travel faster in stiffer tissues. This information, with some important assumptions, can be used to estimate absolute tissue stiffness. Multiple ultrasound methods are available which use different wave generation techniques, frequencies and which vary by the volume of tissue sampled and their ability to image simultaneously. Two MRI based methods have been developed both using relatively similar techniques for wave generation and image processing. MRI methods report liver stiffness using the “Shear” modulus, whereas US methods use “Elastic” or “Young’s” Modulus (typically 3X larger). The MRI methods are probably more accurate for the detection of early and moderate liver fibrosis and sample larger volumes than the US methods, but are more expensive and less widely available. Both approaches have the potential to replace some liver biopsies in clinical practice and have particular screening value in diagnosing the “normal” liver when patients are referred with mild liver function test abnormalities. All these elastography methods are now being applied directly to clinical outcome studies, rather than just comparison studies with liver biopsy and other fibrosis measures, and these may demonstrate additional clinical prognostic and therapeutic applications for the management of liver disease.

Learning Objectives:

1. To recognise the clinical applications and diagnostic performance of MR and US elastography.
2. To be able to compare both techniques.
3. To be familiar with the factors confounding the accuracy of elastography.

A-167 17:01

C. MR contrast agents in liver imaging

M. Karcaaltincaba; *Ankara/TR (musturayk@yahoo.com)*

Contrast choice for liver MR imaging is important for correct diagnosis. Extracellular contrast agents should be preferred for diagnosis of hemangioma. Dynamic contrast-enhanced imaging phases are early and late arterial, portal venous, equilibrium phases. These phases can demonstrate perfusion characteristics of common liver lesions. Hepatocyte specific agents should be preferred for differentiation of focal nodular hyperplasia (FNH) from hepatic adenoma and preoperative planning for metastatic colorectal cancer. Recent evidence suggests use of Gd-EOB-DTPA for diagnosis of early HCC. A hypervascular lesion appearing as focal hyperintensity on hepatobiliary phase images is consistent with FNH in patients without risk factor for HCC and cancer. Oxaliplatin (mostly used for colorectal cancer) can induce focal nodular hyperlasia like lesions. Gd-EOB-DTPA may also be helpful in the assessment of liver function in patients with steatohepatitis, fibrosis and segmental dysfunction.

Learning Objectives:

1. To understand the dynamic contrast-enhanced imaging and liver perfusion.
2. To recognise the role of hepatocyte specific contrast agents in liver function and lesion characterisation.
3. To learn the weaknesses of extracellular and hepatospecific contrast agents.

Author Disclosure:

M. Karcaaltincaba: Speaker; Bayer, GE Healthcare, Philips Healthcare, Pfizer.

Thursday, March 1

08:30 - 10:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 521
Imaging of the skull base

A-168 08:30
A. Non-tumoural pathology of the temporal bone
B. Ozgen Mocan; *Ankara/TR (burce@hacettepe.edu.tr)*

The temporal bone has a complex anatomy, but the pathologies involving the temporal bone structures are somewhat limited with specific and diagnostic imaging findings. During this lecture, the most common non-tumoural causes of conductive and sensorineural hearing loss will be reviewed in an interactive manner with emphasis on the clinical and imaging findings that are helpful for the differential diagnosis.
Learning Objectives:
1. To learn the most common inflammatory lesions of the temporal bone.
2. To become familiar with the most common malformations and non-tumoural pathologies.

A-169 09:15
B. Tumours of the skull base
T. Beale; *London/UK (timothy.beale@uclh.nhs.uk)*

The lecture will describe a classification system for tumours of the skull base that will aid in the differential diagnosis. Using clinical cases the imaging features of the common skull base tumours will be highlighted. The important review areas for the individual tumours will be discussed including those features that may alter the clinical management and help in the differential diagnosis. The common pitfalls and non-neoplastic differential diagnosis will be highlighted and an imaging technique for assessing the skull base will be discussed.
Learning Objectives:
1. To become familiar with the imaging technique of the skull base.
2. To identify imaging criteria for improved differential diagnosis.

08:30 - 10:00 **Room B**

New Horizons Session

NH 5
The machines are coming: how will they change our future?

A-170 08:30
Chairperson's introduction
H.-U. Kauczor; *Heidelberg/DE (Hans-Ulrich.Kauczor@med.uni-heidelberg.de)*

Novel developments in computer science and performance have prepared the ground for the implementation of so-called artificial intelligence algorithms and have computers learn “deeply” from the analysis of big data. This session will provide an introduction into machine based learning algorithms touching reflecting opportunities, but also limitations. Obviously, quantitative image analysis will be a promising field for machine learning and the integration of the “machines” in the workflow of radiology will lead to major challenges to generate benefits for patients, the health care system and their economics as well as our profession. Done properly, machines will help us to cope with the ever increasing volume of imaging exams and scans, increase quality and safety, while radiologists will generate the value from imaging and the added value provided by the machines to strengthen our role as physicians.
Session Objectives:
1. To understand the basics of machine learning.
2. To appreciate the opportunities to improve quality in radiology.
3. To redefine the professional role of the radiologist.
Author Disclosure:
H.-U. Kauczor: Research/Grant Support; Siemens, Bayer. Speaker; Siemens, Boehringer Ingelheim, GSK, Novartis, Astra Zeneca, Philips, Bracco.

A-171 08:35
Deep learning: current performance
B. van Ginneken; *Nijmegen/NL (bram.vanginneken@radboudumc.nl)*

The application of deep learning to medical image analysis has resulted in much-improved performance for many algorithms. There is early evidence that for many specific, narrowly defined detection and interpretation tasks, computers perform on par with or even better than radiologists. A requirement is that these deep learning algorithms are trained on a sufficiently large amount of high-quality annotated data. Larger multi-center validation studies are still needed to demonstrate that these algorithms work correctly on the variety of real-world data, obtained with different scanners and protocols. In this talk, I will showcase several examples of high-performing deep learning algorithms and argue that the radiological community should play a more active role in (1) identifying which tasks should be automated; (2) evaluating and validating automated systems in a fair and comparative manner; (3) collecting the high-quality annotated training and evaluation data; (4) clearly defining the role of human readers together with automated systems.
Learning Objectives:
1. To learn about the principles of machine learning.
2. To appreciate the current performance of deep learning in radiology and beyond.
3. To learn about the limitations due to the complexity of radiology.
Author Disclosure:
B. van Ginneken: Founder; Thirona. Owner; Thirona. Research/Grant Support; MeVis Medical Solutions, Delft Imaging Systems. Shareholder; Thirona.

A-172 08:58
Artificial intelligence applications in radiology
J.B. Seo; *Seoul/US (seojb@amc.seoul.kr)*

The recent advances in artificial intelligence, particularly deep learning algorithm, have shown performances superior to those of human in image recognition of non-medical fields. Accordingly, many researchers and companies have tried to apply artificial intelligence in radiology. Artificial intelligence can be applied in various aspects of medical imaging such as noise reduction, artefact reduction, lesion segmentation, detection, classification, and differential diagnosis. Early studies have shown promising results in several applications such as detecting nodule or tuberculosis on chest radiograph. Furthermore, this technique can applied in finding similar cases from the database, predicting disease outcome and so on. In this talk, general concept of artificial intelligence and early results of various applications of artificial intelligence in medial image will be introduced.
Learning Objectives:
1. To become familiar with first clinical applications.
2. To consolidate knowledge about the integration in the clinical workflow.
3. To appreciate the future roadmap and its impact on training of young radiologists.
Author Disclosure:
J.B. Seo: Shareholder; Coreline Soft Co. Speaker; Siemens / Guerbet.

A-173 09:21
Big data for deep learning
C.L. Schlett; *Heidelberg/DE (christopher.schlett@med.uni-heidelberg.de)*

Deep learning is currently an extremely active research area and has the potential to be the biggest game changer in medical imaging since the advent of digital imaging. It requires massive amount of training dataset with accurate annotation; however, annotation of medical images is particular difficult and resource consuming as compared to other examples outside of medicine. Potentially induced error and bias due to imperfect annotation and/or inconsistency increase further the needed sample size. Several sources of medical images can be considered. While clinically acquired data are broadly available, they are often not interlinked with other data and face the issue of a high variability. A potentially more suitable source for big data could be large, population-based cohort studies such as the Rotterdam Study, the UK BioBank or the German National Cohort, since they have a high level of data quality and consistency regarding imaging, and they further frequently linked with clinical outcomes and annotations. However, deep learning in medical imaging remains a great challenge, not only because of the necessity for big data.
Learning Objectives:
1. To become familiar with the opportunities of big data analysis.
2. To understand that quality of big data is pivotal.
3. To learn how to generate "evidence" from big data analysis in radiology.

09:44
Panel discussion: Machines in radiology: do we still need the radiologist?

08:30 - 10:00 **Room C**

Breast

RC 502
New mammography: tomosynthesis and future techniques

A-174 08:30
Chairperson's introduction
E.M. Fallenberg; *Berlin/DE (eva.fallenberg@charite.de)*

Early detection of breast cancer through X-ray mammography (MG) has been shown to reduce mortality; however, the method is limited by a decreased sensitivity and specificity particularly in young patients and women with radiographically dense breasts due to tissue overlying and masking tumours or architectural distorsions. The introduction of full field digital mammography gave the possibility to develop further technical methods, to overcome these limitations. Some of these are tomosynthesis, contrast enhanced mammography and contrast enhanced tomosynthesis as well as most recently also breast CT. In this talk will be presented the background of 2D-mammography, tomosynthesis and contrast enhanced mammography techniques and breast CT. Potential advantages and disadvantages will be indicated and a sample of clinical cases will be presented to illustrate how the different techniques contribute to the detection of lesions.
Session Objectives:
1. To learn about 2D mammography and digital breast tomosynthesis.
2. To recognise the advantages and disadvantages of tomosynthesis compared to 2D mammography.
3. To look into the future and hear about the potential of new breast imaging techniques in lesion assessment.
Author Disclosure:
E.M. Fallenberg: Board Member; EUSOBI. Research/Grant Support; GE Healthcare, Guerbet. Speaker; GE Healthcare, Bayer Healthcare, Gurbet.

A-175 08:35
A. Should we abandon 2D mammography?
S. Zackrisson; *Malmö/SE (sophia.zackrisson@med.lu.se)*

Full-field digital mammography (FFDM), also called 2D mammography, with flat panel detectors has been broadly used in clinical routine for about a decade. Even if there has been advances in the technical development of the digital detectors, the detectors are not the main limiting factor in breast cancer detection; the challenge is the anatomical noise, i.e., dense breast tissue. FFDM is a two-dimensional modality and inherent in that is that dense breast tissue may cause overprojection and hide or simulate the presence of a tumour on these images even if several views are acquired. Digital breast tomosynthesis, DBT is a 3D mammography technique that, to a large extent, can suppress the confounding effect of the overlapping tissue. DBT is a strong competitor to 2D mammography both for screening and clinical examinations. This presentation will cover 2D mammography in terms of technical background and optimisation of image quality. Furthermore, it will discuss the advantages and disadvantages of 2D mammography compared to DBT and evaluate if there are situations where 2D mammography still could be the preferred method if DBT is transitioned into screening and clinical practice.
Learning Objectives:
1. To understand the technique of 2D mammography and what the limits could be.
2. To learn if there are ways to improve image quality of 2D mammography.
3. To understand when 2D mammography is better than DBT.
Author Disclosure:
S. Zackrisson: Speaker; Speaker's fees and travel support from Siemens Healthineers.

A-176 09:00
B. Clinical validation of tomosynthesis and results in the last 10 years: where do we stand?
P. Skaane; *Oslo/NO (per.skaane@outlook.com)*

Digital breast tomosynthesis (DBT), an advanced mammographic technique, has the potential to improve two inherent limitations of conventional mammography, FFDM: poor sensitivity in women with dense breasts (caused by superimposed parenchyma, “masking effect”) and low specificity (caused by parenchyma simulating a mass, “pseudotumor”). In diagnostic setting, DBT can replace conventional supplemental views for evaluation of indeterminate noncalcified lesions, “downgrade” some indeterminate (BI-RADS 3) lesions, and “upgrade” other equivocal masses indicating the need for biopsy. Thus, fewer lesions need to have follow-up. Evaluation of extent and multifocality of cancer is better demonstrated at DBT, and consequently preoperative cancer staging is improved. All the retrospective US screening studies comparing FFDM versus FFDM+DBT have shown a significantly lower recall rate for DBT, and most studies also an increased cancer detection rate. Lack of significant increase in cancer detection in other US studies might have been caused by study design and lack of power. The four prospective European trials comparing FFDM vs. FFDM+DBT in screening published so far have all demonstrated a significantly higher cancer detection rates for DBT, but variable recall rates. Challenges regarding implementation of DBT in screening include number of projections, reading time, and women with very dense breasts (BI-RADS d). The radiation dose problem is solved by synthetic 2D images. Studies on cost-effectiveness, harm-benefit analyses, overdiagnosis, and subsequent interval cancer rates and potential reduction of advanced stage cancers would be of importance. Overall, DBT has clearly shown a higher accuracy than FFDM in diagnostic as well as screening settings.
Learning Objectives:
1. To become familiar with the technique of DBT.
2. To understand the results of DBT in the screening and diagnostics settings.
3. To know the evolution of tomosynthesis in screening organisation.
Author Disclosure:
P. Skaane: Equipment Support Recipient; Tomosynthesis equipment for the Oslo Tomosynthesis Screening Trial was provided by Hologic..

A-177 09:25
C. The future of mammography: my predictions
E. Giannotti; *Nottingham/UK (Elisabetta.Giannotti@nuh.nhs.uk)*

Breast screening aims to diagnose breast cancer at the earliest opportunity, maximize treatment success and reduce breast cancer-related mortality. Mammography is the mainstay of screening but it is less sensitive for some women, particularly those with dense breasts. Supplemental imaging leads to the detection of additional cancers, but this approach increases unnecessary recalls and healthcare costs and screening tools by definition should be feasible and affordable. In the future, tailored screening based on different (personal) risk factors is expected to replace the current standard (one size fits all) mammography screening programs, in order to reduce the potential harm and costs of screening and increase cancer detection. To achieve this it is crucial to develop more accurate risk assessment models that can be easily adopted in routine clinical practice. Innovative diagnostic techniques (such as digital mammography, quantitative breast density analysis, texture analysis and deep learning) could have a crucial role not only in the early diagnosis, but also being an active part of the risk assessment for developing breast cancer. Lately new digital techniques have been implemented, for example, digital breast tomosynthesis and contrast enhanced spectral mammography, improving mammographic sensitivity and offering new opportunities that will assist in the risk stratification of the patient. In order to increase cancer detection rate and reduce breast cancer related mortality we have the potential to improve mammographic sensitivity and utilization, and use these techniques not only for diagnosis but for stratifying breast cancer risk in order to tailor breast cancer screening for “individual women”.
Learning Objectives:
1. To understand the role of mammography in analysing and characterising breast lesions.
2. To become familiar with new developments in digital mammography such as contrast mammography, tomosynthesis and 3D contrast mammography.
3. To learn about the new potential of combining mammography with molecular imaging, optical imaging and texture analysis.

09:50
Panel discussion: Mammography and/or tomosynthesis: where will we stand in 10 years?

08:30 - 10:00 **Room Z**

Joint Session of the ESR and UEMS

ESR/UEMS 1
ESR and UEMS: a united European voice

A-178/A-179 08:30

Chairpersons' introduction

L. Bonomo[1], M. Adriaensen[2]; [1]*Rome/IT,* [2]*Heerlen/NL*
(lorenzo.bonomo@unicatt.it)[1], (miraude@gmail.com)[2]

The UEMS - European Union of Medical Specialists is the oldest European medical organisation representing the interests of more than 50 different medical specialities and involving more than 1.6 million of healthcare professionals. The ESR - European Society of Radiology is the world's biggest radiological society, encompassing 67.500 members from 155 different countries. It was founded in 2005 by merging the European Congress of Radiology and the European Association of Radiology, aiming at establishing a single, powerful and unified voice for European radiologists. Through the section of radiology of the UEMS, UEMS and ESR share the same ambitious objective of promoting the highest quality of care and medical practice in radiology, by serving the needs of patients and general public, harmonizing radiological training and defending free movement and professional interests of European radiologists. This Joint session will focus on the concept and importance of advocacy at the level of the European Union, with specific emphasis on clinical audit in radiology and the impact of the European BSS Directive. With regard to the harmonisation of radiological training, the history and the future of the assessment programme of European training centers will be discussed. Finally, particular attention will be dedicated to the working methodologies of EACCME (European Accreditation Council for Continuing Medical Education) and ACI (Accreditation Council in Imaging) in the framework of CME - Continuing Medical Education and CPD - Continuing Professional Development programmes.

Session Objectives:

1. To describe the role of the UEMS within the EU.
2. To understand the difference between ESR and UEMS.
3. To understand the importance of cooperation between ESR and UEMS.

Author Disclosure:

M. Adriaensen: Other; Board Member; UEMS SECTION of RADIOLOGY; member, Standards Committee of the European Board of Radiology; member, EBR-UEMS ETAP 2.0 working group.

A-180 08:35

Differences and similarities between ESR and UEMS (part 1)

P.M. Parizel; *Antwerp/BE*

The UEMS and the ESR share a common ideal of serving the healthcare needs of the general public through the support of science, teaching and research and improving the quality of service. However, UEMS and ESR have a different structure: whereas the UEMS is the representative organisation of the National Associations of Medical Specialists in the European Union and its associated countries, the ESR is foremost a society of individual members. The UEMS was founded in 1958 and it is the oldest European medical organisation. With a current membership of 39 National Member Associations, it comprises 43 different Specialist Sections and Boards, 14 Multidisciplinary Joint Committees and over 20 Divisions, involving more than 1.6 million healthcare professionals. As the representative organisation of National Medical Associations (NMAs) in the EU and its associated countries, the UEMS sets standards for high quality healthcare practice, which are transmitted to authorities and institutions of the EU and the NMAs, stimulating and encouraging them to implement its recommendations. With more than 75,500 members from 157 different countries, the ESR, an apolitical, non-profit-organisation, is the world's biggest radiological society. Founded in 2005 by merging the European Congress of Radiology (ECR) and the European Association of Radiology (EAR), the ESR aims to offer a single, powerful and unified voice for European radiologists, thus providing a single house of radiology in Europe. In this session, the speakers will highlight the intense and positive collaboration between ESR and UEMS.

Learning Objectives:

1. To understand the structure of the UEMS and ESR.
2. To understand the differences between ESR and UEMS.
3. To understand the importance of UEMS/ESR political involvement in EU affairs.

A-181 08:40

Differences and similarities between ESR and UEMS (part 2)

B. Maillet; *Brussels/BE (bernie.mail@skynet.be)*

European legislation has three levels, from the highest level to the lowest level the Regulation, the Directive to the Recommendation. The strongest, the Regulation has immediate effect at National level while the Directive has to be transposed into National legislation and here derogations can be included while Recommendations are not really binding. The European Commission drafts those pieces of legislation that have to be then approved both by the European Parliament and by the European Council of Ministers jointly. This is the so-called EU institutional triangle. And the lobbying can be organised, first, at the level of the Drafting of the legislation, contacting the European Commission and trying to explain why we as Medical Specialists have some positions on some issues but also by contacting the individual Members of the European Parliament. There are some MEP's who are physicians and so they are the first "target" of our Lobbying activity at the European Parliament. As both the ESR as well as the UEMS Section of Radiology as an integral part of the UEMS have both as aim the defense of Radiology and the Radiologists for the benefit of better diagnosis for the European citizen and patient, they should lobby together in order to avoid duplication and be much more efficient. In the recent past such a common action has proven to be effective with for instance the derogation for MRI in field of the European Directive on Magnetic Fields.

Learning Objectives:

1. To understand the structure of the UEMS and ESR.
2. To understand the differences between ESR and UEMS.
3. To understand the importance of UEMS/ESR political involvement in EU affairs.

A-182 08:45

The European Perspective (part 1): advocacy at the EU Level (part 1)

V.E. Sinitsyn; *Moscow/RU*

Advocacy in medicine and radiology could be defined as a coordinated combination of problem identification, solution creation, strategy development, and actions taken by all participants in order to achieve the positive changes. Today the European radiological community has been facing a serious problem: the role of our specialty in modern healthcare is undervalued. This situation urgently needs to be corrected with help of large-scale advocacy campaign organised both by UEMS and ESR. Through advocacy, rights and needs of radiologists could be expressed and represented. So far radiologists and national radiological societies have the insufficient political influence to change a view of EU, national governments and health authorities on the new role of radiologists in the value-based system of healthcare. UEMS has contacts with the Authorities and Institutions of the EU, representing multiple organisations of the National Associations of Medical Specialists in the EU. From another side, ESR has vast professional expertise in all fields of radiology, including training of radiologists, setting of standards and guidelines, organisation of quality control, patient safety, information management and value-based imaging. Advocacy and political lobbying of European radiology from multiple combined actions from UEMS and ESR will stimulate and encourage EU and national authorities to implement recommendations from both professional organisations. Digital technologies and social media make such advocacy campaign more visible and effective. Advocacy campaign supporting European radiologists will results also in recognition of UEMS and ESR as trusted and effective organisations providing added value to the healthcare system of EU.

Learning Objectives:

1. To understand the concept of advocacy.
2. To understand the importance of advocacy in the EU.
3. To learn how the advocacy can improve the role of UEMS and the ESR in Europe.

A-183 08:50

The European Perspective (part 1): advocacy at the EU Level (part 2)

B. Maillet; *Brussels/BE (bernie.mail@skynet.be)*

The Union Européenne des Médecins Spécialistes is an umbrella organisation representing the Professional Medical Associations of the European Union and even broader, the European Area. The members are the National Medical Associations (NMA) representing medical specialists in the different Member States (MS) and was created by the NMA's of the six countries that created the European Economic Community (EEC, as was the name of the EU at that time) by the signing of the Rome Treaty in 1957 so the UEMS is the largest and oldest European Medical Organization (EMO) and will celebrate in 2018 its 60th anniversary. Aside the NMA's the UEMS also has 43 specialist Sections one of those being the UEMS Section of Radiology. The aims and objectives of the UEMS are the highest level of training of medical specialists and works also on the harmonisation of CME-CPD in Europe through the European

Council for CME (EACCME) that has an agreement on mutual recognition of Credits with the American Medical Association (AMA) and with the Royal College of Physicians and Surgeons of Canada (RCPSC) as well as harmonisation of training through European Examinations and the Council for European Specialist Medical Assessment (CESMA) that is part of the UEMS European Council for Accreditation of Medical Specialist Qualification (ECAMSQ).

Learning Objectives:

1. To understand the concept of advocacy.
2. To understand the importance of advocacy in the EU.
3. To learn how the advocacy can improve the role of UEMS and the ESR in Europe.

A-184 08:55

The European Perspective (part 2): clinical audit and its implementation in view of the European BSS Directive

B.E. Kelly; *Belfast/UK*

In 2018, Euratom Directive 2013/59 will come into effect. This will mandate the regular use of clinical audit as a tool for measuring, among other parameters, patient safety and radiation protection. In 2017, the audit subcommittee produced a booklet (Esperanto) designed to guide the user through the principles of clinical audit. A pilot study, performed during the summer of 2017, tested the efficacy of the templates within the booklet. The results of this indicated that respondents found the algorithm straightforward, the templates navigable and the subjects audited, relevant.

Learning Objectives:

1. To understand the definition of clinical audit.
2. To learn about the existence and the legal consequences of the current European directive addressing clinical audit in radiology.
3. To hear about best practices with regard to the implementation of clinical audit in radiology

A-185 09:05

ETAP 2.0 (part 1): history of ETAP

H. Aronen; *Turku/FI (hannu.aronen@utu.fi)*

The European Training Assessment Programme (ETAP) is a subcommittee of the education committee of the European Society of Radiology (ESR). It was established in 2001 as a joint initiative between the EAR (European Association of Radiology) and the UEMS (European Union of Medical Specialists). It has been funded equally by the ESR and the UEMS. ETAP is one of the oldest collaboration forms between ESR and UEMS radiology section. The aims of ETAP are to improve and harmonise the standards of radiology training in Europe, provide institutions that offer postgraduate radiology education with objective assessment of their training programmes by external assessors nominated by ESR and UEMS and develop assessment systems and guidelines for use by postgraduate education authorities at the national level. The program has been voluntary, and visits have been made on requests from the individual training centers. ETAP has also developed a self assessment tool for training centres. ETAP programmes encourage self regulation of the specialist training in radiology, further increasing the autonomy of European radiologists. The recommendations in the guidelines are compatible with the European Training Curriculum for Radiology and modern international educational references. ETAP has offered an objective method based on external systematic evaluation and self assessment to develop radiological specialist programs in Europe. It is necessary that we radiologists evaluate our specialist training ourselves.

Learning Objectives:

1. To understand the importance of ETAP in the past years.
2. To know about the structure of ETAP.
3. To learn about facts and figures of ETAP.

A-186 09:15

ETAP 2.0 (part 2): modernisation of ETAP

L. Oleaga Zufiría; *Barcelona/ES (lauraoleaga@gmail.com)*

The European Training Assessment Programme (ETAP) was established in 2001 as a joint initiative of the European Society of Radiology (ESR) with the UEMS (European Union of Medical Specialists) radiology section. The aims of the programme were to improve and harmonise the standards of radiology training in Europe based on the ESR European Training Curriculum for Radiology (ETC) and provide institutions that offer postgraduate radiology education with an objective assessment of their training programmes by external assessors nominated by the ESR. The main limitation of the programme was the limited availability due to the necessity to displace advisors. This constraint made the program inefficient since it could not reach a large number of institutions. Another limitation was the lack of official certification. The new ETAP 2.0 configuration changes from onsite assessment to virtual assessment. The assessment programme is divided into 4 phases: 1st phase: application and completion of the documents. 2nd phase video report of the facilities of the centre. 3rd phase online interviews in a structured manner with the trainees, tutors and head of the department. 4th phase certification by the accreditation council in Imaging (ACI). There are three levels of certification: basic, intermediate and excellence, based on the score reached by the centre after the evaluation of the three phases. A report with recommendations for improvement is sent to the centre that has to report back within the established time frame as it was done in the prior ETAP programme. It is foreseen a reaccreditation every 5 years.

Learning Objectives:

1. To understand the limits of ETAP 1.0.
2. To learn about the new configuration of ETAP.
3. To learn about the "starring system".

A-187 09:25

CME/CPD in Europe (part 1): EACCME 2.0

P. Ricci; *Rome/IT (paolo.ricci@uniroma1.it)*

The European Accreditation Council for Continuing Medical Education (EACCME) has been created by the European Union of Medical Specialists (UEMS) in 1999 and started operating in January 2000 with the aim of encouraging high standards in development, delivery, and harmonisation of Continuing Medical Education (CME) through the international accreditation of CME events, and the establishment of a system for the international acceptance of CME credits (ECMEC). EACCME can validate and grant the official number of ECMEC after professional evaluation has been performed by a CME National Accreditation Authority or UEMS Specialty Board. To facilitate the transfer of credits and allow the free movement of healthcare professionals within Europe, 1 ECMEC equates to 1 hour of CME, with a maximum of 6 ECMECs for a day and 3 ECMECs for half a day. Beyond European member states, mutual recognition agreements have been signed with the American Medical Association and the Royal College of Physicians and Surgeons of Canada, thus enhancing the international status of EACCME. To comply with the growing scopes of CPD-Continuing Professional Development, broader than CME, EACCME currently recognises the review and publication of scientific and educational material, e-learning by teaching and the participation in UEMS examinations as an examiner. As of January 2017, EACCME 2.0 version has become applicable, resulting in a new interactive platform for providers and users, a faster and more efficient accreditation process and in the recognition of e-learning materials (e-platform, e-library, apps).

Learning Objectives:

1. To learn about the European Accreditation Council for Continuing Medical Education (EACCME®).
2. To know about the existence of European CME and CPD credits.
3. To learn about the new EACCME 2.0.

Author Disclosure:

P. Ricci: Other; ACI, Scientific Director; UEMS Section of Radiology, President; UEMS EEC, Member.

A-188 09:30

CME/CPD in Europe (part 2): the Accreditation Council in Imaging

P. Ricci; *Rome/IT (paolo.ricci@uniroma1.it)*

Educational events sent to UEMS/EACCME for European Accreditation have to be evaluated by two distinct structures: the National Accreditation Authority of the country where the activity is to take place, and the related UEMS Section or European Specialty Accreditation Board (ESAB). Based on the mutual agreement between the Accreditation Authorities, the Sections and ESABs, the process is recognised throughout Europe and the different specialties of the UEMS. Recent steps have been taken by the EACCME in order to harmonise the whole system in Europe independently from the specialty or the country where the activity has taken place. The Section of Radiology keeps the role of back-up reviewer for those countries not yet enlisted in EACCME accreditation agreements. In 2015, the Section started a fruitful cooperation with the Accreditation Council in Imaging (ACI), the body established by the European Board of Radiology - an initiative of the European Society of Radiology - in Barcelona to reach homogenisation of radiology education across Europe. Following an amended agreement in 2016, representatives of the Section hold the chair of Scientific Director on alternate basis and sit permanently in ACI Policy and Reviewing Committees, each guided by a chairperson. The necessary adaptation of ACI Terms & Conditions to the revised criteria for the accreditation of Live Educational Events (LEE) and of E-learning materials (ELM) has been recently conducted November 2016 - January 2017. ACI team is offering constructive feedback on the successful implementation of the EACCME 2.0 online platform.

Learning Objectives:

1. To learn about the ESABs under the EACCME umbrella.

2. To learn about the structure of the Accreditation Council in Imaging (ACI).
3. To understand the importance of cooperation with and recognition by the EACCME®.
Author Disclosure:
P. Ricci: Other; ACI, Scientific Director; UEMS Section of Radiology, President; UEMS EEC, Member.

A-189 09:35

CME/CPD in Europe (part 3): the many ways to gain European CME/CPD credits

M.A. Lucic; *Sremska Kamenica/RS (milos.a.lucic@gmail.com)*

Recognising the tendency of continuing-medical-education (CME) shift from voluntary to mandatory within Europe, the European Union of Medical Specialists (UEMS) and its European Accreditation Council for CME (EACCME®) introduced European Continuing Medical Education Credits® (ECMECs), as CME "tokens" reflecting objectively the CME activity that facilitates the exchange of CME credits between European countries and comparable systems outside Europe. Considering CME as educational activities which serve to maintain, develop or increase the knowledge, skills, professional performance and relationships that physician/radiologist uses to provide services for patients or profession, ECMECs are awarded for both live educational events, and e-learning materials, but from recently also for continuing professional development (CPD), defined as the educative means of updating, developing and enhancing how physicians apply the knowledge, skills and attitudes required in their working lives (Basle Declaration, 2001). As CPD incorporates and goes beyond CME, EACCME 2.0, adopted in 2016, enabled EACCME® recognition of the several CPD/CME activities that include reviewing and/or publishing scientific and educational material, learning by teaching, and examining in UEMS exams, including EDiR exam. Being aware that CME/CPD systems in Europe differ between countries, the Accreditation Council in Imaging (ACI) has recently conducted two surveys, addressed to ESR Institutional Member Societies and individual ESR members, which provided valuable information on differences in accreditation systems in European countries, but also reflected several important standpoints, including the recognition of ECMECs as universal European CME "tokens", and unification of CME/CPD systems within Europe, which shall be acknowledged as the "voice of European radiologists" in future considerations.

Learning Objectives:
1. To know about the existence of European CME Credit (ECMEC®).
2. To learn about the concept of CPD.
3. To learn about the importance of credits in different European countries.

Imaging in abdominal emergencies: an (evidence-based) update

Moderator:
C.E. de Lange; Oslo/NO

A-190 08:30

A. The acute abdomen in neonates

S. Stafrace; *Doha/QA (samstafrace@yahoo.com)*

Common causes of neonatal abdominal emergencies are reviewed focusing on congenital intestinal obstruction, malrotation and necrotising enterocolitis (NEC). Radiologists play a pivotal part in the management of neonates with suspected obstruction and are often asked for an opinion on the presence or not of obstruction, the level of obstruction and the cause. The standard choice of radiological modalities includes plain film, ultrasound (US) and fluoroscopy. Neonatal intestinal obstruction is classified as upper/high versus low obstruction done through presenting symptoms and plain film appearances. High obstruction presents with vomiting or increased aspirates. Main differential diagnoses include congenital obstructions of the duodenum/jejunum and malrotation. High obstruction often leads to surgical exploration with some radiographic patterns being diagnostic enough to recommend surgery including the 'double bubble' and 'triple bubble' signs. Bilious vomiting and/or the start of symptoms in the immediate postnatal period increases the clinical suspicion for malrotation. In such cases an urgent upper GI study is indicated. Operators should be comfortable with the fluoroscopic technique, normal duodenal landmarks and with the less common duodenal anatomical variants. Low obstruction presents with distention, vomiting and failure to pass meconium. Multiple dilated loops are seen on radiography. Differential diagnoses include Hirschsprung disease (HD), small left colon, meconium ileus and atresias. Outside HD (when rectal biopsy is diagnostic), suspected low obstruction warrants a contrast enema; providing high diagnostic specificity. NEC is the leading gastrointestinal emergency of the premature neonate. Imaging mainly involves plain films and ultrasound; guided by the clinical course of the neonate.

Learning Objectives:
1. To learn about typical neonatal abdominal emergencies.
2. To understand the choice of modalities in acute abdomen in neonates.
3. To appreciate typical findings and 'red flag' features.

A-191 09:00

B. The acute abdomen in young children

A.D. Calder; *London/UK (Alistair.Calder@gosh.nhs.uk)*

Common causes of the acute abdomen in children beyond the neonatal period are reviewed, with a focus on three conditions with major roles for imaging: hypertrophic pyloric stenosis, intussusception, and acute appendicitis. The evidence base underlying the roles imaging plays is evaluated for each condition.
The role of ultrasound in pyloric stenosis is well established and is generally highly sensitive and specific. Pyloric length and muscle thickness parameters remain robust measures for correct diagnosis, but may need to be adjusted for age and size. Additional signs which may be useful, such as pyloric shape and colour doppler findings are discussed. Surgical management remains the mainstay of treatment, despite evidence of effectiveness of medical therapy in some children. The role of ultrasound in the diagnosis of intussusception is similarly well supported and is highly accurate even in relatively inexperienced hands. Radiologists also typically play the leading role in initial attempts to reduce intussusception, and are mostly successful. Various techniques for reduction are available, each with their own advocates and evidence base. Acute appendicitis is the most common abdominal emergency requiring surgery. Pre-operative imaging diagnosis is now the norm. Ultrasound is recommended as the primary imaging tool in children, but can lack sensitivity and in most centres, equivocal sonography is followed by cross sectional imaging. CT has a strong evidence base for accurate diagnosis of appendicitis, but confers significant radiation burden. Low dose protocol CT and MRI offer alternatives with potentially similar levels of accuracy. Differential diagnoses for appendicitis including adnexal torsion and mesenteric adenitis are briefly explored.

Learning Objectives:
1. To learn about the causes of acute abdominal pain in children.
2. To understand the choice of imaging techniques and their limitations.
3. To appreciate typical radiological features of abdominal emergencies.

A-192 09:30

C. Polytrauma: differences between adult and paediatric protocols

M. Raissaki; *Iraklion/GR*

Trauma is still the most frequent cause of mortality and disability in childhood and adolescence. Emergency physicians have to thoroughly assess injured children following high-energy trauma. Traumatized children differ from adults: haemodynamically stable children may be actively bleeding. Conversely, children have smaller caliber vessels, stronger vasoconstriction, stronger solid organ capsules; bleedings may stop spontaneously, organ rupture is more difficult and delayed rupture rare. This is why children are imaged aggressively although few will undergo surgery or trans-arterial embolisation. Imaging is mandatory for diagnosis and management especially during the primary survey. Its goal is to exclude life-threatening injuries, identify children that may rapidly deteriorate because of clinically silent active bleeding, increase the surgeon's confidence level by clarifying injuries that need to be treated and ultimately determine short and long-term management. Radiographs and ultrasonography play a basic role in haemodynamically unstable patients. Contrast-enhanced ultrasound is an emerging diagnostic tool in low-energy trauma and in suspected isolated abdominal injuries. In stabilized patients CT scanning has been considered a sensitive, specific, and accurate test for identification and grading of multi-organ injuries. Due to children' increased radiosensitivity, CT scans should be indicated based on appropriate early clinical evaluation of the closely monitored child and assessment of risk factors for CNS, chest, MSK and abdominal injuries. ALARA includes avoiding non-contrast scans, avoiding multiple phases and applying age/weight-dependent

exposure parameters and radiation-saving reconstruction algorithms. CT should not be performed for follow-up unless there is clinical deterioration. Objective documentation of injuries is extremely important in suspected child abuse.

Learning Objectives:

1. To learn how paediatric trauma differs from adult trauma.
2. To understand how examination techniques and protocols must be tailored accordingly.
3. To appreciate the importance of multidisciplinary team collaboration in planning and conducting radiological investigations in a trauma setting.

08:30 - 10:00 **Room N**

Cardiac

RC 503

From diagnosis to prognosis: how does cardiac imaging affect patient outcome?

Moderator:
U. Reiter; Graz/AT

A-193 08:30

A. In myocarditis
M. Francone; *Rome/IT (marco.francone@uniroma1.it)*

Natural history of acute and chronic myocarditis is often unpredictable being independent on the clinical onset of disease and even poorly correlated with more traditional clinical predictors like end-distolic volume or ejection fraction. In most cases, patients typically improve within weeks to months, but an unfavourable clinical evolution may be observed in a minority of individuals consisting with the development of chronic ventricular dysfunction progressing leading to transplantation or death in 25% of cases. CMR has emerged as a central prognostic indicator in inflammatory cardiomyopathies, mainly because of its ability to detect tissue fibrosis in vivo. This has been demonstrated with a growing and consistent scientific evidence, derived from late enhancement imaging and more recently from native T1 mapping and ECV. Present lecture will aim to illustrate of CMR capabilities as prognostic indicator in acute and chronic myocarditis, providing an overview of most important published studies and ongoing clinical trials. Particular emphasis will given to the importance of T1 and T2 mapping techniques, being a new standard of reference for CMR diagnosis and patient's prognostic stratification.

Learning Objectives:

1. To learn about the link between clinical presentation and imaging signs.
2. To understand the current state-of-the-art MRI method for the diagnosis of myocarditis.
3. To learn how MRI could be used to assess prognosis in myocarditis.

A-194 09:00

B. In non-ischaemic cardiomyopathy
A. Jacquier; *Marseille/FR (alexis.jacquier@ap-hm.fr)*

Non-ischaemic cardiomyopathy is one of the major indications of cardiac MR worldwide. MRI is now included in all European guidelines for diagnosis and prognosis assessment in cardiomyopathy. During that talk we will focus on dilated cardiomyopathy, hypertrophic cardiomyopathy and arrythmogenic right ventricular dysplasia. MRI is a potent tool to assess phenotype of the myocardium and characterise tissue in both patients and proband. New sequences or post treatment tools could be helpful to better characterise myocardial tissue such as parametric maps and feature tracking.

Learning Objectives:

1. To recognise the tell-tale signs of early ARVC, HCM and dilated cardiomyopathy that affect progression or prognosis.
2. To understand what should be measured and reported.
3. To appreciate the role of MRI in early diagnosis and prognosis assessment in these cardiomyopathies.

Author Disclosure:
A. Jacquier: Research/Grant Support; Guerbet.

A-195 09:30

C. In coronary artery disease
R. Salgado; *Antwerp/BE (rodrigo.salgado@uza.be)*

Non-invasive imaging of the coronary arteries using CT has in the past decade reached worldwide clinical implementation. This is the consequence of both technical advances of CT imaging, as well as the validation of this technique in multiple clinical trials and randomised studies. One of the main strengths of non-invasive coronary artery imaging is the ability to exclude obstructive disease, as such eliminating the need for further invasive examinations. Furthermore, the quantification of coronary calcium provides a quantitative measure of the degree of arteriosclerosis, further helping in the risk stratification of patients. During this lecture, we will review the scientific evidence regarding the use CT-angiography of the coronary arteries in different populations, their impact on actual clinical management and their significance for mid- and long-term prognosis. Additionally, new technologies aimed at improving triage for further testing in patients with intermediate stenosis (including CT-derived fractional flow reserve) and their potential role will be discussed. Finally, a structured reporting scheme will be provided to streamline the communication of findings to referring physicians.

Learning Objectives:

1. To understand which patients will benefit from anatomic assessment or functional assessment of the coronary arteries.
2. To learn about how to report on anatomic and functional assessment of coronary arteries.
3. To appreciate the role of non-invasive imaging in prognosis assessment.

08:30 - 10:00 **Studio 2018**

State of the Art Symposium

SA 5a

Whole-body MRI: ready for prime time?

A-196 08:30

Chairperson's introduction
F.E. Lecouvet; *Brussels/BE (frederic.lecouvet@uclouvain.be)*

WB-MRI is now a commonly applied modality for bone screening for "osteophilic" metastatic cancers, lymphomas, and multiple myeloma and can also assess visceral and nodal involvement. WB-MRI's applications have been expanded to other fields, mainly in rheumatology; it has shown promise for diagnosis and evaluation of treatment response of spondyloarthropathies, and many muscle, bone, neurological, and vascular disorders. The diversity of indications is reflected by the segmentation of this session: the different medical fields where WB-MRI contributes to improvement in patient care will be addressed by expert speakers from varied geographical origins who will share their respective experience. They will Illustrate imaging findings, provide technical recommendations, and describe the place oft he technique amongst others in modern management of diseases.

Session Objectives:

1. To become aware of the feasibility of whole-body MRI.
2. To learn about its roles: detect, monitor and provide prognostic information.
3. To understand the anatomic targets: bone and beyond.
4. To become familiar with current developments in the technique and their implementation.

A-197 08:35

The case of metastatic bone disease
A.R. Padhani; *London/UK (anwar.padhani@talk21.com)*

WB-MRI will replace current, ineffective & indirect methods of malignant disease detection in the bone marrow with applications in myeloma, breast, and prostate cancer. Multiple imaging standards are published including the MET-RADS system which will be summarised. WB-MRI has the potential to alter diagnostic thinking when assessing bone response: by adding new categories that positively assess the success of therapies in bone disease (NOT just absence of progression). It is unclear whether this will allow patients to live better for longer?. WB-MRI can help deliver the promise of high precision medicine for patients with metastatic bone disease.

Learning Objectives:

1. To understand the clinical rationale for the use of whole-body MRI when evaluating metastatic disease.
2. To learn about the use of METRADS data acquisition and response assessment guidelines.
3. To become aware of the potential benefits of whole-body tumour load quantification.
4. To review examples of clinical pathway benefits, including precision medicine approaches.

Author Disclosure:
A.R. Padhani: Speaker; Siemens Healthineers, Janssen, Sanofi.

A-198 08:55

The case of multiple myeloma

L.-A. Moulopoulos; *Athens/GR (lmoulop@med.uoa.gr)*

WBMRI is more sensitive than WBXR and WBCT for the early detection of bone marrow involvement in multiple myeloma and it performs better than PET-CT in the diagnosis of small lesions or diffuse bone marrow infiltration. In the updated (2014) international myeloma working group (IMWG) criteria for the definition of myeloma, MRI is considered a biomarker of malignancy, with the presence of more than one focal lesion on MRI establishing the diagnosis of symptomatic disease. When MRI of the spine and pelvis is performed, an approximately 10% false negative rate may be observed because of focal lesions located exclusively in the appendicular skeleton. WBMRI, on the other hand, provides a means of bone marrow tumour burden assessment and at the same time identifies possible extraskeletal locations of myeloma. Bone marrow patterns of involvement and tumour burden on WBMRI have also emerged as important tools for prognosis. Regarding assessment of response to therapy, even though PET-CT is currently the preferred modality for optimal definition of a complete response to treatment in patients with myeloma, ADC values extracted from DWI images, have been shown to change early after treatment, suggesting a possible role for WBDWI in the evaluation and prediction of successful therapy. In the era of novel therapies for multiple myeloma, the role of a non-ionizing imaging modality like WBMRI for the search of minimal residual disease in the bone marrow and extraskeletal sites of disease at the same time, is appealing and warrants further investigation.

Learning Objectives:

1. To become aware of the value of whole-body MRI in myeloma.
2. To learn about its roles: detect, monitor and provide prognostic information.
3. To understand current imaging protocols.

A-199 09:10

The case of lymphoma

M.E. Mayerhöfer; *Vienna/AT (marius.mayerhoefer@meduniwien.ac.at)*

Lymphomas are a heterogeneous group of hematological malignancies that can be roughly divided into Hodgkin (HL) and non-Hodgkin (NHL) lymphomas, and account for about 5% of all cases of cancer. The NHL group is characterized by a high level of heterogeneity between the different subtypes, not only with regard to their histological features, but also with regard to growth rates and clinical course/prognosis, as well as treatment options. Nevertheless, the majority of lymphomas show a high cell density, which makes them an attractive target for diffusion-weighted imaging (DWI), because of the associated compression of extracellular space. Even though [18F]FDG-PET/CT is generally regarded as the technique of choice for imaging of lymphomas (and in particular, for assessment of treatment response), there are several justifications for the use of whole-body DWI in lymphoma patients. For instance, the fact that some lymphoma subtypes (such as HL) are common in children and adolescents makes DWI attractive due to its lack of exposure to ionizing radiation, which is relevant because these patients may require life-long follow-up. In addition, slowly growing NHL subtypes such MALT lymphoma frequently show low, or no, FDG uptake, whereas they still show the diffusion restriction pattern on DWI, due to their high cell density. Finally, access to MRI, and thus, also to DWI, is far easier than to [18F]FDG-PET/CT due to the relative abundance of MR scanners, which may decrease waiting intervals and lead to earlier treatment initiation. Nevertheless, while several studies have shown that whole-body DWI is only slightly to moderately inferior to [18F]FDG-PET/CT, DWI is still limited with regard to the evaluation of small lymph nodes, the assessment of diffuse bone marrow involvement, and, mainly due to motion artifacts, for lesion assessment in the lower neck and the mediastinum.

Learning Objectives:

1. To become aware of the role of whole-body MRI for imaging lymphoma subtypes.
2. To learn about its roles: detect, monitor and provide prognostic information.
3. To understand the current limitations of whole-body DWI.

A-200 09:25

Beyond oncology: rheumatology and more

S. Weckbach; *Heidelberg/DE (sabine.weckbach@med.uni-heidelberg.de)*

The high soft tissue contrast and anatomical resolution of whole body MI (WBMRI) in combination with an excellent sensitivity and specificity for the musculoskeletal system offer many advantages in the diagnostic process of rheumatological and neuromuscular disorders. Disease specific adaption of different protocol modules allow the replacement of multiple separate exams by one whole-body MRI (WB-MRI) examination so that WB-MRI is capable of a combined visualisation of the spine and all relevant joints, the vessel system and potentially affected organs such as the brain, the kidneys or the heart in only one exam. It is able to directly and simultaneously show (even subtle) active and chronic inflammation including synovial, cartilaginous and bony changes. It is very well suited for the visualisation of enthesitis and arthritis in central and peripheral joints at one examination. Moreover, WB-MRI allows the early detection of bone marrow changes and muscle pathologies. Therefore, it holds the potential to estimate the total disease load and disease activity of different rheumatological and neuromuscular disorders as well as follow-up patients under therapy. Due to the exact localization of inflammatory processes present at multiple sites and visualisation of typical disease pattern, it enables us to distinguish between a variety of rheumatological and neuromuscular disorders.

Learning Objectives:

1. To become aware of the protocols and diagnostic value of whole-body MRI in rheumatological and neuromuscular disorders.
2. To understand the role of whole-body MRI screening for multi-site inflammation in one single examination.
3. To learn about its role in differential diagnosis quantification of disease burden and assessment of therapeutic response.

09:45

Panel discussion: Whole-body MRI: when, how and why should you do it?

08:30 - 10:00 **Room L 8**

A-201 08:30

Imaging prostate cancer: MRI or PSMA-PET/CT?

L. Schimmöller; *Düsseldorf/DE (lars.schimmoeller@med.uni-duesseldorf.de)*

The multiparametric magnetic resonance imaging (mp-MRI) of the prostate and also imaging with prostate-specific membrane antigen (PSMA-PET) are innovative methods that significantly improved the diagnostic of prostate cancer. A remarkable change in clinical routine has been the increasing role of MRI in prostate cancer detection. Mp-MRI examinations (with T2, DWI, and DCE-Images) are already part of international guidelines in secondary diagnostics (after previous negative systematic TRUS-GB) and also in active surveillance. But in primary diagnostic, staging, and recurrence MRI have got a qualification and validly, too. In its updated guidelines 2017 the German Society of Radiology notably insists on the importance of mp-MRI and MRI-guided biopsy for prostate cancer diagnosis. The main significance of the MRI is the detection of clinical relevant prostate cancers with its additional functional sequences, but nationwide coverage of qualitative mp-MRI examinations and qualitative standardized reporting are two of the most important challenges. PSMA-PET is the most promising imaging tool primary for prostate cancer recurrence and may be currently used for detection in unclear cases with high suspicion of prostate cancer, but especially costs and availability are liming this promising diagnostic tool. PSMA-PET shows good results already in patients with low PSA-values regardless of previous applied therapy. As a consequence logically a combination of PSMA-PET and MRI might be very nice, but PSMA-PET/MRI is rarely available and its clinical benefit remains to be demonstrated. Furthermore, with MRI and PSMA a lot of new individual therapeutic opportunities are given.

Learning Objectives:

1. To learn about indications of MRI and PSMA-PET in prostate cancer.
2. To appreciate differences in indications for initial diagnosis and PSA-recurrence.

A-202 09:00

Differentiating radiation necrosis from tumour recurrence: do we need hybrid imaging?

E.-M.B. Larsson; *Uppsala/SE (elna-marie.larsson@radiol.uu.se)*

Magnetic resonance imaging (MRI) without and with intravenous contrast agent injection is the primary imaging method for the evaluation of treatment effects on brain tumours, such as gliomas and metastases. However, the method has difficulties to differentiate tumour progression from reactive, treatment-related changes after surgery, radiotherapy, chemotherapy or immunotherapy. The additional use of positron emission tomography (PET), MR perfusion or proton MR spectroscopy (MRS) may improve the diagnostic specificity. 18F-FDG-PET is widely used for body imaging, but suboptimal for this purpose due to the high glucose uptake in normal brain tissue. Radiolabelled amino acid tracers, such as 11C-MET with short half-life or 18F-FET with longer half-life, show a high tumour-to-background contrast. Amino

acids accumulate in recurrent tumour, but not in reactive or reparative processes after treatment. MR perfusion with evaluation of relative cerebral blood volume (rCBV) is also helpful, since high rCBV usually indicates tumour recurrence. MRS shows the relative concentrations of different metabolites and increase of choline (Cho) supports the suspicion of recurrent malignant tumour with cell proliferation. However, the areas of increased PET uptake and increased rCBV and/or high Cho do not always coincide, which makes the interpretation difficult. In addition, a combination of recurrent tumour and reactive changes is often present. Since each of the PET and MR techniques mentioned above has limitations, hybrid PET/MR combining the information from uptake of radiolabelled amino acids, measurement of rCBV and also of Cho, may provide improved diagnostic accuracy.

Learning Objectives:

1. To learn about different radiopharmaceuticals available for differentiation of tumour from radiation necrosis.
2. To understand typical hybrid imaging findings in radiation necrosis and tumour recurrence.

Author Disclosure:

E.-M.B. Larsson: Research/Grant Support; Bayer Pharma AG, Berlin, Germany. Speaker; Bayer Pharma AG, Berlin, Germany.

A-203 09:30

What can we expect as future targets for new radiopharmaceuticals?

G. Cook; *London/UK*

There are now few hallmarks of cancer that we cannot exploit with imaging. In particular, there are several PET and SPECT probes that can measure abnormal metabolic processes (e.g., 18F-FDG, 99mTc-sestamibi), proliferation (e.g., 18F-FLT, 18F/11C-choline), receptor overexpression (e.g., 68Ga-dotatate, 68Ga-PSMA, apoptosis (e.g., 18F-ML10), hypoxia (e.g., 18F-MISO, 64/62Cu-ATSM) and angiogenesis (e.g., 89Zr-bevacizumab, 18F-RGD) amongst others. Whilst some of these tracers are useful for diagnosis and phenotyping, many are of interest for predicting early treatment response, especially in the setting of targeted biologic therapies where an early reduction in tumour volume is not expected and where morphologic CT and MRI are therefore limited. Of particular current interest is the evaluation of response to immunotherapies that may cause pseudoprogression, caused by immunocellular infiltration before subsequent tumour shrinkage. In this situation early pseudoprogression may also be seen with 18F-FDG PET and hence the interest in more specific tracers such as 89Zr-PDL1 antibody. Whilst PET and SPECT probes are invaluable in reporting on underlying biological tumour characteristics, both CT and MRI provide valuable supportive information in hybrid imaging scanners allowing anatomical reference as well as some functional measurements, e.g., cellularity with DWI and perfusion with DCE MRI / pCT. The ultimate goal of predicting which patients will respond to which treatment, or at least to determine non-response as soon as possible, is not fully achieved in the clinic with imaging as yet but some areas are now contributing to clinical practice, e.g., 18F-FDG PET/CT to guide treatment escalation / de-escalation in lymphoma.

Learning Objectives:

1. To become familiar with future targets in oncological hybrid imaging.
2. To learn how hybrid imaging can support the oncologist in diagnosis and therapy response assessment.

Author Disclosure:

G. Cook: Research/Grant Support; Siemens, GEHC, Alliance Medical, Theragnostics.

08:30 - 10:00 **Room E1**

Pros & Cons Session

PS 527

Do we need dynamic contrast enhancement (DCE) in prostate mpMRI?

A-204/A-205 08:30

Chairpersons' introduction

H.-P. Schlemmer[1], J.J. Fütterer[2]; *[1]Heidelberg/DE, [2]Nijmegen/NL (h.schlemmer@dkfz.de)[1] (jurgen.futterer@radboudumc.nl)[2]*

Multiparametric MR imaging (mpMRI) is increasingly important for individualized decision making in prostate cancer patients. A large number of clinical studies have demonstrated that the combination of morphologic and functional MR parameters are advantageous for detection and localization of significant cancer, for biopsy guidance, for local staging and for active surveillance. Various MR-guided or TRUS/MR image fusion biopsy technologies are already used in clinical practice for transrectal or a transperineal targeted +/- systematic biopsy. High-quality mpMRI including standardized image acquisition and image interpretation is crucial and recommendations according to PI-RADS are meanwhile widely accepted. But there is still controversial discussion about the optimal state-of-the-art mpMRI protocol. While meanwhile several studies have shown compelling evidence that diffusion-weighted MRI (DWI) is fundamental for prostate cancer detection and characterization, the clinical value of dynamic contrast-enhanced MRI (DCE) is still under debate. Different views were brought forward weighting increased examination time and costs against the clinical benefit. This session will point out the controversial discussion to balance pros and cons.

Session Objectives:

1. To understand the clinical significance of mpMRI for detection and local-regional staging of prostate cancer.
2. To learn about the potential and limits of DCE MRI.
3. To understand the controversial discussion about the added value of DCE as part of mpMRI in clinical routine.

A-206 08:35

A. Yes we do!

G.M. Villeirs; *Ghent/BE*

Like many other cancers, prostate cancers can release angiogenic factors that cause growth of existing blood vessels and de novo angiogenesis. As these new vessels are loosely organized, with varying sizes, leaky endothelium and arteriovenous shunts, their permeability is higher than in normal vessels. Dynamic contrast-enhanced (DCE) MRI exploits this difference using a series of rapid T1-gradient-echo sequences (every ≤10 seconds over ≥2 minutes) after a 2-3cc/sec bolus administration of 0.1 mmol/kg of gadolinium contrast agent. Tumor foci show earlier, faster and more intense enhancement due to increased influx of contrast in an expanded vascular space and increased extravasation to the extravascular space, followed by marked washout due to increased backflow to the vascular compartment. These temporal tissue enhancement changes can be evaluated qualitatively (visual analysis of enhancing areas), semi-quantitatively (evaluation of enhancement curve types), or quantitatively. The latter is based on pharmacokinetic modelling techniques that calculate parameters such as Ktrans (leakage to the extravascular space), kep backflow to the blood vessels, and ve (size of the extracellular extravascular space). DCE can be used to detect prostate cancer in the peripheral zone (less in the transition zone due to false positive enhancement in benign prostatic hyperplasia), especially in case of doubt on DWI or poor DWI quality in multiparametric MRI. It also improves the staging accuracy, especially in less-experienced users. Most importantly, it is the best technique to assess the location and extent of recurrent disease, both after radical prostatectomy, external beam radiotherapy or focal therapy.

Learning Objectives:

1. To understand how DCE enables improved cancer detection by revealing microvasculature and perfusion.
2. To become familiar with quantitative analysis of signal intensity-time curves after intravenous contrast agent administration in order to reveal cancer specific perfusion-related parameters.
3. To appreciate the diagnostic potential of DCE to detect significant prostate cancer.

A-207 09:00

B. No we don't!

H. Hricak; *New York, NY/US*

T1-weighted imaging (T1WI) and T2-weighted imaging (T2WI), joined recently by DWI, have become the mainstay of prostate evaluation by mpMRI. The question is whether, in our clinical protocols, we also need to include dynamic contrast-enhanced MRI (DCE-MRI) and/or proton MR spectroscopic imaging (MRSI). DCE-MRI improves assessment of tumor aggressiveness, but its value in tumor detection remains controversial. Based on studies from the last 5 years, in the setting of cancer detection, the combination of DCE-MRI+T2WI has similar or lower accuracy and is significantly less specific than the combination of DWI+T2WI; adding DCE-MRI to DWI+T2WI significantly increased sensitivity, but it also significantly lowered specificity. A recent study of 542 men with elevated PSA levels found that for tumor detection, T2WI+DWI had accuracy comparable to that of T2WI+DWI+DCE-MRI, with diagnosis of clinically significant cancer being the endpoint. Overall, the literature suggests DCE-MRI adds limited or no value in most scenarios. While MRSI can improve tumor characterization, its routine application is not recommended because of long scan times, operator dependence and limited spatial resolution. Therefore, if we are to advocate the inclusion of mpMRI in a prostate cancer screening algorithm, we should recommend a streamlined protocol of T1W+T2WI+DWI, as it provides higher accuracy, reduced scan times, greater patient comfort and safety, and is less costly than protocols also incorporating DCE-MRI or MRSI. However, use of DCE-MRI should be recommended in

searching for recurrence after treatment, in situations where artifacts degrade the quality of DWI, or in patients on experimental medical therapy protocols.
Learning Objectives:
1. To become familiar with the diagnostic potential of mpMRI including T2w, advanced DWI and MRSI.
2. To understand the diagnostic potential non-contrast-enhanced mpMRI to detect significant prostate cancer.
3. To appreciate the benefits of a shortened mpMRI protocol by omitting DCE.

State of the Art Symposium

SA 5b
Current guidelines and diagnostic criteria in multiple sclerosis (MS)

A-208 08:30
Chairperson's introduction
A. Rovira-Cañellas; *Barcelona/ES (alex.rovira@idi.gencat.cat)*

In the last few years, techniques and clinical implementation of MR imaging of multiple sclerosis (MS) have markedly evolved based on the relative large amount of new published data from clinical trials and observational studies, which assessed the value of this tool in the early and accurate diagnosis of MS. However, the role of MR imaging in MS goes far beyond the diagnostic process and differential diagnosis. MR imaging can also provide useful prognostic information in terms of long term disability prediction. Moreover, with the introduction of the new generation of immunomodulating /immunosuppressive drugs for the treatment of MS, MR imaging also plays an important role in treatment monitoring. This includes the prediction of treatment response, the assessment of treatment efficacy and treatment safety. In this state of the art symposium, the speakers will present up to date on the diagnostic criteria of MS, and on the value of MR imaging for monitoring and predicting treatment response and in the detection of treatment related adverse effects. All these information should help radiologists in the standardization and optimization of the use of MR imaging in the management of MS in clinical practice.
Session Objectives:
1. To appreciate the importance of an accurate diagnosis of MS.
2. To learn about the value of diagnostic criteria for MS.
3. To understand the relevance of MRI for monitoring and predicting treatment response.
4. To become familiar with treatment-related adverse effects.

A. Rovira-Cañellas: Advisory Board; Novartis, Biogen, Sanofy-Genzyme. Speaker; Novartis, Stendhal America, Biogen, Bracco, Bayer, Sanofy-Genzyme, TEVA.

A-209 08:40
Update on new clinical diagnostic criteria
C. Enzinger; *Graz/AT (chris.enzinger@medunigraz.at)*

In the diagnostic process applied to people suspected to have multiple sclerosis (MS), MRI of the brain and spinal cord has become an indispensable tool to objectively demonstrate lesions disseminated in time and space, which are considered as a hallmark of the disease. MRI has been formally integrated in the diagnostic criteria first in 2001 by an international panel and - based on accumulating scientific evidence - revisions of these criteria have been provided in 2005, 2010 and, most recently, in 2017. The presentation will briefly review the scientific data underlying the evolution of the current diagnostic criteria, highlight the chances (e.g., rapid diagnosis) and implications (e.g., establishing early therapy) linked with their use, and raise awareness of the challenges (overdiagnosis) and pitfalls (misdiagnosis) potentially associated with the application of the new diagnostic criteria.
Learning Objectives:
1. To understand the scientific data underlying the evolution of the current diagnostic criteria.
2. To recognise chances and implications linked with the use of the new diagnostic criteria.
3. To become aware of the challenges implicated with the application of the new diagnostic criteria.
Author Disclosure:

Consultant; Bayer Schering, Biogen, Merck Serono, Novartis, Roche and Teva Pharmaceutical Industries Ltd./sanofi- aventis. Research/Grant Support; Unrestricted research support from Merck Serono, Biogen, and Teva Pharmaceutical Industries Ltd./sanofi-aventis. Speaker; Funding for travel and speaker honoraria from Biogen, Bayer Schering, Merck Serono, Novartis, Shire, Genzyme and Teva Pharmaceutical Industries Ltd./sanofi-aventis.

A-210 09:00
MRI for MS monitoring: the use of guidelines in clinical practice
M.P. Wattjes; *Hannover/DE (m.wattjes@vumc.nl)*

Magnetic resonance imaging (MRI) plays an important role in the diagnosis of multiple sclerosis and has been incorporated into the McDonald diagnostic criteria for MS. The role of MRI in MS disease monitoring, particularly for MS treatment monitoring purposes, has been less clear defined. The need for standardization in terms of MR acquisition, scan intervals and image interpretation in MS pharmacovigilance is further stressed by the increasing numbers of MS therapeutics in the postmarketing setting. Therefore, MRI in MS pharmacovigilance is becoming increasingly important. The main goals of the use of MRI for this purpose are treatment efficacy monitoring, prediction of treatment response, and safety monitoring. Recent guidelines provided by the MAGNIMS collaboration (www.magnims.eu) and the consortium of MS centers (CMSC) provide some guidance how to implement MRI in the setting of MS pharmacovigilance. The standardized implementation of these guidelines in clinical practice will be of great help for (neuro)radiologists, neurologists, and patients.
Learning Objectives:
1. To understand the importance of standardisation in terms of image acquisition and scan intervals in MS monitoring.
2. To learn about the most relevant and possible future MRI outcome measures for MS treatment monitoring purposes.
3. To appreciate the potential role of MRI in predicting MS treatment response.
Author Disclosure:
M.P. Wattjes: Board Member; European Radiology, Neuroradiology, Journal of Neuroimaging, Frontiers in Neurology. Consultant; Biogen, IXICO, Roche. Speaker; Biogen, Sanofi-Genzyme, Novartis, Roche, Springer.

A-211 09:20
MRI in monitoring treatment complications
J. Hodel; *Créteil/FR (jerome.hodel@gmail.com)*

Several immunosuppressive therapies are available in MS patients with a risk of progressive multifocal leukoencephalopathy (PML). MRI is crucial for the follow-up of treated patients because recognition of PML before the onset of clinical symptoms has important implications for patient care. The diagnosis of presymptomatic PML remains highly challenging due to the coexistence of MS lesions and the various imaging patterns observed at the early stages of disease. Recognition of the most predictive imaging features and comparison with previous MRI data may facilitate the detection of presymptomatic PML. Hyperintensity on diffusion-weighted images, punctate lesions and involvement of U fibers are highly predictive features. Brain magnetic susceptibility changes may be explained by the increased iron deposition and could also constitute a useful tool for the diagnosis of PML. Such imaging findings may be the first imaging feature of PML at the presymptomatic stage. A dedicated MRI protocol including optimized diffusion and high-resolution MR sequences may potentially improve the sensitivity of MRI for the diagnosis of presymptomatic PML.
Learning Objectives:
1. To learn about the most important treatment-related adverse events and their incidence.
2. To learn about the imaging pattern of these adverse events.
3. To become familiar with the algorithms used to monitor these side events and the central role of imaging in them.

09:40
Panel discussion: Do we need MRI to monitor and predict treatment response in MS?

08:30 - 10:00 **Room F1**

E³ - Rising Stars Programme: Basic Sessions

BS 5

Musculoskeletal: bones and soft tissues

Moderator:
D.P. Patkar; Mumbai/IN

A-212 08:30

Bone marrow diseases
K. Verstraete; *Ghent/BE (koenraad.verstraete@ugent.be)*

Bone marrow consists of trabecular bone, a stroma of connective tissue, haematopoietic cells (red marrow) and fat (yellow marrow). Distribution of red and yellow marrow is age dependent, with gradual conversion of red to yellow marrow in the limbs during childhood, and patchy heterogeneity in the spine in the elderly patient. There are many causes of reconversion from yellow to red bone marrow, like smoking, long distance running, obesity, anemia, erythropoietin, etc. Depletion may occur in aplastic anaemia and after radiation therapy. Gelatinous transformation is seen in anorexia nervosa, cachexia, and HIV. Bone infarction and avascular necrosis are well delineated areas of dead bone marrow. The value of different imaging techniques, including plain radiography, dual-energy CT, bone scintigraphy, PET and the most sensitive technique, MRI (conventional T1, T2, fat suppression techniques, in-phase, out-phase and diffusion imaging), will be explained. The imaging characteristics of many diseases will be reviewed (diffuse bone marrow replacement in hematologic diseases, multiple myeloma, metastases; treatment related changes of bone marrow, primary bone tumours, and multiple causes of bone marrow oedema, like bone contusion, stress fracture, insufficiency fracture, Modic changes, spondylodiscitis, osteomyelitis, abscess, arthritis and specific bone tumours).
Learning Objectives:
1. To describe the typical features of normal bone marrow.
2. To determine origin of bone marrow changes.
3. To present the imaging characteristics of a bone marrow disease of the different types.

A-213 09:00

Soft tissue tumours
V.N. Cassar-Pullicino; *Oswestry/UK (Victor.Pullicino@rjah.nhs.uk)*

All imaging modalities can play a role in the diagnosis and management of soft tissue tumours and pseudotumours with a variable contributory performance to both sensitivity and specificity. MRI steals the show with an unparalleled role in soft tissue assessment ranging from detection, localisation, characterisation, identifying multiple lesions, other syndrome stigmata, probability of benignity/malignancy, local staging and recurrence identification. Sonography does have a supporting role especially in initial assessment of the likelihood of cystic/benign/abnormal malignant Colour Doppler flow patterns. This presentation aims to provide a distillation of the knowledge regarding soft tissue tumour imaging which can be applied in practice using a stepwise analytical approach. Despite an overwhelming spectrum of potential histological diagnosis, the radiologist needs to remember that eight benign and six malignant lesions account for 80% of all soft tissue tumours.
Learning Objectives:
1. To determine the origin of a soft tissue tumour (e.g. fat, neural, vascular, etc.).
2. To present current imaging techniques for evaluation of soft tissue tumours.
3. To discuss the imaging findings which are important for the diagnosis of soft tissue tumours.

A-214 09:30

Bone tumours
J.L. Bloem; *Leiden/NL (j.l.bloem@lumc.nl)*

Bone sarcomas are rare (0.2% of all neoplasms, annual incidence in Europe is 0.8 per 100.000 population), in contrast to benign bone tumors and the so-called tumor-like lesions. The incidence of these benign entities is relatively high, but not known exactly as these are often asymptomatic. The WHO (version 2013) classified benign and malignant bone tumors in 13 main categories; chondrogenic, osteogenic, fibrogenic, fibrohistiocytic, hematopoietic, osteoclastic giant cell rich, notochordal, vascular, myogenic, lipogenic, undefined neoplastic nature, and miscellaneous tumors. Each category is further subdivided into 1-14 tumor types. Imaging plays an important role in diagnosis, monitoring therapy, staging, and detecting recurrent disease. Diagnosis is mainly based on conventional radiography using morphologic appearance in combination with location, and age. Advanced imaging techniques are used for local staging (MR), detection of metastases (chest CT), monitoring therapy (MR, ultra-sound, PET-CT), detecting recurrence (MR, ultra-sound, PET-CT). Typical imaging features based on the WHO classification system will be presented with focus on conventional radiography, common tumors, and relevance.
Learning Objectives:
1. To review the classification of bone tumours.
2. To present current imaging techniques for evaluation of bone tumours.
3. To describe the typical features of common bone tumours.

08:30 - 10:00 **Room F2**

Oncologic Imaging

RC 516

Functional imaging in oncology beyond morphology: where are we now?

A-215 08:30

Chairperson's introduction: What are the problems of morphologic evaluation
C.D. Becker; *Geneva/CH*

Morphologic criteria such as size, number or attenuation of solid tumour lesions may be used to assess partial or complete treatment response in certain clinical situations. However, certain tumours in certain organs cannot be reliably assessed without additional biomarkers such as perfusion or diffusion or metabolic activity that can be provided by CT, MRI or PET. This is especially true in the case of immunotherapy or in situ tumour ablation by radio- frequency or chemo-embolisation, where inactivated tumour tissue may remain in place. The most recent advances in the field of functional imaging biomarkers (also called "radiomics") include imathematical analysis of image data (texture analysis) and other quantitative parameters that may correspond with histopathologic and even genotypic features. The goal is to develop image-based predictive models for tumour treatment in specific neoplasms. This course will discuss the most important imaging biomarkers beyond morphology.
Session Objectives:
1. To briefly address the limitations of mere morphological imaging modalities.
2. To introduce the basics of the concept of functional imaging in oncology.
3. To learn about current status of these techniques in daily clinical practice.

A-216 08:35

A. Functional MRI techniques
V.J. Goh; *London/UK (vicky.goh@kcl.ac.uk)*

It is recognised that cancer is a biologically heterogeneous disease. Thus, a 'one size fits all' management approach may not bring about the best outcome for the individual patient. Oncologic therapies have evolved substantially over the last two decades providing cancer patients with a greater opportunity for a cure. This personalised approach has also required a paradigm shift in oncologic imaging to capture this biological heterogeneity and improve patient triage. MRI provides a unique opportunity to combine high contrast and spatial resolution imaging of tumour morphology with physiological imaging of water diffusion, vascularisation and oxygenation status. At initial diagnosis and staging this may allow tumours to be phenotyped better and during therapy for tumours to be assessed more comprehensively, particularly where therapy is cytostatic and will not result in significant size change. In this lecture the different functional imaging techniques that can be applied in clinical practice will be discussed and evidence for practice highlighted. The potential of integrated PET/MRI will also be considered.
Learning Objectives:
1. To learn about the different functional MR techniques (diffusion, perfusion).
2. To understand the basic principle behind each technique.
3. To appreciate the clinical usefulness of these techniques in daily clinical practice.
Author Disclosure:
V.J. Goh: Research/Grant Support; Siemens Healthineers. Speaker; Bayer, Siemens Healthineers.

A-217 08:58

B. CT perfusion techniques
H. Schöllnast; *Graz/AT (helmut.schoellnast@medunigraz.at)*

CT-perfusion imaging is a functional imaging tool which enables qualitative and quantitative evaluation of tumor perfusion and, therefore, assessment of tumor-

related angiogenesis. Clinical applications for CT-perfusion imaging have mainly evolved to include lesion characterization, prediction of prognosis, prediction of response to therapy and assessment of response to local or systemic therapies. Perfusion values have shown significant differences when comparing normal tissue with tumors and between benign and malignant lesions, although there is overlap between benign and malignant lesions. The degree of tumor perfusion is potentially associated with tumor aggressiveness as tumor-related angiogenesis determines the ability of tumors to metastasize and, therefore, affects prognosis. On the other hand, hypoxia within the tumor reflected by restricted perfusion limits the effect of chemotherapy and radiotherapy, potentially allowing for prediction of response. Both, conventional chemotherapy and targeted therapies such as angiogenesis inhibitors may affect tumor vascularization. In contrast to conventional chemotherapy, which mainly shows a cytotoxic effect on the tumor, angiogenesis inhibitors show rather a cytostatic effect. Traditional tumor size-based response criteria may underestimate the response to angiogenesis inhibitors in the early course of treatment due to stable tumor size despite effective therapy. In contrary, CT-perfusion imaging allows detection of decrease in tumor perfusion which precedes decrease in size. Use of different models for perfusion calculation such as compartmental model and deconvolution model, use of different CT-perfusion protocols including contrast media injection protocols and inter- and intraobserver variability when using perfusion software limit use of CT-perfusion imaging in clinical routine.

Learning Objectives:

1. To learn about current approaches for CR perfusion techniques.
2. To understand the basic principle behind each technique.
3. To discuss radiation exposure generated by CT perfusion techniques.
4. To appreciate the clinical usefulness of these techniques in daily clinical practice.

A-218 09:21

C. Assessment by molecular imaging

J. Grimm; *New York, NY/US (grimmj@mskcc.org)*

Molecular imaging describes imaging and measurements of biological processes at the cellular and molecular level. In a clinical setting this entails predominantly PET imaging, measuring increased glycolytic activity. However, other radiotracers allow for detecting different and predominantly structural or even functional entities, e.g., the imaging of PSMA in prostate cancer to detect primary or recurrent or disease; or the imaging with amino acids, reflecting increased amino acid metabolism in brain tumors. However, existing tracers can also be used to explore new signatures, such as in the case of positron lymphography using 18F-FDG to characterize sentinel lymph nodes. Lastly, optical imaging of radiotracers has been achieved and utilized both preclinically and clinically in novel applications. While most of clinical functional and molecular imaging is achieved in the area of nuclear medicine, there are other emerging areas: Intraoperative optical imaging is using available as well as new targeted fluorescent agents, aiding the surgeon visually during surgery to sentinel lymph nodes, remaining tumors and defining the surgical margin. Optoacoustic imaging, where novel scanners are listening to the light absorption in the body from either intrinsic targets or extrinsic specific contrast agents, have reached the clinical realm and have been used to detect specific cancers. Metabolic imaging has enjoyed a new boost beyond nuclear imaging in the form of hyperpolarized MR imaging, enabling interrogating metabolic key pathways to detect and characterize cancers in new ways. All this has been supported by the development of new and specific agents, interrogating disease signatures.

Learning Objectives:

1. To learn about the different concepts in molecular imaging.
2. To see and understand how molecular imaging might be integrated into patient care.
3. To appreciate clinical examples where molecular imaging is already established.

Author Disclosure:

J. Grimm: Board Member; Society of Molecular Imaging. Research/Grant Support; NCI (Clinical Cerenkov Imaging).

Panel discussion: Where are we using functional evaluations in clinical practice?

08:30 - 10:00 **Room D**

Special Focus Session

SF 5

Cystic pancreatic lesions: how to differentiate, how to manage?

A-219 08:30

Chairperson's introduction

C. Matos; *Lisbon/PT (celso.matos@fundacaochampalimaud.pt)*

Increased use of cross-sectional imaging has led to increased detection of pancreatic cysts. Although the most commonly used management guidelines assume knowledge of a specific cyst type, many of detected pancreatic cysts are indeterminate. During this multidisciplinary session we will focus on the clinical significance of small and large pancreatic cysts, we will review how to improve diagnostic accuracy and we will underline shared decision making for successful management.

Session Objectives:

1. To understand how imaging helps make the differential diagnosis of cystic lesions of the pancreas.
2. To address key questions that should be answered when diagnosing an incidental pancreatic cystic lesion.
3. To discuss how to improve patient management through multidisciplinary interaction.

A-220 08:35

Diagnostic accuracy of non-invasive imaging modalities for characterising cystic pancreatic lesions

N. Kartalis; *Stockholm/SE (nikolaos.kartalis@me.com)*

Pancreatic cystic lesions are increasingly diagnosed due to the widespread use of imaging studies (i.e., US, CT and MRI) in the evaluation of abdominal pathologies and to the aging population. They encompass a variety of entities with different biological behavior, ranging from benign lesios such as pseudocysts and serous cystic adenomas (SCA) to premalignant and malignant lesions, such as intraductal papillary mucinous neoplasms (IPMN), mucinous cystic neoplasms (MCN), cystic neuroendocrine tumours and cystic adenocarcinomas. Imaging plays a pivotal role in accurate diagnosis and appropriate management of patients with cystic pancreatic lesions. In this talk, we will analyze the specific imaging features of pancreatic cystic lesions on US, EUS, CT, and MRI. Furthermore, we will discuss the accuracy of cross-sectional imaging in the diagnosis of cystic pancreatic lesions and, finally, comment on the added value of contrast-enhanced US and EUS in the characterisation of cystic pancreatic lesions.

Learning Objectives:

1. To become familiar with the specific imaging features of pancreatic cystic lesions on US, EUS, CT, and MRI.
2. To learn about the accuracy of cross-sectional imaging in the diagnosis of cystic pancreatic lesions.
3. To understand the added value of contrast-enhanced US and EUS in characterising cystic pancreatic lesions.

A-221 08:58

The evolving role of pathology: can we improve patient stratification?

P. Demetter; *Brussels/BE (Pieter.Demetter@erasme.ulb.ac.be)*

Distinguishing between the various types of cystic pancreatic lesions has important prognostic and therapeutic implications. The sensitivity of cytology varies depending on the expertise of the endoscopist and the pathologist. Diagnostic accuracy can increase up to 80-90% if cytology is complemented with measurements of CEA, amylase levels and mucin staining. Although cyst fluid analysis is a tool in preoperative diagnosis, final diagnosis if often obtained only after histopathological analysis. Molecular markers in the cyst fluid are being increasingly studied in recent years. The four most common cystic pancreatic tumours bear tumour-specific genetic alterations, such as GNAS mutations in intraductal papillary mucinous neoplasms, β-catenin mutations in solid pseudopapillary neoplasms and VHL mutations or loss of heterozygosity in serous cystadenoma. Molecular tests of the aspirated cystic fluid seem particularly useful for detecting the accumulation of genetic mutations associated with lesion progression from early dysplasia to carcinoma. DNA-based biomarkers have made the most progress and are offered clinically, but prospective data are lacking and how DNA testing should be integrated into pancreatic cyst evaluation is unclear. In addition to the analysis of DNA, there are promising approaches in distinguishing benign and premalignant/malignant cystic tumours by evaluating miRNA profiles. At

present, however, molecular analyses cannot replace more conventional tests, but should be used in parallel with them and clinical findings.
Learning Objectives:
1. To understand the carcinogenic pathway in pancreatic cystic lesions.
2. To become familiar with the most frequent molecular alterations seen in pancreatic cystic lesions.
3. To learn how the integration of cytohistomorphology, cyst fluid biochemistry and molecular testing helps better stratify patients before therapy.

A-222 09:21

When not to operate and when to operate an incidental cystic pancreatic lesion

M. Del Chiaro; *Stockholm/SE (marco.del.chiaro@ki.se)*

Pancreatic cystic neoplasms (PCNs) are a very common group of diseases with a prevalence of 20-30% in the general population. It is today well known that some of these lesions (SCN) are benign. In contrast, others, can progress from adenoma to cancer (i.e. IPMN or MCN).In front of a so different biological behaviour, the differential diagnosis of these lesions still remains a major clinical problem. The accuracy in pre-operative diagnosis, independently by the diagnostic modality used, remain low and not superior to 70% even in high specialized centers. IPMNs are the most common cystic neoplasms of the pancreas (50%). Considering the high prevalence of these lesions and the low incidence of pancreatic cancer, it is quite logical to understand that only the minority of these lesions will progress to cancer. At the moment, no biomarkers are available to discriminate the grade of dysplasia and surgery is recommended according mostly with radiological signs. When the IPMNs are involving the main pancreatic duct, the risk of malignancy is extremely higher. MPD dilatation over 5-6 mm represents probably the optimal cut-off for resection. More complicated is the management of IPMNs involving the branch ducts (BD-IPMN). The large majority of these patients can be managed conservatively trough a radiological follow-up. Considering however the risk of progression, the surveillance of these patients can´t be discontinued until the patient is potentially fit for surgery. Traditionally MCNs should be always removed. No surgery is required for SCNs, excluding cases of symptomatic lesions or unclear diagnosis.
Learning Objectives:
1. To become familiar with surgical options for the management of pancreatic cystic lesions.
2. To understand how information obtained by imaging impact surgical management.
3. To learn how to avoid unnecessary surgery in patients with benign pancreatic cystic lesions.

09:44
Panel discussion: Are current management recommendations appropriate?

08:30 - 10:00 **Room K**

Radiographers

RC 514
Successful paediatric imaging

A-223 08:30

Chairpersons' introduction: Paediatrics: more than just 'small adults' (part 1)

V. Syrgiamiotis; *Athens/GR (syrgiamiotisvasilis@gmail.com)*

From paediatricians usually one listens the very common phrase “children are not just small adults”. It is for sure idea for the calculation of drug doses and the assessment of physiological parameters, the definition of child medicine in such defensive, negative and exclusionary terms deals with some inherent dangers and misconceptions as well. In the last decades it is a common phrase used in radiology as well. Both children and adults belong to the human race. Progress in medicine more often can be applied to and be of benefit to all and the transition from childhood to adulthood should be one of continuity rather than migration. Indeed we recognise that children, including the embryo, fetus, infant and all life stages until the completion of adolescence, are often at a different and increased risk from environmental hazards from that of adults. Children often have different, and sometimes unique, exposures to environmental hazards from those of adults. Due to their dynamic developmental physiology children are often subjected to higher exposures to pollutants found in air, water, food and radiation. These exposures may be handled quite differently by an immature set of systems to the way they are dealt with in adults. Children have a longer life expectancy. Therefore, they have longer to manifest a disease with a long latency period, and longer to live with toxic damage. Finally, children are politically powerless; they are defenceless. With no political standing of their own, they must rely on adults to protect them.
Session Objectives:
1. To appreciate strategies for successful imaging of uncooperative children and those with disabilities.
2. To review current guidelines on imaging in suspected non-accidental injury.
3. To demonstrate potential techniques to avoid sedation during paediatric MRI.

A-224 08:33

Chairpersons' introduction: Paediatrics: more than just 'small adults' (part 2)

N. Mitreska; *Skopje/MK (mitreska_nadica@hotmail.com)*

Paediatric radiology is a unique subspecialty of diagnostic radiology. Radiological findings as well as diagnoses are frequently different in infants and children from adults and knowledge and expertise are important for evaluation of the images. The child and its parents need special care and diagnostic methods must be appropriate selected. Mental development, position and structure of organs, increased susceptibility to radiation are different from adults. Reduction of radiation dose and radiation protection in radiographic examination of children is critical. In paediatric imaging risk-benefit dialogue obtain risk control and maximizing the benefit. Radiographers working with paediatric patients always are facing unique problems, so they must develop competence in knowledge, understanding and skills in paediatric imaging. Exposure is reduced by appropriate selection of study, using non-ionizing examination whenever possible, shielding the gonads and other organs. Radiographer have to capture the attention of the child to keep it still, response to verbal direction , use immobilization devices , understand the role of the family and other modalities for optimization of exposure. For good image quality paediatric protocols should be used to prevent repeat examinations and sedation or general anesthesia is usually require for MRI in children under 7 years of age. Radiologist, paediatric radiologist and radiographers must create team work, partnership and close cooperation.
Session Objectives:
1. To appreciate strategies for successful imaging of uncooperative children and those with disabilities.
2. To review current guidelines on imaging in suspected non-accidental injury.
3. To demonstrate potential techniques to avoid sedation during paediatric MRI.

A-225 08:35

A. Imaging the uncooperative child and children with disabilities

C. Simcock; *London/UK (clare.simcock@gosh.nhs.uk)*

Paediatric radiography and imaging requires modification of techniques by the radiographer or imaging technologist to ensure that optimal radiographs are produced. Following textbook methods, is simply not always possible in children and for successful outcomes, adaptation of practice is necessary. When faced with imaging children with learning disabilities and challenging behaviours, the task can appear daunting. There is limited literature available to assist the radiographer to meet the needs of children with disabilities. Over 40% of children attending our institution have complex needs and it is important that we learn strategies that both benefit the patient and result in a successful examination across all modalities. Therefore, reasonable adjustments should be made, whilst imaging this cohort of patients which will ensure that the radiographers actions do not have a negative impact on future visits to the imaging department for the patient.
Learning Objectives:
1. To learn about behaviours and disabilities that can present a challenge to successful imaging.
2. To understand practical techniques and strategies during projection radiography examinations.
3. To appreciate practical advice for imaging in specialist modality areas such as CT, MRI and US.

A-226 08:58

B. Suspected non-accidental injury: best practice and advice

B.R. Mussmann; *Odense/DK (bo.mussmann@rsyd.dk)*

Sub optimal imaging in suspected non-accidental injury (NAI) has major consequences for the child and family. The procedures must work properly each time and the images must be of superior quality to point out the abusers and withdraw the suspicion when no abuse has taken place. Furthermore, performing NAI imaging is a specialist task and special attention should be

paid to radiation dose, image quality ,and number of projections. The talk will focus on current guidelines and legal issues in NAI imaging.
Learning Objectives:
1. To appreciate non-accidental injury imaging as a highly specialised procedure.
2. To understand the image quality requirements in non-accidental injury imaging.
3. To be aware of the legal aspects of performing non-accidental injury imaging.

A-227 09:21

C. Reducing the need for sedation and anaesthesia in MRI: the role of play therapy and other techniques
J. Gårdling; *Lund/SE (jenny.gardling@med.lu.se)*

When a child undergo MRI the unfamiliar environment, meeting new healthcare professionals and the need to keep still might imply anxiety, fear and/or stress. Depending on the child´s age or inability to comply, sedation or general anaesthesia may be required, which implies risks and additional anxiety and discomfort for the children and their parents. Previous research have shown that children needs to have their parents close, play and feel joy, participate in care and have good relation with the healthcare professionals. Furthermore, children needs to know what to expect as this enables them to handle the situation better with increased coping and compliance, and with decreased anxiety. Age-appropriate information and preparation procedures have shown an impact on the child´s anxiety and their ability to comply during different procedures. It have also shown to decrease the need for general anaesthesia. Since children learn and understand situations differently depending on age and cognitive development combining different information and preparation procedures might be considered as an advantage.
Learning Objectives:
1. To review the current use of sedation and anaesthesia in paediatric MRI.
2. To understand how play therapy and other techniques can be used to prepare patients for imaging.
3. To become familiar with practical skills and techniques that might reduce sedation rates in paediatric MRI.

ESR/EFOMP

CT screening: benefits, doses and associated risks

Moderators:
J. Damilakis; Iraklion/GR
D. Tack; Baudour/BE

A-228 08:30

Dose and risk assessment
M. Brambilla; *Novara/IT (marco.brambilla@maggioreosp.novara.it)*

The radiation output of a CT system can be measured in a consistent and robust fashion through CT dose indexes (CTDIw for axial scans and CTDIvol for spiral scans). The CTDI tells precisely how the machine was operated, and it can be used, in conjunction with information regarding patient size and the scanned anatomy by mean of the dose length product (DLP), to estimate patient dose. The CTDI and DLP values are not, however, patient dose estimates. Similarly, the use of effective dose and the application of the nominal coefficient of risk, averaged over sex, several populations and all ages to calculate the cancer risk is in principle inappropriate. Estimates of individual patient risk, and epidemiologic studies assessing potential late effects, must use patient size-specific organ dose estimates in conjunction with the BEIR VII model. The BEIR VII committee has derived risk models for cancer mortality. The models consider the cancer site, sex, age at the exposure and attained age. Risks models have been developed for leukaemia, solid cancers in some organs and for all solid cancers combined. The cancer risks are non-zero only after a latency period (5 years for solid cancer and 2 years for leukaemia). For practical purposes, at typical dose levels encountered in X-ray diagnostics, risk of exposure-induced death (REID) and lifetime attributable risks (LAR) can be interpreted to present the excess radiation-induced cancer risk and their numerical values are close enough to be interpreted identical considering the uncertainties involved in the models.
Learning Objectives:
1. To learn about the correct methodology to assess the stochastic risk associated with radiation exposure.
2. To understand the differences between exposure indexes (CTDI, DLP, etc.), organ doses, effective doses and risk.
3. To appreciate the risks associated with CT screening.

A-229 08:50

Quantitative benefit-risk analysis
J. Damilakis; *Iraklion/GR (damilaki@med.uoc.gr)*

CT is an important tool for screening such as lung cancer screening and colorectal cancer screening in high-risk patients. Can screening reduce mortality? Are radiation doses and radiogenic risks associated with the above screening methods an important disadvantage for their acceptance as a mass screening tool? Studies have found that screening with low-dose CT could reduce lung cancer mortality by 20% in comparison with chest radiography. Decision for CT screening should be based on careful consideration and discussion between patient and health care provider. Low dose CT screening for lung cancer has its risks. Thus, individuals screened with low dose CT have a high rate of false positive results that may lead to unnecessary follow-up invasive testing for example bronchoscopy or biopsy. Another point of concern is radiation dose from low dose CT. Patient dose from a low-dose chest CT examination is about 1.5 mSv. Little information exists in the literature regarding the risk for radiation-induced cancer following low dose CT for lung cancer screening. Studies are needed to determine absorbed doses to the primarily irradiated radiosensitive organs of female and male patients subjected to low-dose CT screening for lung cancer on modern multi-slice CT scanners and assess the potential risk of radiation-induced cancer for a typical patient cohort subjected to screening. CT colonography (CTC) has been used as a method to screen for colorectal tumours as well as for large colorectal polyps mainly because of its accuracy, less-invasiveness in comparison with colonoscopy and potential for detection of extra-colonic abnormalities. Effective dose from CTC ranges from about 3 mSv to about 9 mSv. A single low-dose CTC would result in about a 0.01% lifetime cancer risk, i.e., 1 in 10000 for a typical patient cohort.
Learning Objectives:
1. To learn about medical benefits of CT screening and how they can be expressed quantitatively.
2. To compare the benefits of CT screening with potential radiogenic risks.
3. To learn the limitations of benefit-risk analyses.

A-230 09:10

Breast CT
W.A. Kalender; *Erlangen/DE (willi.kalender@imp.uni-erlangen.de)*

Efforts of improving the early detection of breast cancer are a necessity further on. Breast screening programs are being criticized frequently because of their cancer detection rates considered as too low. X-ray computed tomography (CT) has been proposed and evaluated multiple times as a potential alternative method for breast imaging. All efforts shown so far suboptimal because of their limited spatial resolution and high patient dose when compared to mammography. In consequence, we developed a new concept for breast CT (BCT) aiming at both high isotropic spatial resolution of about 100 µm and average glandular dose levels of 5 mGy or below. For this we chose single photon-counting technology, not available in CT so far, combined with spiral scanning. The complete scanner concept was evaluated by simulations and measurements; the results for dose and technical image quality parameters were confirmed. For comparison purposes, lumpectomies and mastectomies were imaged with digital mammography, breast tomosynthesis and BCT; these tests also confirmed expectations. The direct-conversion photon-counting detector technology showed revealed BCT's unprecedented performance. It provided the highest quality in imaging microcalcifications in specimens; combined with contrast medium injection as in standard clinical CT use, it outperformed the other modalities. Conclusion: CT scanners dedicated to breast imaging with photon-counting detectors and spiral scan capability can provide superior, unprecedented performance.
Learning Objectives:
1. To learn about early efforts at CT imaging of the breast.
2. To note image quality requirements for improving breast cancer diagnosis.
3. To understand the importance of advanced detector technology for the low-dose high-resolution breast CT.

How to communicate

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

Medical imaging departments present an excellent test environment to study interventions to enhance patient satisfaction as: (a) the imaging environment is highly complex and workflow and time schedule constraints are extensive; (b) there is a wide spectrum of patients referred from multiple clinical specialties whose conditions vary in acuity, ranging from outpatients undergoing routine examinations to critically ill patients undergoing emergency imaging studies. Research indicate that training radiologists and radiographers to make simple modifications in their language and behavior, during patient, care can significantly impact patient satisfaction which can impact quality-of-care. We need to incorporate into our daily practice the fact that the 21st century patients have higher expectations and are becoming more demanding, as they are progressively being part of the process and therefore have access to information, allowing them to make better informed choices. Imaging departments should adopt communication strategies and policies in the new digital environment, explaining the procedure in an understandable manner, adapted to patient social and economic characteristics, with the objective to give the patient the adequate information for him/her to be able to make a proper decision. Radiographers usually are the ones that contact with patients and are the only professionals who might notice duplicate or inappropriate examinations before they occur and the ones to be asked about the risk. Therefore, its crucial to develop guidelines with clearly defined roles and responsibilities on how to communicate risks in a harmonized way, to avoid patient misinterpretation in their imaging clinical pathway.

Learning Objectives:

1. To become familiar with the principals of patient communication strategies.
2. To be aware of patients' needs and fragilities at the point of care.
3. To understand the patients' fears and perceptions about risk.

State-of-the-art imaging of postoperative joints

Moderator:
M.F. Reiser; Munich/DE

A-232 08:30

A. Postoperative shoulder

C.W.A. Pfirrmann; *Zurich/CH*

Imaging of the postoperative shoulder is challenging because of various surgical techniques, distorted anatomy and the presence of artifacts because of metallic implants. The most commonly performed surgical procedures include rotator cuff reconstruction, instability surgery, and joint replacements. The radiologists should have knowledge of these techniques. In this presentation these surgical techniques, the normal imaging findings after these procedures and the abnormal findings as well as imaging strategies will be discussed.

Learning Objectives:

1. To become familiar with the most frequently used surgical techniques for glenohumeral instability, subacromial decompression, rotator cuff repair, and arthroplasty and their imaging appearance.
2. To learn about potential postoperative complications.

A-233 09:00

B. Postoperative knee

E.H.G. Oei; *Rotterdam/NL (e.oei@erasmusmc.nl)*

In this masterclass we will review the indications for the most commonly performed surgical techniques in the field of meniscal repair, knee ligament reconstruction, and knee cartilage repair, followed by a brief explanation of the surgical procedure. We will also highlight recent advances in joint preserving procedures around the knee. Of each discussed technique, the normal postoperative appearance on imaging will be presented, with an emphasis on MR imaging. This is followed by a discussion on the assessment of potential complications. Among the discussed topics will be complications after ACL reconstruction (tunnel positions, graft rerupture, impingement, arthrofibrosis, cyclops lesions), assessment of meniscus re-tear after surgical repair and assessment of the success after cartilage repair procedures.

Learning Objectives:

1. To become familiar with the most frequently used surgical techniques for meniscal repair, ligament reconstruction and cartilage repair techniques.
2. To learn about potential postoperative complications.

A-234 09:30

C. Postoperative ankle and foot

M.J. Ereno Ealo; *Galdacano/ES (mjereno@gmail.com)*

Foot and ankle traumatic pathologies are frequent conditions, and sometimes cause big deformities. Our objectives are to focus on all aspects of diagnosis, treatment and subsequent management of these injuries. The most current and innovative techniques of internal fixation and their applications will be showed. Identifying problems and complications and also talking about reconstructive surgery of the lower extremity is important. Very different injuries and cases are detailed: surgical management and complications of high-energy distal tibial and pilon fractures, other fractures like calcaneus, talus, lisfranc, toe and forefoot fractures and stress fractures. Other conditions like Achilles pathology, bunions, diabetic (Charcot) foot, Morton's neuroma, hammer toe, tarsal coalition, and adult acquired flatfoot are also shown. Patients with arthroplasty, arthrodesis, triple fusion, ankle replacement should be recognised

Learning Objectives:

1. To become familiar with the most frequently used surgical techniques for osteosynthesis, instability, tendon repair and arthroplasty and their imaging appearance.
2. To learn about potential postoperative complications.

08:30 - 10:00 **Room M 3**

Interventional Radiology

RC 509

Musculoskeletal interventions: what every radiologist should know

Moderator:
A. Gangi; Strasbourg/FR

A-235 08:30

A. Musculoskeletal ablation and embolisation

A. Basile; *Catania/IT (basile.antonello73@gmail.com)*

During the past decade we have seen an increasing role of interventional radiology (IR) in the treatment of musculoskeletal both benign and malign lesions with palliative or curative goal. A common indication for treatment is the presence of localized pain, furthermore in some situation the disease progression can lead to pathologic fracture, with or without mechanical instability. Most frequent malign lesions are spinal and bone metastases. Percutaneous tumor ablation is performed under imaging guidance and generating cytotoxic temperatures that cause tumor necrosis. Ablation may be considered for example for symptomatic spinal metastases, with tumor control indication, for uncomplicated painful spinal metastases and stable pathological vertebral compression fracture. Ablation can be also performed in association to radiation therapy with a better control of local tumor; also vertebral augmentation can be performed as fracture prophylaxis at the same time as ablation through the same percutaneous access cannula. There are many instruments employed for the treatment of the bone lesions: ablation (thermal ablation with radiofrequency, microwaves MW, laser ablation and magnetic-resonance-guided focused ultrasound surgery MRgFUS and cryoablation), osteoplasty and vascular procedures. Another indication for percutaneous ablation are painful benign tumours such as osteoid osteoma, osteoblastoma, chondroblastoma, osteochondroma, giant cell tumour, aneurysmal bone cyst, eosinophilic granuloma, vertebral haemangioma and fibrous dysplasia; all these lesions can be treated either via ablation and/or embolisation. Embolisation can be also performed in the preoperative management of bone metastases to reduce perioperative blood loss. Physicians involved in the care of patients with oncological musculoskeletal disease should be familiar with these treatments and refer patients appropriately based on best available evidence. This is challenging, but necessary because of the increasing diagnosis of this kind of lesions and the major role that the IR will assume in the future in this field.

Learning Objectives:
1. To appreciate the indications for ablations and embolisation.
2. To learn about different techniques and combination of them.
3. To discuss the results and literature data of interventional radiology procedures.

A-236 09:00

B. Vertebral augmentation and discectomy techniques: can we challenge surgery?

D. Filippiadis; *Athens/GR (dfilippiadis@yahoo.gr)*

Vertebral augmentation and discectomy techniques: can we challenge surgery? Vertebral augmentation techniques include standard vertebroplasty or vertebral augmentation on terms of balloon kyphoplasty or percutaneous implant insertion combined to PMMA injection. Indications include osteoporotic, traumatic, pathologic, and cancer-related fractures as well as benign (eg symptomatic atypical aggressive hemangiomas) or malignant (e.g., metastatic) lesions. Under proper patient selection these techniques provide pain relief and functional improvement along with spine alignment height restoration and endplate reduction. Additionally, kyphotic angle restoration or maintenance seems to prevent future vertebral fracture in the adjacent levels and improved sagittal balance. Studies in the literature report that load distribution in patients with vertebral fractures post vertebroplasty returns to values of normal population. Variety in the morphology, location, and etiology of vertebral fractures demands a tailored patient centered approach. Percutaneous technique for intervertebral disc herniation and discogenic pain can be either decompression or biomaterial implantation techniques. The former can be classified into mechanical (discectomy), thermal (RF, laser, coblation, IDET) or chemical (Discogel, ozone) methods whilst the later include hydrogel, PRP and stem cell therapies. Decompression techniques are indicated for small- to medium-sized symptomatic contained hernias. Percutaneous techniques are performed as outpatient, low cost procedures and are governed by good patient compliance, high success (75-85%) and low complication rates (<1-2%). In case of treatment failure, percutaneous techniques can be repeated without interfering with surgery at a later stage. Percutaneous vertebral augmentation and discectomy techniques compared to surgical approaches are favored in terms of reduced blood loss and operating time, shorter hospital stay, fewer complications, and less postoperative pain.

Learning Objectives:
1. To appreciate the rationale for the using of interventional radiology procedures.
2. To learn about different techniques and treatment strategy.
3. To discuss results and literature data in comparison with other treatments.

A-237 09:30

C. Bone biopsy and pain treatment using cone-beam CT (CBCT)

L. Tselikas; *Villejuif/FR (lambros.tselikas@gustaveroussy.fr)*

Oncology has dramatically changed the last decade, and new therapies have been proven to be effective in metastatic cancer patients. But bone tumours remain difficult to treat, and interventionnal radiology plays a key role in their management. Both biopsy, ablation and consolidation techniques are feasible and effective with a very good safety profile. Cone beam CT is the guidance method of choice because because of its versatility, and comfort of use. Guiding softwares are mandatory to improve te technic results and take full advantage of this technology. Futur developments including combined guiding systems based on optic or electromagnetic needle position estimation and dose reduction solutions.

Learning Objectives:
1. To appreciate the high imaging quality and guidance accuracy using CBCT for biopsy and pain treatment.
2. To learn about the advantages of CBCT-guided interventions, reconstruction algorithms, image enhancement and dose reduction.
3. To discuss about techniques, limitations of CBCT and future applications.

E³ 526b

TEVAR/EVAR: where we are and where we are going

Moderator:
F. Fanelli; Rome/IT

A-238 08:30

A. TEVAR

H. Rousseau; *Toulouse/FR (rousseau.h@chu-toulouse.fr)*

Thoracic endovascular aneurysm repair (TEVAR) has proven to be a safe and effective therapy. In the last 2 decades, TEVAR has been established as first-line treatment for most descending thoracic aortic pathology due to reductions in perioperative morbidity and mortality compared to open surgical repair. Improvements in materials, reduction in delivery sheath size, improved conformability, tapered grafts, and a wider range of sizes have improved TEVAR applicability and outcomes over this initial decade of widespread use, for traumatic aortic transection, aneurysms, as well as acute and chronic type B aortic dissection. Looking into the future, industry and physicians are working together to improve thoracic stent-graft design (branched and fenestrated stent-grafts, chimney technique) to further improve safety, effectiveness, and applicability to a wider range of patients and aortic pathologies. Treatment of the ascending aorta remains less established, but is expected to evolve as technology allows integration of ascending, and arch devices. Hybrid ORs combining optimal imaging with the ideal environment to perform complex open and endovascular operations are available, allowing several features such as CTA fusion, CB-CT, and low-dose protocols to reduce the radiation exposure to a patient and an operator.This presentation will review the indications, technical aspects and results of endovascular TAA repairs. We also examine the advantages and limitations of new stent graft treatment of the arch and our experience in technological innovation in performing these complex procedures.

Learning Objectives:
1. To understand the evidence supporting endovascular therapy vs surgery.
2. To learn what is new for aortic arch disease.
3. To learn the impact of technological innovation in planning and performing the procedure.

A-239 09:00

B. EVAR

E. Brountzos; *Athens/GR (ebrountz@med.uoa.gr)*

To understand the evidence supporting endovascular therapy vs surgery EVAR is the method of choice because three principal, randomised controlled trials have shown better 30-day mortality for EVAR compared to open surgery. However, the mortality benefit was lost (catch-up of mortality) after 2 to 5 years. The main cause of aneurysm-related mortality in the EVAR group was secondary aortic sac rupture, caused by late device failures. Careful patient selection, diligent adhesion to instructions for use and meticulous life long imaging follow up are mandatory for a successful EVAR. Thoracobdominal aneurysms are rare and various. Open surgery carries a mortality rate of 2-12% depending on the aneurysm type. Endovascular treatment includes the use of fenestrated and branched devices with high technical success rates and significant improvement in perioperative mortality. Additional strategies such as hybrid techniques and parallel grafts (chimneys and snorkels) are also successful. Standard EVAR requires bilateral or unilateral surgical exposure of the common femoral artery. Complications specific for this surgical procedure include hematoma (5%), seroma (10%), and femoral nerve damage. Following the introduction of the new low profile devices and the development of the suture mediated closure devices EVAR can be performed without the need of surgical cut down. Recent studies have shown that percutaneous EVAR is possible with 96-100% technical success rates, with complication rates less than 2%.

Learning Objectives:
1. To understand the evidence supporting endovascular therapy vs surgery.
2. To learn what is new for thoracoabdominal aortic disease and iliac axis.
3. To learn when and how to perform a percutaneous approach.

A-240 09:30

C. Post-EVG complication

R. Uberoi; *Oxford/UK (Raman.Uberoi@ouh.nhs.uk)*

Abdominal endovascular repair (EVAR) and thoracic endovascular aortic repair (TEVAR) have become an accepted alternative to surgery for the treatment of aortic pathologies, particularly aneurysm disease and dissections. Lifelong surveillance is obligatory following EVAR and TEVAR to monitor the aortic morphology and detect associated complications. The main imaging techniques used in evaluating TEVAR follow up are computed tomography angiography (CTA), magnetic resonance angiography (MRA) and catheter angiography in assessing the technical success, outcome and complications, which may necessitate re-intervention. In the abdominal aorta ultrasound (duplex) including contrast enhanced ultrasound (CEUS) with plain X-ray may also be used as alternative imaging modalities. Of these, computed tomography angiography offers a fast, accessible and sensitive imaging modality and is established as the default surveillance tool. Long term common complications include thrombosis, limb kinking and occlusion, aneurysm sac leak which may result in persistent pressurisation of the sac called endoleaks type I-V. Device migration, and device failure can contribute to endoleaks and need to be closely monitored. Type I and III endoleaks need urgent treatment usually with placement of a proximal or distal cuff and or relining of the graft. However not all type II endoleaks need treatment, but where there is continued sac expansion or aneurysm development his will require embolization of feeding vessels. Type IV is less common with the newer devices and usually resolve over a period of weeks and months. Type V endoleaks also may require relining of the whole device or conversion to an open procedure.

Learning Objectives:

1. To learn about individualised post-EVG surveillance programme.
2. To learn which are the most common complications.
3. To understand how to select and perform the optimal treatment.
4. To understand the role of contrast-enhanced US (CEUS).

E³ - ECR Academies: Update on Hepatobiliary Imaging

E³ 520
Imaging of HCC

A-241 08:30

Chairperson's introduction

A. Palkó; *Szeged/HU (palkoand@gmail.com)*

Imaging of hepatocellular carcinoma is one of the important tasks of abdominal radiology. Early detection and accurate characterisation of this disease is challenging, especially in cases of advanced cirrhosis, nevertheless of utmost importance since it allows for conducting timely and effective treatment which may be curative or palliative, depending on the overall condition of the patient. Speakers of this session introduce the state of the art CT and MRI examination techniques, the typical morphological characteristics of HCC, the objective criteria for establishing the diagnosis and the difficulties of differential diagnosis.

A-242 08:35

A. CT or MRI for diagnosis and follow-up?

G. Brancatelli; *Palermo/IT (gbranca@yahoo.com)*

Multiphasic CT and MRI allow non-invasive diagnosis of hepatocellular carcinoma in cirrhotic patients. Moreover, they are able to stage the tumour burden to choose the most appropriate treatment for each patient. Furthermore, they have a role in the follow-up of; (1) indeterminate nodules such as LI-RADS 3 and (2) treated HCC nodules to confirm the effectiveness of treatment or to detect residual tumour or recurrence. LI-RADS is a classification system that allows; (1) predicting with CT and MR the likelihood that a lesion is HCC in patients with chronic liver disease or cirrhosis and (2) standardising terminology among different centers.

Learning Objectives:

1. To understand the CT and MR imaging protocols to identify HCC in cirrhotic liver.
2. To be familiar with LI-RADS .
3. To review the role of each modality in detecting, staging and follow-up of HCC.

Author Disclosure:

G. Brancatelli: Speaker; Bayer.

A-243 09:03

B. Early HCC and well-differentiated HCC

C. Ayuso; *Barcelona/ES (cayuso@clinic.ub.es)*

Non invasive criteria for the diagnosis HCC ≥10 mm in patients with liver cirrhosis are based on the developement of neoangiogenesis and on the progressive reduction of portal supply within the tumour, leading to the characteristic arterial wash-in and portal wash-out pattern detected on dynamic CT/ MR studies performed with extracellular contrast agentes (CA). Imaging criteria have a sensitivity of 60% and a specificity close to 100% for the diagnosis of small HCC. When RM is obtained with gadoxetic acid, the arterial and early portal phases demonstrate also the typical wash-in/wash-out pattern of HCC. In the transitional and hepatobiliary phases, another key imaging is found, the hyposignal intensity of close to 90% of HCCs compared to the surrounding liver parenchyma, based on the progressive reduction/absence of the expresion of organic anion transporting polypeptides (OATPs) during the hepatocarcinogenesis process. LI-RADS can be applied on CT, on MR independenly of the CA used, and also on contrast enhanced ultrasound. The sensitivity, specificity and interobserved concordance of the stanadardised imaging interpretation do not have strong proscpective data availble. Early diagnosis is the only way to improve the outcome of patients with HCC. Up to now, the active work-up for the diagnosis of HCC is recommended for new liver lesion ≥10 mm detected in the context of surveillance programmes. A confident imaging diagnosis of HCC in smaller lesions is limited and treatment of such a tiny possible pre-malignant but not confirmed HCC lesions is not recommended to avoid overdiagnosis and overtreatment.

Learning Objectives:

1. To review key imaging criteria of HCC in a cirrhotic liver.
2. To be able to differentiate HCC from other lesions in a cirrhotic liver.
3. To reflect the role of early diagnosis of HCC in the management of the patient.

A-244 09:31

C. Mimickers and pitfalls

D. Akata; *Ankara/TR (dakata@hacettepe.edu.tr)*

HCC can develop in non-cirrhotic liver and even without identifiable risk factors. In this setting it is more likely to manifest as a symptomatic dominant lobulated mass. Non-invasive diagnostic criteria such as, arterial enhancement and subsequent ‘‘washout’’ during portal venous or equilibrium phases on both CT and MR are present in more than 90% of cases. The imaging findings of HCC are the same in both cirrhotic or non-cirrhotic liver. However, focal liver lesions mimicking HCC in non-cirrhotic liver are different than the ones in cirrhotic liver. This presentation describes the typical and atypical imaging features of common hypervascular lesions such as hemangiomas, focal nodular hyperplasia, metastasis, cholangiocarcinoma and fat containing liver lesions such as angiomyolipoma and adenomas. It outlines a general approach to distinguishing between benign and malignant hepatic lesions. The role, pearls, and pitfalls of the hepatobiliary specific contrast agents as well as diffusion weighted imaging in the detection and characterization of the lesions will be discussed in detail.

Learning Objectives:

1. To review a diagnostic algorithm to detect HCC mimics in non-cirrhotic liver.
2. To review the imaging characteristics of a wide spectrum of potential pitfalls.
3. To understand the potential role of extracellular and hepatobiliary contrast agents as the problem solvers.

10:30 - 12:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 621
Basic breast imaging

A-245 10:30
A. Calcifications in mammography
C.S. Balleyguier; *Villejuif/FR (Corinne.BALLEYGUIER@gustaveroussy.fr)*

Breast calcifications are common findings detectable on mammography. Breast calcifications are most likely benign; nevertheless irregular microcalcifications cluster may be the only imaging findings suggesting a ductal carcinoma in situ (DCIS). Analysis of microcalcifications on mammography remains on magnification views; size, density, number, pleomorphism and distribution within the breast have to be carefully analysed to differentiate benign and suspicious microcalcifications clusters. Benign calcifications are categorised as BI-RADS 2 and are more likely round, regular, with a calcified rim, tea-cup or egg-shell shape. Suspicious microcalcifications may be amorphous, irregular, with a linear or segmental distribution. When a microcalcifications cluster is categorised as BI-RADS 4, a stereotactic biopsy should be performed. Ultrasound may be performed first to detect non-calcified mass. Vacuum assisted stereotactic biopsy with at least 6 11 Gauge samples must be performed. New technologies such as BLES biopsy, associating biopsy and radiofrequency can be performed to remove entirely the cluster. In this topic, biopsy techniques and diagnostic strategies to diagnose microcalcifications will be presented on a basis of clinical cases.
Learning Objectives:
1. To become familiar with different types of calcifications.
2. To learn the differential diagnosis of different calcifications.
3. To learn the different tools to biopsy calcification clusters.

A-246 11:15
B. Asymmetry and architectural distortion
L.J. Pina Insausti; *Pamplona/ES (ljpina@unav.es)*

Asymmetries and architectural distortions: Asymmetries are unilateral deposits of fibroglandular tissue not conforming to the definition of a mass. Four types of asymmetries can be considered: (1) Asymmetry as an area of fibroglandular tissue visible on only one mammographic projection, mostly caused by superimposition of normal breast tissue. (2) Focal asymmetry visible on two projections, hence a real finding rather than superposition. (3) Global asymmetry consisting of an asymmetry over at least one quarter of the breast and is usually a normal variant. (4) Developing asymmetry new, larger and more conspicuous than on a previous examination After the detection of one of the previous asymmetries, it is mandatory to compare with previous mammograms, if available. Palpation and additional techniques can be used to study the lesion, such as spot compressions, tomosynthesis, US and in some cases MRI. A biopsy is needed if malignancy cannot be excluded. The term architectural distortion is used when the normal architecture is distorted with no definite mass visible. This includes thin straight lines or speculations radiating from a point, and focal retraction, distortion or straightening at the edges of the parenchyma. Architectural distortion can also be seen as an associated feature. Tomosynthesis is a very sensitive technique to detect architectural distortions. Surgery, radial scar and carcinoma are the most common causes of distortions. A biopsy is mandatory if a surgical scar is excluded. The management of radial scars needs further work-up after a core needle biopsy: both surgery or vacuum-assisted biopsy can be used.
Learning Objectives:
1. To understand the concept of asymmetry and architectural distortion.
2. To become familiar with the respective imaging features.
3. To learn about the diagnostic approach using all breast imaging modalities.

EuroSafe Imaging Session

EU 2
Strategies for dose reduction in computed tomography: from technical concepts to clinical practice
Moderator:
R.W.R. Loose; Nuremberg/DE

A-247 10:3s0
Chairperson's introduction
W. Stiller; *Heidelberg/DE (wolfram.stiller@med.uni-heidelberg.de)*

In the field of computed tomography (CT) technical improvements have constantly extended the range of clinical applications and made new radiodiagnostic indications accessible. As CT examinations always involve the exposure of patients to ionizing radiation, dose reduction is an imperative when applying CT in clinical practice and approaches for reducing the dose associated with CT are required. To this end, different strategies for dose reduction in CT have been developed, spanning technical approaches as well as specific examination techniques applied in clinical practice. To date, several technical possibilities such as automated tube current modulation and voltage selection as well as dynamic beam collimation are available for reducing the dose associated with CT examinations. Of late, methods for iterative image reconstruction in CT enable noise suppression in image data, which may be exploited for enabling further dose reduction. While all scanner technology currently available should be exploited for reducing the radiation exposure of CT examinations in general, this is especially important in pediatric CT imaging. Careful selection and individual adaptation of the CT protocol parameters to each specific diagnostic task have the potential to enable systematic dose reduction, e.g., for pediatric and chest CT examinations. While dose reduction is imperative in CT, excessive reductions will result in a loss of diagnostic image quality. In clinical routine, dose reduction of CT examinations therefore is limited by the image quality requirements inherent to each specific diagnostic task that have to be fulfilled for ensuring confident diagnosis.
Session Objectives:
1. To raise awareness of different strategies for dose reduction in computed tomography.
2. To learn about and understand technical concepts facilitating dose reduction in CT.
3. To become familiar with methods for dose reduction in CT applied in clinical practice.

A-248 10:35
Systems for dose reduction in CT: more than automated exposure control
M. Prokop; *Nijmegen/NL*

"no abstract submitted"
Learning Objectives:
1. To learn about the technical possibilities available for reducing the dose associated with CT examinations.
2. To become familiar with the functionality of technical systems for dose reduction in CT.
3. To understand the potential and limitations of these dose reduction systems.

A-249 10:51
Iterative image reconstruction for dose reduction in CT: technical background and concepts for clinical practice
P.B. Noël; *Munich/DE (peter.noel@tum.de)*

After introduction in the 1970s, computed tomography has developed to be a major tool in day-to-day clinical routine. A rapid growth in CT examinations can be attributed to its wide availability, speed, and diagnostic benefits. In the same time, public health concerns have arisen with respect to patient and population radiation dose. Industrial and academic CT development teams have, therefore, worked on strategies to reduced radiation exposure from CT, for example, with concepts like: tube-current modulation, over-beam reduction, or organ-specific dose reduction. Over the last decade one promising development is the paradigm of advanced reconstruction algorithms. The idea of this software solution is to reduce image noise and improve image quality. Image noise as well as image quality are directly linked to the radiation exposure, and thus the reduction of noise via iterative reconstruction allows a reduction in dose. This presentation will give insight into the different flavors of

reconstruction algorithms, including hybrid-, model-based, and full statistical iterative algorithms. Furthermore, we will discuss its clinical translation and the challenges associated with its introduction into the clinical routine. Additionally, the talk will provide an outlook of potential solutions to further reduce CT radiation dose.

Learning Objectives:

1. To learn about current methods for the iterative image reconstruction in CT.
2. To raise awareness about the potential of the iterative image reconstruction for enabling dose reduction in CT.
3. To understand technical limitations of the iterative image reconstruction in view of image quality at very low doses.

Dose reduction strategies in paediatric CT

E. Castellano; *London/UK (elly.castellano@rmh.nhs.uk)*

The benchmarking of paediatric CT imaging practice at non-specialist centres is likely to show that there is scope for radiation dose reduction because general radiologists are not as accustomed to noisy images of small patients as their paediatric counterparts. Dose reduction endeavours should first focus on reducing local diagnostic reference levels (DRLs) below national or European ones, then on adopting specialist centre DRLs as performance targets and moving towards them in small steps to permit the radiologists to adapt to the image quality. The outcome will be an imaging practice better aligned with that of specialist paediatric centres. Scan protocols may need to be developed along the way for specific clinical indications and weight categories. The slice thickness set for the reporting image set strongly influences the radiation dose and must be appropriate for the diagnostic task. Particular attention must be given to the choice of tube voltage: lowering the kV from 120 kV to 100 kV for body imaging will permit the tube current to modulate with patient size; 80 kV is feasible for contrast-enhanced studies of the thorax, resulting in increased conspicuity of iodine-perfused vessels and tissues. Decreasing the tube voltage will also reduce patient dose if the tube current modulation settings are reviewed alongside. Iterative reconstruction can be used to improve the appearance of lower-dose images. Good radiographic practice must be promoted at all times: careful centering of the patient, effective immobilisation and correct positioning of the arms are essential.

Learning Objectives:

1. To become familiar with dose reduction strategies employed in paediatric CT.
2. To understand how scanner technology can be used for reducing dose of paediatric CT examinations.
3. To raise awareness of the importance of dose reduction in paediatric CT examinations.

A-251 11:23

Adapting protocols towards dose reduction in chest CT

D. Tack; *Baudour/BE (denis.tack@skynet.be)*

Once a new CT device is installed, it is the responsibility of users to check all parameters to fit with the ALARA principle. This is made in a team approach. Objectives for dose delivery should not be based on DRLs, but rather on P25 of national surveys or on best-published practices in agreement with their equipment. Default protocols include standard CT, low or ultra-low-dose CT (ULD-CT) and CT pulmonary angiography (CTPA). Submillisievert routine CT scanning in standard-sized patients is feasible (DLP<70 mGy.cm) in routine as standard acquisitions. DLP of ULD-CT could be lower than 15 mGy.cm. CTPA can be obtained at DLP lower than 100 mGy.cm in standard patients. Subjective image quality should be assessed by radiologists on a five-point scale (1=non-diagnostic; 5=excellent). An optimised dose would have a score approximating 3,5, whereas a ULD CT would have a sore of 2,5. Inter-observer variability in assessing image quality if often observed. Training and consensus readings for choosing the final acceptable IQ are mandatory. Adjustments of automatic exposure control and tube potential selection for optimising the dose are vendor-specific, and include pitfalls that will be detailed. Specific technical settings available on some CT devices can also be utilised such as volumetric sequential scanning, Sn filtering, and high-pitch acquisitions.

Learning Objectives:

1. To become familiar with strategies for dose reduction applied in chest CT.
2. To learn about the adaptation of acquisition protocol parameters for reducing dose of chest CT examinations.
3. To raise awareness of the potential for dose reduction in chest CT in clinical routine.

A-252 11:39

Dose reduction and image quality: when low is too low

S.T. Schindera; *Aarau/CH (sschindera@aol.com)*

Dose reduction in CT, according to the ALARA principle is very well known but at the same time also very challenging. Depending of the clinical task, different magnitudes exist to reduce the dose (e.g., detection of hepatic metastasis vs. renal stone detection). Many radiologists are still afraid of losing the diagnostic accuracy while reducing the dose. The key question is, how low can we go while preserving the diagnostic accuracy. To date, various possibilities (e.g., phantom studies, studies with virtual added noise) exists of evaluating the possibility of dose reduction in CT. In the future, task specific model observer will play an increasing role in the dose optimization process in CT.

Learning Objectives:

1. To learn about the implications of dose reduction on the image quality of CT examinations.
2. To become familiar with examples of excessive dose reduction from clinical practice.
3. To understand that dose reduction potential in CT is limited by the image quality requirements inherent to each specific diagnostic task.

Radiologic anatomy: lower extremities

Moderator:
U. Aydingoz; Ankara/TR

A-253 10:30

Hip

A.H. Karantanas; *Iraklion/GR (akarantanas@gmail.com)*

The painful hip is a common clinical problem in all age groups. Magnetic resonance imaging (MRI) is an invaluable tool to assess the hip joint because of its ability to directly visualize bone marrow, cartilage and soft tissues in multiple planes. MR arthrography (MRa) using intra-articular contrast material is the standard method for imaging labral lesions and cartilage degeneration and trauma. Understanding normal hip anatomy and common variants is important, in order to accurately detect and localize areas of pathology and to prevent misinterpreting normal structures as diseased. Plain radiographs should always be available when reporting MRI because basic measurements allow assessment of underlying deformities which might explain the clinical and MRI findings. The most important to know are: joint space width (JSW), CE angle, VCA angle, alpha angle and acetabular retroversion. Among the disorders causing hip pain, osteoarthritis (OA) is the most common one. Age is a risk factor strongly correlated with OA. Early OA is related to CAM type femoroacetabular impingement, developmental dysplasia and previous trauma, inflammation or infection. The diagnosis of OA is based on a combination of radiographic findings and characteristic symptoms. The progression of OA traditionally has been measured using radiographic JSW. Weight-bearing radiographs centered on the hip are the most reproducible and reliable ones. The sequence of degeneration includes the following radiographic findings: joint space narrowing, osteophyte formation, subchondral sclerosis, and cyst formation. In cases that radiographs show minor changes and high clinical suspicion of early disease, OA can be confirmed with MRI and/or MRa.

Learning Objectives:

1. To identify intra- and extra-articular anatomy on MRI.
2. To learn what we see and what we miss on radiographs.
3. To understand osteoarthritis and learn its key features on imaging.

A-254 11:00

Knee

M. Klontzas; *London/UK (miklontzas@gmail.com)*

Knee pain is one of the most prevalent musculoskeletal symptoms which is increasing together with the steady increase in life expectancy and the prevalence of obesity. MRI is the imaging modality of choice for the evaluation of knee disorders, offering a comprehensive evaluation of the bone marrow, the soft tissues and the articular cartilage. As an imaging modality it combines high sensitivity and specificity aiding the investigation and differential diagnosis of pathology such as cruciate ligament and meniscal tears, which cannot be visualized with plain radiographs. This lecture will provide the outlines of the normal cross-sectional anatomy of the knee with a special focus on MRI. An outline of pathology missed or identified on plain films will be provided before focusing on more detail in MR imaging anatomy which is extremely important

for the evaluation of knee pathology and the differential diagnosis between anatomical variations and clinically relevant knee lesions. Finally, an outline of meniscal lesion evaluation with the use of MRI will be providing since they are one of the most commonly injured knee structures. The combination of imaging with data provided from the clinical examination and medical history can lead to the correct diagnosis and this is why the knowledge on the normal anatomy as well as variants can lead to the successful diagnosis and the avoidance of unnecessary diagnostic arthroscopic procedures.

Learning Objectives:

1. To identify intra- and extra-articular anatomy on MRI.
2. To learn what we see and what we miss on radiographs.
3. To understand and learn the key features of meniscal injury.

A-255 11:30

Ankle

F. Smithuis; *Amsterdam/NL*

E³ 618

The heart between the lungs

A-256 10:30

Chairperson's introduction

J.E. Wildberger; *Maastricht/NL (j.wildberger@mumc.nl)*

Modern high end CT scanners with faster scan acquisition times allow for routine assessment of cardiac pathologies, even on a standard chest CT. Relevant information regarding the heart can be retrieved, incidental cardiac findings will play a major role for patient management in the future. Plain CT allows for fat distribution as well as for coronary calcium analysis. On contrast-enhanced scans, coronary arteries and myocardial changes can be assessed. During this session, three esteemed speakers will present an overview on the diagnostics and the clinical impact of various cardiac pathologies on standard thoracic CT scans.

A-257 10:35

A. Cardiomyopathies

D.J. Murphy; *London/UK (murphy.84@gmail.com)*

Cardiomyopathies are a heterogeneous, important group of diseases with significant morbidity and mortality. They can be broadly classified into five major subtypes based on morphology (hypertrophic, dilated, restrictive, arrhythmogenic and unclassified). Diagnosis is based on a composite of clinical history and examination, laboratory and genetic testing, electrocardiography and cardiac imaging. Despite advances in medical therapy, overall prognosis remains poor, and early diagnosis is important. Echocardiography is the first-line imaging test for the evaluation of cardiac structure and function, with cardiac magnetic resonance imaging (CMR) the gold standard. Computerised tomography (CT) has a growing role in this area. ECG-gated cardiac CT is a well-established test for coronary artery imaging, but it also allows an excellent opportunity to assess for structural cardiac abnormalities characteristic of an underlying cardiomyopathy, such as septal hypertrophy in asymmetric hypertrophic cardiomyopathy, or left ventricular dilatation in dilated cardiomyopathy; the CT features of the common cardiomyopathies will be reviewed with comparison to CMR, along with a revision of normal cardiac chamber anatomy. The improved temporal resolution of modern CT scanners has reduced the deleterious effect of cardiac motion artefact on routine non-ECG gated chest CT, allowing an opportunity for the detection of cardiac structural abnormalities. Standard non-ECG gated chest CT has a reported sensitivity of 68% in the detection of cardiomyopathies and the most reliable imaging features of cardiomyopathies on standard chest CT will also be reviewed.

Learning Objectives:

1. To review the normal anatomy on standard chest CT.
2. To learn about the CT signs of various cardiomyopathies.
3. To learn about CT performance for the diagnosis of cardiomyopathy.

A-258 11:03

B. Coronary artery disease

M. Williams; *Edinburgh/UK (michelle.williams@ed.ac.uk)*

The heart and coronary arteries can be identified on imaging performed specifically to assess the heart and also on imaging of the chest performed for other reasons. Normal imaging coronary artery anatomy will be reviewed. Coronary artery calcification (CAC) is a marker of atherosclerotic plaque burden. CAC identified on electrocardiogram gated computed tomography (CT) is associated with an increased risk of cardiovascular morbidity and mortality. Randomised controlled trials have shown that management guided by CT coronary angiography can improve outcomes for patients with suspected coronary artery disease. CAC can also be identified on non-gated CT performed for other reasons. Calcium scoring or ordinal assessment of CAC on non-gated CT correlate with results from gated imaging. CAC on non-gated CT is associated with increased mortality in a variety of diseases, including patients with respiratory diseases. Evidence of previous myocardial infarction can also be identified on non-gated CT with features including mural thinning, fatty infiltration, and complications such as aneurysms.

Learning Objectives:

1. To review the normal coronary artery anatomy.
2. To learn about calcium scoring on non-gated CT.
3. To learn about the CT signs of healed myocardial infarction.

A-259 11:31

C. Fat and calcium in the heart

F. Pontana; *Lille/FR (francois.pontana@chru-lille.fr)*

Population ageing and other risk factors are not only associated with calcification of coronary arteries but are also likely to induce changes in the cardiac structure. These changes can be evaluated by CT and MR. Calcifications of the cardiac valves may be a sign of valvulopathy. Aortic valve calcium scoring by CT is useful to estimate aortic stenosis severity when echocardiography is not feasible or not conclusive. Physiological age-related fat deposits within the myocardium or the atrial septum are frequent and must not be misreported as pathological. Benign or more rarely malignant cardiac tumors may present fatty component. More recently epicardial adipose tissue seems to be a new cardiac risk factor quantifiable by imaging.

Learning Objectives:

1. To learn about physiologic changes.
2. To review the main causes of fat and calcium.
3. To learn how to differentiate pathologic from physiologic images.

10:30 - 12:00 **Room M 5**

E³ - ECR Academies: Update on Hepatobiliary Imaging

E³ 620

Characterisation of focal liver lesions

A-260 10:30

Chairperson's introduction

C. Stoupis; *Männedorf/CH (c.stoupis@spitalmaennedorf.ch)*

One of the most important focus of current liver imaging techniques is the potential to characterize liver lesions, facilitating the final diagnosis and avoiding unnecessary biopsies. Upon detection of a focal liver lesion on a routine imaging study, the question of characterization arises and may times the differentiation between a benign and a malignant lesion can be challenging. In this session, the important role of current imaging techniques will be discussed, reviewing typical imaging appearances of liver lesions, targeting to their underlying pathology; the differential diagnosis of hypervascular lesions, fat containing or fibrotic lesions, will be discussed, to provide helpful information to approach to correct diagnosis.

A-261 10:35

A. Hypervascular lesions

R. Manfredi; *Rome/IT (riccardo.manfredi@unicatt.it)*

Liver parenchyma is fed by both the hepatic artery and portal vein; classical hepatocellular carcinoma (HCC) is usually fed by the hepatic artery only. Therefore, imaging of hepatic blood flow, including arterial and portal venous flow, is important for diagnosing liver tumours. Dynamic computed tomography (CT) and magnetic resonance imaging (MRI), have been developed to evaluate hepatic blood flow. In particular, dynamic CT or MRI are essential for diagnosis and characterisation of liver tumours. Moreover, MRI with tissue-

specific MR contrast media and enhanced ultrasonography with real-time high-spatial-resolution imaging are clinically available. Hypervascular liver tumours may be both benign and malignant being important to avoid unnecessary interventions for benign lesions. There are many types of benign liver tumours that may have typical and atypical imaging features, therefore, describe an approach to distinguishing between benign and malignant hepatic lesions may help in clinical practice. Dynamic imaging is helpful in diagnosing hypervascular pseudotumors, such as focal nodular hyperplasia, and nodular lesions associated with alcohol-induced hepatitis, from hepatocellular carcinoma. There are also some hypervascular malignant tumours, such as cholangiocarcinoma, cholangiocellular carcinoma, mixed type tumours, and metastatic liver tumours, which also required differentiation from HCC. Imaging information enables us to deliver precise diagnoses, but some benign tumours are still difficult to differentiate from malignant lesions. In such cases, patients require invasive examinations, such as biopsy.

Learning Objectives:

1. To understand the imaging techniques to characterise focal liver lesions.
2. To get familiar with the typical and atypical imaging features of hypervascular lesions including haemangioma, focal nodular hyperplasia and liver cell adenomas.
3. To be able to differentiate benign hypervascular lesions from malignant ones.

A-262 11:03

B. Fat-containing lesions

O. Benjaminov; *Petach Tikva/IL*

"no abstract submitted"

Learning Objectives:

1. To list the wide spectrum of fat-containing lesions of the liver.
2. To be able to identify the imaging features of fat-containing liver lesions.
3. To describe the patterns of fatty change within hepatic neoplasms, in order to use them for differential diagnosis.

A-263 11:31

C. Fibrotic lesions

V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Fibrotic lesions of the liver are defined by tumours that have a fibrous stroma. The most common fibrotic tumours are represented by liver metastases in particular of colorectal origin and intrahepatic cholangiocarcinoma. Less common fibrotic tumours are fibrolamellar carcinoma, epithelioid hemangioendothelioma, and solitary fibrous tumours. On contrast-enhanced CT or MR imaging, the fibrotic tumours share common findings such as delayed and persistent enhancement, and capsular retraction. Venous involvement when present is usually not endoluminal invasion, but encasement. On MR imaging during hepatobiliary phase, central enhancement may be seen. This lecture will review these imaging features and highlight the one enabling specific diagnosis.

Learning Objectives:

1. To be aware of the imaging techniques and contrast enhancement patterns of the fibrotic lesions.
2. To get familiar with the spectrum of fibrotic lesions in the liver and their imaging features.
3. To be able to differentiate benign from the malignant conditions.

Every step counts: imaging and treatment of peripheral arterial disease

Moderator:
C. Loewe; Vienna/AT

A-278 12:30

State-of-the-art: non-invasive imaging of peripheral arteries

T. Leiner; *Utrecht/NL (t.leiner@umcutrecht.nl)*

The diagnosis of peripheral arterial disease is made on the basis of the typical history and an abnormal ankle/brachial index (ABI). It is important to understand that imaging is only indicated when an invasive intervention is contemplated. Both CTA and MRA are highly reliable methods for depicting vascular anatomy prior to peripheral arterial intervention. Multiple meta-analyses have reported high sensitivity and specificity for the detection of angiographically significant peripheral arterial disease. In my presentation I will discuss imaging protocols and strategies to optimise both techniques in daily clinical practice.

Learning Objectives:

1. To learn about state-of-the-art technique of peripheral MRA and CTA.
2. To understand the indications for non-invasive peripheral imaging.
3. To appreciate the importance of radiological diagnosis for treatment decision making in pAOD.

A-279 13:00

Endovascular treatment in peripheral arterial disease

M. Das; *Duisburg/DE (Marco.Das@helios-kliniken.de)*

Endovascular therapies are important treatment options in patients with peripheral artery disease. Following regular treatment options like medical therapy and exercise training endovascular therapies have become the first choice in most clinical stages of the disease. While endovascular treatment used to be applied only in limited disease (TASC A/B), endovascular therapies nowadays are often seen as first choice option in almost all stages (TASC C/D). This is mainly due to the successful evolvement of experience of interventional radiologists as well as new developments in endovascular material. Percutaneous transluminal angioplasty (PTA) with plain balloons is usually the first method of choice, while balloons loaded with anti-proliferative drugs such as paclitaxel [drug eluting balloons (DEB)] are often used in restenosis. Stents are commonly used as second option or as first choice in complex lesions. Evidence has to be found when to use drug eluting stents. Stentgrafts are often used in difficult situation when acute bleeding is involved, while scaffolds are often used in long lesions in areas with a lot of movement, in which regular stents would easily be compressed or kinked. This presentation will give an overview about different endovascular techniques including indications when to use which material and provide current evidence.

Learning Objectives:

1. To learn about different possible access routes in endovascular treatment in pAOD.
2. To understand the meaning of different acronyms and terms used in pAOO treatment including PTA, DEB, stents, stentgrafts, scaffolds.
3. To appreciate the value of interventional radiology for the treatment of pAOD.

V.N. Cassar-Pullicino; Oswestry/UK

A-280 12:30

Chronic trauma: spectrum of bone response
A.H. Karantanas; *Iraklion/GR (akarantanas@gmail.com)*

Bones are able to develop adaptive mechanisms which are sensitive to their mechanical environment. Thus, bone is constantly remodeled, throughout life, by the coordinated action of bone-resorbing osteoclasts and bone-forming osteoblasts. This remodeling process serves to prevent and heal fatigue-related microinjuries due to overloading. The balance between the amount of bone resorption and formation determines whether the process of bone remodeling leads to a net loss or gain of bone mass. Chronic trauma may be applied on normal or weakened bone and on the mature or immature skeleton. The imaging findings of the resulting painful syndromes cover a wide spectrum. Chronic overload ranges from a stress reaction to a stress fracture. The former is occult and the latter rarely obvious on radiographs. Fatigue injuries result from stress on normal bone and insufficiency injuries from stress on weakened bones. Both pathomechanisms may coexist in certain groups of adults. In the immature skeleton, the repetitive injury may cause in addition osteochondritis dissecans, osteochondral lesions, physiolysis, and chronic apophysitis. Abnormal loading matched with various parameters may result in periprosthetic fractures. Bisphosphonates may induce suppression on the bone turnover, particularly in the jaw and proximal femur, resulting in osteonecrosis and insufficiency fractures. Plain films remain the first imaging modality for exploring a pain response in chronic trauma. However, very often, plain films are normal. MRI is able not only to show even subtle findings, responsible for the clinical syndrome, but also to grade lesions and matched with known risk factors to guide the treatment.

Learning Objectives:
1. To become familiar with the pathomechanisms that can affect the axial and peripheral skeleton in chronic trauma.
2. To understand the radiological manifestation of these pathological mechanisms.
3. To appreciate how to best use imaging modalities in diagnosing occult and overt injury and monitoring the response to treatment.

Artificial intelligence: a strategic view

A-979 12:30

Chairperson's introduction
E. Neri; *Pisa/IT*

A-980 12:35

Keynote lecture
E.L. Siegel; *Baltimore, MD/US*

A variety of difficult challenges in statistics can be solved best with the creation of a “machine” which can provide a simulation or model to discern patterns in a dataset and make predictions. The rapid adoption of “Deep Learning” in Diagnostic Imaging has resulted in the development of algorithms for detection, diagnosis, and quantification of medical images at an ever accelerating pace. Major successes in the application of “Deep Learning/AI” in speech recognition, self-driving cars, translation and strategic games such as Chess, Go, and Poker have resulted in major financial investments and bold and controversial predictions by “experts” about the rapidity of general adoption in Radiology and other medical imaging specialties such as pathology, dermatology, and ophthalmology. However, tremendous challenges exist in the implementation of machine learning. The current state of the art would require thousands of algorithms and many millions of imaging studies to replace more than a tiny fraction of the tasks of a diagnostic radiology and would require hundreds of thousands or millions of hours of “expert” time to tag these. Although algorithm development times have been drastically reduced, the time and effort required for testing, verification, and validation of these algorithms in clinical practice has not decreased. Regulatory bottlenecks and medico-legal issues and constraints will need change substantially for widespread adoption within the next several years or decades. Finally, Deep Learning may actually have its greatest initial success in solving non-image related challenges such as image quality, workflow efficiency, improved communication and patient safety.

Learning Objectives:
1. Describe the relationship between artificial relationship, machine learning and deep learning.
2. List the challenges associated with the adoption of a general AI programme that could interpret studies in a manner similar to a radiologist.
3. Explain the reason for the recent excitement about “AI” in diagnostic imaging when the technology has been around for many years.
4. List applications that are not related to image pixel interpretation that can benefit imaging departments that use machine learning.

A-981 12:45

Image computing in radiology
P. Suetens; *Leuven/BE*

The 1970s was the decade that “computed imaging” radically changed the field of radiology. Today “image computing” has become sufficiently mature to have a similar influence on this discipline. In this talk the principles and history of image computing will be shortly summarized and its potential will be illustrated on clinical examples of computer-assisted detection, screening, quantitative measurements, evidence-based diagnosis, early outcome prediction of therapy, and imaging biomarkers. Exploiting this new technology is a logical evolution in the context of value-based health care and should therefore not be postponed or neglected. Instead, it should be considered as an opportunity and embraced by radiologists as an indispensable tool for quality assurance.

Learning Objectives:
1. To become familiar with the principles and history of image computing (automated image analysis, artificial intelligence (AI), artificial neural networks (ANN), deep learning).
2. To learn about the opportunities of image computing in radiology.
3. To have a realistic view of the current and future role and impact of image computing to radiology.

Deep learning: basic principles
M. de Bruijne; *Rotterdam/NL (marleen.debruijne@erasmusmc.nl)*

With deep learning techniques computers can now solve some image interpretation tasks as good as - or even better than - human experts. This lecture explains the basic principles of deep learning and its application in radiology, discusses technical requirements, and presents examples of successful application of deep learning techniques in radiology.

Learning Objectives:
1. To become familiar with the basic principles behind deep learning.
2. To understand the requirements and limitations of deep learning.
3. To learn about successful applications of deep learning in radiology.

Author Disclosure:
M. de Bruijne: Grant Recipient; NWO, DFF, Vertex. Patent Holder; US8126240, US7561727, US7844090, US8811724, US7463758. Research/Grant Support; Quantib, Cosmonio.

A-983 13:15

Machine learning for analysing medical images
B. Glocker; *London/UK*

Due to an ever-increasing complexity, large volume of data and high economic pressure the interpretation of medical images pushes human abilities to the limit. Machine learning has emerged as a key technology to address some of the major challenges in medical imaging. In particular, machine learning-based algorithms can be employed to accurately extract quantitative measures such as volumes of anatomical and pathological structures from 3D medical scans, a task that is very difficult to achieve by a human expert. Additionally, ML has potential to discover new patterns of disease, identify abnormalities and extract clinically useful information from high-dimensional, multi-modal imaging data which otherwise would remain hidden. This presentation will provide an overview of the recent successes and challenges of today's machine learning approaches when applied to the automatic analysis of brain, cardiac and whole-body imaging. Particular focus is put on the interaction between

computational and clinical disciplines and we argue for the need of an even closer collaboration between these disciplines and the importance for a common language and understanding of the demands of successful employment of machine learning in clinical practice.

Learning Objectives:

1. To learn how machine learning can help to analyse medical images.
2. To appreciate the need for close cross-discipline collaboration.
3. To understand what are the key ingredients for successful use of today's machine learning technology.

Author Disclosure:

B. Glocker: Advisory Board; Definiens. Consultant; Kheiron Medical Technologies. Grant Recipient; Research Councils UK, European Research Council.

A. Inflammatory bowel disease

J. Rimola; *Barcelona/ES (jrimola@clinic.ub.es)*

Cross-sectional imaging has an established role in evaluating patients with Crohn's disease (CD) providing additional information to clinical and endoscopic assessment, which is crucial for therapeutic decision-making algorithms. Imaging findings are highly predictive of tissue inflammation and can be used in clinical practice in evaluating disease activity and identifying both stricturing and penetrating complications. Recent evidence demonstrates that cross-sectional imaging is useful for the assessment of therapeutic response and monitoring the course of the disease. The latter represents a clear advantage over endoscopy providing a more global assessment of treatment efficacy including luminal activity and disease-related complications (i.e., stenosis and fistula). The overall cross-sectional imaging techniques characteristics and benefits have driven a rapid increase in their use for CD imaging as part as routine practice in many institutions.

Learning Objectives:

1. To review the spectrum of imaging findings in inflammatory bowel disease, mainly in Crohn's disease.
2. To learn about the management options.

ESOR Session

Trends in quality education in radiology

Moderators:
B. Brkljačić; Zagreb/HR
N. Gourtsoyiannis; Athens/GR

A-283 14:00

Introduction

B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

The European School of Radiology (ESOR) is an institution, fulfilling the mission of the European Society of Radiology (ESR) in the field of education. One of its main goals is to assist in harmonising radiological education in Europe. With its wide range of activities, ESOR additionally aims to raise standards in the field of scientific radiology, extend and coordinate teaching resources worldwide and help young radiologists achieve the knowledge and skills to fulfil tomorrow's requirements.

A-284 14:05

ESOR in action 2018

A-285 14:15

The beauty of face-to-face teaching

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

Today, many ways of teaching are available. In addition to press and books, video recorded sessions and webinars play an increasing role in teaching. Advantages are many: the offer endlessly increases, access is obtained via personal equipment, distances are deleted, availability is defined by the trainee who selects recorded sessions. Face to face teaching has none of these advantages, but nevertheless remains necessary for three main reasons; (1) It is the only manner for the trainer to sample in real time the exact level of the trainees and to calibrate his teaching objectives, (2) It is the only way to install full and appropriate interactivity, and (3) communication between the teacher and the trainees goes through much more tunnels than scientific knowledge, including non-verbal communication. All of these cannot be transmitted electronically until now.

A-286 14:30

Flipped classroom: paradigm shift with pathologists

V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Flipped classroom is an instructional strategy and a type of blended learning that reverses the traditional learning environment. Residency education in radiology is individual and mostly based on image interpretation with faculty and conference teaching. Education is completed by reading textbooks and online material. Interaction with clinicians is also very important for residents and senior radiologists. Yet radiology is close to pathology and radio-pathologic correlations give many insights to radiology. The purpose of this lecture is to show that interaction with pathologists is very helpful for the two medical specialties. Examples will be provided showing that both contribute to a better understanding of the diseases and increase the diagnostic performance.

A-287 14:45

Integration of big data in radiological education

L. Martí-Bonmatí; *Valencia/ES (marti_lui@gva.es)*

Big data are challenging the way radiology is being performed and taught. In a big learning data world, rethinking our data sources and adopting a strategic approach to presenting data is crucial. Most efforts with big data and radiology relate to the discovery on new diagnostic pathways and opportunities to better diagnose and treat diseases. Access to data can help residents and radiologists define their learning goals and strategies. Medical imaging big data analysis and the use of biobanks' data recently emerged for advancing on the

study of rare diseases, the identification of early surrogate biomarkers and the development of population studies. These new aspects will change the way radiological science is being taught, as better information on new radiomic biomarkers on early disease diagnosis, disease phenotyping, disease grading, targeting therapies, and evaluation of disease response to treatment will develop. Big data results' analysis will help radiology providing new model of cooperative science to share knowledge within the scientific community; to increase production of scientific researcher contribution from radiology; to improve healthcare through image quality and radiation dose, technical and protocol comparisons and follow-up assessment of clinical guidelines; to improve the therapeutic process through the translation of research findings into clinical trials with guided imaging, assessment of imaging biomarkers endpoints, and early assessment of treatment response; to improve epidemiological knowledge of the population through the introduction of quantitative diagnostic tests markers; and to create knowledge databases from representative cases, semantic, and semiotic advanced searches.

E³ 719
Shoulder

A-288 14:00
Chairperson's introduction
A. Karantanas; *Iraklion/GR (akarantanas@gmail.com)*

Shoulder pain is a common clinical problem. A painful syndrome may result from previous trauma, chronic degeneration or rupture of tendons with or without impingement, internal derangement of the glenohumeral joint and failure of a previous operation. Imaging methods include plain X-rays, ultrasonography, MR imaging and rarely CT. Each modality has its own and distinct role depending on the clinical indication. Current indications, as well as advantages and limitations of one or more imaging methods for evaluating patients with shoulder pain, will be discussed in the following 3 lectures on common and uncommon disorders.

A-289 14:05
A. Post-traumatic
K.-F. Kreitner; *Mainz/DE (Karl-Friedrich.Kreitner@unimedizin-mainz.de)*

The most common sequelae of shoulder trauma comprise fractures of the humeral head, glenohumeral instabilities, SLAP lesions and traumatic ruptures of the rotator cuff. Conventional radiography with use of the so-called trauma series consisting of true ap, true lateral and axial views of the affected shoulder is useful in documentation of dislocations, fractures and fracture dislocations of the shoulder, their direction, the result after reduction as well as in first assessment of humeral head fractures. CT is mandatory in complex humeral head fractures for planning of the operative procedure. In instability, it delineates humeral impression fractures and defects of the bony glenoid, and thus allows for assessment of on-track and off-track lesions. Direct MR-arthrography is the imaging modality of choice especially in younger patients with glenohumeral instability and SLAP lesions due to its superior resolution of soft tissue structures. Furthermore, it enables differentiation of atraumatic and microinstabilities of the shoulder, especially when using sequences obtained in abduction and external rotation of the shoulder (ABER position). In the acute phase after shoulder trauma, unenhanced MR imaging may be sufficient due to an existing joint effusion. Precise planning of sequences are the basis for assessment of bony defects of the glenoid and humeral head, and thus MR is also capable for assessment of on-track/off-track lesions in shoulder instability. Direct CT arthrography may be an alternative for assessment of patients with glenohumeral instability and SLAP lesions when MR imaging is not available or when there contraindications for its use.
Learning Objectives:
1. To identify the most common post-traumatic entities.
2. To know the role of MR imaging, and MR arthrography (direct/indirect) and how to optimise MR protocols.
3. To differentiate post-traumatic changes from typical reasons for chronic pain.

A-290 14:33
B. Chronic pain
P. Omoumi; *Lausanne/CH (patrick.omoumi@chuv.ch)*

Chronic shoulder pain, defined as shoulder pain persisting over six months, is frequent, representing about 15% of all musculoskeletal complaints. In the work-up of chronic shoulder pain, conventional radiography is the first diagnostic modality to perform. Radiographs can reveal a wide range of common shoulder pathology that can be source of pain, including glenohumeral or acromioclavicular osteoarthritis, calcific tendinitis, indirect signs of large rotator cuff tendon tears, as well as sequelae of previous trauma. MRI is the diagnostic modality of choice to further clarify the cause of the pain. MRI has high diagnostic performance for rotator cuff tears, tendinitis, and subacromial bursitis. The diagnosis of adhesive capsulitis is made clinically, but signs of capsulitis have been described at MRI, which mostly serves at ruling out other diagnoses in case of atypical presentation. In case of chronic instability, MR arthrography should be preferred because of its higher performance in detecting labra-ligamento-cartilaginous lesions. Findings of shoulder pathology at MRI are not necessarily related to symptoms, however. For instance, as many as 50% of asymptomatic patients over 60 years old have partial or full-thickness rotator cuff tears.
Learning Objectives:
1. To identify the most common entities leading to chronic shoulder pain.
2. To know the role of MR imaging and MR interventions in the shoulder.
3. To differentiate entities leading to chronic pain from post-traumatic changes.

A-291 15:01
C. Postoperative
S. Waldt; *Munich/DE (simone.waldt@tum.de)*

Scope of this course is to discuss technical requirements and strategies concerning the interpretation of MR examinations in the postoperative setting. The quality of MR images of the shoulder obtained after surgery can be significantly impaired by susceptibility artifacts due to metallic implants and metal shavings from use of surgical instruments. The use of artefact reduction techniques, which will be summarized in this presentation, is a prerequisite for a sufficient diagnostic accuracy. Basic knowledge concerning different surgical techniques, their common complications and sources of failure are necessary to interpret MR examinations. This talk gives an overview on the most commonly performed surgical procedures that are used for treatment of shoulder instability, impingement syndromes, and rotator cuff lesions. Criteria that may be used to differentiate between normal and abnormal postoperative findings will be discussed in detail, because findings that indicate pathology in non-operated patients are often less significant and unreliable in the postoperative situation.
Learning Objectives:
1. To identify the most common postoperative changes.
2. To know the role of MR imaging and MR arthrography (direct/indirect) and how to optimise MR protocols for the postoperative patient.
3. To understand the typical appearances and complications following rotator cuff repair.

14:00 - 15:30 **Room M 5**

E³ - ECR Academies: Update on Hepatobiliary Imaging

E³ 720
Personalised medicine in liver tumours

A-292 14:00
Chairperson's introduction
B.J. Op De Beeck; *Antwerp/BE (bart.op.de.beeck@uza.be)*

Metastatic disease to the liver is one of the most common problems encountered in patients with cancer. However, not all focal liver lesions in oncologic patients are metastases. Although the true prevalence of metastatic disease is unknown, some individuals who die of malignancy will have liver metastases at autopsy. Autopsy series also reveal the presence of benign hepatic lesions in up to 52% of the general population. Imaging protocols and findings to differentiate benign lesions from metastases will be presented. Management of malignant liver lesions depends on the tumour stage, liver function reserve, and patient performance status, and requires a multidisciplinary approach for optimal treatment. Treatment options and strategies for liver tumours will be discussed including indications of ablation techniques and intra-arterial embolisation techniques and their outcome. Radiologists must become familiar with the different methods of assessing tumour response. Size criteria, including the WHO criteria and RECIST, have

served for years as methods to standardise outcomes of therapy. New evolving methods of treatment including antiangiogenic and locoregional therapy do not always cause a decrease in size. Therefore, assessment of necrosis will need to be incorporated into size-related criteria. Finally, the imaging findings of cancer therapy-induced toxicities and their adverse effects will be discussed.

A-293 14:05

A. Focal liver lesions in oncology patient

F. Caseiro Alves; *Coimbra/PT (caseiroalves@gmail.com)*

Currently, the widespread use of volumetric cross-sectional imaging methods, has led to an increased fortuitous detection of focal liver lesions in all groups especially in the oncologic context of extra-hepatic cancer patients. Since imaging techniques can now provide high spatial resolution small nodules are easily depicted posing the problem of the characterization of the so-called incidental liver lesions. The vast majority correspond to cysts, hemangiomas, benign hepatocyte-specific-cellular tutors and pseudo lesions such as focal fatty infiltration, and focal fatty sparing. Additionally, intra-hepatic vascular shunting and vascular variants can be an important source of false positives for malignancy in the oncologic setting. A particular sub-set to nodules relates to multiacinar regenerative nodules, closely linked to sinusoidal obstruction syndrome observed after chemotherapy. The scope of this lecture is to provide guidance regarding the imaging aspects that may assist to the differentiation of metastases. Emphasis will be put on a multimodality approach generally using MR as a problem solver to this important issue in current oncological practice.

Learning Objectives:

1. To be aware of the most common incidental liver lesions in patients with extrahepatic cancer.
2. To understand the imaging protocols and findings to differentiate benign lesions from metastases.
3. To be familiar with the strategies for optimising patient management of these incidental hepatic lesions.

A-294 14:33

B. Treatment options and strategies for liver tumours

T.K. Helmberger; *Munich/DE (Thomas.Helmberger@klinikum-muenchen.de)*

Primary and secondary hepatic malignancies are a common clinical issue. Considering the general oncological (isolated hepatic tumor load; prognostic benefit), and technical (size, number, location of hepatic metastases; expected hepatic functional reserve) framework surgical resection is usually considered to be the method of therapeutical choice. However, in clinical reality only 15-30 % of patients with liver malignancies may qualify for resection. In consequence, the majority of patients need other or at least modified therapeutical pathways including adjuvant or neoadjuvant chemotherapy and more and more image guided local ablative therapies. Interventional oncology (IO) provides mainly three image-guided local and loco regional cytoreductive therapeutic approaches: (1) percutaneous thermal-ablation (mainly radiofrequency and microwave ablation) with current techniques 3 cm tumors can safely be coagulated achieving 5-year survival rates of up to 50% comparable to surgical results, (2) transarterial chemo-ablation for larger, multifocal, or diffuse HCC is established and is currently getting adopted in metastatic disease. While classic (Lipiodol) TACE is worldwide still well accepted in HCC transarterial chemo-embolization with drug eluting beads (DEB-TACE) is gaining promising results with comparable response rates to classic TACE in HCC and to systemic chemotherapy in metastases, and (3) transarterial radio-embolization (TARE, SIRT) could proof its efficacy in HCC patients not suitable for TACE and in chemorefractory patients improving hepatic progression free survival. Minimal-invasive, image-guided therapies are suitable in a large number of cases and getting implemented increasingly in multimodality treatment regimens according to interdisciplinary consensus of oncologists, interventional radiologists, and surgeons.

Learning Objectives:

1. To understand the main options of tumour treatment and to be able to discuss the appropriate method for treatment given the results of imaging.
2. To recognise the indications of ablation techniques and their outcome.
3. To know when intra-arterial embolisation techniques are needed and what their outcome is.

Author Disclosure:

T.K. Helmberger: Consultant; Boston Scientific.

A-295 15:01

C. Assessment of response to treatment

V.J. Goh; *London/UK (vicky.goh@kcl.ac.uk)*

Imaging is essential to the management of cancer patients. Better assessment of disease burden, prognostication, treatment triage, and treatment response is required to improve patient outcome. For patients with liver tumours undergoing systemic or locoregional therapy, imaging provides an objective method for assessing response/non-response to therapy, allowing patients to transition to alternative therapies when therapy is ineffective. Imaging also enables therapy related adverse effects to be depicted and treated. The strengths and limitations of the different imaging modalities including CT, MRI, PET/CT, and PET/MRI will be discussed for systemic and locoregional therapies of liver tumour. The different response criteria will also be highlighted and future directions discussed.

Learning Objectives:

1. To appreciate the value of different imaging techniques and the criteria for assessment of tumour response to systemic therapy.
2. To become familiar with post-treatment imaging after intra-arterial therapies and ablation techniques.
3. To be aware of imaging findings of cancer therapy-induced toxicities and adverse effects.

Author Disclosure:

Dementia and movement disorders

A-302 16:00

A. MR contribution to diagnosis and differential diagnosis in dementia

M. Sasiadek; *Wroclaw/PL (marek.sasiadek@umed.wroc.pl)*

Imaging methods play an increasing role in diagnosing, differentiating, prognosing and follow-up of dementia. The most important imaging methods are: CT, MR, SPECT, and PET. Among them MR, including MR spectroscopy (MRS), perfusion MR (PWI), diffusion tensor imaging (DTI) and functional MRI (fMRI), appears to be the most valuable modality. Plain MR might provide important contribution to the diagnostics of dementia. The distribution of the brain atrophy indicates the specific dementia disease, e.g., hippocampal atrophy is highly suggestive of Alzheimer disease and frontotemporal atrophy-of frontotemporal dementia. There are also specific MR patterns of progressive supranuclear palsy (mesencephalic atrophy) or multiple system atrophy (cerebellar/brainstem or putaminal atrophies). Vascular dementia changes (e.g., small vessel disease, CADASIL, amyloid angiopathy) could be reliably diagnosed with MR, including MR angiography and susceptibility weighted sequences. There are also typical MR patterns of many other diseases, which may be accompanied by dementia, e.g., normal pressure hydrocephalus, multiple sclerosis, Wilson disease, Fahr disease, Creutzfeldt-Jakob disease, etc. Advanced MR techniques provide further contribution to diagnosing dementia by adding quantitative data. MRS could reveal increase of myoinositol level in degenerative diseases or of choline in multiple sclerosis. PWI shows decrease of perfusion in vascular dementia, but also in Alzheimer disease. DTI detects decrease of fractional anisotropy in white matter tracts affected by degenerative, ischaemic or inflammatory process. fMRI provides assessment of the impaired cognitive functions in dementia disorders. MR, due to the advantages described above, should be a part of routine diagnostic protocol in patients with dementia.

Learning Objectives:

1. To become familiar with imaging in different types of dementia.
2. To learn the imaging criteria for differentiation.

A-303 16:45

B. Imaging in Parkinsonism and other extrapyramidal disorders

T. Stosic-Opincal; *Belgrade/RS (stosic.tanja@yahoo.com)*

Extrapyramidal disorders can be classified as pathologies that affect basal ganglia (*caudate*, *putamen*, and *globus pallidus*), subtalamic nucleus and structures that are functionally connected with them (substantia nigra). On histological level affected tissues exhibit high level of deposits ofparamagnetic ions (presumably iron and copper) and loss of neural tissue. This is manifested in loss of volume of brain structures and dysfunction of specific neural tracts. Parkinsonism refers to any condition that causes a combination of the movement abnormalities such as tremors, slow movement, impaired speech or muscle stiffness. Beside idiopathic Parkinson's disease, a several conditions fulfill definition, such as progressive supranuclear palsy, multisystem atrophy, and corticobasal degeneration. Role of imaging techniques is assessment of structural and physiological changes caused by EPD. Magnetic resonance imaging is primary choice since it provides morphological, structural, and physiological insight in changes caused by extrapyramidal disorders. Positron

emission tomography gives additional information about physiological changes using neurotransmitters labeled with positron emitters. Computerised tomography has limited possibilities which are restricted to assessment of morphological changes.

Learning Objectives:

1. To become familiar with the different imaging modalities.
2. To learn the imaging criteria.

16:00 - 17:30 **Room C**

Chest

RC 804

Chronic obstructive pulmonary disease (COPD)

A-304 16:00

Chairperson's introduction

K. Irion; *Manchester/UK (klaus.irion@mft.nhs.uk)*

"Chronic Obstructive Pulmonary Disease (COPD) is a common, preventable and treatable disease that is characterized by persistent respiratory symptoms and airflow limitation that is due to airway and/or alveolar abnormalities usually caused by significant exposure to noxious particles or gases". "The clinical diagnosis of COPD requires the presence of a post-bronchodilator FEV1/FVC < 0.70 to be established." Both sentences above are from the 2017 Global Initiative for Chronic Obstructive Lung Disease (GOLD) Report. They probably represent the biggest challenge to the imaging diagnosis and phenotyping of COPD patients. The GOLD statements above imply that COPD cannot be diagnosed without persistent respiratory symptoms and a post-bronchodilator FEV1/FVC < 0.70: as if a persistent airflow limitation due to airway and/or alveolar abnormalities without the two criteria would not be COPD. One of the key methodological problems in quantitative CT for the assessment of COPD is that the selection of patients is tied up to the above criteria, where correlations with pulmonary function tests are taken as the references for the diagnostic capability of CT or MRI. To learn how to avoid the progression of emphysema and/or chronic airway disease to a symptomatic phase when the FEV1/FVC reaches the critical level (< 0.70) for a COPD diagnosis, the medical community should first accept that a significant extent of the anatomical changes that lead to various degrees of chronic airflow limitation (i.e. COPD) will be present much before the current threshold set as a diagnostic criteria of COPD is met.

Session Objectives:

1. To describe the current challenges of COPD phenotyping.
2. To learn how to personalise management in COPD.
3. To understand the methodological problems at the stages of selection of patients.

A-305 16:05

A. CT phenotyping and visual assessment

P.A. Grenier; *Paris/FR (philippe.grenier@aphp.fr)*

COPD is a slowly progressive obstructive airway disorder resulting from an exaggerated inflammatory response to cigarette smoking and air pollution that ultimately destroys lung parenchyma and induces irreversible reduction in caliber and number of small airways. Both phenomena [emphysema and small airway disease (SAD)] are responsible for airflow limitation. Because often SAD precedes lung destruction, patients having equal impairment of lung function may present different morphologic appearances on CT scans. Although quantitative CT is useful for identifying and sequentially evaluating the extent of emphysematous lung destruction, changes in airway walls, and expiratory air trapping, visual assessment of CT scans is important to describe patterns of altered lung structures in COPD. Emphysema is classified as centrilobular (subclassified as trace, mild, moderate, confluent, and advanced destructive emphysema), panlobular and paraseptal (subclassified as mild of substantial). Airway disease is commonly found with all forms of emphysema but also commonly occurs in the absence of emphysema as a predominant expression of COPD. The CT features of bronchial disease include thickening of the walls of segmental and subsegmental airways. CT features of SAD include peripheral centrilobular micronodular opacities (inflammatory SAD) and gas trapping on expiratory CT (obstructive SAD). Associated features may be seen on large airway disease (tracheobronchomalacia, saber sheath trachea, tracheobronchial outpouching/diverticula). Interstitial lung abnormalities include patchy ground glass abnormality and/or mid subpleural reticular abnormality. Other associated features include pulmonary arterial enlargement suggesting pulmonary hypertension, and bronchiectasis

Learning Objectives:

1. To learn about imaging-based phenotypes.
2. To understand the strengths and limitations of visual assessment.
3. To review the phenotypes and comorbidities approachable by CT.

A-306 16:28

B. Quantitative imaging biomarkers

J.B. Seo; *Seoul/KR (seojb@amc.seoul.kr)*

With excellent spatial and contrast resolution, CT can be used as an important tool to evaluate quantitative imaging biomarkers of COPD. The extent of low attenuation area and bronchial wall thickening at segmental and distal level on volumetric CT scan acquired at suspended inspiration state are commonly used as useful markers for evaluating the severity of emphysema and airway wall inflammation, respectively. The clinical values of these two imaging biomarkers are as follows: (1) Many studies have proved that the extent of emphysema and bronchial wall thickening are independently related with the degree of airflow limitation, (2) The extent of emphysema is correlated with other clinical parameters such as osteoporosis, exercise capacity, respiratory symptoms, and most importantly with BODE index, (3) Both parameters may be useful in subgrouping/phenotyping of patients, prediction of treatment response, disease progression, and exacerbation. The extent of air trapping can be assessed by quantitative volumetric expiratory CT or by comparing the density changes on matched inspiratory/expiratory CT. Other potential imaging biomarkers on CT include peripheral vascular changes, size and shape distribution of emphysema holes, and so on. Despite these advances, several important challenges remain before these quantitative imaging biomarkers can be used in clinical practice. In patient side, variation in inspiratory and expiratory lung volumes is most important issue, which has a major influence on lung attenuation values. Technically, variation in measured CT attenuation across scanner manufacturers and models, differing reconstruction kernels, and varying methods of automatic exposure control should be considered.

Learning Objectives:

1. To learn about the COPD biomarkers that may be helpful for managing COPD patients.
2. To understand the potential role for quantitative imaging in identifying imaging phenotypes.
3. To appreciate the recent development of quantitative imaging methods.

Author Disclosure:

J.B. Seo: Shareholder; Coreline Soft Co. Speaker; Siemens / Guerbet.

A-307 16:51

C. Is there a role for MRI?

B.J. Jobst; *Heidelberg/DE*

Today, computed tomography (CT) is the imaging modality of choice for the assessment of pulmonary diseases, but it requires ionizing radiation. Unfortunately, magnetic resonance imaging (MRI) of the lung is complicated by low proton density and high magnetic susceptibility of the alveolar structures, decreasing the MR-signal obtained from the lungs. Hence, the depiction of the pulmonary morphology is hampered by low contrast and spatial resolution. Besides, respiratory and cardiac motion artifacts have impact on image quality. In the recent years, novel MRI techniques based on parallel imaging and advanced gating techniques have been developed and implemented in routine MRI protocols, which lead to improved depiction of pulmonary structures. Innovative MRI techniques such as ultra-short echo time acquisitions (UTE) further improve the structural characterization of airways and parenchyma. Although MRI is still inferior to CT concerning the depiction of subtle morphological features, MRI offers a broad spectrum of functional acquisitions, especially for perfusion, ventilation, and respiratory mechanics. Lacking ionizing radiation, MRI can be repeated as often as necessary and represents a powerful instrument for longitudinal observations. In this context, MRI provides quantitative and semi-quantitative biomarkers which may be helpful in the evaluation of the course of lung disease as well as monitoring of the therapeutic response.

Learning Objectives:

1. To learn about the morpho-functional pulmonary measurements achievable with MRI.
2. To review the various methodological approaches.
3. To appreciate current and forthcoming developments.

17:14

16:00 - 17:30 **Room O**

Special Focus Session

SF 8a

CT examination of pregnant patients: a dilemma for the radiologist and the mother

A-308 16:00

Chairperson's introduction

V. Gershan; *Skopje/MK (vesna.gershan@pmf.ukim.mk)*

CT examinations of pregnant patient when the fetus is within the primary beam are challenging for radiologist and mother, as well. Two main scenarios in CT examination of pregnant patient are possible. The first one is so call inadvertent exposure, while patient is scanned and pregnancy is still unknown. The second one is when there are strong CT indications due to non-obstetrical emergencies like as appendicitis, renal colic, ovarian torsion, hemorrhagic ovarian cysts, trauma, and pulmonary embolism. Explanation of benefits vs. risks to mother could be challenging and it is good practice to obtain informed consent before proceeding with the examination. If CT examination is duly justified, then an acquisition protocol that ensures diagnostic image quality at lowest possible dose should be applied. There are several dose reduction techniques like is decreasing of kV, mA, limit the field of view, increasing of pitch, using of iterative reconstruction techniques, etc. There are several models for assessment of fetal dose, like is MC simulated whole-body or individual organ doses, patient-specific voxel-based computational phantoms or dose assessment using of dose conversion factor and exposure parameters. Delivered dose to the fetus from a single diagnostic abdominal CT is highly unlikely to exceed the estimated threshold dose of 100 mGy for induction of malformations. Estimated radiation risk depends on the dose, gestational age and applied risk model, and for example, for 50 mGy dose it can be 1 in 909 to 1 in 334. All these aspects will be addressed under the current session topics.

Session Objectives:

1. To give an overview of radiation risk associated with the CT examination of pregnant patients.
2. To learn how to optimise CT imaging of pregnant patients.
3. To suggest actions for dose management of pregnant patients in CT.

A-309 16:05

Radiation risks vs clinical benefits

M. Prokop; *Nijmegen/NL*

"no abstract submitted"

Learning Objectives:

1. To give an overview of radiation risks of pregnant patients during CT examinations.
2. To learn about the choice of the modality.
3. To learn how to manage risk in the CT examination of pregnant patients.

A-310 16:23

How to reduce radiation dose and keep CT diagnostics

M. Kortesniemi; *Helsinki/FI (mika.kortesniemi@hus.fi)*

A developing fetus has an increased sensitivity to ionizing radiation exposure. Therefore, dose monitoring and optimisation of CT exposures of an expecting mother is important. The typical clinical indications related to CT scans during pregnancy include pulmonary embolism, appendicitis, and trauma. In these situations, the fetus can be fully or partially in the primary CT scan range or in its immediate vicinity. In pulmonary embolism scans, increased distance of the fetus from the scan range serves as a practical tool for fetal dose optimisation. Modern CT scanners have several technical tools for dose reduction. Those tools include automatic tube current modulation, automatic tube voltage selection, dynamic z-collimation and iterative reconstruction algorithms. When used together in a proper way, they may provide tens of percentages of dose reduction for the mother and the fetus, depending of the clinical indication and individual patient characteristics. The actual purpose is not to use as little radiation as possible but to achieve a maximum benefit-to-risk ratio for the patient (mother and fetus). Adequate image quality for reliable diagnosis must always be reached. Otherwise the dose is unnecessary, however, small it could be.

Learning Objectives:

1. To give an overview of optimisation methods and techniques in CT.
2. To describe the method of choice in particular cases.
3. To learn about examples for different clinical requests.

A-311 16:41

Dosimetry methods available

J. Damilakis; *Iraklion/GR (damilaki@med.uoc.gr)*

Several methods for the estimation of conceptus dose from CT examination have been developed during the last years. Twenty four patient models selected to represent a range of gestational ages were created using image data from a group of pregnant patients who had previously undergone abdominal and pelvic CT examination (Radiology 2008, 249, 220-227). The authors provide an equation for the estimation of conceptus dose. A methodology has been created for the accurate estimation of conceptus dose from CT examinations performed on pregnant patients during the first weeks of gestation (Radiology 2010, 257, 483-489). This period of early pregnancy is particularly important because the conceptus is considered to be sensitive to radiation in the period of organogenesis. A two-variable equation provided a relationship among normalised conceptus dose, body perimeter and skin-to-conceptus-distance. A general-purpose Monte Carlo simulation code and mathematical phantoms simulating pregnancy during all trimesters of gestation were used to provide normalised dose data for conceptus dose estimation from any CT examination performed in the trunk of the pregnant patient (Medical Physics 2010, 37, 6411-6420). CoDE (conceptus dose estimation) online software tool allows; (a) calculation of conceptus radiation dose and associated risk from X-ray examinations performed on the expectant mother and (b) anticipation of conceptus dose for the pregnant employee who participates in fluoroscopically-guided interventional procedures. CoDE is available free of charge.

Learning Objectives:

1. To provide information about the available conceptus dosimetry methods in CT.
2. To understand the accuracy and limitations of the dosimetry methods.
3. To learn how to estimate radiation dose in pregnant patients during CT examinations.

A-312 16:59

Dose and risk communication to doctors and patients

P. Gilligan; *Dublin/IE (PGilligan@materprivate.ie)*

Pregnant patients are recognised as a high risk and sensitive group in radiation protection. There may be perceived conflict between the benefit of the required treatment of the mother and the risk to the foetus. Patient focussed care requires open disclosure of any risks. The implications of these risks must be well understood by the patient. Radiation risks in the foetus can be complex, dependent on the modality, procedure type, radiation dose, and stage of pregnancy. The communication of appropriate risks to the mother particularly in an emergent context can be challenging. Experience has shown that preparation of accurate and well contextualised information assists the patient and their care providers to make appropriate health care decisions. The environment, context, timing delivery of such information is also important. Patients are reassured when good radiation protection culture is evident. The use of methods to identify possible pregnancy and minimise the risks in early pregnancy have proved divisive and have led to divergent practices and opinions even among experts. Inadvertent exposure in pregnancy occurs in most hospitals on an occasional basis. Follow up with such patients, particularly after systems failures, requires a tailored approach. This talk examines the possible risks from diagnostic procedures during pregnancy and the contexts and environments in which such information is delivered. It looks at both pre planned foetal exposures and inadvertent exposures. The multidisciplinary approach involving radiology is essential in providing accurate and relevant information on which medical decisions can be based.

Learning Objectives:

1. To provide information about the latest scientific knowledge about conceptus risk.
2. To learn how to manage incidents and accidents involving pregnant patients in CT.
3. To learn how to communicate to doctors and patients about dose and risk.

17:17

Panel discussion: CT during pregnancy: what are the suggested actions for patient dose management?

16:00 - 17:30 **Room N**

Head and Neck

RC 808

Pitfalls in interpretation of head and neck disease

Moderator:
S. Robinson; Vienna/AT

A-313 16:00

A. Anatomical variants without clinical consequence
F.A. Pameijer; *Utrecht/NL (f.a.pameijer@umcutrecht.nl)*

Variant: “Something that is slightly different." Imaging methods can provide an extraordinary amount of useful data to specialists treating head and neck (cancer) patients. It is crucial that these data are used to full advantage of individual patients. The most important factor in this process is mutual cooperation between the physicians in charge of patient care and the diagnostic imaging specialist. Anatomical variants in the head and neck are frequently encountered and may result in interpretation problems for the radiologist: usually, anatomical variants are without clinical consequence. However, normal variants may simulate disease. If not recognised, normal variants (or pseudolesions) may lead to unnecessary interventions. The presentation aims to familiarise general radiologists, who have an interest in head and neck imaging, with common anatomical variants encountered on head and neck CT and MR studies. Many examples from daily practice will be discussed.

Learning Objectives:
1. To gain insight into the great variability of head and neck anatomy.
2. To be able to recognise pseudo lesions.

A-314 16:30

B. Anatomical variants posing surgical risks
D. Farina; *Brescia/IT (nappaje@yahoo.it)*

Several anatomic variants may pose a threat during surgery. A large part is found in the sinonasal region, basically due to the widespread use of endoscopy which, inherently, provides the operator with narrow accesses and limited exposure of submucosal anatomic structures. Onodi cell is probably the most feared anatomic threat, because if not correctly indicated by the radiologist and identified by the surgeon, it generates a high risk of disastrous intracranial penetration. Similarly, bone dehiscence of the lamina papyracea of the ethmoid increases the risk of iatrogenic damage, mainly of intrinsic ocular muscles. The inferior alveolar nerve is at high risk of surgical damage during molar teeth extraction, particularly when the curved apices of roots embrace the inferior wall of the nerve canal. In the neck the main threats are related to anomalous course of major vessels: not infrequently the common and/or internal carotid artery display a medialized course reaching the lateral aspect of the pharyngeal wall or even protruding in the retropharyngeal space towards the midline. Simultaneous medial deviation of the arteries on both sides is referred to as kissing (common or internal) carotids. The risk in these eveniences are mainly related to the possible effects of a deep biopsy performed by an unaware surgeon. At the cervico mediastinal junction, vascular rings may embrace the trachea or the oesophagus and, consequently, pose a threat during intubation or tracheostomy.

Learning Objectives:
1. To learn about structures at risk during functional endoscopic sinus surgery (FESS).
2. To become familiar with vascular variants in the head and neck.
3. To appreciate surgical anatomical landmarks in the head and neck.

A-315 17:00

C. Distinct head and neck disease or systemic disease?
M.G. Mack; *Munich/DE (m.mack@radiologie-muenchen.de)*

Head and neck manifestations of systemic disease is characterized by a multitude of maladies that have manifestations in the head and neck. This lecture relates commonly encountered head and neck symptoms and signs to an array of diseases and disorders that should be considered in the differential diagnosis. During this lecture, systemic disorders with head and neck manifestation (e.g., Sjögren`s syndrome, Adamantiades-Behcet's disease, granulomatous disease like Wegener`s granulomatosis), infectious disease (e.g., tuberculosis fungal rhinosinusitis and HIV related disease), malignant disease (e.g., lymphoma, myeloproliferative disorders and leukemia, malignant melanoma, histiocytosis, sickle cell anaemia, and rhabdomyosarcoma) or other systemic disorders (e.g., Paget`s disease of bone and fibrous dysplasia) will be presented.

Learning Objectives:
1. To recognise head and neck manifestations of systemic disease.
2. To categorise lesions into different pathologic entities.

Imaging of the prostate

Moderator:
P. Puech; Lille/FR

A-316 16:00

A. MRI diagnosis of prostate cancer
A.R. Padhani; *London/UK (anwar.padhani@talk21.com)*

The PI-RADS v2 analysis system for mpMRI detection of prostate cancer was developed by expert opinion, using the observed performance and utilization of the PI-RADS v1 system. Test performance of PI-RADS v2 in research and clinical practice has been shown to an improvement over v1, maintaining high accuracy compared to systematic TRUS biopsies for prostate cancer diagnosis. PI-RADS v2 fails to detect all cancers, but does detect the majority of tumors capable of causing patient harms; test performance is dependent on the definition used to identify clinically significant disease. Good performance can be attained in practice provided that the quality of the diagnostic process can be assured (including MRI scanner, PI-RADS compliant imaging protocol, biopsy procedures, image interpretation, reporting, and communication), backed up by the robust training of radiologists and urologists working jointly within multidisciplinary teams. This talk summarises the accuracy, strengths, and weakness PI-RADS v2, discusses potential pathway implications and outlines opportunities for improvements and future developments.

Learning Objectives:
1. To become familiar with the different components of mpMRI of the prostate (T2, DWI and DCE).
2. To discuss the role of PI-RADS version 2 in the diagnosis of clinically significant prostate cancer.
3. To understand the correct indications and guidelines on the use of mpMRI.

Author Disclosure:
A.R. Padhani: Speaker; Siemens Healthineers, Janssen, Sanofi.

A-317 16:30

B. MRI staging of prostate cancer
G.M. Villeirs; *Ghent/BE*

Staging involves the correct assessment of the local tumour situation (T), involvement of lymph nodes (N) and of distant metastases (M). According to the European Association of Urology (EAU) Guidelines, assessment of lymph nodes is only useful in patients with a PSA >10, Gleason score >7, >cT2b. Imaging can be performed using the well known size criteria (round node >8mm, short axis of oval node >10mm) on CT or MRI, but this approach clearly lacks both sensitivity and specificity. Diffusion-weighted MRI incorporating morphologic features, MR-lymphangiography using ultra-small particles of iron oxide (USPIO), and nuclear medicine techniques such as choline- and PSMA-PET/CT offer higher sensitivity and specificity, but cannot (yet) replace the current gold standard (pelvic lymphadenectomy). The search for distant metastases (T) primarily involves skeletal assessment in patients at increased risk (PSA >20, Gleason >8, cT3-cT4). The current gold standard is the bone scan, but whole body MRI and new PET tracers seem to be on track to replace the bone scan as gold standard. In the absence of N+ or M+ disease, MRI can be used to assess the local status (T). High-resolution T2-weighted images are used to assess potential extracapsular extension or seminal vesicle invasion. Although this is a recommended approach according to the EAU guidelines, the accuracy of such T-staging is currently still quite variable. However, standardization of scanning techniques for staging and standardization of diagnostic criteria may solve this problem.

Learning Objectives:
1. To understand the current role of prostate MRI.
2. To learn how to optimise imaging and reporting.
3. To illustrate the staging approach.

A-318 17:00

C. Imaging of PSA recurrence

H.-P. Schlemmer; *Heidelberg/DE (h.schlemmer@dkfz.de)*

Ca. 40% of prostate carcinoma patients develop biochemical recurrence after radical prostatectomy and radiotherapy, which are nevertheless in accordance to current guidelines first-line treatment options for patients with organ-confined prostate cancer. In the situation of PSA recurrence, early detection and precise localization of cancer is essential for individualized treatment decision making and for prognosis assessment. Early detection of local recurrence after radical prostatectomy is particular challenging as salvage radiotherapy is feasible with curative intention only in case of very low PSA serum levels. Conventional TRUS has limited sensitivity and specificity for detection of local recurrence. Multiparametric MRI (mpMRI) has been shown to be superior for detection of local recurrence, although early detection of small cancer foci is also significantly limited. Concerning early detection of lymphatic cancer spreading CT and MRI are significantly limited. Highest sensitivity for cancer detection is achieved by PET, although it is important to note that the accuracy significantly depends on the used radiotracer. In clinical routine most frequently C-11 or F-18 choline and Ga-68 or F-18 PSMA PET/CT is performed. PET/MR imaging provides additional advantaged by combining the highest sensitivity of PET with superior anatomical referencing as well as soft tissue and bone marrow assessment by MR. This lecture will provide an overview about the currently available imaging methods for detection of recurrence in case of PSA relapse. Their clinical relevance will be discussed against the background of the potential therapy options.

Learning Objectives:

1. To understand the clinical need and indications for imaging in patients with PSA recurrence.
2. To discuss the optimal imaging modalities for detection of local recurrence.
3. To illustrate the potential of whole-body MRI and new radiotracers for detection of distant recurrence.

16:00 - 17:30 **Room L 8**

EIBIR Session

EIBIR Research Session: European imaging researchers united in diversity

A-319 16:00

Chairperson's introduction

G.P. Krestin; *Rotterdam/NL*

The European Institute for Biomedical Imaging Research (EIBIR) is an organization aiming to coordinate research in, and innovation of, biomedical imaging technologies within Europe and support the dissemination of knowledge with the ultimate goal of improving prevention, detection, diagnosis, and treatment of disease. EIBIR promotes networking activities within Europe and ensures the pooling of resources among members to promote a culture of cooperation between them. EIBIR also generates publicity concerning new opportunities for access, provide dissemination of knowledge, and training courses for potential users. In the competitive landscape of European funding, EIBIR has enabled numerous consortia to successfully apply and perform large collaborative research projects. Recently within the Horizon 2020 framework EIBIR is supporting a number of innovative ventures related to cancer research. The expertise that the office has built up over the past years did not only provide a competitive edge in obtaining funding, but will also guarantee the dissemination of the promising results of these projects. This session should provide information on how the EIBIR services can help the researchers in their endeavors and give an overview of three successfully running projects aiming to have an impact in cancer diagnostics and therapy.

Session Objectives:

1. To learn about major EU-funded research projects related to cancer imaging in which EIBIR is a partner.
2. To appreciate the impact these projects will have on cancer diagnosis and care.
3. To understand the role of the European Institute for Biomedical Imaging Research (EIBIR) in such projects.

A-320 16:10

Laser and Ultrasound Co-analyser for Thyroid Nodules (LUCA) Project: latest results

U. Weigel; *Barcelona/ES (udo.weigel@hemophotonics.com)*

Near-infrared diffuse optics is receiving increasing interest in cancer diagnostics for its capability to measure unique and complementary parameters based on hemodynamics (microvascular blood flow, blood oxygen saturation and blood volume), tissue structure (cell density, size) as well as water and other chromophore concentrations in combination with established imaging technologies in a non-invasive, relatively fast and safe procedure. After description of the background physics, the basics of the technology, and different approaches for probe development, a particular focus will be given to hybrid technologies that combine diffuse correlation spectroscopy (DCS) and diffuse optical time resolved spectroscopy (TRS) for biomedical applications. Finally, I will introduce and report the present status of LUCA (http://www.luca-project.eu), a European project, aiming at development and validation of a combined ultrasound- optical prototype for thyroid cancer diagnostics.

Learning Objectives:

1. To learn about the application of diffuse optics to human tissue.
2. To understand the technology of LUCA.
3. To learn about the project's status and its initial results.

A-321 16:30

Testing hybrid MR/PET (HYPMED) device for enhanced breast diagnosis in a multicentre clinical trial

T.H. Helbich; *Vienna/AT (Thomas.Helbich@meduniwien.ac.at)*

With a consortium of ten partners from across Europe, including major universities, research institutes, SMEs and major industry corporations, the HYPMED project brings together a wide range of expertise. In this project “Digital Hybrid Breast PET/MRI for Enhanced Diagnosis of Breast Cancer (HYPMED)”, we aim to develop a hybrid system combining MRI and PET that facilitates earlier diagnosis of breast cancer and personalized therapy control. To achieve this, we are designing and testing a combined PET-radiofrequency (RF) insert that can be connected to a conventional clinical MR scanner, transforming the device into a high-resolution PET/MRI hybrid system. This PET-RF insert can be used to identify even the smallest breast cancer foci and better characterize the cancer, as well as its response to therapy. Another key benefit of this technology for patients is that the radiation dose of the new technology will, unlike other PET-MRI examinations, be comparable to the low dose of a regular digital mammogram. Apart from merely diagnosing the presence or absence of breast cancer, HYPMED will improve the non-invasive biological classification of breast cancers, in other words it will improve the assessment of its aggressiveness, therefore facilitate better selection of appropriate treatments. In a bench to bedside approach HYPMED includes several work packages spanning the spectrum from designing to clinical testing.

Learning Objectives:

1. To learn about a multicentre clinical trial of the project's hybrid MR/PET insert.
2. To understand how the trial will validate the project's ground-breaking MR/PET technology.
3. To appreciate the complexity of undertaking such a multicentre clinical trial at European level.

A-322 16:50

Smart Optical and Ultrasound Diagnostics of Breast Cancer (SOLUS) Project: aims and objectives

P. Taroni; *Milan/IT (paola.taroni@polimi.it)*

Due to the high false-positive risk of mammography, there is an unmet clinical need for higher specificity in breast cancer imaging following screening. Photonics and ultrasound-based imaging are both non-invasive and have, to some extent, been proven effective in characterising breast lesions, discriminating malignant from benign ones. However, up to now, no individual technique proved to be adequate in replacing conventional methods. The EU-funded research project SOLUS will develop innovative photonic components, combining photonics with ultrasound techniques, and clinically validate the resulting multi-modal approach in breast cancer patients. To meet the clinical need, SOLUS develops novel pulsed laser sources and high dynamic range single-photon detectors, providing unprecedented sensitivity and depth penetration, making diffuse optical tomography feasible in real clinical settings. For the first time, this approach will allow; (1) a comprehensive quantitative characterisation of breast tissue, including composition (water, lipid, collagen content) and functional blood parameters as provided by diffuse optical tomography; (2) morphologic information from B-mode ultrasound imaging; and (3) mechanical parameters (stiffness) from shear wave elastography. Subsequent multi-parametric data analysis, using new reconstruction algorithms, allows high specificity in the discrimination between borderline malignant and benign breast lesions. SOLUS is a trans-disciplinary, 48-month

project that brings together 9 partners (industry, academia and hospitals) from 5 countries.

Learning Objectives:

1. To understand how the system developed by the project will combine optical methods with ultrasound.
2. To appreciate how the technology developed by the project will improve the ability to differentiate between benign and malignant lesions.

A-323 17:10

EIBIR's role in imaging research projects

P. Zolda; *Vienna/AT (pamela.zolda@myesr.org)*

Due to shrinking national research budgets, European researchers more frequently apply for EU funding sources. However, navigating through the rules and regulations of large EU projects while simultaneously carrying out innovative research with partners from across Europe can be challenging. Thus, multidisciplinary and multinational consortia require professional project management to ensure the successful accomplishment of their project goals. The European Institute for Biomedical Imaging Research, EIBIR, is a non-profit organisation founded by the European Society of Radiology and supports researchers and industry partners in the coordination of biomedical imaging research throughout Europe and beyond. EIBIR offers expert advice, professional project management and coordination, dissemination and exploitation services for dedicated international collaborative research projects. The EIBIR services also include advice on funding opportunities, identifying consortium partners and proposal writing support by a team of experienced writers with knowledge of the European Commission's requirements. Partners also benefit from EIBIR`s established, extensive network for dissemination. Through the large and diverse landscape of network members, shareholder organisations, industry partners and media contacts the conducted research is be widely and rapidly communicated. EIBIR is currently partner and/or coordinator of seven projects that are funded under Horizon 2020, the biggest EU Research and innovation programme. The offered support relieves researchers of the administrative burden, allowing them to focus on the scientific aspects and thereby ensuring the best possible outcome for the project.

Learning Objectives:

1. To learn about EIBIR and its services for researchers.
2. To understand project management and dissemination activities of European projects.
3. To appreciate how EIBIR can support your research project.

16:00 - 17:30 **Room E1**

Special Focus Session

SF 8b

My three top tips for breast imaging

A-324 16:00

Chairperson's introduction

M.H. Fuchsjäger; *Graz/AT (michael.fuchsjaeger@medunigraz.at)*

This session will provide practical information on the fundamental tips and tricks of the most renowned European breast radiologists for everyday clinical practice with a focus on a tertiary setting. All relevant topics from screening with tomosynthesis and automated ultrasound to image-guided interventional techniques as well as post-therapy evaluation will be addressed. Attendees will be able to learn and experience the most important aspects for successfully performing and avoiding common pitfalls at diagnostic and interventional breast examinations.

Session Objectives:

1. To appreciate fundamental tips and tricks of the most renowned European breast radiologists for clinical practice.
2. To acknowledge the single most important aspects for successfully performing breast examinations.
3. To learn how to avoid common pitfalls in breast radiology.

A-325 16:05

Screening with tomosynthesis

S. Zackrisson; *Malmö/SE (sophia.zackrisson@med.lu.se)*

It is well known that digital mammography (DM) has limitations in detecting breast cancers, especially in women with dense breasts. Studies show that up to 30% of the cancers in screening may not be detectable with DM, mainly due to the overlapping tissue effect, i.e., dense breast tissue or the so-called anatomical noise obscuring the tumor on the two-dimensional images. Digital breast tomosynthesis (DBT) is an emerging pseudo 3D technique in breast imaging based on the acquisition of low-dose projections over a limited arc, reconstructed into a volume of generally up to 50 images of the breast. This reduces the overlapping tissue effect and hence tumors may be more easily detected with DBT. The published population based European screening trials with DBT (alone or in combination with DM or synthetic DM) show incremental breast cancer detection attributed to DBT in the range of 2.2 to 2.7 cancers per 1000 screens. In other settings, mainly in the US, retrospective studies with the combination of DBT and DM has been conducted with large reductions in recall rates as the main effect. In this presentation, the use of DBT in screening will be presented and discussed in terms of screening performance measures and what needs to be further investigated before DBT can fully implemented in routine screening.

Learning Objectives:

1. To understand why tomosynthesis is better than mammography for breast cancer screening.
2. To appreciate the current scientific evidence of tomosynthesis in screening.
3. To acknowledge what further steps are needed before implementation in screening.

Author Disclosure:

S. Zackrisson: Speaker; Speaker's fees and travel support from Siemens Healthineers.

A-326 16:11

Automated breast ultrasound

R.M. Mann; *Nijmegen/NL (r.mann@rad.umcn.nl)*

ABUS is a relatively novel automated ultrasound technique that enables volume scanning of large portions of the breast. In fact the entire breast can usually be imaged in 3 to 5 volumes. The standardised approach for image acquisition enables remote interpretation and therefore, the reporting radiologist is no longer required to obtain the images him/herself. As such specific artefacts such as non-black cysts and wandering shadows (due to a suboptimal angle of the transducer to the coopers ligaments) need to be understood as these cannot be prevented. A further advantage of ABUS is the possibility to perform multilane reconstructions of the image volume. Particularly the coronal reconstruction is useful. Not only because it reduces the amount of images to be evaluated substantially, but also because in the coronal plane often a retraction pattern becomes evident around malignant lesions. Therefore, it improves diagnostic accuracy. ABUS has been developed as a screening tool and seems to have most benefit as a supplemental screening tool in women with dense breasts on mammography. It also improves ultrasound staging of breast cancers as the extent of especially multifocal and diffuse lesions are easier grasped than with single ultrasound shots. A further possibility is the evaluation of lesions treated with me-adjuvant chemotherapy, however, data for this indication are limited.

Learning Objectives:

1. To recognise artefacts that are specific to ABUS.
2. To appreciate the value of multiplanar reconstruction and the coronal spiculation pattern.
3. To gain insight into possible indications for ABUS.

Author Disclosure:

R.M. Mann: Advisory Board; Screenpoint Medical, Transonic imaging. Grant Recipient; Siemens Healthineers, Bayer Healthcare, Medtronic, Elswood, Identification Solutions inc., Seno Medical, Micirima.

A-327 16:17

Complex cystic and solid lesions

P. Kapetas; *Vienna/AT (panagiotis.kapetas@meduniwien.ac.at)*

Cysts are the most usual breast pathology and up to one third of all women between 30 and 50 years of age are diagnosed with them. According to the BI-RADS® lexicon, cystic breast lesions are classified into simple cysts, complicated cysts and complex cystic and solid lesions. Simple cysts are anechoic fluid collections with an imperceptible wall and constitute the biggest part of cystic breast lesions. Complicated cysts also have an imperceptible wall, but present either with homogeneous hypoechoic content due to the presence of debris or with fluid-fluid levels. Complex cystic and solid lesions represent either a cystic lesion with a thick (>0.5mm) wall or thick septations or a lesion with a combination of cystic and solid components. Several complementary sonographic techniques can aid in the correct identification of the cyst type. These include compound and harmonic imaging, elastography, Doppler, and contrast enhanced ultrasound. A complex cystic and solid lesion represents a BI-RADS® 4 or 5 finding and merits histopathological work-up with a percutaneous, ultrasound-guided biopsy. In cases of cystic lesions with thick walls or thick septations or of predominantly cystic lesions with a small solid component a 9-10G vacuum assisted biopsy system should be used, to ensure proper sampling and reduce the risk of a false negative result. A post-

biopsy marker needs to be introduced after the intervention if the residual mass is difficult to identify.

Learning Objectives:

1. To understand the difference between complex cystic and solid lesions from other cystic lesions of the breast.
2. To become familiar with complementary sonographic techniques for the accurate characterisation of cystic breast lesions.
3. To be able to properly manage complex cystic and solid lesions of the breast.

16:23
Questions and discussion

A-328 16:29

Imaging the axilla

F. Kilburn-Toppin; *Cambridge/UK (fleur.kilburn-toppin@addenbrookes.nhs.uk)*

Evaluation of regional lymph node status is important for staging, treatment planning, and prognosis in breast cancer patients. Pre-operative axillary ultrasound and ultrasound-guided biopsy are routinely used to detect nodal metastases, allowing patients to proceed directly to axillary lymph node dissection thereby avoiding sentinel lymph node biopsy. However, following recent clinical trials and with improvement in systemic and radiation therapies, the role of staging sonography has been questioned. In this lecture, the current role of axillary staging will be reviewed and the future for nodal staging in the advent of evolving surgical management of the axilla and a trend towards less aggressive surgery will be considered.

Learning Objectives:

1. To understand the clinical role of axillary staging.
2. To learn imaging features of abnormal lymph nodes and criteria for biopsy.
3. To understand the importance of discriminating minimal vs advanced nodal disease.

A-329 16:35

Contrast-enhanced spectral mammography

E.M. Fallenberg; *Berlin/DE (eva.fallenberg@charite.de)*

In this talk the technical principles and possible artefacts will be addressed. In a couple of example cases the image appearance depending on lesion size and 2D images will be explained. The value of CESM in comparison to mammography MRI and ultrasound will be demonstrated.

Learning Objectives:

1. To understand the technical principles of contrast-enhanced spectral mammography.
2. To understand the added value of information provided by contrast-enhanced spectral mammography.
3. To become familiar with the information provided by contrast-enhanced spectral mammography and breast MRI regarding lesion morphology and enhancement.

Author Disclosure:

E.M. Fallenberg: Board Member; EUSOBI. Research/Grant Support; GE Healthcare, Guerbet, Siemens Healthcare. Speaker; GE Healthcare, Guerbet, Bayer Healthcare.

A-330 16:41

Stereotactic-guided biopsy

E.J. Cornford; *Cheltenham/UK (eleanor.cornford@nhs.net)*

Stereotactic guided breast biopsy has become increasingly sophisticated over the past 15 years due mainly to improvements in equipment. It was initially used to biopsy mammographic abnormalities not visible on ultrasound, but indications have expanded to include diagnostic excision of histopathologically indeterminate lesions. Although the underlying principle is the same, the technique varies in terms of needle biopsy device, equipment type, and patient positioning. More recently the introduction of tomosynthesis guided biopsy has facilitated even faster biopsy times. Post procedure placement of marker clips is important to confirm accurate biopsy and to facilitate subsequent removal of the mammographic abnormality should prove this necessary.

Learning Objectives:

1. To understand the indications for stereotactic-guided breast biopsy.
2. To learn about the technical aspects of stereotactic biopsy.
3. To understand the importance of marker clip placement post-biopsy.

16:47
Questions and discussion

A-331 16:53

US-guided biopsy

A. Athanasiou; *Athens/GR (aathanasiou@mitera.gr)*

Ultrasound-guided percutaneous biopsies are nowadays widely used in clinical practice. They include FNA (Fine Needle Aspiration, with 19-21 gauge needles), core-biopsy (14-gauge or rarely 16-gauge automated or semi-automated systems) and vacuum-assisted biopsy (11-gauge to 8-gauge systems). They are minimally invasive, well tolerated, rapid and cost-effective. They can provide histological diagnosis in a safe and accurate way, comparable to open surgical biopsies. According to the international guidelines, pre-operative diagnosis should preferably be ensured by imaging-guided procedures; open surgical biopsies should be exceptional and performed only when percutaneous procedures are not feasible. BI-RADS 4 and 5 lesions as well as abnormal lymph nodes represent the main indications for performing US-guide biopsies. Simple or complicated cysts are subject to FNA when symptomatic or when it is not clear if the lesion is indeed a complicated cyst and not a solid nodule. Contraindications include allergies, anti-coagulant medications or inability to correctly visualize the target lesion. Post-biopsy markers are helpful and should be used, notably in case of small, difficult to visualize lesions or in case of complex-cystic lesions. Technique should be rigorous and optimized to ensure result accuracy. Radiologic-pathologic correlation is mandatory and all discordant cases should be discussed in MDT.

Learning Objectives:

1. To understand current indications, contraindications and possible complications of US-guided biopsy.
2. To be familiar with different available biopsy systems and know which one to choose according to the clinical setting.
3. To learn the most important technical tips for performing a US-guided biopsy successfully.

A-332 16:59

MRI-guided biopsy

G. Esen; *Istanbul/TR (gulesenicten@gmail.com)*

MRI frequently detects suspicious lesions that cannot be demonstrated on other imaging modalities and need to undergo MRI-guided biopsy. Before an MRI-guided biopsy is scheduled, we have to make sure that the lesion is real and not a benign hormonal change; and then to check again with a second-look US. If it is not detectable on US, the patient can be scheduled, preferably during the second week of the menstrual cycle. On the day of the biopsy, patient has to be informed that it is possible to cancel biopsy, because the lesion is no longer detected on MRI. During biopsy, patient has to be informed that she will be coming in and out of the magnet, and she should not move. The sequences that are needed for a biopsy session should be prepared in advance, and employed in a standard fashion. MRI-guided biopsy is a team work and if everybody involved know what to do, it can be performed efficiently and rapidly, before the contrast washes out. CAD or a biopsy software would be very helpful in MRI-guided biopsies. Vacuum-assisted biopsy is the procedure of choice, because it is fast and accurate. It is possible to achieve more tissue from the suspicious region, if the lesion-needle relation is determined from the image and more samples are collected from that location. A marker should be placed at the biopsy site in each case and radiological-pathological correlation should always be performed.

Learning Objectives:

1. To understand the importance of pre-biopsy preparation including patient information.
2. To be familiar how to relate lesion and needle positions.
3. To appreciate tricks for targeting lesions in complicated locations (superficial, deep, retroareolar).

A-333 17:05

Treatment response and therapy monitoring

C. Van Ongeval; *Leuven/BE (chantal.vanongeval@uz.kuleuven.ac.be)*

Neoadjuvant therapy is increasingly been used in the treatment of breast cancer. For the monitoring of treatment (chemotherapy or hormonal therapy) response, an adequate staging of the breast cancer is needed: marking invasion or skin thickening, size of the index tumour, description of multifocal or multicentric disease, presence of bilateral breast cancer, and evaluation of nodal status (level 1, 2, 3). Besides mammography, ultrasound and biopsy procedures, magnetic resonance imaging (MRI) can be added to come to the correct staging. During the neoadjuvant treatment, a radiological investigation (ultrasound) is performed after 3 to 4 cycles of therapy or earlier in case of a tumor growth is suspected (non-responder). In the latter case , MRI will be added to the radiological investigation. After the last cycle of treatment, a new staging of the tumour is necessary to decide the optimal surgical treatment, i.e., mastectomy, breast conserving therapy and or lymphadenectomy or

sentinel node resection. The imaging characteristics of tumour response or tumour growth during therapy will be discussed.
Learning Objectives:
1. To learn what is important in the reporting of the treatment response.
2. To understand the accuracy of mammography, ultrasound and magnetic resonance in the monitoring of therapy.

A-334 17:11

Post-therapy evaluation
J. Camps Herrero; *Valencia/ES (juliacamps@gmail.com)*

To understand the changes that occur in the breast after treatment, one must know the different phases of fat necrosis and their translation in mammographic, ultrasound or MRI images. In reporting the findings, it is important to focus on the ones that have the greatest clinical value for the requesting physician. It will also be very important to know how to diagnose recurrence and, most of all, how to proceed when mammography or ultrasound are equivocal.
Learning Objectives:
1. To understand and learn the different phases of fat necrosis and its imaging correlates in all modalities.
2. To know what to report in patients with breast implants and oncoplastic reconstructions.
3. To learn the different appearances of breast cancer recurrence.
Author Disclosure:
J. Camps Herrero: Consultant; Bayer, Bard. Speaker; Bayer.

Questions and discussion

16:00 - 17:30 **Room E2**

Neuro

RC 811
State-of-the-art paediatric neuroradiology

A-335 16:00

Chairperson's introduction
C. Amarnath; *Chennai/IN (amarrd02@yahoo.co.in)*

This session highlights concepts of myelination and its maturation, role of imaging in diagnosing leukodystrophies. The topics focusses on wide spectrum of developmental disorders entity and importance of our role in diagnosis and add points on some relevant genetic or predisposing factors in pediatric CNS tumours. This session review the structural MRI findings in myelination disorders, paediatric CNS tumours, with an emphasis on posterior fossa tumours. The session emphasizes the contribution of advanced MRI techniques in pediatric neuroradiology. This lecture list the spectrum of applications and indications for imaging in paediatric neuroradiology. Spectators will be able to understand the relevance to apply the appropriate image acquisition protocols of disease in the field and appreciate the clinical relevance of imaging for the diagnostic process of neurological disorders in infants and children.
Session Objectives:
1. To learn the spectrum of applications and indications for imaging in paediatric neuroradiology.
2. To understand the relevance to apply the appropriate image acquisition protocols of disease in the field.
3. To appreciate the clinical relevance of imaging for the diagnostic process of neurological disorders in infants and children.

A-336 16:05

A. Imaging myelin maturation disorders
N. Wolf; *Amsterdam/NL (n.wolf@vumc.nl)*

Hypomyelinating leukodystrophies are frequent and have to fulfill both criteria of significant and permanent myelin deficit. Hypomyelination can be diagnosed by MRI. Care should be taken that, in children younger than 12 months of age, two MRIs at least 6 months apart are needed to make the diagnosis, in order to differentiate hypomyelination from the more frequent finding of delayed myelination. Severe atrophy in young children usually indicates a primary grey matter disorder with secondary myelin deficit and comes with its own differential diagnosis. MRI findings in hypomyelination consist of diffuse white matter signal hyperintensity on T2-weighted images and, depending on the amount of myelin deposited, hypo-, iso- or hyperintensity on T1-weighted images. Additional features may be cerebellar atrophy, signal and volume changes of deep grey matter structures and signal changes of the pyramidal tracts. These findings, when present, help differentiating the diverse hypomyelinating conditions. Some entities (e.g., 4H syndrome, H-ABC, HBSL, HCC, Salla disease, Pelizaeus-Merzbacher like disease···) can be easily diagnosed by MRI pattern recognition. This allows direct confirmation of the diagnosis by sequencing of the appropriate gene(s). Other hypomyelinating disorders do not come with extra features, necessitating a different genetic approach.
Learning Objectives:
1. To learn about normal and pathological patterns of myelination.
2. To understand the role of imaging with respect to narrowing the differential diagnosis and supporting the clinical diagnosis.
3. To appreciate the importance of pattern recognition for the diagnosis of myelination disorders in children.

A-337 16:28

B. Imaging of developmental disorders
B. Ertl-Wagner; *Munich/DE (Birgit.Ertl-Wagner@med.uni-muenchen.de)*

To understand congenital abnormalities of the brain, it is important to be familiar with the embryologic development. Neuronal proliferation, migration and cortical organization are important steps in the development of the cortex. Group I disorders of cortical development are disorders of neuronal and/or glial apoptosis or proliferation. Among these are congenital microcephalies (I.A), congenital megalencephalies (I.B), and diffuse or focal cortical dysgenesis or dysplasia (I.C). Microlissencephaly is characterised by a reduced gyration and microcephaly. Hemimegalencephaly is a hamartomatous overgrowth of one cerebral hemisphere or parts thereof. Group II disorders are disorders of neuronal migration. Among these are periventricular (subependymal) heterotopia (II.A), lissencephalies (II.B), focal subcortical heterotopia (II.C), or disorders of terminal migration, e.g. cobblestone lissencephalies (II.D). Heterotopia are defined as areas of grey matter in an ectopic location; they are isointense to cortex. Group III disorders are disorders of postmigrational development. Among these are polymicrogyria with schizencephaly (III.A), polymicrogyria without clefts or calcifications (III.B), focal cortical dysplasia (III.C), or postmigrational microcephaly. In schizencephaly, there is a cleft that extends from the ependymal to the cortical surface and that is lined by dysplastic grey matter. In polymicrogyria, there are too many too small gyri and sulci. Agenesis and dysgenesis of the corpus callosum are common disorders with a wide clinical spectrum. They may be associated with other congenital abnormalities. Important infratentorial congenital abnormalities include Chiari malformations, cystic abnormalities of the posterior fossa/the Dandy Walker spectrum, molar tooth malformations/Joubert syndrome and dysplastic cerebellar gangliocytoma/Lhermitte-Duclos syndrome.
Learning Objectives:
1. To learn about the spectrum of developmental disorders of the brain.
2. To understand the key imaging features that lead to the correct diagnosis.
3. To appreciate the importance of making a correct imaging diagnosis.

A-338 16:51

C. Imaging in paediatric neuro-oncology
E. Vázquez; *Barcelona/ES (evazquez@vhebron.net)*

Central nervous system tumours are the most common group of solid tumours in the paediatric age and the main cause of death from solid tumours in childhood. The clinical onset commonly includes signs and symptoms related to increased intracranial pressure, gait disorders, or cranial nerve deficits. Magnetic resonance (MR) imaging has an important role in characterizing these lesions, planning surgery, and follow-up. Advanced MR techniques, especially diffusion, help to predict the histological type and degree of malignancy, and facilitate the diagnosis of recurrence during follow-up. Identification of taurine within the tumour on spectroscopy is typical of medulloblastoma. Perfusion imaging, including dynamic susceptibility of contrast perfusion and arterial spin-labelling perfusion are particularly useful in differentiating recurrence versus radiation necrosis. Specifically referring to cerebellar tumours, they may be associated with diverse inherited cancer syndromes such as neurofibromatosis type 1 (pilocytic astrocytoma), Von Hippel Lindau syndrome (hemangioblastoma), Cowden syndrome (gangliocytoma), Li-Fraumeni syndrome (astrocytoma, medulloblastoma) and Gorlin and Turcot syndromes (medulloblastoma). In the differential diagnosis, conditions that can mimic neoplasms should be included, such as infections (e.g., rhombencephalitis), autoimmune processes (e.g., acute disseminated encephalomyelitis and multiple sclerosis), and radionecrosis. Proper recognition of these entities can help to prevent unnecessary surgery. Of note, certain previous histological classifications, such as that of medulloblastoma, are being replaced by new classifications based on genetic characteristics, which enable better prediction of tumour aggressiveness and help to guide

therapy according to the specific tumour type. Current research focuses not only on prolonging survival, but also on improving long-term quality-of-life.
Learning Objectives:
1. To learn about the spectrum of neuro-oncological diseases in children.
2. To understand the role of imaging beyond the diagnostic process.
3. To appreciate the increasing clinical relevance of advanced imaging techniques in paediatric neuro-oncology.

17:14
Panel discussion: Ask the expert: what is relevant for my own daily clinical practice?

E³ - Rising Stars Programme: Joint Sessions with ESOR

ESR/ESOR 2
Radiologic anatomy: abdomen

Moderator:
S. Gourtsoyianni; Athens/GR

A-339 16:00
Liver
G. Brancatelli; *Palermo/IT (gbranca@yahoo.com)*

The liver is the largest organ in the human body. The penetration and branching of the hepatic artery, portal vein, and hepatic veins allow dividing the organ into the eight traditional segments of the Couinaud scheme. Knowledge of vascular and segmental anatomy is important to correctly locate the site of disease and to perform increasingly demanding and challenging liver resection and transplantation. Anatomy of the liver can be altered by congenital variants, diseases causing hepatic dysmorphy and after surgery.
Learning Objectives:
1. To locate and identify, using cross sectional medical imaging, superficial and internal structures of common liver anatomy.
2. To learn and understand how the vasculature defines the eight Couinaud segments.
3. To explain how common pathological conditions affect the structure of the liver.
Author Disclosure:
G. Brancatelli: Speaker; Bayer.

A-340 16:30
Biliary tree
O. Benjaminov; *Petach Tikva/IL*

"no abstract submitted"
Learning Objectives:
1. To discuss current imaging techniques for evaluation of normal biliary anatomy.
2. To learn and understand possible anatomical variants that may occur.
3. To explain how common pathological conditions affect the bile ducts.

A-341 17:00
Pancreas
M. Dioguardi Burgio; *Clichy/FR (marco_dioguardi@hotmail.it)*

The pancreas is a retroperitoneal gland, which is anatomically divided in 4 portions: head, neck, body and tail. Main anatomical relationships of the head are duodenal loop, the porta hepatis and the superior mesenteric vessels. Body and tail anatomical relationships include left kidney and adrenal gland, posterior gastric wall and lesser sac, splenic hilum, celiac region, and duodenojejunal junction. Main pancreatic duct (Wirsung) drains into the major papilla most of the pancreatic secretions. A common biliopancreatic tract may be present. An accessory duct (Santorini) is usually present draining the anterior part of the pancreatic head in the minor papilla. Pancreatic gland is the results of the fusion of two buds. During the seventh gestational week the ventral bud rotate around the duodenum and it locates inferiorly and posteriorly to the dorsal bud. The fusion of the two buds leads to anastomosis of the ductal systems. Anomalies of this fusion process are at the base of the wide spectrum of anatomical variants which pancreatic parenchyma and ductal system may present. Most common anatomical variants include pancreas divisum, ansa pancreatica and annular pancreas. Knowledge of normal CT and MR appearance of the pancreas is crucial to recognize anatomical variants as well as to identify pancreatic anomalies. The use of both techniques is often necessary for an exhaustive evaluation of the pancreatic gland and to reach a proper diagnosis.
Learning Objectives:
1. To review and illustrate the imaging features of normal pancreatic anatomy.
2. To review the possible congenital variants and anomalies of the pancreas and pancreatic duct.
3. To explain how common pathological conditions affect the pancreas.

16:00 - 17:30 **Room F2**

Oncologic Imaging

RC 816
Monitoring response: the essential guide for all radiologists

A-342 16:00
Chairperson's introduction
P. Brader; *Graz/AT (peter@brader.md)*

Imaging-based therapy monitoring is essential to visualise and quantify the effect of cancer therapy. Therefore, criteria-based reporting methods were established to ensure standardised and reproducible results for response evaluation of oncologic patients. Response Evaluation Criteria in Solid Tumors (RECIST) as the most widely accepted morphologic, size-based evaluation system is based on imaging assessment of change in tumor burden, to determine if the tumor has shrunk or grown. However they only evaluate the size of the lesion, not its viability, proliferative rate or physiologic state. In recent years a broad range of novel molecular cancer therapeutics were introduced into clinical use. These new therapy regimes demonstrated significant effects on tumor angiogenesis and tumor metabolism, but often only subtile effects on tumor morphology. Established methods of monitoring cytotoxic tumor therapies, such as RECIST have been shown to be not sufficiently sensitive for monitoring the therapeutic effects of molecular anti-cancer agents to allow for a timely differentiation of responders from non-responders because such treatments are less likely to result in tumor shrinkage. The complementary acquisition of morphological, functional and molecular information using advanced imaging methods such as diffusion weighted imaging or perfusion imaging as well as hybrid imaging techniques (PET/CT, PET/MRI) allows for a higher sensitivity and specificity in the timely differentiation of responders from non-responders. The tremendous development in oncology and technical innovations in imaging present a particular challenge for radiology.
Session Objectives:
1. To understand the correlation of functional imaging evaluation with the pathophysiological effect of treatment on oncological pathology.
2. To understand the necessity of functional imaging for an accurate (early) evaluation of the therapy regimen on the response (or non-response) of oncological disease.
3. To learn about the added value of functional imaging for evaluating treatment (e.g. anti-angiogenic treatment).
4. To learn about the technical principles of functional imaging in correlation with the impact of the therapy on tumour cells and neo-vasculature.

A-343 16:05
A. RECIST made easy
A.G. Rockall; *London/UK (a.rockall@imperial.ac.uk)*

A significant part of modern day cancer imaging involves the assessment of change in the extent of tumour in the context of a clinical trial or research study. The reporting requirements for these imaging studies are documented in the research protocol. A standardized response assessment is important to be able to collate data between different centres, as well as to evaluate published data from different studies. Response evaluation criteria in solid tumours (RECIST) were developed and published in 2000. RECIST criteria have been widely adopted for the evaluation of treatment response in the clinical trial setting. A revised version, RECIST 1.1 was subsequently published in 2009, to address several problems that had been encountered with RECIST 1.0. New studies frequently use RECIST 1.1 but in some cases, new studies will still use RECIST 1.0 to allow direct comparison with a previous similar study. In this lecture, the key features of RECIST will be presented with worked examples. Selection of appropriate target lesions will be illustrated. Frequently asked questions will be addressed and the criteria for response will be illustrated.
Learning Objectives:
1. To learn about the basic idea of RECIST.
2. To understand how to use RECIST in daily clinical practice.
3. To become familiar with the detailed rules of RECIST.

A-344 16:28

B. PERCIST: PET response criteria

C.C. Cyran; *Munich/DE (clemens.cyran@med.uni-muenchen.de)*

With the implementation of novel oncologic strategies and prolonged survival of cancer patients, early and longitudinal monitoring of therapy response to treatment in individual patients has become a key request to imaging. Known limitations of morphological size-based criteria (e.g., RECIST) for the monitoring of tumor response led to the investigation of additional functional and molecular imaging techniques to allow for a reliable and timely distinction of responders and non-responders, particularly under novel molecular cancer therapies. Particularly hybrid imaging techniques, such as PET/CT or PET/MRI, demonstrated significantly improved diagnostic accuracy for the evaluation of treatment response in different tumor entities under a variety of treatments with a reported change-in-intended management of up to 35% in oncologic indications compared to conventional imaging alone. To allow for a standardized evaluation of therapy response, criteria-based reporting of target and non-target lesions has been established to classify therapy response into different categories ranging from complete response to progressive disease and has found broad application particularly within clinical studies. Similar to the size-based RECIST (response criteria in solid tumors) criteria, PERCIST (PET response criteria in solid tumor) criteria were developed to provide a systematic, standardized approach for the criteria-based evaluation of metabolic tumor response to therapy using ^{18}F-FDG PET. Studies evaluating PERCIST criteria suggest, that the inclusion of standardized metabolic criteria may allow for an increased sensitivity, specificity and diagnostic accuracy in the evaluation of therapy response compared to morphological imaging criteria alone.

Learning Objectives:

1. To learn about the basic principles of PERCIST.
2. To understand how to use PERCIST for structured quantitative research and clinical reporting.
3. To appreciate the advantages of PERCIST over mere morphological methods.

A-345 16:51

C. Assessment of response using functional MR and CT imaging: the essentials

L.S. Fournier; *Paris/FR (laure.fournier@aphp.fr)*

Key issues in oncology include patient selection based on pre-treatment tumour characteristics, and assessment of tumour response in the absence of actual shrinkage. There is accumulating evidence that functional imaging using advanced techniques such as dynamic contrast enhanced imaging (MRI, CT or ultrasound), diffusion weighted-MRI, magnetic resonance spectroscopy, and positron emission tomography-CT using various labelled radioactive tracers has the potential to address these challenges. New approaches quantifying heterogeneity such as texture and radiomics are also emerging.Functional imaging allows quantifying physiological or molecular processes, yielding information not accessible to morphological imaging. In preclinical animal studies, they may give insight into biological mechanisms of efficacy and help select best candidate drugs. In human studies, early phase studies can use functional imaging to indicate early likelihood of response to a specific therapy, and guide the optimal biological dose and drug schedule.Though a very large number of studies have been performed using functional imaging, very few are used to make clinical decisions. Among the challenges facing functional imaging for the past years are standardisation of acquisition and image processing, as well as validation of clinical utility.

Learning Objectives:

1. To learn about the portfolio of functional imaging response methods in CT and MRI.
2. To understand the current clinical value of each technique.
3. To appreciate potential advantages compared to PERCIST.

Panel discussion: When and how will functional imaging overcome morphological assessment?

16:00 - 17:30 **Room D**

Musculoskeletal

RC 810

Musculoskeletal ultrasound in the management of sports injuries

Moderator:

M. Reijnierse; Leiden/NL

A-346 16:00

A. Ultrasound of ankle injuries: technique and diagnosis

C. Martinoli; *Genoa/IT (carlo.martinoli@libero.it)*

In sports medicine, the role of ultrasound (US) has become increasingly important in the assessment of ligaments, tendons, joints, and other soft-tissue injuries about the ankle. Being many structures to be examined, the US examination should be focused on clinical findings in an attempt to save time and increase the efficacy of the study. In the area around the lateral malleolus, that is the most frequently involved in inversion trauma, ligaments and tendons can be injured individually or in association. US can assess the status of the anterior talofibular and calcaneofibular ligaments with effective results by means of static and dynamic scans. Some midtarsal ligaments, such as the dorsal calcaneocuboid, the superior talonavicular and the bifurcate, can be also evaluated. In high sprains, US can provide evaluation of the anterior inferior tibiotalar ligament, including the Bassett fascicle. US can give demonstration of peroneal tendon instability based on tendon displacement relative to the malleolar groove and is able to recognise retinacular/periosteal tears. Dynamic scanning can help to detect cases of intermittent subluxation that often go unnoticed at MR imaging. Some predisposing conditions of peroneal tendon instability (e.g. convex retromalleolar groove, peroneus quartus, low myotendinous junction of the peroneus brevis) may also be identified. Longitudinal splits of the peroneus brevis often occur in athletes. US can depict early changes with weakening and thinning of the central part of the tendon. In more advanced lesions, a complete cleft with formation of two distinct hemi-tendons, irregularities of the tendon substance and tenosynovitis is observed.

Learning Objectives:

1. To become familiar with ultrasound findings seen in ankle instability.
2. To learn about the ultrasound patterns of tendon abnormalities.

A-347 16:30

B. Ultrasound of the hip and knee: what is it good for and what are its limitations?

A. Klauser; *Innsbruck/AT*

The hip and knee are anatomically and biomechanically complex joints, often causing diagnostic uncertainty for clinicians, therefore, most often MRI is requested. But does US have any value in knee and hip sport injuries? In cases of intraarticular pathology US can accurately detect effusion and synovitis, paralabral and meniscal cysts, however, further imaging assessment as by MRI (arthrography) is necessary. Extraarticular pathologies like tendinopathy, enthesopathy, tendon strains, different types of bursitis (trochanteric, iliopectinea, iliopsoas, prepatellar, infrapatellar, semimembranosus ...), muscle strains and ruptures, and collateral knee ligament injuries can be assessed and graded by US. US is also great in delineation of various neuropathies. The major advantage of US is the possibility of dynamic evaluation, for example, in the assessment of iliopsoas abnormalities, including snapping iliopsoas tendon and iliotibial band friction syndrome. In terms of sport injury management, ultrasound guided punctures and injections are highly appreciated by patients and clinicians as well and also the ability for therapeutic short terms follow-up is of great importance to better understand point of sport return in the athletes.

Learning Objectives:

1. To become familiar with examination technique and typical findings of ultrasound of the hip and knee.
2. To understand the limitations of ultrasound of the hip and knee.

A-348 17:00

C. Ultrasound-guided intervention in the athlete: indications and techniques

H. Guerini; *Paris/FR*

Diagnostic and interventional ultrasound is a rapidly evolving field in sports medicine. The use of ultrasound has increased exponentially during the past decade. Ultrasound-guided procedure is performed for joint and tendon sheath

injections with PRP or steroid drugs. We will discuss of the the indications, technical considerations about interventional ultrasound in sports medicine.
Learning Objectives:
1. To become familiar with the indications for ultrasound-guided interventions in the athlete.
2. To learn about the different injection techniques.

16:00 - 17:30 **Room G**

Special Focus Session

SF 8c
The ten-minute abdominal MRI: make the dream come true!

A-349 16:00
Chairperson's introduction
N. Papanikolaou; *Lisbon/PT (nickolas.papanikolaou@research.fchampalimaud.org)*

Abdominal MRI images are sensitive to a variety of artifacts related to respiratory, cardiac and peristaltic motion, the presence of air in the gastrointestinal tract and chemical shift due to abdominal fat. One factor that enhances respiration-related artifacts is the level of patient collaboration and compliance either to breath-hold commands, or the capability of the patient to achieve a steady respiratory pattern during image acquisition. Technical advances related to a further reduction of scan times have been applied for abdominal imaging purposes, including parallel imaging algorithms, alternative ways to fill k-space, radial scanning and compressed sensing. Apart from improving the patient experience due to shorter examination times, these techniques may result in enhancing the problematic image quality of abdominal MRI exams by minimizing the level of artifacts. Additionally, new diagnostic information related to the amount of angiogenesis can be obtained by novel perfusion sequences that can simultaneously provide very high temporal resolution and adequate in-plane resolution and anatomical coverage maintaining acceptable image quality. Innovative RF coil designs, taking into consideration the patient body habits are also improving the acquired MR signal, that can be exploited by further increasing spatial resolution.
Session Objectives:
1. To become familiar with technical challenges of MRI examinations in the abdomen.
2. To review current MR examination protocols of the abdominal organs.
3. To discuss future developments.
Author Disclosure:
N. Papanikolaou: Advisory Board; Advantis Medical Imaging. Owner; MRIcons LTD.

A-350 16:05
Liver
T.C. Lauenstein; *Essen/DE (thomas.lauenstein@evk-duesseldorf.de)*

MRI has vast potential to non-invasively diagnose and characterize focal liver lesions as well as diffuse liver disease. Due to the large extent of different sequence types, various information about pathological changes can be obtained. Hence, it is sometimes difficult to shorten MRI protocols and to withdraw certain MRI sequences without losing relevant information. Furthermore, MRI of the upper abdomen can be challenging. Motion and breathing artifacts can considerably impede a reliable diagnostic workup. In addition, it can be difficult to acquire MR images during the correct contrast phases after i.v. gadolinium injection. Hence, it is crucial to choose and apply the right contrast delay. Strategies to overcome limitations and to handle the outlines challenges will be proposed in this lecture. A comprehensive and abbreviated examination protocol for liver MRI will be presented with a special focus on diffusion weighted imaging and liver specific contrast agents. Eventually, clinical cases and pitfalls will be discussed.
Learning Objectives:
1. To briefly review MRI challenges in the liver.
2. To review techniques and methods to optimise image quality.
3. To compare comprehensive and abbreviated protocol strategies.

A-351 16:28
Pancreas
N. Kartalis; *Stockholm/SE (nikolaos.kartalis@me.com)*

Magnetic resonance imaging/magnetic resonance cholangiopancreatography (MRI/MRCP) is increasingly used for the evaluation of patients with pancreatic diseases, such as pancreatic cystic neoplasms (PCN), pancreatic cancer and pancreatitis as well as for screening purposes, such as in individuals at increased risk of developing pancreatic malignancy (i.e. family history of pancreatic cancer, genetic factors, etc.). Particularly for the surveillance of patients with PCNs, MRI is the suggested imaging modality according to various existing clinical practice guidelines due to its exquisite contrast resolution, high sensitivity for the detection of lesion communication with the pancreatic ductal system and lack of ionizing radiation. However, MRI/MRCP protocols are time-consuming, costly and, in the case of serial follow-up examinations, the repeated use of gadolinium-based contrast agents raises potentially safety concerns. In this presentation, we will discuss various strategies for the development of abbreviated protocols useful in everyday clinical practice.
Learning Objectives:
1. To briefly review MRI challenges in the pancreas.
2. To review techniques and methods to optimise image quality.
3. To compare comprehensive and abbreviated protocol strategies.

A-352 16:51
Ovaries
E. Sala; *Cambridge/UK (evis.sala@gmail.com)*

Magnetic resonance Imaging (MRI) is recommended as a second line investigation for characterisation of complex adnexal masses indeterminate on US. MRI gives superb contrast resolution and involves non-ionizing radiation. Typical protocols include both T1 and T2 weighted sequences, with imaging acquisition performed in 3 planes. Coronal FSE T2WI is very helpful in evaluating complex adnexal lesions. Adnexal lesions can be characterised by their specific signal characteristics on T1WI and T2WI. Simple fluid has homogeneous low signal on T1WI and high signal intensity on T2WI. Fat and haemorrhage have high signal intensity on T1WI. Fat suppression (FS) on T1W sequences is utilised to differentiate these entities. If the adnexal lesion demonstrates low or intermediate signal intensity on T1WI and low signal intensity on T2WI, these characteristics suggest fibrotic and/or smooth muscle components. Such lesions include pedunculated leiomyoma, fibroma, fibrothecoma, cystadenofibroma and Brenner tumours. Multi-phase contrast enhanced (CE) MRI after administration of intravenous gadolinium is very useful for characterisation of adnexal masses. Solid components will demonstrate enhancement, enabling the distinction between debris or retracting clot in the cyst wall from papillary projections. Subtraction images are essential to evaluate enhancing nodules within a background of hyperintense T1W lesion. Gadolinium also improves detection of peritoneal and omental implants in case of ovarian carcinoma. Dynamic-CE (DCE)-MRI are not yet routinely performed in evaluation of adnexal masses. Diffusion-weighted imaging (DWI) is very useful for visualisation of peritoneal implants.
Learning Objectives:
1. To briefly review MRI challenges of the adnexa.
2. To review techniques and methods to optimise image quality.
3. To compare comprehensive and abbreviated protocol strategies.

RC 814
Contrast media in imaging
Moderators:
M.-F. Bellin; Le Kremlin-Bicêtre/FR
L. Popovic; Belgrade/RS

A-353 16:00
A. Contrast-enhanced ultrasound: principles and applications
G. Johnson; *Manchester/UK (gerry.johnson@tgh.nhs.uk)*

The use of contrast enhanced media in medical imaging is well established allowing greater visualisation and characterisation of disease processes.Ultrasound imaging has been relatively late in creating an specific contrast agent, but many contrast agents or micro bubbles exist and are being used routinely in clinical practice to aid better diagnoses in a non invasive manner. Mircobubbles are the scientific basis for all current developments in ultrasound contrast media. The principal characteristic is their backscatter effect, simply put when gas filled microbubbles are present in a region of interest, a higher proportion of the ultrasound beam is backscattered and

therefore a stronger return echo is received at the transducerThe clinical use of contrast media was first used in cardiac imaging in the 1968 by Gramiak and Shah (Invest Radiol 3:356-366), their early work found the microbubble technology to be "rough and ready", microbubbles were very large and size distribution was poorly defined. It was not until the mid 1980's that methods were developed to produced smaller more stable microbubbles by means of sonication, although the use of this media was limited as they were unable to survive passage through the lungs after i.v. injection. Since then there have been numerous developments in generating stable and reliable ultrasound contrast agents.This presentation will review their basic physical principles, try to elaborate on the technical requirements required to perform it, and learn about various clinical indications and applications of CEUS.

Learning Objectives:

1. To review the basic physical principles of contrast-enhanced ultrasound.
2. To understand the technical requirements to perform it.
3. To learn about the various clinical indications and applications of contrast-enhanced ultrasound.

A-354 16:30

B. Radiotracers in PET/RNI

P. Laverman; *Nijmegen/NL (Peter.Laverman@radboudumc.nl)*

Different types of radiopharmaceuticals for both PET and SPECT imaging are used for various indications. In this session we will focus on recent developments in the field of radiopharmaceuticals. A brief overview of current radiotracers for PET and SPECT will be given and - in more general - the development and production of these tracers as well as their in vivo behaviour will be discussed. The biodistribution and uptake mechanism of a radiotracer will be examplified by radiolabeled PSMA-ligands for imaging of prostate cancer. The use of these radioatracers have become very popular over the last few years and are now an important tool in PET and SPECT imaging. Differences in these prostate cancer imaging tracers will be explained and their various applications will be discussed.

Learning Objectives:

1. To learn about current radiotracers in use in PET/RNI.
2. To understand the mechanism of distribution and uptake of various radiotracers.
3. To appreciate the most appropriate clinical indications and applications of PET/RNI radiotracers.

A-355 17:00

C. How safe really are gadolinium agents?

A. Cradock; *Dublin/IE (andrea.cradock@ucd.ie)*

Gadolinium based contrast agents (GdBCA's) have been used in MRI to aid diagnosis since the 1980's. The gadolinium ion (Gd+3), a heavy metal ion, is toxic to within the body and is chelated to prevent deposition of the gadolinium ion in tissues. The stability of the chemical bonding between Gd+3 influences the tendency for release of free Gd+3 over time. Macrocyclic agents tend to have a higher stability than linear agents. Ionic agents tend to have a higher stability than non-ionic agents. However, in 2006 the first reports of the association between nephrogenic systemic fibrosis (NSF) and GdBCAs were described. NSF can progress to a debilitating disease and is potentially fatal. It is thought that patients with severe renal insufficiency are more at risk than patients with normal renal function. The advent of these reports introduced restrictions for the administration of GdBCAs to patients with impaired renal function in clinical departments. In recent times, there have been reports of accumulation of gadolinium within the brain tissues of patients with normal renal function.

Learning Objectives:

1. To be aware of the differences between macrocyclic and linear gadolinium-based contrast agents.
2. To review current advice regarding the use of gadolinium on patients with renal impairment.
3. To become familiar with our current understanding of gadolinium deposition in the body.

16:00 - 17:30 **Room M 1**

RC 815

Post-treatment evaluation: what every radiologist should know

A-356 16:00

Chairperson's introduction

P. Haage; *Wuppertal/DE (patrick.haage@helios-kliniken.de)*

Appropriate post-treatment evaluation after any intervention is key for a good outcome and superior long term success rates. Accordingly it is necessary to supervise the outcomes, define follow-up strategies and to identify potential complications and possibly prepare for re-intervention. In this refresher course, pathways and most common complications after thoracic aortic interventions, abdominal aorta surgical, and endovascular repair and endovascular peripheral arterial disease treatment will be presented including imaging specifics, i.e., normal and pathological appearances and indications for re-intervention. Ample information on the selection of modality (ultrasonography, CT, MRI), the typical time interval between follow-up examinations plus specific suggestions including items to cover in a structured report will be given.

Session Objectives:

1. To briefly introduce the distinctive role of proper post-treatment evaluation after intervention.
2. To control the results and to know possible complications in order to be prepared for re-intervention.

A-357 16:05

A. Thoracic aorta

T. Leiner; *Utrecht/NL (t.leiner@umcutrecht.nl)*

The aorta plays a central role in connecting the heart to various end organs. Pathological changes in the aorta have a retrograde effect on the heart, as well as affecting perfusion of end-organs. In my presentation I will discuss CT and MR imaging protocols optimised for imaging the post-operative aorta and the typical appearance of various post-operative conditions. Topics covered will include choice of modality, acquisition strategies as well as practical tips on how to report important findings. Theoretical considerations will be illustrated with case material from clinical practice.

Learning Objectives:

1. To learn about the most common complications after thoracic aortic interventions.
2. To understand imaging specifics after thoracic aortic interventions.
3. To know indications for re-intervention.

Author Disclosure:

T. Leiner: Research/Grant Support; Philips Healthcare; Bayer Healthcare. Speaker; Philips Healthcare; Bayer Healthcare.

A-358 16:28

B. Abdominal aorta

C. Loewe; *Vienna/AT (christian.loewe@meduniwien.ac.at)*

The endovascular treatment (EVAR) has become a well established treatment option for aortic diseases. In contrary to patients after surgical repair, patients after EVAR require lifetime follow up imaging since the chronic and progressive character of atherosclerosis can cause progression of aortic dilatation leading to movement of the prosthesis or insufficient aneurysm exclusion with time. Additionally, persistent perfusion of the aneurysm sac (endoleaks) can occur even years after stentgraft placement. Finally, the life expectancy of the materials used for endovascular treatment might be limited. CT angiography was established as the first method of choice for follow up after abdominal aortic repair. The advantages of CT angiography are manifold and include optimal comparability with the pre-treatment examination (usually done by means of CT angiography), high resolution, direct visualisation of the device itself and the possibility of multiphasic acquisition to detect even slow flow endoleaks. As it is true for all treatment-follow up examinations knowledge about primary procedure and typical post-therapeutic findings as well as about most common complications is a prerequisite in patient care after abdominal aortic repair. Device migration, device fracture and/or persistent sac perfusion - in most of the cases related to each other - are the most common procedure related complications. In this presentation, different therapeutic means for abdominal aortic disease will be presented as well as the typical, normal findings after treatment. Furthermore, most common complications will be introduced and discussed based on clinical examples. Finally, possible follow up strategy depending on disease and procedure should be proposed.

Learning Objectives:
1. To learn about the most common complications after abdominal aortic interventions.
2. To understand imaging specifics after thoracic aortic interventions.
3. To know indications for re-intervention.

Author Disclosure:
C. Loewe: Speaker; GE Healthcare, Bracco, Siemens.

A-359 16:51

C. Peripheral arterial disease

M. Anzidei; *Rome/IT (michele.anzidei@gmail.com)*

CT and MR angiography (CTA and MRA) substantially changed the diagnostic approach in planning and follow-up of treatment for peripheral arterial disease (PAD), enabling early identification of treatment failure or treatment-related complications after endovascular and surgical procedures. Doppler ultrasound is the first line imaging modality during follow-up after treatment, but CTA and MRA enable more detailed and panoramic imaging that is extremely valuable in the assessment of treatment outcome. The aim of this presentation is to review the imaging findings in the most common complications after endovascular treatment for PAD, to discuss the best imaging modality in the various clinical scenarios and to explain when and how to re-intervene on the basis of imaging findings.

Learning Objectives:
1. To learn about the most common complications after PAD endovascular repair.
2. To understand what imaging technique is preferred (any diagnostic).
3. To explain when to re-intervene and how to prepare for it.

17:14
Panel discussion: How to optimise post-treatment imaging: getting proper diagnosis without performing too many examinations

16:00 - 17:30 **Room M 2**

Computer Applications

RC 805
Daily use of mobile devices in radiology

A-360 16:00

Chairperson's introduction

O. Ratib; *Geneva/CH*

Mobile devices such as tablets and high-resolution smartphones are becoming widely available providing convenient mobile solutions for physicians and healthcare providers to access imaging data. This is particularly attractive in medicine where “nomad” physicians who need to be able access relevant patient data and images anywhere-anytime in their daily practice where they are rarely a single location. While they may not always be adequate for routine diagnostic tasks they provide a convenient mobile solution for on-call and remote consultations. There are different types of software architecture that can be implemented for such tasks. Two major different design are: (1) online web-based applications where the device serves as a “thin-client” to display images rendered and manipulated on a remote computer and (2) local applications that reside on the mobile device and can run independently after images have been downloaded on the device. The first solution requires the user to be constantly connected to the network, while the second solution can continue to function after disconnecting from the network. Most vendors are starting to provide web access to their imaging solutions that can be accessed from mobile devices. Web access can however be slow and dependent on reliable access to wireless network.

Session Objectives:
1. To give an overview of tools available on mobile devices for education and exam reporting.
2. To underline the impact of mobile devices in routine clinical activity.
3. To learn about the legislative backbone and potential drawbacks of mobile technology.

A-361 16:05

A. What did mobile devices change in radiology education?

E. Kotter; *Freiburg/DE (elmar.kotter@uniklinik-freiburg.de)*

E-learning has been used in radiology for more than 30 years. The lecture will give an introduction to and an overview of e-learning systems for radiology with emphasis on e-learning on mobile devices. Advantages and limitations of mobile e-learning will be discussed. An outlook to future development of e-learning will be given.

Learning Objectives:
1. To give an overview of tools available for e-learning.
2. To explore the potential impact of e-learning in the daily radiological practice.
3. To explore future developments and limits of e-learning.

A-362 16:28

B. Is it appropriate to read a study on a smartphone or a tablet?

N.H. Strickland; *London/UK (nicola.strickland@nhs.net)*

The portability of tablets and smartphones make them suitable for accessing and displaying digital radiological imaging studies particularly in on call or remote settings, in wards or clinics and in the emergency setting. The purpose of this display can be for primary diagnosis or for review. The portable device must be fit for purpose. The small screen size and limited display resolution of smartphones limits their appropriateness for primary diagnosis. However studies have shown equivalent diagnostic accuracy of tablets compared with DICOM-calibrated PACS workstation displays. It is now technically possible to satisfy the requirements for viewing large multi-image studies on mobile devices: processor and network speeds are fast enough to receive images quickly from a PACS; screen resolutions and DICOM conformance can display images with appropriate fidelity; memory and graphics processor capacities can allow image viewing and manipulation similar to that on a PACS workstation; and hospital information technology departments can institute appropriate management to ensure functional stability of mobile devices and security of the patient data displayed on them. Simultaneous comparative viewing of multiple studies is inevitably suboptimal on portable devices due to their limited screen real estate. Radiologists should consider exploiting mobile devices to raise their profile as clinical doctors, for example, using them to interact in person with their clinical colleagues on ward rounds and in out-patient departments, and with patients to explain their imaging to them.

Learning Objectives:
1. To give an overview of available DICOM viewers and software for reporting imaging studies.
2. To discuss technical requirements of mobile devices for use in imaging interpretation.
3. To provide insight on future developments of imaging viewing technology.

A-363 16:51

C. Security and ethical issues of mobile device technology

E.R. Ranschaert; *Mol/BE (ranschaert@telenet.be)*

Medical specialists and radiologists are using mobile devices to share and exchange medical information and images with other health care professionals. Usually they need the advice regarding a diagnosis or treatment, sometimes in an acute setting. Popular messaging services such as whatsapp are often used for such purpose. Transmission of patient data with mobile devices and messaging services, however, does have several ethical and legal limitations, mostly related to the security and privacy of patients. Some questions need to be answered: is this type of communication unsafe and/or illegal, and if yes, why? Are there any regulations and/or guidelines available? Are there any secure solutions available? In this refresher course these issues will be discussed in more detail.

Learning Objectives:
1. To provide an overview of technical solutions for patients' image and data mobility.
2. To provide a risk assessment analysis (data loss, privacy, etc.) of mobile technology.
3. To give an overview of European legislation in relation to patient image and data mobility.

17:14
Panel discussion: Can mobile technology supplement stationary technology in radiology?
Discussion will address main controversies of the use of mobile technology in a clinical environment such as image quality, data mobility, safety and legal issues, etc.

16:00 - 17:30 **Room M 3**

Interventional Radiology

RC 809

Percutaneous interventional procedures: a practical guide

A-364 16:00

Chairperson's introduction

R. Iezzi; *Rome/IT (roberto.iezzi.md@gmail.com)*

Percutaneous imaging-guided interventions are making an increasing contribution to the treatment of patients with many non-vascular conditions. Minimally invasive techniques enable effective treatment that is followed by rapid recovery, with a low morbidity and mortality rate. However, the effectiveness of such methods of treatment is enhanced by an accurate preprocedural planning, an adequate selection of image guidance technique, as well as an optimal intra/periprocedural sedation. In detail, analgesia and sedation before, during, and after interventional procedures allow a safe, comfortable, and technically successful procedure to be performed. This session will explore different imaging-guided methods to define advantages, disadvantages, as well as tips and tricks for successful percutaneous intervention.

Session Objectives:

1. To appreciate the importance of pre-procedure planning and selection of image guidance technique.
2. To learn about intra-procedure patient analgesia and adjunctive techniques for access to sites for intervention.
3. To discuss tips and tricks for successful percutaneous intervention.

A-365 16:05

A. How to safely perform US-guided procedures

D. Akinci; *Ankara/TR (akincid@hotmail.com)*

Ultrasound (US) guidance is a frequent modality of choice in percutaneous biopsy, drainage, and ablation procedures, because it enables continuous real-time visualization, is radiation-free, has a lower cost, is better for angled access. In most of the abdominal organ biopsies (e.g., liver, kidney, pancreas, and spleen) and drainage of fluid collections, local ablation of liver tumors, drainage of pleural collections, biopsy of peripheral pleural based thoracal lesions, US guidance is utilized. Endocavitary approaches can be used safely in pelvic biopsy and drainage procedures with transvaginal or transrectal US guidance. Fusion techniques combine US images with CT or MRI images, enabling targeted US guided procedures for lesions that are difficult to see on US.

Learning Objectives:

1. To learn about patient positioning for US-guided percutaneous and endocavitary approaches to sites in the body.
2. To learn about real time guidance advantages of US-guided intervention.
3. To explain image fusion techniques for US-guided intervention.

A-366 16:28

B. How to safely perform CT-guided procedures

R. García Marcos; *Valencia/ES (raulgamar@hotmail.com)*

Percutaneous computed tomography (CT) guided is a minimally invasive approach for interventional procedures. Although is a procedure with few complications precise planning and knowledge of the indications, technique and material. CT-guided interventions may be divided into diagnostic (biopsies) and therapeutic interventions (drainages, thermal ablation, vertebroplasty, etc.). The main problems of access to lesions depend on the situation due to poor imagery, mobility and distance. Therefore, we are obliged to know and identify the structures along the established route. Different techniques of CT exist. Multidetector CT is commonly used for guiding percutaneous biopsy and catheter drainage of fluid collections. CT fluoroscopy has the potential to improve the efficacy of CT-guided interventions and to reduce the procedure time. C-arm cone-beam CT (CBCT) is a real-time needle guidance technique that can be used to visualise the needle trajectory from skin to target lesions. The aim of this study is to present the types and advantages of the CT-guided interventions, the patient positioning and adjunctive techniques for access to sites for intervention.

Learning Objectives:

1. To learn about patient positioning for CT-guided percutaneous approaches to sites in the body.
2. To learn the types of CT guidance and advantages of CT-guided intervention.
3. To learn about adjunctive techniques for access to sites for intervention.

A-367 16:51

C. Post-procedure follow-up and complication management

M. Seidensticker; *Munich/DE (max.seidensticker@med.uni-muenchen.de)*

Biopsy procedures bare - although commonly at a low rate - potentially life threating risks. To know about potential complications and proper patient monitoring is the key to identify the complications and to react accordingly. The lecture will give informations about common and uncommon complications after biopsy procedures and help will be given to identify the patient at risk and how to avoid/reduce specific complications. Further on, management of complications will be addressed. Of note, not all complications are avoidable, but proper patient management helps to reduce associated morbidity and mortality.

Learning Objectives:

1. To appreciate the potential for complications in common biopsy procedures.
2. To learn about management of post-procedure complications.
3. To discuss the role of quality improvement.

Author Disclosure:

M. Seidensticker: Advisory Board; BAYER. Grant Recipient; SIRTEX Medical, BAYER. Speaker; Cook, Bayer, Sirtex.

17:14

Panel discussion: Tips and tricks for choosing your first cases. Controversial case-based review of approaches to difficult lesions

16:00 - 17:30 **Room M 4**

E³ - ECR Academies: State-of-the-Art and Advanced MR Imaging of the Musculoskeletal system

E³ 819

Lower extremity

A-368 16:00

Chairperson's introduction

C.W.A. Pfirrmann; *Zurich/CH*

A-369 16:05

A. Hip and pubic symphysis

S.J. Eustace; *Dublin/IE (eustacesj@gmail.com)*

This presentation will review common causes of groin pain arising from the hip and from the symphysis pubis. In relation to hip pain the talk will focus on the role of the acetabular labrum in maintaining hip stability in normality, dysplasia and in patients with forms of impingement. The talk will outline appearances on non contrast MR studies and following arthrographic evaluation. The presentation will then review common pathologies in the symphysis pubis that can contribute to the development of groin pain contrasting symptoms and appearances of micro tearing of the adductor longs attachment (superior cleft sign) with appearances of micro tearing at the short adductor attachment (secondary cleft sign) with appearances of primary osteitis pubis.

Learning Objectives:

1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and MR arthrography (direct/indirect) and how to optimise imaging protocols for the hip.

A-370 16:43

B. Post-traumatic ankle

M.-A. Weber; *Rostock/DE*

MRI is excellent for depicting normal ankle anatomy and it can elegantly demonstrate ligamentous injuries of the ankle and associated conditions after ankle sprain. In 85% of all ligament ruptures, the lateral ligament complex is affected and the anterior talofibular ligament is the most often ruptured ligament followed by the calcaneofibular ligament. Additionally, dedicated MRI protocols can delineate the cartilage, as well as the appearance of acute and chronic osteochondral lesions of the talus. Recent advances in MRI include 3D

isotropic ankle joint imaging. Subchondral microfractures, osteochondral fractures and solely chondral fractures are different manifestations of impaction injuries, the two last-mentioned affect the articular surface. Since osteochondral lesions of the talus may eventually result in post-traumatic osteoarthritis, recognition of early cartilage damage and associated lesions may help determining the proper treatment of the patient to delay or prevent progression to osteoarthritis. Additionally, osteochondral injuries can often explain persisting symptoms. MRI, where necessary complemented by CT-arthrography, has become a decisive tool in diagnosing and characterizing cartilage lesions of the ankle. In case of disrupted cartilage layers and fluid around undetached fragments as well as in case of a dislodged fragment operative treatment may be indicated after consideration of the patient's general clinical condition. The interventional procedures, which have been developed for the repair of such lesions, essentially include abrasion, microfracture, autologous osteochondral transplantation, allograft transplantation, and (matrix-associated) autologous chondrocyte implantation. MRI enables the non-invasive assessment of the repair tissue, the success of implantation, and the state of cartilage maturation.

Learning Objectives:

1. To identify the most common post-traumatic entities.
2. To know the role of MR imaging and MR arthrography (direct/indirect) and how to optimise imaging protocols for the ankle.
3. To differentiate post-traumatic changes from typical reasons for chronic pain.

A-371 17:06

C. Chronic ankle pain

J. Teh; *Oxford/UK (jamesteh1@googlemail.com)*

This lecture will focus on the causes of chronic ankle pain, other than osteochondral and ligamentous injuries. The topics covered will include: (1) Tendinopathy: The spectrum of tendinopathy in the ankle ranges from tendinosis through to complete ruptures. There are specific abnormalities that occur in relation to the tibialis posterior tendinopathy such as spring ligament disruption and pes planus. On the lateral aspect of the ankle splits of the peroneus brevis, the painful os peroneum syndrome (POPS) and peroneal dislocation are discussed. (2) Plantar fascia: The plantar fascia is prone overuse injury resulting in plantar fasciitis. Acute disruption may also occur. Baxter's neuropathy is discussed. (3) Masses: For many soft tissue masses the position of the lesion is often useful for narrowing the differential. For some benign soft tissue masses (e.g., Morton's neuroma, lipomas, hemangiomas, cysts, abscesses), the MRI findings may be sufficient to clinch a diagnosis. In some cases further imaging and biopsy may be required. (4) Diabetic foot: Certain features may help us differentiate between the infected diabetic foot from Charcot arthropathy. The key to diagnosing infection is the presence of soft tissue ulceration contiguous to the bone abnormality. Ulceration in the foot tends to occur in weight bearing areas such as at the heel, the ball of the foot and around the toes. Charcot arthropathy is characterized by destruction, disorganization, increased density and debris.

Learning Objectives:

1. To identify the most common entities leading to chronic pain.
2. To know the role of MR imaging and MR arthrography (direct/indirect).
3. To differentiate entities leading to chronic pain from post-traumatic changes.

16:00 - 17:30 **Room M 5**

E³ - ECR Academies: Update on Hepatobiliary Imaging

E³ 820
Liver and bile duct pathologies

A-372 16:00

Chairperson's introduction

M. Zins; *Paris/FR (mzins@hpsj.fr)*

In this liver and bile duct session we will review, through interactive case presentations, challenging cases of liver abscesses, acute cholangitis, intra, and extrahepatic cholangiocarcinoma as well as benign and malignant conditions of the Gallbladder. The main differentials will be discussed and many tips in assessing accurate diagnosis in liver and bile ducts diseases will be presented.

A-373 16:05

A. Inflammatory and infectious disease

A. Arora; *Worthing/UK (Ankur.Arora@wsht.nhs.uk)*

Infective and inflammatory disorders of the hepatobiliary system are routinely encountered in a radiologist's day to day practice and one ought to be aware of their common and uncommon clinico-radiological manifestations. Imaging undoubtedly plays a crucial role in their timely detection and characterisation and guiding appropriate clinical management. A broad spectrum of infective/inflammatory disorders can affect the hepatobiliary system which for simplicity can be broadly classified into disorders affecting the liver, gallbladder, and the biliary tree, although often these structures are concomitantly involved. We shall appraise the common imaging appearances of different liver infections (bacterial, viral, parasitic, and fungal) on multimodal imaging and discuss relevant differential diagnoses. Whilst in most instances US and CT are sufficient to diagnose and characterise hepatic infections MRI may be resorted to as a problem solving tool for, e.g., to exclude necrotic liver tumours. We shall also review the key imaging manifestation of biliary and gallbladder inflammation/infections with a view to familiarise ourselves with pertinent diagnostic pointers on cross-sectional imaging.

Learning Objectives:

1. To recognise and describe the radiological appearance of the inflammatory-infectious processes that may involve the liver.
2. To describe the imaging findings in inflammatory-infectious processes that may involve bile ducts.
3. To assess the role of different imaging modalities in the detection, characterisation, and management of patients with inflammatory-infectious hepatobiliary disease.

A-374 16:43

B. Cholangiocarcinoma: diagnosing and staging

C. Matos; *Lisbon/PT (celso.matos@fundacaochampalimaud.pt)*

The goals of imaging in patients with suspected or known cholangiocarcinoma (CCA) are multiple: (a) to show the size and the location of a primary lesion and assess the longitudinal and radial extent of bile duct involvement; (b) to enable the characterization of a biliary stenosis; (c) to show involvement of the hepatic artery main and lobar branches and of the portal vein main and lobar branches for the purpose of surgical planning; (d) to depict the presence and extent of liver invasion and of lobar atrophy or hypertrophy, and (e) to enable the detection of regional lymph nodes and metastases. The lecture will address the complementary role of non-invasive and invasive imaging modalities to achieve those goals and will illustrate imaging characteristics that may indicate a specific diagnosis and may help predict prognosis.

Learning Objectives:

1. To be familiar with the multimodality imaging techniques and protocols.
2. To be aware of the imaging findings of different types of cholangiocarcinoma in diagnosing and staging.
3. To be able to recognise recurrent and metastatic disease in the follow-up.

A-375 17:06

C. Gallbladder pathologies

R. Maksimović; *Belgrade/RS (ruzica.maksimovic@med.bg.ac.rs)*

Imaging of gallbladder is including variety of diagnostic imaging modalities such as ultrasonography (US), multidetector computed tomography (MDCT), magnetic resonance imaging (MRI), positron emission tomography (PET), and scintigraphy. Wide variety of diagnostic armamentarium provides accuracy of noninvasive imaging of benign and malignant gallbladder conditions, and thus improves laparoscopic surgery as well as endoscopic and radiologic interventional techniques. US has been the first imaging modality for evaluating gallbladder disease, due to its high sensitivity and specificity for evaluating not only morphology, but also for functional evaluation of the gallbladder. MDCT is valuable diagnostic procedure in differential diagnosis, and for preoperative assesment of different conditions, including the tumour and its sagting, as well as to evaluate therapy response MR is taking place in gall bladder imaging preferentially in patients with limited assessment by US. It allows assesement of anatomic and physiologic features of not only a gallbladder but also biliary tract in preinterventional and postoperative setting. Furthermore, respiratory-triggered three-dimensional MR cholangiopancreatography (3D-MRCP) is a promising new toll for better visualisation of gall bladder lumen, bile duct, and pancreatic duct. The utility of 18F-fluorodeoxyglucose positron emission tomography-computed tomography (18FDG PET-CT) is to provide optimal pre-treatment staging of patients and to tailor subsequent treatment. Cholescintigraphy is the use of radiotracers to assess the anatomy and function of the biliary system, and liver indirectly. Currently this is most commonly performed with Tc99m-IDA analogues, for evaluation of different conditions including biliary atresia where it could be a problem solving tool.

Learning Objectives:

1. To understand the multimodality approach to gallbladder diseases.
2. To be able to identify gallbladder cancer.
3. To be able to differentiate benign conditions from the malignant ones.

Friday, March 2

08:30 - 10:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 921
Emergency radiology II

A-379 08:30
A. Urinary system trauma
V. Logager; *Copenhagen/DK (vibeke.loegager@regionh.dk)*

According to the American Association of Surgeons in Trauma (AAST), approximately, 10% of all trauma admissions have kidney injuries. Blunt traumas can be graded in a 5-point Renal Injury Scale. On the basis of the patient's clinical findings an imaging algorithm is set. In general, patients that are normotensive with microscopic hematuria have less than 0.2% risk of serious kidney damage and imaging is unnecessary, whereas patients with either: (A) gross hematuria, (B) microscopic haematuria and blood pressure less than 90 mmHg or occasionally, (C) microscopic haematuria will require imaging. Contrast-enhanced CT is the way to go. Imaging should be in 3 phases (cortico-medullary, delayed 3-5 min and late phase (more than 10 min). Image reading should be by multiplane approach. Most of the findings do not require surgical intervention. But the rest do. On the basis of case presentations, findings will be analysed, discussed and correlated to the patient's clinical status and treatment possibilities, including where and which signs to look for. Which modality could be used to solve the diagnostic problem when the clinical picture does not fit with the radiological picture. Relevant questions will be asked during this session for the participants to vote and the results will be discussed.

Learning Objectives:
1. To identify the signs of trauma.
2. To outline the clinical impact of these findings.

A-380 09:15
B. Non-traumatic urinary tract emergencies
G. Masselli; *Rome/IT (gabrielemasselli@libero.it)*

Urinary tract (UT) obstruction secondary to urolithiasis is the most common urologic emergency in patients presenting with abdominal pain. Serious complications of acute obstruction include ureteral rupture, pyelonephrosis or abscesses. Radiologists need to define the extent of obstruction, its likely duration and whether an intervention is required, aware that ultrasound (US) is usually normal in case of acute onset. In such cases computerised tomography (CT) is the gold standard diagnostic tool. UT infection (UTI) is another common emergency and it may vary in severity, from ureteral to focal renal infection, emphysematous pyelonephritis or pyonephrosis. UTI diagnosis is usually clinical, but in case of uncertainty CT provides early diagnosis, outlining the extent and severity of the disease. Magnetic resonance diffusion-weighted imaging (DWI) is of particular value when differentiating pyonephrosis from simple hydronephrosis. DWI of the kidneys is highly sensitive for the detection of focal or diffuse infections, reason why is gaining more and more popularity. T2-weighted (static fluid) urography is performed in pregnant women to outline the ureters in their entirety. A challenge of MR urography is the differentiation between physiologic hydronephrosis and pathologic obstruction. Vascular UT emergencies include renal infarcts (commonly of thromboembolic origin), renal vein thrombosis (typical of hypercoagulable states and neoplastic patients), and spontaneous hemorrhage (due to angiomyolipoma rupture). These are among the most common non-traumatic UT emergencies and it is fundamental for every radiologist to be fully confident in their diagnosis. The role of each imaging modality will be interactively discussed in the different clinical scenarios.

Learning Objectives:
1. To understand the imaging technique.
2. To become familiar with the differential diagnosis.

08:30 - 10:00 **Room B**

Abdominal Viscera

RC 901
Imaging of benign liver lesions: still difficult?

A-381 08:30
Chairperson's introduction
L. Martí-Bonmatí; *Valencia/ES (marti_lui@gva.es)*

Benign liver tumours are a heterogeneous group of lesions with different cellular origins and clinical relevance. In this session there will be an interesting discussion on the difficulties and imaging strategies to properly diagnose liver cysts, haemangiomas, FNH and adenomas. These benign lesions are frequently found incidentally during imaging exams perform for unrelated reasons. Most often they do have a benign course, but management difficulties might arise. Radiologist have to recognize the best radiological approaches in terms of modalities and the use of contrast media, the pearls and pitfalls commonly related to these lesions, the main radiological features and diagnostic criteria, and the epidemiological data, pathology, pathophysiology, and their natural progression. Radiological reports should also include recommendations for their management.

Session Objectives:
1. To understand the role of different imaging techniques in characterisation of focal liver lesions.
2. To be aware of malignant lesions which may mimic benign liver conditions.
3. To underline current guidelines for characterisation of equivocal liver lesions.

A-382 08:35
A. Hepatic cysts: always simple?
I. Santiago; *Lisboa/PT (ines.santiago@fundacaochampalimaud.pt)*

The differential diagnosis of cystic liver lesions is as broad as their clinical significance, which ranges from benign to malignant and/or potentially lethal conditions. These lesions include foregut and ductal plate malformations, infectious diseases, primary and secondary neoplasms and traumatic/iatrogenic fluid collections. The number of lesions, morphology, fluid content characteristics, presence/absence of septae and/or solid components are the key imaging features for the diagnostic approach and different imaging modalities pose different advantages and disadvantages for their characterisation. Given imaging characteristics may overlap between distinct conditions, patient history and laboratory data should be integrated to allow a more definitive diagnosis.

Learning Objectives:
1. To learn about different types of cystic lesions in the liver including giant biliary hamartomas or foregut cysts.
2. To understand diagnostic approach to differentiate simple and complex cysts/cystic lesions.
3. To appreciate advantages and limitations of imaging for differentiating simple cyst from other cystic lesions.

A-383 08:58
B. Liver haemangiomas and mimickers
P.R. Ros; *Cleveland, OH/US (Pablo.Ros@UHhospitals.org)*

Hemangioma is the most common benign tumor-like condition in the liver, with a prevalence up to 20% of the general population. Unfortunately its demographics (predominance in women, post-menopausal and without geographic distribution) is similar to that of other primary benign and malignant neoplasms and secondary malignancies. On the other hand, and fortunately, is one of the most successful focal liver lesions to be characterized by imaging. Particularly if a contrast agent is used. Hemangiomas have a (1) distinct morphology, (2) enhancement pattern and (3) signal characteristics by MRI scans. These 3 parameters allow the characterization of hemangiomas in almost all cases. This ease of characterization obviates in almost all cases the use of percutaneous biopsy. Image guided percutaneous biopsy particularly in superficial hemangiomas and using a true cut needle can have serious complications. Hemangiomas can have an atypical imaging appearance since they may contain cystic change, calcification, sclerosis and large central scars, particularly when giant (more than 10cm in size). There is overlap with some other focal lesions that mimic the imaging findings of hemangioma by all imaging modalities: (1) epithelioid hemangioendothelioma (2) angiosarcoma, (3) other vascular sarcomas and (4) treated breast cancer metastasis, which can present with a pseudohemangioma pattern. We offer throughout the presentation imaging/pathologic correlation approach to support the typical and

atypical ultrasound, CT and MRI appearance of hemangioma and its major mimickers.
Learning Objectives:
1. To learn about typical imaging findings of liver haemangioma.
2. To understand the atypical imaging findings of liver haemangiomas.
3. To appreciate the role of multiparametric and liver-specific contrast MRI in differentiation between haemangiomas and malignant lesions mimicking haemangiomas.

A-384 09:21

C. FNH or adenoma?
A. Ba-Ssalamah; *Vienna/AT (ahmed.ba-ssalamah@meduniwien.ac.at)*

FNH and HCA are liver lesions of hepatocellular origin. Whereas FNH commonly occurs, HCA is very rare. Distinguishing FNH from HCA is of great importance clinically, as FNH is considered a benign lesion and needs no further management. In contrast, HCA, according to its subtype, can be considered a borderline tumor due to the risk of hemorrhage, growth, and even malignant transformation, and requires individualized management. The genotype/phenotype classification of HCA is an evolving issue and there is now a recent HCA molecular classification by which to stratify patients according to the risk of complications. On imaging, HCA is no longer a distinct entity and imaging features reflect the tumor subtypes. Contrast-enhanced MRI is much more accurate because of its ability to visualize the textural composition of the HCA. However, even after the administration of MRI hepatobiliary contrast agents, a small proportion of HCA subtypes still show either inhomogeneous uptake or inhomogeneous washout in the hepatobiliary phase (HBP); therefore, it is difficult to differentiate these subtypes from FNH on the basis of imaging presentation alone. This may pose a diagnostic dilemma as both FNH and HCA tend to occur in women of child-bearing age. Clinical presentation and risk factors, male gender, patient age, presence of storage disease, obesity, metabolic syndrome or inflammatory syndrome, hepatitis, alcohol abuse and tumour over 5 cms, as well as significant growth have been identified as factors associated with an HCA subtype of higher malignant potential. In difficult cases histological analysis remains the gold standard.
Learning Objectives:
1. To learn the imaging features associated with FNH and adenoma on contrast-enhanced CT and MRI.
2. To understand how the imaging characteristics are related to the underlying pathological findings.
3. To appreciate the optimal use of liver-specific contrast media for distinguishing between FNH and adenoma, and current classification and pathological characteristics and its impact on the management.

New Horizons Session

NH 9
Immunotherapy: a revolution in cancer care?

A-385 08:30

Chairperson's introduction: What the radiologist needs to know
V.J. Goh; *London/UK*

Evasion of the immune system plays an important role in the development and progression of cancers. Cancer immunotherapies are a promising class of agents that re-engage the immune system in its fight against cancer cells. Strategies range from activating innate/adaptive immune effector mechanisms to neutralising inhibitory/suppressive mechanisms. For example, treatment with interleukin 2 (IL-2) or interferon-α (IFNα) stimulate effector immune cells; conversely antibodies against immune-checkpoint molecules, e.g., cytotoxic T lymphocyte-associated protein 4 (CTLA4)-targeted antibodies and programmed cell death 1 (PD1)-targeted antibodies neutralise immune suppressor mechanisms. Immunotherapies have been shown to be effective in a number of advanced cancers including melanoma, renal cancer, and non-small cell lung cancer. As immunotherapies generate anti-tumour effects by enhancing tumour-specific T cell responses rather than the direct cell killing, response assessment may be challenging. Response may take longer to be detectable by imaging and standard methods, such as response evaluation criteria in solid tumours (RECIST) may be misleading. In this session the role of imaging will be explored and future directions considered.
Session Objectives:
1. To be familiar with the concept of immunotherapy.
2. To be aware of the current imaging methods for assessing immunotherapies.
3. To learn about new methods in development for assessing immunotherapies.
Author Disclosure:
V.J. Goh: Research/Grant Support; Siemens Healthineers. Speaker; Bayer, Siemens Healthineers.

A-386 08:40

CT: looks bigger, but it's better
C. Dromain; *Lausanne/CH (Clarisse.Dromain@chuv.ch)*

A wide range of cancer immunotherapy approaches have been developed including non-specific immune-stimulant such as cytokines (Interferon, IL2), cancer vaccines (peptide or dendritic cell-based vaccines), adoptive T-cell therapy (TILs, CAR, TRC) and immune checkpoint inhibitors (anti CTLA-4, anti PD1 and anti PDL1). The most commonly used and intensively studied are the immune checkpoint inhibitors (ICIs). Their mechanism of action signifies a true shift in oncology where instead of targeting the tumor cells, ICIs target the immune system to break the cancer tolerance and stimulate the anti-tumor immune response. These new drugs have, since 2011, received marketing authorisation for melanoma, lung, bladder, renal, and head and neck cancer with remarkable and long-lasting treatment response. The novel mechanism of action of these drugs, with immune and T-cell activation, lead to unusual patterns of response with presence of flare phenomenon or pseudo-progression more pronounced and more frequent than previously described responses. Pseudo-progression, that has been described in about 3-10% of patients treated using ICIs, corresponds to increase of tumor burden and/or appearance of new lesions due to Infiltration of the tumor by activated T cells before the disease responds to treatment. To overcome the limitation of RECIST criteria to assess this specific changes in tumour burden, new criteria so-called irRC and then irRECIST were proposed. The major modification involved the inclusion of the measurements of new target lesions into disease assessments and the need of a 4-week CT re-assessment to confirm progression. More recently (2017) a consensus guideline iRECIST was developed by the RECIST working group.
Learning Objectives:
1. To be aware of the different types of immunotherapies and to understand their mode of action.
2. To understand the limitations of RECIST and be aware of immune response criteria.
3. To understand the limitations of CT for assessment of immunotherapies.

A-387 09:03

The MR armoury in follow-up
D.-M. Koh; *Sutton/UK (dowmu.koh@icr.ac.uk)*

Drugs that modulate the body immune responses are being utilised to treat a range of cancers, including malignant melanoma, non-small cell lung cancer, hepatocellular and bladder carcinomas. In patients receiving immunotherapies, CT is still the most widely used imaging technique for assessing tumour response to treatment and to identify drug related side-effects. However, anatomical MR imaging can also be effectively applied to evaluate tumour regression with treatment using size measurement criteria (e.g., iRECIST). Like CT, increase in tumour size may be observed on MRI in pseudo-progression, which can confound response assessment. Nonetheless, the superior soft tissue contrast of MRI helps to depict subtle disease (e.g., intracranial) and specific complications (e.g., hypophysitis) that are difficult to visualise on CT. There is great interest in applying quantitative MR imaging, including whole body MRI techniques, to study functional changes in tumour cellularity (diffusion-weighted MRI), vascularity (contrast-enhanced MRI) and macromolecules (magnetisation transfer). These are areas of on-going research. Whole body MRI can provide information about inter-tumoural heterogeneity, thus allowing insights into tumour evolution and differential response to treatment. Active research in molecular probes is being undertaken to develop PET imaging tracers that can identify and predict treatment response, which can be explored alongside multi-parametric MRI measurements on a MRI/PET hybrid system as imaging biomarkers.

Learning Objectives:
1. To be aware of the advantages and limitations of MRI for assessment of immunotherapies.
2. To describe the potential role of whole-body MRI and quantitative MRI techniques in follow-up.
3. To consider the potential of integrated MRI/PET for the assessment of immunotherapies.

A-388 09:26

Systemic and immunologic effects of image-guided interventions in oncology

S.N. Goldberg; *Jerusalem/IL (sgoldber@bidmc.harvard.edu)*

Although interventional oncologists have traditionally assumed that our local therapies including tumor ablation and chemoembolization have minimal systemic effects, there is increasing compelling animal evidence to back up anecdotal clinical reports suggesting that these therapies can stimulate distant effects and can potentially have more widespread effects than just eliminating a focal tumor. On the positive side, several studies have reported that tumor ablation can, under poorly defined “favorable” conditions, induce systemic immunologic “abscopal” effects that induce distant tumor regression. Thus, several groups are pioneering combining interventional oncologic procedures with immunotherapies with the express goal of stimulating immune anti-cancer responses. Simultaneously and by contrast, we and others have demonstrated that radiofrequency and other therapies can in some cases also cause increased cancerous effects by inducing tumor initiation and progression in non-ablated areas. For liver ablation, this has been linked to an increased inflammatory response including cellular recruitment of neutrophils, macrophages, and activated myofibroblasts to the peri-ablated zone and several pro-tumorigenic cytokines such as IL-6 and HGF that increase following ablation. Thus, in all likelihood, there is a balance between pro-oncogenic and pro-immunogenic effects that differs from patient to patient. Thus, our ultimate goal - achievable only through additional mechanistic study - should be to alter the post-ablation milieu to prevent any untoward tumorigenic effects while simultaneously promoting desired abscopic effects.

Learning Objectives:
1. To be aware of abscopal effects with immunotherapy.
2. To describe how focal therapies can be combined with immunotherapies.
3. To be aware of the challenges of focal treatments for systemic effects.

Dose reduction: tips and tricks

Moderator:
C. Granata; Genoa/IT

A-389 08:30

A. Dose reduction in paediatric CT

D. Aadnevik; *Bergen/NO (daniel.aadnevik@helse-bergen.no)*

Computed tomography (CT) is an invaluable tool in diagnostics and the use of CT has rapidly increased since the 1970s. Ionising radiation can damage human tissues, and is associated with an increased risk of cancer. The effect is of particular concern in children as they have a higher radiosensitivity and longer life expectancy. Modern CT scanners have a high level of automatisation regarding acquisition parameters which may leave the imaging professionals insecure whether the radiation dose is appropriate for the diagnostic task at hand. Studies have shown that in some cases adult protocols are directly implemented in paediatric imaging, resulting in unnecessary high doses. As radiation professionals, it is our duty to keep the radiation dose as low as reasonably achievable (ALARA). It is important to have a basic understanding of how technical factors influence image quality and how to properly balance the output parameters of the scanner in accordance with the ALARA-principle. A review of how the basic imaging parameters like tube-current (mA) and tube voltage (kV) affect image quality and patient dose will be given. The use of technique charts and size-specific dose estimates (SSDE) as a tool to ensure appropriate dose levels and consistent image quality for children will be explained. Examples from local optimization studies will also be shown, and a brief review of some vendor-specific solutions for dose reduction will be given.

Learning Objectives:
1. To explain the factors that affect patient radiation exposure from CT exams.
2. To discuss the importance of dose reduction in paediatric CT.
3. To give an overview of CT dose-reduction strategies and techniques.

A-390 09:00

B. Diagnostic reference levels in paediatric imaging: international recommendations

R. Seuri; *Helsinki/FI (raija.seuri@hus.fi)*

The small number of paediatric patients is a challenge to the optimization of imaging protocols. Optimization of parameters and image quality for children of all sizes requires both time and expertise, which might not be easy to find in daily practice. Diagnostic reference levels (DRLs) are a tool to help the optimization process. DRLs are used by collecting patient dose values and comparing the median value to the reference level. In this comparison dose should always be considered together with the indication of imaging and image quality. Diagnostic reference levels were introduced already in 1990s, but only recently have the challenges of paediatric imaging got more attention in the international recommendations. The huge variation of sizes of paediatric patients has usually been tackled by establishing DRLs for different age-groups. Now both ICRP and EC recommend the use of weight for grouping of paediatric patients. Instead of different groups, also a continuous DRL-curve can be used. Detailed advice for the use of DRLs in practice is included in the recent international publications. The international guidelines also provide recommended dose metrics for each modality to be used in DRL comparison. By European recommendation the National DRLs should be based on collection of doses from representative institutions in the country, not phantom measurements. The European DRLs offer a guidance level for optimization in those countries which have not yet established their National DRLs. The most recent European guidelines including the paediatric DRLs were published by the EC in 2017.

Learning Objectives:
1. To discuss the need for establishing diagnostic reference levels (DRLs) in paediatric diagnostic imaging.
2. To give an overview of DRL values for typical paediatric examinations.
3. To understand the way of implementation and use of DRLs in dose reduction and protocol optimisation.

A-391 09:30

C. The impact of dose management systems

L.A. Rainford; *Dublin/IE (louise.rainford@ucd.ie)*

It is mandated by European directive that the establishment and use of DRLs is fulfilled by all member states. Existing levels of dose information varies across imaging sub-specialities, as evidenced by the recent European PiDRL project. Specific challenges continue to confound paediatric dose data collections, including: reduced frequency of examinations compared to adults, patient age/weight/size variations, procedural variability and varied data survey methodologies. Increasing numbers of dose tracking software packages, including those providing web-based dose data collection, tracking and analytics are available. These systems although varied in scope of content offer services, including: dose documentation; dose reference levels setting; performance benchmarking; imaging protocol management; and outlier identification. An overview of products and their management of big data will be provided. Furthermore the current clinical reality that substantial amounts of both unstructured and structured dose data is routinely being captured, with the employment of varied mechanisms of data recording, will be evidenced. Why this information is potentially not being used optimally will be discussed, as will communication matters relevant to dose management products. Practical issues relevant to clinical data required for dose and imaging protocol evaluation will be incorporated based on feedback from a number of European sites. Finally the role of dose management systems in the review of population dose data and protocol optimisation will be discussed and the potential barriers to the successful completion of multi-centre surveys will be considered.

Learning Objectives:
1. To discuss the importance of dose monitoring in paediatric imaging.
2. To have an overview of the features and functions of dose-monitoring systems.
3. To understand the role of dose-monitoring systems in the evaluation of population dose and protocol optimisation.

08:30 - 10:00 **Room N**

Cardiac

RC 903

Novel ways to characterise myocardial tissue: T1 and T2 mapping

Moderator:
L.P. Lawler; Dublin/IE

A-392 08:30

A. T1 mapping: technical considerations
M.R. Makowski; *Berlin/DE (marcus.makowski@charite.de)*

This lecture will introduce the physical principles of T1 mapping for the characterisation of the left ventricular myocardium. Different MR sequence types for the acquisition of T1 mapping will be discussed. The technical challenges of T1 mapping will be highlighted and strategies to overcome these challenges will be introduced. The evaluation of datasets derived from T1 mapping will be discussed. The clinical relevance of T1 mapping techniques in the context the different myocardial diseases will be highlighted.
Learning Objectives:
1. To learn about the principles of T1 mapping.
2. To learn about specific issues of T1 mapping.
3. To learn how to do and assess T1 mapping.

A-393 09:00

B. T2 mapping: technical considerations
C. Tessa; *Lido di Camaiore/IT (ctessa@sirm.org)*

Cardiac T2-mapping is a technique that allows to measure myocardial T2 relaxation time. To this purpose, T2-prepared steady-state free-precession sequences, turbo-spin-echo or gradient-spin-echo sequences with a minimum of 3 source images can be employed. T2 mapping sequences can be acquired both in breath-hold or during free breathing, utilizing respiratory navigators. Cardiac motion is normally avoided by acquiring for a short duration at end diastole, but it is also possible to obtain the maps in systole. Motion correction algorithms are usually applied to source images to compensate for image-to-image displacement. T2 maps are often acquired on a short-axis view at basal and mid-ventricular level. At apical levels, long-axis views should be preferred to avoid partial-volume effects. T2 maps can be analyzed both visually and quantitatively, by means of ROIs or automatic thresholds. Small ROIs (<20 pixels) should be avoided. The reproducibility of T2 mapping sequences is very good. However T2 relaxation time is very sensitive to cofactors and it is therefore, necessary to generate reference values specific for each site, technique and imaging setting. In clinical report, the local reference ranges (mean ±2 standard deviations of the normal data) should be quoted. Additionally, phantom-based periodic control of the CMR system is recommended. Until recently, T2 mapping sequences have not been commercially available, and therefore, current recommendations rely mainly on single-center studies. Nevertheless, there is now growing evidence on the clinical value of T2 mapping, that is expected to become part of a routine cardiac MR examination.
Learning Objectives:
1. To learn about the principles of T2 mapping.
2. To learn about specific issues of T2 mapping.
3. To learn how to do and assess T2 mapping.

A-394 09:30

C. Clinical use of T1 and T2 mapping
J. Bremerich; *Basle/CH (jens.bremerich@usb.ch)*

Comprehensive tissue characterisation is a unique feature of cardiac MRI. Today, a variety of quantification sequences are available as clinical tools. This paper shall illustrate clinical applications of T1- and T2-mapping techniques. Late Gadolinium enhanced MRI (LGE-MRI) opened the door to scar imaging, today even more refined techniques such as T1- and T2-mapping have matured to clinical tools. The combination of pre- and postcontrast T1-mapping might even be used to calculate extracellular volume (ECV), when hematocrit is measured from blood samples. Contrast enhanced T1-mapping enables assessment of structural changes such as in mild inflammation. ECV enables detection and quantification of fibrosis such as in treatment with cardiotoxic medication or infiltrative diseases such as amyloidosis. It should be emphasized, however, that normal T1-values may vary among sequences and magnets. This explains the requirement to establish normal values for every hardware and sequence system. Moreover, T1-times at 3 Tesla are typically longer than at 1.5 Tesla. T2-mapping helps to identify tissue edema as an unspecific imaging marker of myocardial injury. Moreover, T2*-mapping is used to measure iron overload of the heart in hemosiderosis or haematologic diseases. Detailed myocardial tissue characterization with T1- and T2-mapping has matured to a robust clinical tool and adds value to cardiac MRI.
Learning Objectives:
1. To learn about the main fields of application for T1-T2 mapping.
2. To learn the specific parameters useful for the clinical implementation of T1-T2 mapping.
3. To understand the incremental value of T1-T2 mapping over current methodologies.

08:30 - 10:00 **Studio 2018**

Special Focus Session

SF 9a

Focal treatment of prostate cancer

A-395 08:30

Chairperson's introduction
H.-P. Schlemmer; *Heidelberg/DE (h.schlemmer@dkfz.de)*

PSA-screening has led to a higher detection rate of localized, early stage prostate cancer. In this situation whole gland treatment by radical prostatectomy could bear the risk of overtreatment with side effects that may significantly reduce quality of life. To reduce the treatment-related toxicity, alternative therapy options causing less damage of prostate tissue and adjacent structures are increasingly considered. Hemiablation and focal ablation therapies are delivered with intention to cure and are on principle achievable for patients with localised PCa. But a lot of open questions still exist concerning e.g. eligibility criteria of patients, preinterventional diagnostic workup, type of ablation therapy, need for additional treatment, etc. This session will provide the current knowledge about opportunities and challenges of focal therapy of prostate cancer The role of imaging for diagnosis and image-guided interventions by high-intensity ultrasound (HIFU) and irreversible electroporation (IRE) will be discussed in detail.
Session Objectives:
1. To recognise the demand for minimal invasive therapy of prostate cancer.
2. To understand the technologies as well as the pros and cons of focal therapies.
3. To be aware of the value of multiparametric MRI for planning and guidance of focal therapy.

A-396 08:35

Focal treatment of prostate cancer: opportunities, challenges and indications
R. Sanchez-Salas; *Paris/FR (rafael.sanchez-salas@imm.fr)*

Focal therapy (FT) has emerged as an alternative to whole-gland radical treatments with the objective to reduce treatment-related toxicity by sparing prostatic tissue. The FT approach stands on the concept of identifying and treating de index lesion. Selection criteria, optimal treatment modalities and follow-up strategies remain divergent across published series. A recent consensus from field-experts brings guidance to focal treatment strategies in PCa while standardizing the selection criteria and follow-up schemes. Efforts are being made to improve di agnostic tools to optimize patient selection. Multiparametric MRI represents the cornerstone imaging tool for guided diagnostic, treatment and follow-up of these patients. With further development of image-guided diagnostics and deployment of transperineal prostate mapping (TTMB) and MRI-ultrasound fusion biopsies, the histological accuracy at diagnosis has increased with optimal risk definitions and patient selection. Post-ablation surveillance protocols entail monitoring residual post-ablated and preserved tissue. It should be noted that while serum prostate-specific antigen (PSA) kinetics is considered a reliable tool for following patients after local whole-gland treatment, its role after focal therapy is yet to be defined and the thresholds for defining success and failure have not been defined. Key energy sources delivering FT for PCa include cryotherapy, high-intensity focused ultrasound (HIFU), irreversible electroporation (IRE), photodynamic therapy (PDT) and focused laser ablation. In the future, the natural history of non-index lesions in the post ablative setting needs to be addressed. Combined immunological or hormonal interventions could be considered to further improved cancer control of FT.
Learning Objectives:
1. To learn the conceptual possibilities and limitations of focal therapy for prostate cancer.
2. To understand indications and patient selection criteria.
3. To know achievable cure rates, possible causes for failure and treatment-related toxicity.

Author Disclosure:
R. Sanchez-Salas: Consultant; EDAP-TMS. Speaker; EDAP-TMS.

A-397 08:52

Imaging of prostate cancer: how accurately can prostate cancer be localised?

C. Allen; *London/UK (clare.allen@uclh.nhs.uk)*

Successful focal treatment of prostate cancer requires accurate anatomical localisation which can only be provided by Mp MR. Exclusion of disease in the rest of the prostate is also essential. Mp MRI technique is well established and documented in Pirads vs2. However despite this scan quality remains variable. The assessment of quality will be discussed along with the current status of tumour detection within the gland. The size, position and concordance of the MR target with histological target will be discussed. Critical to the success of focal ablation is the communication of a well defined target. The various techniques available to deliver this are discussed along with contouring techniques.

Learning Objectives:
1. To know the examination protocol and the required quality standard of multiparametric MRI.
2. To recognise opportunities and limits of prostate MRI for cancer localisation and delineation.
3. To learn about standardised reporting necessary for precise communication with urologists.

A-398 09:09

Image-guided focal treatment using high-intensity ultrasound (HIFU)

S. Crouzet; *Lyon/FR*

"no abstract submitted"

Learning Objectives:
1. To understand the technology of image-guided high-intensity focused ultrasound (HIFU).
2. To recognise the value of MRI for treatment planning and guidance.
3. To learn about indications, achievable therapeutic results and side effects.

A-399 09:26

Image-guided focal treatment using irreversible electroporation (IRE)

F. Collettini; *Berlin/DE (federico.collettini@charite.de)*

In recent years, focal therapy of prostate cancer has gained great interest from both health care professionals and patients. Irreversible electroporation (IRE) has emerged as a promising technique for tumor ablation and is currently one of the most intensively studied technologies. IRE refers to the generation of permanent, nanoscale pores in the cell membrane by ultra-short, high voltage impulses, resulting in cell death. Features that make this technique particularly attractive comprise its negligible thermal effect on tissue and the lack of connective tissue destruction distinctive of thermal ablative techniques. Available data from clinical studies indicate IRE as a safe and feasible technique for treatment of selected patients suffering from localized prostate cancer, with limited genitourinary toxicity and promising short-term oncological results. Herein we will to review the rationale, as well as the preclinical and clinical data supporting the use of IRE for the treatment of prostate cancer. Furthermore, we will discuss the importance of patient's selection and pretreatment workup with emphasis on the value of magnetic resonance imaging (MRI) for treatment planning.

Learning Objectives:
1. To understand the technology of irreversible electroporation (IRE).
2. To recognise the value of MRI for treatment planning and guidance.
3. To learn about indications, achievable therapeutic results and side effects.

Author Disclosure:

ESR Research Committee Session

How to foster clinical research in imaging departments

Moderator:
O. Clément; Paris/FR

A-400 08:30

Results of the ESR Survey on European Research

O. Clément; *Paris/FR (olivier.clement@aphp.fr)*

A survey about the imaging research was launched by the European Society of Radiology in october 2017. There was questions about: (1) preclinical imaging research and small animal imaging platforms. (2) clinical research with the radiologist as a provider of imaging for the clinician. (3) imaging research performed by the radiologist. The results of the survey will be presented, future actions for the development of research in radiology will be discussed.

Learning Objectives:
1. To learn about the results the European survey on research.
2. To understand how preclinical and clinical research in radiology is organised in Europe.
3. To appreciate the differences between countries.

A-401 08:50

An overview of the roles of radiographers in research

J. McNulty; *Dublin/IE (jonathan.mcnulty@ucd.ie)*

Research and evidence-based practice (EBP) underpin modern health care and can lead to enhanced patient safety, improved patient outcomes, and efficiencies in service delivery. The contribution of radiographers, academic and clinical, to this evidence through undertaking quality research, on any scale, and subsequent dissemination is essential and will also serve to raise the profile and standing of radiography beyond our profession. Radiographers are much more than facilitators, or data providers, in medical imaging research and some of the leading radiography researchers in the world can be found in Europe. These individuals lead large research groups, successfully compete for national and international research funding, collaborate beyond their profession, and publish in high-impact peer-review journals. In 2016, the European Federation of Radiographer Societies (EFRS) published a Statement on Radiography Research in Europe which clearly sets out the EFRS position on encouraging, supporting and developing high-quality radiographer-led research to strengthen the knowledge base underpinning our profession. This statement, together with the 2015 Statement on Evidence-Based Practice in the Undergraduate Curriculum and the European Qualifications Framework (EQF) Level 6 (bachelors) and Level 7 (masters) Benchmarking documents for radiographers, clearly sets out the importance of a clear research focus on educational programmes. Radiographers can add value at all stages of the research process and for medical imaging research to have a true impact, and to benefit our patients it must be inclusive and multidisciplinary and span the academic-clinical divide.

Learning Objectives:
1. To learn about radiographer roles in research studies.
2. To explore the current status of research education and training for radiographers across Europe.
3. To appreciate the added value radiographers can bring to imaging research.

A-402 09:10

How to structure a research management unit in an imaging department

S. Mallard; *Bordeaux/FR (Sabine.mallard@chu-bordeaux.fr)*

To structure imaging platforms in our hospitals is a necessity to meet the current criteria of quality insurance in clinical research. Strengthening optimisation and harmonisation of organisations and practices in our imaging departments will increase their attractiveness to pharmaceutical and industrial companies and will provide better chances of success in research calls. Management of such a research unit requires conciliating perspectives of business management, administrative rationalisation and scientific interests. The purpose of this presentation is to report the experience of implementing a research unit in the imaging department of the University Hospital of Bordeaux since 2011.

Learning Objectives:
1. To learn about the role of a specific imaging research unit in an imaging department.
2. To understand how to structure a research unit in an imaging department.
3. To appreciate the results in terms of quality and performance.

A-403 09:30

Implementing quality imaging in multicentre trials

Y. Liu; *Brussels/BE (yan.liu@eortc.be)*

Imaging is a key component of clinical cancer research and essentially used for trial eligibility confirmation and response assessment in most cases. Nevertheless, difficulties associated with integrating imaging biomarkers into trials have often been ignored, especially for sites that are not familiar with imaging biomarker driven studies. The principles of imaging quality assurance ad quality control (QA/QC) are therefore critical to be embedded in infrastructure to guarantee therapeutic progress, taking into account inherent challenges in the complexity of imaging technologies, standardisation of image acquisition across multivendor platforms, and various post-processing options available with advanced software. Ignorance of these pitfalls has a direct negative impact on the quality of the imaging read-out, even leading to trial failure. The imaging modality by which QA is applied varies substantially within and across the disciplines. The imaging quality requirements should be adapted to the role of imaging, disease types, feasibility, and potential variability of imaging readout, additionally with full operational support through the entire conduct of the trial. In this regard, a risk-based framework is practical and recommendations for trials driven by imaging biomarkers will be introduced in this presentation, including identification of risks at trial initiation to better allocate resources and prioritise key tasks.

Learning Objectives:

1. To learn about the role of imaging in clinical trials.
2. To understand the importance of imaging standardisation in multicentre trials.
3. To appreciate the implementation of quality imaging based on risk assessment.

Breast

RC 902

Minimally-invasive local treatment of breast cancer: the time is now

A-404 08:30

Chairperson's introduction

A. Athanasiou; *Athens/GR (aathanasiou@mitera.gr)*

Breast cancer management has been evolving toward minimally invasive approaches. Image-guided percutaneous biopsy techniques can provide accurate histologic diagnosis thus replacing open surgical biopsies in more than 90% of cases. Breast conservation therapy has become the treatment standard for early-stage breast cancer. Sentinel lymph node biopsy has replaced routine axillary lymph node dissection in selected cases. Is treating early breast cancer without surgery the next challenge? For liver metastases, treatment by means of ablative techniques has widely replaced surgery. Is there any place for minimally invasive treatment of early breast cancer? During this course three main procedures will be presented, and current possible indications, advantages and disadvantages will be analyzed. These procedures include radiofrequency ablation, high intensity focused ultrasound ablation, and cryotherapy ablation. They may offer effective tumor management in selected cases (small<2cm tumors, elderly patients) and provide treatment options that are psychologically and cosmetically more acceptable than traditional surgery. By means of excessive local heating or freezing under imaging guidance, these procedures can cause cell death and tumor destruction. Surgical excision remains the standard local treatment of breast cancer. However, these procedures may represent an interesting alternative of successful treatment in selected cases. Large prospective trials should evaluate the efficacy, cost-effectiveness, cosmetic results and long-term outcome of minimally invasive, imaging-guided local treatments compared with traditional open surgery approach.

Session Objectives:

1. To learn about HIFU, radiofrequency ablation and cryotherapy that challenge traditional surgical excision in the management of breast cancer.
2. To become familiar with role of imaging in using these new technologies.
3. To understand the potential advantages and disadvantages for each of these techniques.

A-405 08:35

A. High-intensity focused ultrasound (HIFU) therapy

F. Pediconi; *Rome/IT (federica.pediconi@uniroma1.it)*

Surgical treatment of breast cancer has changed overtime, evolving from radical mastectomy to more conservative approaches. This has been possible thanks to technical advantages in the field of diagnostic imaging that allowed early diagnosis of breast cancers with very small dimensions. Mini-invasive technologies (radiofrequency ablation, cryoablation, etc.) can preserve the original breast volume avoiding glandular resections and surgical scars and ensuring at the same time complete tumor ablation. Ablation with high-intensity focused ultrasound (HIFU) is based on the use of an extra-corporeal ultrasound transducer that selectively destroys target tissue avoiding thermal damages to surrounding structures. The technique can be performed under ultrasound or magnetic resonance (MR) guidance. MR guidance offers several advantages that improve safety and efficacy of the procedure: a visualization of the planned US beam during each phase of the procedure, a real-time monitoring of the progressive temperature increase within the target tissue and surrounding tissues, an accurate treatment planning, an evaluation of the treatment efficacy thanks to the use of intravenous gadolinium-based contrast agent. HIFU ablation of breast cancer is a new and promising technique that deserves large interest in the field of clinical research in order of its potential application in the clinical practice.

Learning Objectives:

1. To learn about the basics of HIFU therapy.
2. To become familiar with the different types of imaging guidance.
3. To appreciate its role in treating benign and malignant lesions.

A-406 09:00

B. Radiofrequency ablation therapy

B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

Radiofrequency ablation (RFA) is a promising, but quite rarely used minimally invasive modality to treat small breast cancer in patients in whom general anaesthesia is contraindicated or who refuse surgery. In most studies, cancers were surgically excised shortly after RFA. In very few studies, RFA was used as the only treatment modality, instead of surgery. The procedure is most conveniently performed under ultrasound guidance, in local analgesia, which allows constant contact with the patient during the procedure. Precise preprocedural imaging is crucial, and should include contrast-enhanced MRI in addition to mammography and ultrasound. Preprocedural core biopsy is mandatory, with the precise assessment of the tumour type, grade, and immunohistochemical features. Typical US findings of hyperechogenicity of ablated mass are noted during the procedure. Postprocedural mammographic and MRI findings are characteristic and will be presented. The complete ablation can be achieved in small T1-2 N0 M0 breast cancers that present as masses of maximum 2-3 cm in diameter, with the sufficient distance from the skin and pectoral muscle to avoid the thermal lesion of these tissues. In larger lesions only partial ablation may be achieved. Only solitary, unicentric, invasive ductal cancers, preferably ER/PR positive should be treated. Invasive lobular cancers should not be treated with RFA. Our results will be presented in a small group of patients who were treated with RFA, and who refused surgery, had contraindication to general anaesthesia and opted for RFA. The technique, preprocedural, intraprocedural and postprocedural imaging findings, as well as long-term result will be presented.

Learning Objectives:

1. To learn about how radiofrequency works.
2. To become familiar with its use in clinical practice.
3. To appreciate the advantages and disadvantages.

A-407 09:25

C. Cryotherapy

M.H. Fuchsjäger; *Graz/AT (michael.fuchsjaeger@medunigraz.at)*

Cryotherapy is a new, minimal-invasive image-guided treatment option for breast tumours. A specific 12-17G probe is applied into the tumour. Argon gas making use of the Joule-Thomson effect cools down the needle tip to minus 187 degrees centigrade. An ice ball covering lesion and an adequate safety margin is formed. Coagulative necrosis of the tumour cells after two freezing cycles is the result. Cryoablation for breast tumours can be performed under US, CT or MRIguidance. Several studies showed an overall success rate of more than 90%. Indications for cryotherapy are small tumours, contraindications to general anaesthesia or increased risk of complications, support of standard therapies and palliative approach. Cryotherapy can be performed under local anaesthesia on out-patient basis with a potential better cosmetic outcome than standard surgical therapies. Minimal-invasive therapies ask for a paradigm-shift as the eradicated tumour is left in situ and resection with clear margins will not be proven histopathologically, but functionally by MR imaging. It is important to emphasize that radiology is not aiming to take over

therapy of breast cancer patients but to help with innovative, less invasive treatment options as a member of a multidisciplinary team. Close cooperation with our clinical partners (surgery, gynaecology, oncology, radiation therapy, etc.) is the key to success and avoidance of turf battles. The goal for the future should be minimal-invasive ablation therapy for breast cancer as a valid therapeutic option.

Learning Objectives:

1. To learn about cryotherapy technique.
2. To become familiar with its use in clinical practice.
3. To appreciate its role in treating benign and malignant lesions.

Cerebrovascular disease

Moderator:
J.-F. Meder; Paris/FR

A-408 08:30

A. Vascular distribution territories: arterial and venous
T. Engelhorn; *Erlangen/DE (Tobias.Engelhorn@uk-erlangen.de)*

After a short overview on the vascular anatomy of the brain with a focus on vascular distribution territories, the main focus of this talk is to present neurovascular pathologies closely associated with arterial and venous vascular distribution territories. One focus is also put on the acute stroke and subsequent patient selection for interventional stroke therapy. Another aim is to provide a better understanding of pathophysiology of different neurovascular diseases in an interactive matter. In addition, advantages and limitations of CTA, flat-panel CTA and MRA compared to conventional angiography are presented.

Learning Objectives:

1. To become familiar with the vascular anatomy of the brain.
2. To understand the advantages and limitations of CTA and MRA.
3. To recognise the different imaging patterns in stroke and their prognostic value.

A-409 09:00

B. Arterial dissection and vasculitis
L. van den Hauwe; *Antwerp/BE (lucvdhauwe@mac.com)*

Cerebrovascular disease may arise from diverse vessel wall pathologies such as atherosclerosis, dissection, and vasculitis. Careful evaluation of the supra-aortic vessels from the aortic arch through the intracerebral vessels is mandatory in all stroke patients, especially in young stroke patients as the second most common cause of stroke in the young is cervicocerebral arterial dissection accounting for 10-25% of ischemic strokes. Reversible cerebral vasoconstriction syndrome (RCVS) and CNS vasculitis are two distinct disease entities with overlapping presenting symptoms. Conventional vascular imaging techniques such as DSA, MRA, and CTA fail to distinguish both entities, as a result of shared nonspecific luminal findings. More recently, there is a growing interest in high-resolution MRI vessel wall imaging that allows direct characterization of the vessel wall abnormalities. Distinct spatial characteristics of arterial wall thickening and wall enhancement have been described. Moreover, differences in the temporal evolution exist with a long period of stable persisting arterial wall findings for CNS vasculitis compared with a shorter period of resolution of vessel wall abnormalities for RCVS. Also these techniques can help to differentiate vasculitis from other causes of vasculopathy, such as atherosclerosis.

Learning Objectives:

1. To learn how to image dissections of the neck vessels and intracranial arteries.
2. To learn about the imaging features of cerebral vasculitis and how to differentiate it from reversible cerebral vasoconstriction syndrome.
3. To become familiar with the most important causes of secondary vasculitis, including infectious causes such as TB and HIV.

V. Bérczi; Budapest/HU

A-411 08:30

Kidney
O. Akhan; *Ankara/TR (oakhan@hacettepe.edu.tr)*

Renal Cell Carcinoma (RCC) is the most common malignant renal tumour seen for an estimated 2% to 3% of all malignancies in the United States. The incidence of renal tumours has reached to a plateau in the developed countries in recent period it is still an increasing problem in the developing countries. However the incidence of the incidentally detected renal masses has increased in the last decade. Therefore, the management of RCC has greatly changed in this period from radical nephrectomy to nephron-sparing treatment options such as partial nephrectomy or local ablative therapies carried out with RFA, Microwave or Cryoablation. Although the guideline of the American Urological Association suggests partial nephrectomy as a standart treatment option for T1 renal masses, local ablative approach with RFA, Microwave or Cryoablation are getting to be more applied for the treatment. Relative contraindications for the ablative procedures include proximity to the central collecting system, bowel or adrenal glands. These limitations are overcome by the fluid injection along the margin of the targeted lesion by displacing these anatomical structures. The main indications for Renal Artery Embolisation (RAE) include preoperative embolisation before nephrectomy, angiographic treatment of angiomyolipoma, an adjunctive treatment for RCC ablation and for palliation of advanced-stage RCC. RAE is also indicated to reduce blood loss before resection of metastatic RCC.

Learning Objectives:

1. To have a basic knowledge about indications and limitations of interventional radiology procedures in renal malignancies.
2. To have a basic knowledge about embolisation of renal tumours.
3. To become familiar with ablation of renal tumours.

A-412 08:53

Lungs
M. Bezzi; *Rome/IT (mario.bezzi@uniroma1.it)*

Percutaneous needle biopsy has been a mainstay of oncologic diagnosis for more than three decades, since the advent of CT and ultrasound. Percutaneous needle biopsy has become the standard of care in the diagnosis of most lung tumors and is also used to diagnose non cancerous conditions, such as infection. The technique is also beneficial in the staging of patients with cancer, particularly when another treatment method may be more appropriate than surgical resection. Advantages of percutaneous biopsy over surgical excisional biopsy include time and cost savings and reduction in morbidity. Aim of this presentation is to discuss the practical aspects of lung biopsy, needle selection, and guidance techniques and to show how to approach difficult lesions and avoid complications. About 70% of patients with lung cancer are not surgical candidates, either due to advanced disease or comorbidities. Thermal ablation is a minimally invasive treatment that is commonly used in this group of patients, with promising results. Currently, the most widely used ablation techniques in the treatment of lung malignancies are radiofrequency ablation (RFA), microwave ablation, and cryoablation. This presentation reviews the application of thermal ablation in the thorax, including patient selection, basics of procedure technique, imaging follow-up, and treatment results.

Learning Objectives:
1. To have a basic knowledge about indications and limitations of interventional radiology procedures in lung malignancies.
2. To have a basic knowledge about image-guided biopsy.
3. To become familiar with ablation of lung cancer.

A-413 09:15

Bones

A. Gangi; *Strasbourg/FR (gangi@unistra.fr)*

Different image-guided percutaneous techniques can be used for treatment of musculoskeletal tumours. The management of patients with bone tumours requires consideration of: histology of the tumour with differentiation of benign and malignant tumours, careful clinical evaluation of the patient's general condition, understanding of the disease process, appreciation of the degree of bone destruction (biomechanics and consolidation), thorough working knowledge of available treatment options, multidisciplinary decision-making, and precision of the treatment goal: curative or palliative. Curative ablation can be applied for the treatment of specific benign or in selected cases of malignant localized bone tumours. Curative treatment: the therapeutic goal is to ablate the tumour completely and definitively. Pain palliation therapy of primary and secondary bone tumours can be achieved with safe, fast, effective, and tolerable percutaneous methods. Palliative treatment: the therapeutic goal is not complete ablation of the tumour, but pain palliation. Ablation (chemical, thermal, mechanical), and consolidation (cementoplasty, screw fixation···), embolisation techniques can be used separately or in combination.

Learning Objectives:
1. To have a basic knowledge about indications and limitations of interventional radiology procedures in bone malignancies.
2. To understand the basic concepts of embolisation of bone tumours.
3. To have a basic knowledge about bone tumours ablation.

Liver

J.I. Bilbao; *Pamplona/ES (jibilbao@unav.es)*

The liver has a dual vascular supply with seventy five percent of the blood comes from the portal vein and the rest from the hepatic artery. Small (< 1mm) tumors are initially nourished by portal branches; however, when they start growing they deliver pro-angiogenic agents which may create an arterial network that ensures its vascularization. Thus, liver tumors are almost exclusively vascularized by the hepatic artery and can be safely treated by an endovascular approach. The angiographic appearance of a liver tumor depends on the amount of the arterio-capillary network and hypervascular tumors are easily detected and more adequate for receiving endovascular treatments. One therapeutic possibility is to occlude the vascular network and close the afferent vessels ("embolization") provoking ischemia that will lead to necrosis. However, since the tumor send continuous pro-angiogenic signals, if there is a decrease in the blood supply, the ischemic effect will trigger an increase in angiogenesis. For abolishing such effect it is possible to add chemotherapeutic agents ("chemoembolization"), together with the occluding particles, with the aim of obtaining a more complete antineoplastic effect. A different approach consists in the use of small particles just as carriers, with no occluding effect, that will place an anticancer agent intratumourly. When the agent is a radioisotope the procedure is called "radioembolization", a form of brachytherapy. By using a percutaneous access, some tumors (<3cm) can be punctured with probes through which energy (heat radiofrequency/microwaves or cold cryotherapy) is delivered which will lead to tumoural necrosis ("ablation").

Learning Objectives:
1. To understand the basic concepts of chemoembolisation in liver malignancies.
2. To understand the basic concepts of radioembolisation in liver malignancies.
3. To have a basic knowledge about liver tumours ablation.

Imaging the hip and thigh

Moderator:
M. Klontzas; London/UK

A-415 08:30

A. Femoroacetabular impingement: what is it, how do I image it and does it matter?

R. Sutter; *Zurich/CH*

The last decade has seen a constant rise in the number of patients diagnosed and treated for femoroacetabular impingement (FAI). However, there are ongoing controversies about the accuracy of measurements for assessing FAI and an associated overdiagnosis of FAI. This refresher course covers the pathophysiology of FAI, the classic osseous hallmarks, and the characteristic damage to the articular cartilage and labrum. It gives an overview of state-of-the art FAI imaging with different radiological modalities, including the use of traction at MR arthrography, and addresses possible pitfalls when evaluating the hip joint. Additional anatomical factors are described that contribute to the development of FAI, such as abnormal femoral antetorsion and acetabular version. And finally, the relevance of the different parts of the diagnostic algorithm for evaluating FAI are discussed.

Learning Objectives:
1. To understand the mechanism of femoroacetabular impingement.
2. To learn about the imaging findings in patients with femoroacetabular impingement.

A-416 09:00

B. Groin pain in the athlete: what causes it and what does imaging contribute?

P. Robinson; *Leeds/UK (philip.robinson10@nhs.net)*

Groin pain in the athlete is a complex process with different researchers focusing on the symphysis pubis joint, the adductor longus enthesis, pubic subchondral stress fractures, lower abdominal muscle abnormalities as well as inguinal muscular and aponeurotic tears. There is also confusion over terminology with, for example, osteitis pubis and sportsman's hernia encompassing many different potential conditions for different clinicians. In reality there is a lot of crossover with many or all of the above regions thought to be involved by chronic shearing forces acting through the symphysis pubis and surrounding soft tissues. This lecture will review: (1) Biomechanics and functional anatomy of the anterior pelvis in relation to athletes especially kicking sports. (2) Theories and nomenclature for the pathogenesis of chronic groin pain in athletes. (3) Imaging findings in symptomatic and asymptomatic athletes focussing on the use of MR imaging. (4) The interpretation of these findings and what research shows they relate to in terms of diagnosis, prognosis and decision making for treatment.

Learning Objectives:
1. To understand the anatomy of the groin region.
2. To learn about the imaging findings in athletes with groin pain.

A-417 09:30

C. Muscle injury of the hip and thigh

M.-A. Weber; *Rostock/DE (marc-andre.weber@med.uni-rostock.de)*

This lecture will focus on MRI for the assessment of muscle injuries at the hip and thigh using fluid sensitive sequences. Muscle injuries include a large variety of imaging patterns from occasionally subtle changes in muscle strain to complete muscle tears. Exercise-related chronic changes such as delayed onset muscle soreness, compartment syndrome, and muscle hernias, as well as complications of muscle injuries such as myositis ossificans may be encountered. The MRI appearance of a muscle contusion may be similar to a muscle strain/tear. Mild post exercise oedema can persist for some time and can mimic a low grade muscle strain injury. 35% of all soccer injuries are muscle injuries and they are the most frequent cause for missing a game. The myotendinous junction is the weakest link in the muscle-tendon-bone chain. The widely used grading system for muscle injuries divides muscle injuries in four grades (grade 0: normal MRI, i.e., functional injury of the muscle, grade 1: oedema, grade 2: partial rupture, grade 3: complete tear). However, this grading system is only a rough estimate, because grade 2 injuries comprise a wide range from tiny fibre discontinuities to subtotal muscle ruptures. Measures of the longitudinal length as well as the percentage and volume of the muscle injury in MRI have some predictive value with respect to time to return to sports

activities. Moreover, injury to the intramuscular component of the tendon has prognostic significance. A complete tear (grade 3) may require surgery.
Learning Objectives:
1. To understand the imaging patterns of muscle injury at the hip and thigh.
2. To learn about grading and prognostic values of muscle injuries.

EFOMP Workshop: Radiation dose management systems and repositories: the present and the future

EF 1
Dose management systems and repositories: part A

Moderator:
A. Trianni; Udine/IT

A-418 08:30
Chairperson's introduction
J. Damilakis; *Iraklion/GR (damilaki@med.uoc.gr)*

Dose management systems collect dose data from imaging systems that can be displayed in a variety of formats for analysis and benchmarking. Reviewing practices helps identify areas for improvement. They also play an important role in the establishment of local dose reference levels. Dose repositories are central places directly accessible to users in which an aggregation of dose data is kept in an organised way for benchmarking, research, dose optimisation, and patient dose reduction. However, there are challenges in developing these systems. Their creation is an expensive process, there are technological difficulties, security and legal issues and issues related to coding systems. Coding is required in different steps across the imaging workflow, i.e., for ordering and performing of imaging procedures, reporting of findings and for quality processes such as radiation exposure measurement and reporting. The degree of variability in procedure names is a considerable challenge. A tool is needed to help facilities map names of procedures, clinical symptoms, anatomical locations, findings, etc. to the closest matching of a standardised catalogue.
Session Objectives:
1. To become familiar with the main features of dose management systems and repositories.
2. To discuss the services provided by these systems.
3. To understand how dose management systems can optimise medical imaging.

A-419 08:35
The 'EuroSafe Imaging' campaign's point of view
G. Frija; *Paris/FR (guy.frija@aphp.fr)*

"no abstract submitted"
Learning Objectives:
1. To become familiar with the EuroSafe Imaging campaign's point of view regarding dose management systems and repositories.
2. To understand why collaboration among radiologists, medical physicists and radiographers is needed for the optimum use of these systems.
3. To learn the impact of dose management systems and repositories in the clinical practice.

A-420 09:05
Strategies for dose management for achieving optimised imaging
J.N. Vassileva; *Vienna/AT (j.n.vassileva@gmail.com)*

International standards and guidelines express the need for medical facilities to monitor patient radiation doses for the imaging procedures they perform. The monitoring process includes several steps: recording of relevant patient exposure and dose-related data at the facility and their collection and analysis. The amount of information and the method of recording and collecting depend on the purpose, modality, and model. Collected data from different patients, modalities, and units are combined and processed to perform relevant dose analysis, which might include statistics, trending, tracking, or comparisons. This can be done at local, regional, national, or international level. Data quality evaluations should be conducted at all steps. Analysis of collected data may be at the level of group of patients, or at the level of individual patients. Analysis at the level of group includes setting typical doses and diagnostic reference levels, procedural optimisation, monitoring operations and trends in the clinical practice, and tracking over time. Samples based on specific examination, patient group, or acquisition conditions should be well defined. Availability of a good coding system of examination and protocol nomenclature is crucial. Tracking of exposure history of individuals requires patient identification. It is useful to avoid performing redundant radiological examination and optimise the overall patient care. A dose data management infrastructure may deploy an integrated electronic system, the interface and functionalities of which depend on the intentional user groups. Ideally, it should be integrated with the general patient information systems. If properly implemented, the patient exposure data management contributes to the improvement of radiation protection and patient care.
Learning Objectives:
1. To learn about the main features of a system for collection and analysis of dosimetric data.
2. To become familiar with different analytical uses of collected dose data.
3. To understand how patient exposure data management fits into the framework of continuous optimisation of medical imaging.

A-421 09:35
The benefits of dose management systems in view of the new Euratom Directive
V. Tsapaki; *Athens/GR (virginia@otenet.gr)*

The New Council Directive 2013/59/Euratom lays down basic safety standards for protection against the dangers arising from exposure to ionising radiation, repealing relevant previous directives. It forms a solid pillar for radiation protection in Europe and aims to enhance it according to the state of science and technology. Dose management systems are sophisticated software with friendly interface, that provide a structured way to monitor all data included in the digital Imaging and communication in medicine (DICOM) header of digital X-ray machines or data recorded in the picture archiving and communication system (PACS) of the hospital. They can facilitate in defining diagnostic reference levels, in identifying unusual high patient radiation dose, in detecting incidents and/or accidents in all imaging X-ray modalities of the radiology department. The presentation will go through the articles of the directive and show possible ways that these systems can help to comply with the directive.
Learning Objectives:
1. To understand how the dose management tools can help in implementation of the new European Directive.
2. To become familiar with the different capabilities of the dose management tools and their connection with the European Directive.
3. To identify the possible limitations of dose management tools in relation with the European Directive.

08:30 - 10:00 **Room K**

Special Focus Session

SF 9b
Radiographers in preclinical imaging research

A-422 08:30
Chairpersons' introduction (part 1)
C. Buissink; *Groningen/NL (c.buissink@pl.hanze.nl)*

The role of radiographers in preclinical imaging research - that's the question? There are several methods and opinions to give answers on this question. To formulate your own opinion you need background information. Get familiar with the preclinical imaging research objectives and constraints and the impact of the radiographers in this process.
Session Objectives:
1. To learn more about the techniques devoted to preclinical imaging research.
2. To become familiar with the preclinical image research objectives and constraints.
3. To appreciate the impact of radiographers in preclinical imaging research.

A-423 08:33
Chairpersons' introduction (part 2)
N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Involvement of radiographers in preclinical imaging remains limited because most centres are driven by researchers. Radiographers' skills covering technical, anatomical and clinical fields could be highly beneficial to these research centres. On the other hand, involvement of radiographers in new preclinical molecular and quantitative imaging methods, which are highly growing fields, could be highly beneficial for their own professional development and to clinical structures when returning to clinical imaging. This

session will develop these win-win issues as well as, several fields of quantitative imaging using MRI and nuclear medicine.

Session Objectives:

1. To learn more about the techniques devoted to preclinical imaging research.
2. To become familiar with the preclinical image research objectives and constraints.
3. To appreciate the impact of radiographers in preclinical imaging research.

Author Disclosure:

N. Grenier: Advisory Board; Supersonic Imagine, Aix-en-Provence, France.

A-424 08:35

Radiographers in preclinical research: challenges and chances

J.-P. Dillenseger; *Strasbourg/FR (jpdil@me.com)*

Small animals imaging is a growing field which is appearing as an essential step filling the gap between preclinical and clinical research domains; at the University Hospital of Strasbourg, a preclinical imaging unit has been identified since 2011. This unit is located in the middle of the clinical imaging department. Its philosophy is to apply translational imaging research with the same modalities that can be found in a clinical imaging department (e.g., SPECT, CT and clinical field MRI), but it also aimed at working with a similar organisation. We believe that the best way to achieve this goal is to recruit a radiographer in such preclinical department. The place of radiographers in such a preclinical laboratory seems evident for us to benefit from their clinical experience, practical skills as well as general and deep knowledge in medical imaging. All the tasks performed are in accordance with the new French decree (decree 2016-1672 - Dec. 5, 2016); preparation of the subject before any imaging act (e.g., care and registration). - Radiation safety procedures implementation (e.g., dosimetry management, laboratory contamination controls, management of radioactive waste products) - Quality controls - Preparation and administration of contrast agents and radioactive tracers - Imaging devices operation (positioning, parameters setting, post-processing and data management) - Research and training (e.g., close relationship with researchers, physicians and engineers; radiographers trainees). Our experience demonstrates that the integration of a radiographer in a preclinical imaging department is an added value to scientific projects and provides a fluent organisation. Radiographer collaboration with a research team improves and facilitates sequence of procedures and consequently increases the throughput. We believe that preclinical imaging will offers new opportunities for radiographers in the future.

Learning Objectives:

1. To learn about the importance of translational imaging research.
2. To understand the contribution radiographers can play in preclinical research.
3. To appreciate essential skills and knowledge required in preclinical imaging.

A-425 08:53

Preclinical evaluation of PET tracers

M. Zeilinger; *Wiener Neustadt/AT (markus.zeilinger@fhwn.ac.at)*

Molecular imaging, especially the field of PET, becomes a vital and versatile modality for modern medicine, as well as for applied medicinal research. Common indications belong to diagnosis, differential diagnosis, therapy control, prevention of diseases and research of pathophysiological processes. The potential of molecular imaging and their capabilities strongly depends on the presently developed and established imaging probes. Hence the evaluation and development of new selective radiopharmaceuticals would be an indispensable part to increase the scope of application for molecular imaging. The key factor in the evaluation of potential PET radiotracers is the selection of substances with high affinity, selectivity and low unspecific binding. Thus, several preclinical procedures, such as biodistribution experiments, ex-vivo and in-vitro autoradiography, metabolic stability testing, cell binding studies, µPET-experiments, and the appropriate data post-processing, as well as biomedical imaging quantification procedures are necessary.

Learning Objectives:

1. To understand the connection between molecular imaging and the drug discovery process.
2. To become familiar with quantitative molecular imaging approaches.
3. To review technical and biomedical limitations and future perspectives.

A-426 09:11

SPECT/CT

S. Heskamp; *Nijmengen/NL (Sandra.Heskamp@radboudumc.nl)*

MicroSPECT/CT imaging can provide important information regarding the biology of tumours and other disease processes. It can be used to measure the expression of tumour-associated antigens, for example, to develop a novel biomarker for targeted therapies. Furthermore, theranostic agents can be developed which combine the potential of diagnosis and radionuclide therapy. For example, ^{111}In-PSMA targeting molecules have been used to image prostate cancer xenografts and to calculate the maximum tolerable dose before kidney toxicity would occur during ^{177}Lu-PSMA-targeted radionuclide therapy. Finally, microSPECT/CT imaging can be used to monitor therapy induced changes in the tumour microenvironment, such as the expression of growth factors, tumour vasculature, and the presence of immune cells.

Learning Objectives:

1. To understand the basic principles of preclinical SPECT/CT and the differences with clinical SPECT/CT.
2. To become familiar with the practical aspects which are relevant for preclinical SPECT/CT.
3. To appreciate how preclinical SPECT/CT can help to answer basic oncological research questions.

A-427 09:29

Small animal imaging studies

F. Pichler, M. Zeilinger; *Wiener Neustadt/AT*

Several topics like species differences, technical limitations, anaesthesia, and physiological constraints have to be taken into account for small animal imaging studies. Considering that mice are approximately 20 times smaller and 1500 times lighter compared to humans certain challenges occur. Furthermore, nuclear medicine positron emission tomography (PET) systems for humans are around 5 times larger in diameter compared to preclinical µPET-systems. Besides that, injected activities are increased in small animals to compensate for the lack of sensitivity in preclinical systems. In this regard, also the substance volume that can be administered is a limiting factor, especially when several substances like the radiotracer, inhibitors and possibly contrast media have to be applied. Anaesthesia effects are another source of error which have to be considered on an individual basis. For instance, intraperitoneal administered ketamine/xylocaine leads to increased FDG uptake in peripheral regions while inhaled isoflurane decreases FDG uptake in the brain. The origin of these effects is not yet fully understood. The choice of anaesthesia can also influence the final positioning in the field of view of the scanner. This means that with injection anaesthesia a free positioning is possible whereas with gas anaesthesia the inhalation mask limits the final position. Lastly, all experiments have to be planned in compliance with the 3R principle (replacement, reduction, and refinement), which has to be considered for all decisions.

Learning Objectives:

1. To understand work-related challenges in preclinical small animal imaging.
2. To consider limitations in the quantification of preclinical µPET data.
3. To appreciate the radiographers role in a preclinical environment in contrast to clinical work.

09:47

Panel discussion: Is there a role for radiographers in preclinical imaging research?

08:30 - 10:00 **Room M 1**

Professional Challenges Session

PC 9

How can radiologists expand their role in peripheral vascular intervention?

A-428 08:30

Chairperson's introduction

R. Iezzi; *Rome/IT (roberto.iezzi.md@gmail.com)*

Peripheral arterial disease (PAD) continues to grow in global prevalence, consuming an increasing amount of resources in the health care system. Overall rates of intervention for PAD have been rising steadily in recent years. Changing demographics, evolution of technologies, and an expanding database of outcomes studies are primary forces influencing clinical decision making in PAD. The management of PAD is multidisciplinary, involving primary care physicians and vascular specialists with varying expertise in diagnostic and treatment modalities. This approach has the greatest chance of providing optimal care for the patients and ensuring ongoing surveillance of the patient's overall health, ultimately resulting in better quality of life and increased longevity. Furthermore, it has been recognized that clinical management of patients undergoing interventional radiological procedures is an essential component of a successful, contemporary interventional radiology practice, with several well-respected interventional radiologists emphasizing the importance of direct patient management. To effectively participate in patient

management, interventionalists require a clinical knowhow as well as an infrastructure within their practice to support these services. All these clinical as well as radiological aspects need to be integrated and implemented in dedicated vascular intervention training programmes. Main goals of these programs should be to provide IR fellows with an organized, comprehensive, supervised, full-time educational experience including the ability to provide consultation and case selection, perform the full array of vascular and interventional procedures, identify and manage potential complications, provide appropriate peri-procedure care, and assist in long-term management integrated with the clinical management of referring physicians.

Session Objectives:

1. To focus on the needs for and challenges in organising a multidisciplinary team.
2. To understand the role of clinical as well as radiological evaluation for outpatients consultation and post-procedure visits.
3. To understand how to implement vascular intervention training programmes.

A-429 08:35

How to improve your clinical knowledge

C.W. Kopp; *Vienna/AT (christoph.kopp@meduniwien.ac.at)*

For decision-making within the vascular board, it is important to understand not only the anatomy and potential revascularisation strategies, but also to respect the patient's clinical status, age and frailty, renal impairment, as well as cardiovascular and bleeding risk to impact on both symptom relief and prognosis in PAD patients, regarding wound healing and limb salvage. Cutting edge studies have recently changed our understanding of how to implement the best medical treatment for the underlying disease of atherosclerosis and atherothrombosis. This talk will focus on major cardiovascular risk factors and their respective best medical treatment, ranging from goals of antihypertensive and lipid-lowering treatment and vascular protection from new antidiabetics to strategic changes in the treatment of atherothrombosis, including the current recommendation of NOACs and antiplatelet therapy in PAD. Finally, caveats of age such as frailty, renal impairment and the safe use of contrast media will be covered.

Learning Objectives:

1. To become familiar with clinical diagnosis and classification of arterial occlusive disease.
2. To understand the disease states being treated and their clinical management.
3. To learn about intraprocedural and postprocedural medical treatment.

A-430 08:53

How to improve your diagnostic skills

T. Leiner; *Utrecht/NL (t.leiner@umcutrecht.nl)*

Non-invasive vascular imaging is now considered a cornerstone of the pre-interventional workup of patients with peripheral arterial disease. Although imaging is not needed to establish the diagnosis, imaging provides a roadmap for endovascular intervention and it can outline surgical therapeutic options. In my lecture I will discuss the strengths and limitations as well as the practical implementation of the most commonly used non-invasive imaging tools to asses peripheral arterial disease.

Learning Objectives:

1. To understand the crucial role of US in the diagnostic assessment and patient recruitment.
2. To learn when is needed to perform a MRA, CTA, or DSA examination.
3. To learn the optimal imaging algorithm for diagnosis and follow-up.

Author Disclosure:

T. Leiner: Research/Grant Support; Philips Healthcare; Bayer Healthcare. Speaker; Philips Healthcare; Bayer Healthcare.

A-431 09:11

How to improve your relationship with the vascular surgeon

C. Ferrer; *Rome/IT*

"no abstract submitted"

Learning Objectives:

1. To understand the challenges of open surgical treatments.
2. To learn about hybrid (surgical and endovascular) treatments.
3. To learn about outcomes of open surgical procedures.

A-432 09:29

How to improve your technical/procedural skills

K. Katsanos; *Patras/GR (katsanos@med.upatras.gr)*

Percutaneous endovascular interventions have evolved to the mainstay treatment of peripheral arterial disease manifesting as short distance claudication or critical limb ischemia (CLI). Several new technologies, such as biomimetic metal stents, drug-eluting stents, covered stents, and drug-coated balloons, have emerged to address the Achilles heel of neointimal hyperplasia and restenosis, and thereby improve long-term patency outcomes. Novel techniques of arterial access and recanalisation, like the pedal or transradial approach, the pedal-loop techniques, and complex rendezvous strategies may help save legs in cases of advanced CLI with severe anatomical complexity. Transcatheter atherectomy may achieve atherosclerotic plaque clearance by means of directional plaque excision or rotational plaque removal or laser plaque ablation. Debulking atherectomy may allow for a more uniform angioplasty result at lower pressures with consequently less vessel barotrauma, improved luminal gain and potential combination with drug-coated balloons without permanent stent implants. Newer functional imaging modalities such as perfusion angiography and near infrared spectroscopy to monitor deep tissue oxygen levels will be part of multimodality peripheral interventions of the future.

Learning Objectives:

1. To understand how to perform an accurate treatment planning.
2. To learn how to select the right endovascular treatment for the right patient.
3. To understand the challenges and future prospective of endovascular devices and treatments.

09:47

Panel discussion: Are we ready to be more of a clinician rather than an operator?

08:30 - 10:00 **Room M 2**

E³ 926

Distant metastases of head and neck cancer

A-433 08:30

Chairperson's introduction

P.-Y. Marcy; *Ollioules/FR (brozpy@gmail.com)*

We aim to understand the impact of distant metastases diagnosis in head and neck treatment. Imaging modalities are important in diagnosis and treatment planning, post-treatment assessment, and residual mass (DCE MR), local failure (early intra-treatment DW MR), and locoregional and distant metastases recurrence/second primary/complication assessment. They provide anatomical images, but also functional-based MRI/ PET: molecular/metabolic/physiological information. Cost-effectiveness studies are mandatory to evaluate the impact of imaging on the Qol and overall survival in head and neck cancer patients.

Session Objective:

1. To understand impact of the distant metastases in the head and neck treatment.

A-434 08:35

A. Incidence and prognosis of synchronous cancer or distant metastases from head and neck tumours

A.D. King; *Hong Kong/CN (king2015@cuhk.edu.hk)*

Distant metastases: The advance in treatment of head & neck carcinoma (HNC) has improved locoregional control and so distant metastases (DM) are emerging as a major determinant of survival. Therefore, a more active approach is being taken to detect and manage distant site disease, including the use of a new generation of immunotherapy agents. Most DM do not manifest until after initial treatment, prognosis tends to be poor with patients succumbing to disease within a year. However, prognosis is dependent on many factors which include histology, site and number of DM. Notably some patients survive long term and there is a subgroup of patients with oligometastases who have potentially curable disease. In this presentation, incidence, risk factors, sites, prognosis, and management will be discussed according to the main histological groups of carcinoma that arise in the aerodigestive tract including squamous cell carcinoma (SCC), thyroid and salivary glands. Second primary tumours: Head & neck cancer has one of the highest associations with a second primary tumour (SPT). Risk factors for SCC

include smoking and high alcohol intake, and so these patients are also at risk of SPTs in other sites of the head & neck, lungs and oesophagus. Less commonly SPTs arise in the colon, pancreas and bladder. SPTs are usually metachronous, with synchronous tumours being diagnosed in only ~ 4% of patients. SPTs are a leading cause of death in patients with early stage SCC, but those SPTs detected early are potentially curable.

Learning Objectives:

1. To become familiar with the incidence of the synchronous tumours in the head and neck population.
2. To become familiar with the incidence of the distant metastases in the patients with newly diagnosed head and neck cancer.
3. To understand the consequences in a prognosis.

A-435 08:58

B. Is morphologic imaging enough to stage patients with head and neck tumours before therapy?

S. Rohde; *Dortmund/DE (stefan.rohde@klinikumdo.de)*

The lecture will focus on the importance of morphologic imaging in the management of patients with head and neck malignencies. Imaging features of local and distant tumour recurrence will be presented, and the potential and limitations of morphologic imaging modalities including diffusion and perfusion techniques will be discussed.

Learning Objectives:

1. To review current guidelines and clinical practice.
2. To understand the advantages and disadvantages of the conventional imaging modalities.
3. To appreciate cost-effectiveness of different imaging modalities.

A-436 09:21

C. Is functional imaging necessary to detect distant metastases in head and neck cancers?

R. Maroldi; *Brescia/IT*

"no abstract submitted"

Learning Objectives:

1. To learn about functional imaging (DWI, DECT, PET) in head and neck cancer patients.
2. To understand the advantages and disadvantages of the functional imaging modalities.
3. To review the advanced imaging for detection of distant metastases of head and neck cancer.

09:44

Panel discussion: Where and how to search for distant metastases in head and neck cancer

08:30 - 10:00 **Room M 3**

ESR Working Group on Ultrasound

WG 2
Tips and tricks for abdominal ultrasound

A-437 08:30

Chairpersons' introduction (part 1)

M. Claudon; *Vandoeuvre-les-Nancy/FR (m.claudon@chu-nancy.fr)*

The evaluation of normal and abnormal abdomen is one of the major clinical indications for sonography. Flow imaging, including Doppler techniques and contrast-enhanced ultrasound (CEUS), are now commonly used for the liver and more and more often for the spleen, pancreas and intestine. Elastography of the liver has slowly arisen as a current modality in many institutions. The ability to fuse CT, MRI, or PET-CT/MRI with real-time ultrasound has further increased the interest of ultrasound as a second- or third-level diagnostic modality as well as for interventional purpose. Radiologists, especially juniors, should be confident in using these modalities and be aware of the many tips and tricks they offer.

Session Objectives:

1. To learn about actual indications and applications of ultrasound Doppler imaging, CEUS, elastography and ultrasound fusion imaging.
2. To show better parameter settings for optimal technical results illustrating tips and tricks for technical and clinical successful examinations.
3. To become familiar with the new ultrasound imaging techniques and applications.

Author Disclosure:

M. Claudon: Speaker; Philips Ultrasound.

A-438 08:35

Chairpersons' introduction (part 2)

V. Valek; *Brno/CZ (vlvalek@med.muni.cz)*

Ultrasound is a non-invasive accessible and versatile diagnostic technique that uses high frequency ultrasound waves to outline organs of the human body without ionising radiation in real time and with the capacity to visualise several planes. The high diagnostic yield of the technique has made it a routine method in daily medical practice. CEUS has the ability to characterise parenchymal organ lesions and has been proven superior to colour and power Doppler ultrasound in the detection of tumour vascularity. Ultrasound Tissue Doppler imaging (US-TDI) has been used to diagnose regional wall motion (WM) abnormalities in coronary artery disease and other indications. The recent development of ultrasound elastography techniques allows a non-invasive method of estimating organ structure. Transient elastography (TE) is a non-imaging elastographic technique, while point shear wave (p-SWE) and 2D-SWE combine imaging with elastography. The evidence at this time suggests that p-SWE is as accurate but more reliable than TE, while 2D-SWE is more accurate than TE. Fusion imaging combines the advantages of ultrasound and CT/MRI while avoiding their disadvantages. It is often achieved by using an external electromagnetic field system with a position sensor mounted on an ultrasound transducer. This allows tracking of transducer movements and matching ultrasound and CT/MRI image datasets, the real-time ultrasound image moves with the CT/MRI image. Once the two images match well, the target lesion on ultrasound image can be located according to the CT/MRI image. It is important to become familiar with these new ultrasound imaging techniques and their applications.

Session Objectives:

1. To learn about actual indications and applications of ultrasound Doppler imaging, CEUS, elastography and ultrasound fusion imaging.
2. To show better parameter settings for optimal technical results illustrating tips and tricks for technical and clinical successful examinations.
3. To become familiar with the new ultrasound imaging techniques and applications.

A-439 08:40

Doppler imaging

F. Calliada; *Pavia/IT (fabrizio.calliada@gmail.com)*

Doppler is surely not a new imaging technique, but an adequate knowledge of the basic physics and of the scanner tuning is essential to avoid errors and misunderstanding. The first part the presentation will cover the principal sources of error that should be avoided during a Doppler examination and the major tuning tricks needed for an optimal and successful examination. In the second part, we will try to become familiar with new Doppler imaging techniques dedicated both to very low velocity microvascular flow and to high velocity complex flow representation.

Learning Objectives:

1. To learn about actual indications and applications of Doppler imaging.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new Doppler imaging techniques and applications.

Author Disclosure:

F. Calliada: Speaker; Toshiba, Mindray, Hitachi.

A-440 09:00

CEUS

M. D'Onofrio; *Verona/IT (mirko.donofrio@univr.it)*

Contrast-enhanced ultrasonography (CEUS) is a safe and accurate imaging method to evaluate the vascularity of abdominal organs. CEUS improve the ultrasound characterization of tumoural masses. CEUS should be performed when possible immediately after the US detection of indeterminate mass in abdominal organs. CEUS is accurate in the characterization of neoplastic lesions such as liver metastases and pancreatic ductal adenocarcinoma. The use of CEUS in studying focal liver and pancreatic lesions found at US, especially in the same session of ultrasound examination, is therefore recommended to promote faster diagnosis. In particular, liver metastases detection could be improved by the use of contrast-enhanced ultrasound with respect to basal examination. The actual indications and applications of CEUS are presented in official published guidelines. Every CEUS examination should be performed with the better parameter settings for optimal technical results.

Learning Objectives:
1. To learn about actual indications and applications of CEUS.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new CEUS techniques and applications.

Author Disclosure:
M. D'Onofrio: Advisory Board; Siemens, BRACCO. Consultant; Bracco, Siemens. Speaker; Bracco, Siemens.

A-441 09:20

Elastography

D.A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Elastography has become a standard-of-care supplementary ultrasound imaging modality in modern radiological diagnostic in recent years and is an ideal tool for the detection and characterization of tissue properties. With different elastography techniques, it is possible to quantitatively as well as qualitatively assess tissue properties. In daily clinical routine, elastography is mostly used in oncological imaging as well as in the quantification of liver stiffness for the evaluation of liver fibrosis and cirrhosis. The benefits of elastography are the cost-effectiveness of the method, being a non-invasive imaging modality and the easy application of the technique. This course describes the most common applications of ultrasound elastography in daily clinical routine.

Learning Objectives:
1. To learn about actual indications and applications of elastography.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new elastography techniques and applications.

Author Disclosure:
D.A. Clevert: Advisory Board; Siemens, Samsung, Philips, Bracco. Speaker; Siemens, Samsung, Philips, Bracco.

A-442 09:40

Fusion imaging

C. Ewertsen; *Copenhagen OE/DK (caroline.ewertsen@dadlnet.dk)*

Image fusion software is available on most high-end ultrasound systems and several publications for different clinical applications are available. Ultrasound images can be fused with images from CT, MRI or PET/CT, which enables the user to target biopsies or verify the nature of inconspicuous lesions. In order to fuse the images a co-registration or alignment must be made. This can be done manually, by choosing common points or planes in the different datasets, or automatically by the system by recognition of pixel intensities in the images. This applies for some systems, but not for all modalities. The theory behind these different co-registration methods will be covered as well as their accuracy. Furthermore examples of clinical applications will be demonstrated. The technique is more time consuming than conventional B-mode ultrasound but time spent decreases with increasing user experience. Depending on the body size of the patient and the organ of interest patient positioning should be identical to when the previously recorded data set was recorded, but this is not mandatory. However, for liver applications accuracy of the co-registration may improve if this is taken into account. Also identical in- or expiration may improve the accuracy. Real time image fusion enables real-time assessment of lesions in several anatomical regions.

Learning Objectives:
1. To learn about actual indications and applications of fusion imaging.
2. To show better parameter settings for optimal technical results.
3. To illustrate tips and tricks for technical and clinical successful examinations.
4. To become familiar with the new fusion imaging techniques and applications.

E³ - ECR Academies: State-of-the-Art and Advanced MR Imaging of the Musculoskeletal system

E³ 919
Upper extremity

A-443 08:30

Chairperson's introduction

M.C. De Jonge; *Amsterdam/NL (mdjonge@zuwehofpoort.nl)*

DISI and VISI are descriptions of the position of the lunate bone on plain radiographs. They are not diagnoses as such but a reflection of underlying pathology. It is important to realise that this description is made on standard plain radiographs and not on cross sectional imaging. The X-rays have to be made in the correct way for ulnar and radial deviation of the hand will result in a different position of the lunate and therefore false-positive DISI and VISI descriptions. Calling DISI and VISI inappropiately will lead to additional imaging to look for the cause of the 'abnormal' lunate position. It is important to realise this so that patients will not undergo unneccessary imaging. The concepts of DISI and VISI will be discussed together with its implications.

A-444 08:35

A. Elbow

A.J. Grainger; *Leeds/UK (andrewgrainger@nhs.net)*

The elbow is subject to both acute and chronic trauma, including ligamentous, osteochondral and tendon injury. MRI is well suited to demonstrate these injuries, but due to the complex anatomy of the elbow joint, optimisation of the imaging is required in terms of plane of section, sequence employed and the decision of whether to use intravenous or intraarticular contrast medium. The talk will address acute injury, looking at mechanisms and appearances of ligamentous, tendon and osteochondral injury at the elbow. The anatomy of these structures will be discussed along with imaging optimisation. Patterns of injury will be highlighted. Causes of chronic elbow pain will also be discussed and the relevant appearances on MRI will be illustrated. Patterns of impingement at the elbow will be shown and the relationship between chronic repetitive injury and pain will be reviewed. Important nerves pass by the elbow and the movement of the elbow and muscular structures around the elbow can lead to entrapment of nerves - another cause of chronic pain. Common patterns of nerve entrapment will also be discussed.

Learning Objectives:
1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and MR arthrography (direct/indirect) and how to optimise imaging protocols for the elbow.

A-445 09:17

B. Wrist

M. Shahabpour, M. De Maeseneer; *Brussels/BE (maryam.shahabpour@uzbrussel.be)*

The wrist is highly vulnerable to injuries with significant long-term consequences if diagnosis is delayed. When initial radiographs are negative in presence of strong clinical suspicion, further imaging is appropriate including CT and MRI. MRI can accurately show scaphoid fractures or other unsuspected fractures of distal radius or carpus as well as soft-tissue injuries. CT is recommended preoperatively for displaced fractures where surgery is performed to avoid complications. It helps evaluate intra-articular fractures and detect fractures of the hook of hamate, subluxations of distal radioulnar joint, and fractures-dislocations of metacarpal bases. MRI of hand and wrist requires high spatial resolution. The patient is placed in supine position with the hand along the body using a dedicated phased-array wrist coil or in prone position with the arm overhead. Imaging protocols include 2mm coronal PDFS and T1 (or PD), sagittal PD and T2, axial PD and PDFS for analysis of ligaments and tendons. Using MR arthrography (with double or triple compartment injection), 2mm thick coronal T1FS and PDFS or 0.5mm 3D PDFS and 3D DESS sequences followed by multiplanar reconstructions are performed for the detection of ulnar attachments TFCC tears and lesions of extrinsic and intrinsic ligaments, especially in (sub)acute trauma to determine if the patient requires surgery. In chronic phase, indirect MR arthrography is obtained after addition of intravenous contrast prior to the examination to assess ligaments and cartilage despite the presence of scarring. For nonunion, SNAC, avascular necrosis and SLAC lesions, images are obtained before and after intravenous contrast administration.

Learning Objectives:
1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and MR arthrography (direct/indirect) and how to optimise imaging protocols for the wrist.

08:30 - 10:00 **Room M 5**

E³ - ECR Academies: Chest Imaging

E³ 918
Updates on lung cancer management

A-446 08:30
Chairperson's introduction
A.R. Larici; *Rome/IT (annarita.larici@unicatt.it)*

Several studies on lung cancer screening have been performed by low dose computed tomography (LDCT) in the last decades. Among these, only the US National Lung Screening Trial demonstrated a benefit for the annual LDCT (a 20% reduction of lung cancer mortality). So far, a major concern in all published studies has been the high rate of false positive results leading to an increase risk of overdiagnosis whose effects are still not completely known. Lung cancer may present as nodule or mass. Mass has a high likelihood of being malignant while the majority of lung nodules remains indeterminate at CT scans. The most reliable method to characterise lung nodules is to follow them over time with CT. In the recently published guidelines for managing solid and subsolid nodules by the Fleischner society, the most relevant change is the reduction of CT examinations performed during the follow-up period. Once a lung lesion is characterised as malignant, the further step is staging the disease. The 8TH edition of the TNM classification introduced relevant changes regarding the descriptors T (from 1 to 5 cm every centimeter counts; T3 if greater than 5 cm; T4 if greater than 7 cm) and M by introducing the category M1b and M1c to indicate, respectively, one (oligometastatic disease) and more than one extrathoracic lesion. Several limitations still remains, as the classification of lymphangitic carcinomatosis and the evaluation of multiple lung lesions. Certainties and controversies of each proposed topic will be argued in this session.

A-447 08:35
A. Lung cancer screening
M.A. Heuvelmans; *Groningen/NL (m.a.heuvelmans@umcg.nl)*

After the largest randomised-controlled lung cancer screening trial, the National Lung Screening Trial (NLST), published a 20% decrease in lung cancer specific mortality in heavy (ex)-smokers screened by annual low-dose chest CT compared to annual chest radiography, lung cancer screening has been implemented in clinical practice in the United States. Although in Europe the results of the second largest trial, the Dutch-Belgian randomized-controlled lung cancer screening trial (NELSON trial) are still awaited, planning for implementation of low dose CT screening in high risk individuals is recommended by the EU position statement expert group, since lung cancer screening can save lives.
Learning Objectives:
1. To review the results of the large randomised trials.
2. To learn about the lung cancer screening modalities.
3. To understand the overdiagnosis risk.

A-448 09:03
B. Lung nodule management
A.A. Bankier; *Boston, MA/US*

This presentation will discuss the background, novel elements, and clinical implications of two recently published guidelines on the management and the measurement of pulmonary nodules. Participants will learn about the required framework for the application of the guidelines, and their potential and limitations. The intention of the guidelines, i.e., a more standardised and rationale approach to the management of pulmonary nodules will be highlighted.
Learning Objectives:
1. To review the current guidelines for solid nodule management.
2. To learn about the subsolid nodule management guidelines.
3. To review the role of computer-aided tools.

A-449 09:31
C. Lung cancer staging
G. Aviram; *Tel Aviv/IL (aviramgalit@hotmail.com)*

Lung cancer continues to be the leading cause of cancer-related mortality worldwide. Accurate staging is fundamental for estimating prognosis, selecting treatment, and conducting and reporting clinical trials internationally. The International Association for the Study of Lung Cancer (IASLC) has recently published the eighth edition of the tumour, node, and metastasis (TNM-8) staging system used for lung cancer. This revised classification is based on significant differences in patient survival identified on analysis of a new large international database. Key changes include: further modifications to the T descriptors based on 1 cm increments in tumour size; grouping of tumours resulting in partial or complete lung atelectasis/pneumonitis, and those involving a main bronchus regardless of distance from the carina, and reassignment of diaphragmatic invasion. In addition, specific new coding for adenocarcinoma in situ and minimally invasive adenocarcinoma was incorporated as well as their recommended measurements method. The clinical N descriptors used are unchanged from the 7th edition; however, the description of the number of pathological lymph node stations involved, has been added. Further subdivision of metastatic disease into distinct descriptors based on the number of extrathoracic metastases and involved organs were also added. As a result of the new modifications, several new stage groups have been developed, and others have shifted. Although TNM-8 represents more advanced understanding of tumour behavior and patient management, several limitations, controversies and unaddressed issues persist.
Learning Objectives:
1. To learn about the eighth edition of the TNM classification.
2. To review the main differences with the 2009 edition.
3. To review the persisting limitations.

ESR meets Switzerland

EM 1
Radiology and Swiss chocolate: a sweet combination

Presiding:
B. Hamm; Berlin/DE
D. Weishaupt; Zurich/CH

A-450 10:30
Introduction: What Swiss radiology and Swiss chocolate have in common
D. Weishaupt; *Zurich/CH (dominik.weishaupt@triemli.zuerich.ch)*

The Swiss Society of Radiology, with more than 100 years of history and about 1,000 members, is a professional medical society dedicated to promoting radiology in Switzerland. The aims of the society - among others - are: to assure high-quality postgraduate training in radiology by maintaining the radiology residency training curriculum as well as conducting the Swiss board examinations in radiology, to support education in radiology by organising the Swiss Congress of Radiology, offer activities dealing with quality assurance, patient safety and radiation protection, improve patient care and the health of the population through medical imaging, support the professional and economic interests of our members, and serve as a responsible counterpart to the Swiss Health authorities and other official bodies. The aim of providing high quality radiology and the pursuit of excellence are important characteristics of radiology in Switzerland. These characteristics link Swiss radiology with Swiss chocolate, which is considered to be one of the highest quality products manufactured in our country. Within this session, three educational presentations by three renowned Swiss radiologists will underline the broad spectrum of cutting edge radiology performed in the country. In addition, you will learn about the secret of production and refinement of high-quality chocolate made in Switzerland. A representative of a leading family owned Swiss chocolate manufacturer will present the fascinating chocolate production process and illustrate how high quality chocolate is handmade and how innovative chocolate products are designed for the future.
Session Objectives:
1. To become familiar with the status of radiology in Switzerland.
2. To learn how Swiss Society of Radiology supports radiology in Switzerland.
3. To discuss the link between Swiss radiology and top-quality innovative Swiss chocolate culture.

A-451 10:35

Truffle No. 1: MR-diffusion of the urogenital tract: where it really helps

H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

After its initial application in the brain diffusion-weighted MRI (DWI) is now part of most MR exams in the abdomen. In the urogenital tract DWI is particularly helpful because it can be applied without contrast medium administration which is a major advantage in patients with renal impairment. For daily clinical routine image analysis of DWI is performed qualitatively based on visual assessment of the high b-value images and the corresponding ADC map. However, image interpretation of DWI has always to be performed in combination with morphological images to avoid misinterpretation, e.g., a tumour, an abscess and a haematoma have the same findings on DWI but can be differentiation in combination with anatomical sequences. The ADC value, the quantitative parameter of DWI can further provide more detailed information of the underlying tissue. DWI in the urogenital tract can be applied for detection, characterisation and monitoring of various pathologies. DWI helps to detect pyelonephritis in adults and children without contrast medium administration and typically normal findings on morphology. It is also routinely applied to detect significant prostate cancer and provides even information on tumour aggressiveness when the ADC value is taken into account. The differentiation between cystic renal cell carcinoma and an abscess is also possible based on DWI and even the differentiation of renal cell carcinoma subtypes is possible in many cases based on the underlying ADC-value. Several applications and examples showing the usefulness of this technique in the urogenital tract will be discussed and explained.

Learning Objectives:

1. To learn how DWI can be integrated in the acquisitions protocols and whether it precludes the need for other sequences.
2. To learn if DWI can provide useful information for tissue characterisation.
3. To understand the clinical circumstances in which DWI is most helpful.

Truffle No. 2: hip preservation surgery: a fast evolving field also for imaging

C.W.A. Pfirrmann; *Zurich/CH*

Joint-preserving surgery of the hip is one of the most important fields of innovation in orthopedics and sports medicine. Before the era of hip replacement hip osteotomies were popular to treat osteoarthritis of the hip. Hip osteotomies lost a lot of their importance with the introduction of the total hip arthroplasty which is considered one of the most successful surgical procedures. With the scientific work of Reinhold Ganz and his team at the University of Bern in Switzerland joint-preserving surgery of the hip has regained importance and has become one of the fastest evolving fields in the last two decades. The goal of joint- preserving hip surgery is to prevent osteoarthritis in the hip before degeneration becomes evident. Studies on the detailed anatomy of the blood supply of the femoral head were the scientific bases to develop a new approach for open surgical dislocation of the hip without the risk of avascular necrosis. This gave new insights in hip biomechanics and the development of the new concept of femoroacetabular impingement (FAI). FAI has been identified as the leading cause of the premature osteoarthritis of the hip. Imaging of the hip has become increasingly important to assess morphology of the hip joint as well as the structural damages mainly to the cartilage and the labrum.

Learning Objectives:

1. To learn about the history and recent advances in hip preservation surgery.
2. To understand the biomechanics of the abnormal hip and how to integrate biomechanical aspects in the imaging protocol and image interpretation.
3. To know imaging pitfalls and asymptomatic findings.

Truffle No. 3: multiparametric imaging in head and neck oncology

M. Becker; *Geneva/CH (minerva.becker@hcuge.ch)*

Contrast enhanced CT and MRI with diffusion-weighted imaging (DWI) are routinely used for the assessment of submucosal tumour spread in head and neck carcinoma, to stage nodal disease, to monitor treatment response and to detect recurrent disease. PET/CT is widely used to stage nodal disease, to detect distant metastases and synchronous tumours, to identify unknown primary tumours in patients with metastatic neck nodes, to assess treatment response and prognosis after chemo radiotherapy and for radiotherapy planning. Recent data regarding the complementarity of multiparametric information derived from hybrid MR/PET systems in clinical settings holds promise because it can combine morphologic, functional and molecular information and helps to avoid diagnostic pitfalls. This lecture focuses on clinical applications of multiparametric imaging in head and neck cancer. Current evidence about the complementarity of CT, MRI, DWI, perfusion and PET is discussed with particular emphasis on the added value of multiparametric information and quantification. The variable appearance of functional phenomena mimicking disease as well as diagnostic pitfalls and how they can be avoided are discussed. Current research trends regarding texture analysis are addressed. Emphasis will be put on ongoing developments in head and neck oncology.

Learning Objectives:

1. To understand the complementary role of morphologic, functional and metabolic imaging techniques in head and neck oncology.
2. To review the role of diffusion and perfusion imaging for the diagnosis and follow-up of head and neck cancers.
3. To discuss diagnostic pitfalls and how they can be avoided with multiparameteric imaging.

Panel discussion: The way of maintaining and improving quality of Swiss radiology

10:30 - 12:00 **Room G**

EFOMP Workshop: Radiation dose management systems and repositories: the present and the future

EF 2

Dose management systems and repositories: part B

Moderator:
M. Mahesh; Baltimore, MD/US

A-456 10:30

Chairperson's introduction

M. Brambilla; *Novara/IT (marco.brambilla@maggioreosp.novara.it)*

The purposes of this session are to provide an overview of imaging and dose repositories, to explain the possibilities and limitations of current implementations and standards, to illustrate the technical challenges faced by already established dose index registries, such as the ACR dose index registry, and to emphasize the role that such systems could have in boosting researches on radiation protection. This session will introduce the IHE REM profile as one of the potential benchmark standard, explaining its limitations in the field of radioprotection and how this standard could be complemented by other technologies to cover present and future needs in the domain of radioprotection and biomedical research. An overview of the services provided by imaging and dose repositories will be provided illustrating how these services could be used in the field of radioprotection and biomedical research. The issues of security, data protection, privacy and other legal issues associated with the implementation of such repositories will be discussed. Finally, an existing and well established example of dose repository systems, such as the ACR dose index registry, will be introduced and illustrated in its past technical development and in its future perspectives.

Session Objectives:

1. To provide an overview of imaging and dose repositories.
2. To understand the main strengths and limitations of these systems.
3. To understand why dose management systems and repositories are capable of supporting research.

A-457 10:35

Organisation of dose management systems and repositories for radiation protection and biomedical research: possibilities and limitations of current implementations and standards

B. Gibaud; *Rennes/FR (bernard.gibaud@univ-rennes1.fr)*

Radiation protection and related biomedical research require that dosimetric information can be estimated and shared. To meet this objective, the integrating HealthCare Enterprise initiative developed an integration profile called radiation exposure monitoring (REM). This profile "facilitates the collection and distribution of information about estimated patient radiation exposure resulting from imaging procedures". This profile specifies the roles of the various actors involved, namely: 'Imaging modality', that creates and transmits the dose information; the 'Image Manager/Image Archive' that may store and manage dose objects; the dose information consumer (e.g., implemented in a RIS or a reporting workstation) that may query/retrieve and analyze such dose objects; the 'Dose Information Reporter' that may submit dose information to national or regional repositories implementing a 'Dose register' actor. The presentation will introduce this integration profile and present in detail the DICOM objects and services involved in the previous transactions. The presentation will highlight the possibilities and the limitations of this profile, especially regarding the DICOM encoding of the dose reports. It will also introduce other complementary technology, based on the semantic web technologies, that allow complementing these standards, in a way that is compatible with the needs of biomedical research.

Learning Objectives:

1. To introduce the IHE REM profile.
2. To discuss its relevance and limitations regarding radiation protection needs.
3. To introduce other technology that may complement IHE REM to cover future needs of both radiation protection and biomedical research.

A-458 11:05

Imaging and dose repositories: tools to boost radiation protection and research?

E. Neri; *Pisa/IT (emanuele.neri@med.unipi.it)*

The dose monitoring tools allows a precise internal audit of the dose behaviour in the radiological department, tracking the general dosimetric trend, that mainly depend on the adopted imaging protocols. Such imaging protocols are frequently designed by an anatomical orientation with few concern about the specific clinical context in which the exam is performed. In parallel the attention of dose reference levels (DRL) is oriented to the anatomical segments, and not the clinical context.

Learning Objectives:

1. To provide the rationale of imaging and dose repositories.
2. To describe the services provided by imaging and dose repositories.
3. To understand the security, legal and other issues associated with the implementation of imaging and dose repositories.

E. Neri: Advisory Board; QUIBIM.

A-459 11:35

The ACR dose index registry: setting a benchmark

M. Mahesh; *Baltimore, MD/US (mmahesh@jhmi.edu)*

Radiation dose information is essential towards establishing standards, reviewing and optimising protocols, to develop safe imaging practices. In this regard, Dose Index Registry (DIR) is one of the registry with in National Radiology Data Registries (NRDR) hosted by the American College of Radiology (ACR). Launched in 2011, the ACR-DIR is a tool for quality improvement enabling facilities to review dose indices and optimise protocols. The goal of ACR-DIR is to assist in establishing national and regional benchmarks and practice patterns and to develop patient size specific diagnostic reference levels (DRLs). As of now, ACR-DIR is primarily collects CT dose data, however, it has plans to expand registry for interventional fluoroscopy, computed and digital radiology ,and nuclear medicine. The presentation will discuss what is DIR and how it works, the type of CT dose data collected and reported. Presentation will also discuss how certain sites are using feedback from DIR reports to plan, implement, and measure the success of CT dose reduction program. Technical implementation issues a site needs to address upon signing with the registry will be discussed. Finally, the presentation will discuss how DIR data were used to establish US national dose levels for the most common adult CT examinations based on patient size.

Learning Objectives:

1. To give an overview of the ACR dose index registry.
2. To understand issues related to technical implementation of the registry.
3. To learn about the new prospects of the ACR dose index registry.

A-460 10:30

Achieving homogeneity in radiology education: linking content to competence through the European training curriculum

L. Oleaga Zufiría; *Barcelona/ES (lauraoleaga@gmail.com)*

There is a great heterogeneity in the training programmes across Europe. The curriculum defines the process of training and the competences needed to ensure trainees provide a high-quality service after the completion of the training programme. The European Training Curriculum (ETC) represents a guide to standardised education and harmonise skills and competences among radiologists in Europe. Assessment of the competences acquired during the training period is not harmonised and there is not a standardised method applicable to all European countries. A common e-Portfolio with the individual record of each year trainee's progress, based on the European Training Curriculum (ETC) could be a useful tool to standardise education. A final examination to assess clinical competence is not mandatory in all countries. The European Diploma in Radiology (EDIR) represents a valuable certificate to standardise and facilitate the accreditation of radiologists across the EU borders. Education is evolving; new technologies and innovative approaches are integrated into the radiology field. e-Learning online activities, simulator programmes and artificial intelligence are getting incorporated into the clinical work and training. Trainees must embrace and participate in value-adding activities in radiology using guidelines and appropriateness criteria to lead imaging decisions to provide high-value care. Communication skills in radiology including the interaction between radiologists, radiographers, referring physicians, and patients constitute important aspects of radiology education; failure of communication can result in negative results. They have to be trained in communication and conflict management. Learning these skills is critical for their future.

Learning Objectives:

1. To discuss the impact of major inhomogeneities on European radiology.
2. To describe the European training curriculum's role in achieving homogeneity and the importance of linking content to competence.
3. To evaluate the current status and what must happen next in radiology education.

A-461/A-462 10:45

Establishing competence in radiology: a UK perspective

C. Rubin[1], W. Ramsden[2]; *[1]Southampton/UK, [2]Leeds/UK (caroline.rubin@uhs.nhs.uk)[1], (william.ramsden1@nhs.net)[2]*

Radiology training in the UK is undertaken in quality assured training programmes, over 5 years for clinical radiology, 6 years for subspeciality training in interventional radiology and aspires to produce proficient radiologists. National systems of assessing competence in the UK are divided into summative formal examinations and formative workplace based assessments (WPBAs). Allied to these are local evaluations of performance in specific techniques such as acute ultrasound and CT. Formal examination material is rigorously tested for validity and reliability, and the Royal College of Radiologists (RCR) sets national standards. Although examinations address knowledge and some elements of competence, they are weaker in assessing performance. Passing examinations does not invariably equate to trainees performing satisfactorily in the workplace. Although WPBAs occur in clinical departments and addresses trainees' performance of day-to-day tasks, they are only used formatively as mandated by national guidance. The RCR is improving standardisation, with particular emphasis upon the oral (viva) component of the final FRCR examination, to ensure similar material is seen by all candidates and it is blueprinted to the curriculum. WPBAs are being revised to remove most scoring, allowing greater use of free text comment to help trainees' development. The RCR curricula are being rewritten, and specific assessments mapped to individual areas. This ensures that the evaluation of competence covers all subjects, both generic and radiology specific. National roll-out and training of assessors and examiners are particularly important factors in ensuring the success of this work.

Learning Objectives:
1. To explore the current UK structures for establishing competence in radiology.
2. To discuss the challenges and opportunities arising from these systems.
3. To consider the key steps to facilitate the successful implementation of a competence system in radiology.

A-463 11:00

The value of the European Diploma

P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

The number of young colleagues in Europe that site for the European Diploma in Radiology (EDiR) is constantly increasing and the number of examinations performed per year is now 8 with a potential to further increase in the coming years. In some countries the EDiR is part of the educational program for radiology residents. In some countries the Diploma has been discussed to, in part, replace national examination. The curriculum level I and II for residents in training is the ground for the EDiR while level III is considered subspecialisation and is therefore, not covered in questions and cases at the current form of EDiR. By establishing the EDiR and increase the number of participants sitting the exam reinforces the homogenization of the radiology education and training in Europe which is favourable for the residents regardless of country and may in the future open the European market or young radiologist to seek work outside their own country - a more flexible market.

Learning Objectives:
1. To demonstrate the value of the European diploma in overcoming issues relating to competence.
2. To discuss the areas of competence which are currently outside the scope of the European diploma.
3. To propose a route through which the European diploma could form part of a European radiology competence structure.

Author Disclosure:
P.C. Maly Sundgren: Board Member; chair written evaluation committee, member of the EDiR Scientific Board, member in the ESR Research committee.

A-464 11:15

Obstacles to establishing competence in radiology

P. Valdés Solís; *Marbella/ES (pabvalsol@gmail.com)*

A competence focused professional system in Radiology is important to improve quality and safety. The Spanish Society of Radiology, aware of this, began a strategy to develop an advanced system of measuring competence in radiology. We had the first experience in interventional radiology and after creating a working group and defining the model, a book including the competence elements was successfully published. However, when trying to adapt the model in other radiology subspecialities, the experience was everything but successful: we realized that spanish radiologist did not believe in the necessity of going through an exam of their performance and competence. Now we are facing a new chance to give life to the project, because the Spanish National Medical Association will ask their members to apply for a professional validation which, though not compulsory, will probably be the standard. The Spanish Medical Association has asked SERAM to define the minimum required to radiologist to get the professional validation, so just minimal changes in the competence model will be needed. Our experience was useful to redesign the way of facing complex projects as this. First of all, you have to face the possibility of rejection. Many radiologists in Spain are civil servants, and won't get many advantages when passing a competence evaluation exam, and personal recruitment is not designed taking into account professional competence in many cases. Knowing this, we are now facing a new project that we hope will be successful in a few years.

Learning Objectives:
1. To show the difficulties that, as a Society, the Spanish Society of Radiology has faced in order to establish a national system of competences.
2. To explain why radiologists are reluctant to join competence programmes, especially those that are not proposed by their own health authorities.
3. To discuss the strategies that should be kept in mind before beginning a national competence programme in order to get radiologists compliance and participation.

A-465 11:30

How to manage the incompetent professional?

J.K. Bell; *Manchester/UK (Jon.Bell@christie.nhs.uk)*

Radiologists must achieve and maintain a certain level of competence to be safe and effective. However, the definition of competence is challenging and may differ between countries. European accreditation continues to develop to define standards of practice in order to ensure that Radiologists perform to an acceptable level. There are multiple factors that influence performance in the work place and these need to be addressed to ensure a healthy working environment. Early signs that a Radiologist is experiencing professional and/or personal difficulties should be identified and addressed within a supportive management structure. Here we explore clinical competence, optimisation of the working environment, identification of colleagues in difficulty and the development of a supportive management structure.

Learning Objectives:
1 To define competence and how to identify radiologists in difficulty.
2. To assess factors that lead to poor performance and what can be done to promote well-being.
3. To outline processes for helping incompetent radiologists and managing those that cannot be helped.

11:45

Panel discussion: Overcoming heterogeneity in radiology competence across Europe: a dream or reality?

E³ 1019
Knee

A-466 10:30

Chairperson's introduction

J. Kramer; *Linz/AT (kramer@ctmri.at)*

In this session acute postraumatic as well as chronic disorders leading to pain/complaints in the knee region are focussed on. Further more postoperative changes including postop. complications are debated. To some extent technical considerations for imaging of the cartilage and to avoid artifacts are mentioned. At the beginning of the session some cases are demonstrated and the final diagnosis is shown after the end of the 3 lectures.

A-467 10:35

A. Post-traumatic

A.P. Parkar; *Bergen/NO (apparkar@gmail.com)*

Knee trauma with injury of the menisci, ligaments, cartilage and bone, all contribute to the development of osteoarthritis. Acute/traumatic meniscal ruptures run obliquely or vertically and affect the articular surface (either femoral or tibial). Degenerative ruptures run horizontally and do not affect the articular surfaces. Long standing chronic ruptures thin out the meniscus and lead to lateral extrusion. Complex ruptures with displaced fragments, be it medially/anteriorly/posteriorly, need to be treated swiftly as they cause knee locking. Considering isolated injury to the lateral knee stabilisers, a total rupture is important to recognise, as this requires surgical reconstruction, while partial ruptures are treated conservatively. Chronic injuries may be recognised by healed bony avulsion (like Segond or Pellegrini Stieda). MRI findings of ruptured ACL with direct and indirect signs is well established. Awareness of the reporting “not to be missed” concomitant injuries (posterolateral corner, anterolateral ligament, meniscal root avulsions) is on the rise. Chronic post-traumatic ACL may develop mucoid degeneration or ganglion cysts within the ligament. The acute PCL injury is recognised when fibres are disrupted, or with high signal and when thickened >8mm. An indirect sign is posterior sagging of the medial tibia. It is important to know that intact PCL fibres does not exclude a chronic PCL injury, as MRI has very low sensitivity and indirect signs may be the only clue. Patella luxations may occur due to underlying dysplasia or severe trauma. The acute findings are femoral/patellar bone edemas, rupture of the medial retinaculum, and cartilage damage.

Learning Objectives:
1. To identify the most common post-traumatic entities.
2. To know the role of MR imaging and MR arthrography (direct/indirect).
3. To differentiate post-traumatic changes from typical reasons for chronic pain.

A-468 11:03

B. Chronic pain

P. Van Dyck; *Antwerp/BE (pieter.van.dyck@uza.be)*

Many conditions can cause or contribute to chronic knee pain, including trauma, degenerative disease, infections, connective tissue disorders, metabolic disorders, and tumors. Imaging continues to play an important role in

the assessment of these entities to select an appropriate treatment. This presentation will give an overview of the most common entities leading to chronic knee pain and discuss the basic and advanced imaging methods for evaluating the knee joint with particular emphasis on MR imaging techniques (including 2D and 3D turbo-spin-echo, 3D gradient-echo, 3D ultrashort echo-time and quantitative mapping techniques). Degenerative osteoarthritis (OA) is the most common form of chronic knee arthritis. It is currently diagnosed using clinical and radiographic findings. However, in recent years, MRI has increasingly been used to study OA. The diagnostic utility of MRI for diagnosis of OA in a clinical setting will be discussed. Chronic anterolateral rotatory laxity, typically occurring after injury of the anterior cruciate ligament (ACL) or ACL surgery, is a major cause of degenerative OA. A brief update will be provided on the anatomy of the anterolateral knee complex (including the superficial and deep fibers of the iliotibial tract and the anterolateral ligament) and how to assess it on MR images. Finally, clinical case series will illustrate how to differentiate entities leading to chronic pain from post-traumatic changes.

Learning Objectives:

1. To identify the most common entities leading to chronic pain.
2. To know the role of MR imaging in evaluating cartilage (including new techniques).
3. To differentiate entities leading to chronic pain from post-traumatic changes.

A-469 11:31

C. Postoperative

P.M. Jungmann; *Zurich/CH*

Surgical techniques and MR imaging techniques are undergoing continuous developments and optimization. At the knee, frequently a standard MR imaging protocol is sufficient to account for most clinical queries; however, cases in which dedicated protocols and sequences, intravenous contrast administration or intraarticular contrast administration (arthrography) are required will be demonstrated as well. Current orthopedic surgical techniques with respect to ligament, meniscus and cartilage reconstruction at the knee will be explained to allow the radiologist to provide specific information to the demanding orthopedic surgeon. Knowledge of the techniques is crucial to fulfill the expectations and requirements of the clinicians. This part of the knee session discusses normal and pathological postoperative findings on MR imaging of the knee during postoperative follow-up after several knee surgeries, such as ligament reconstruction (ACL, PCL, MPFL), meniscectomy and meniscus repair and after different cartilage repair techniques. Typical and severe complications will be pointed out using clinical examples. Particularly, also novel metal artifact reduction sequences (MARS) will be explained using examples of knee prostheses and other implants. Not only technical background knowledge, but also typical postoperative findings at the knee will be discussed, that may be depicted using these new sequences. The session aims to provide clinically important knowledge on MR techniques and postoperative findings at the knee to the interested MSK- or non-MSK radiologist.

Learning Objectives:

1. To identify the most common postoperative changes.
2. To know the role of MR imaging and how to optimise protocols for postoperative imaging including the use of MR arthrography.
3. To understand the different techniques of ligament reconstruction and meniscal repair and their complications.

Hybrid imaging: the story so far and what to expect next

K. Riklund; *Umea/SE (katrine.riklund@umu.se)*

Hybrid imaging, the combination of structural and functional or molecular imaging started with visual and software fusion and has developed into new scanners with hardware fusion of PET or SPECT together with CT or MRI. During the session I will take you on an amazing tour behind the scenes in secret chamber; the human body, visualised in structures and biochemistry, and molecular medicine. I will present a fascinating story of the development of something really astonishing on one hand and on the other hand something you cannot be without in daily imaging work.

Learning Objectives:

1. To learn about the development of hybrid imaging.
2. To understand the principles for molecular imaging exemplified in PET/CT and MR/PET.
3. To appreciate the combination of molecular and functional imaging.
4. To become familiar with a few clinical areas with high potential in hybrid imaging.

Open and closed: the role of radiology in treatment of valvular heart disease

Moderator:

M. Gardarsdottir; Reykjavik/IS

A-483 12:30

How to approach valvular heart disease using MRI

A. Redheuil; *Paris/FR (alban.redheuil@gmail.com)*

Magnetic Resonance Imaging (MRI) has recently evolved as a comprehensive modality to provide a reference non-invasive assessment study of cardiac remodeling and dysfunction related to valvular disease, but also to quantify valvular dysfunction - either stenotic or regurgitant valvular lesions - using 2D and 4D phase contrast-based flow imaging. Furthermore, comprehensive vascular assessment such as of the thoracic aorta or pulmonary arterial tree is feasible within a single exam. If MRI is established for the assessment of complex congenital valvular and heart disease it may also be very helpful in case of incomplete or non-diagnostic echocardiography to evaluate valvular disease mechanism, anatomy and quantify disease severity in the more common valvular heart disease settings. Finally, new myocardial mapping tools may provide an insight into myocardial tissue changes including diffuse fibrosis that may be at play in valvular heart disease and precede heart failure. A review of the aforementioned issues and potential value of MRI in valvular heart disease will be provided in this lecture.

Learning Objectives:

1. To learn about the MR techniques available for functional assessment in valvular heart disease.
2. To understand possibilities and limitations of cardiac MR in valvular heart disease.
3. To appreciate the advantages of cardiac MR in valvular heart disease.

A-484 13:00

What to measure prior to transcatheter aortic valve implantation (TAVI)

R. Salgado; *Antwerp/BE (rodrigo.salgado@uza.be)*

Aortic valve stenosis is the most common valvular heart disease in the Western World. When symptomatic, aortic valve stenosis is a debilitating disease with a dismal short-term prognosis invariably leading to heart failure and death. Elective surgical valve replacement is traditionally considered the standard of care for symptomatic aortic valve stenosis. However, several studies have identified various subgroups of patients who have a significant elevated risk for operative complications and death. Accordingly, not every patient is suitable for surgery. Recent developments in transcatheter-based therapies have provided an alternative therapeutic strategy for the non-surgical patient population, replacing the native aortic valve by a bioprosthetic valve brought in place using a non-surgical endovascular or trans-apical pathway. This procedure has been named transcatheter aortic valve replacement or implantation (TAVR, TAVI), or also percutaneous aortic valve replacement (PAVR). Nevertheless, several anatomic and technical criteria have to be fulfilled to safeguard procedural eligibility and success. Therefore, there is a crucial role for non-invasive imaging in both patient selection and subsequent matching to a specific transcatheter valve size, to ensure accurate prosthesis deployment and minimize peri- and post-procedural complications. In this lecture, the relevant anatomy will be reviewed, emphasising anatomic pitfalls, their implications for correct reporting of imaging-derived measurements, and highlighting important differences between imaging modalities. Furthermore, the evolving role of CT-imaging and the role of the radiologist in the triage of patients will be discussed, reviewing current viewpoints in both patient and proper device size selection and the pre-procedural evaluation of the possible access routes.

Learning Objectives:
1. To learn about prerequisites prior to TAVI.
2. To understand the importance of accurate measurements for TAVI planning.
3. To appreciate the need for communication with implanting physicians.

12:30 - 13:30 **Room D**

E³ - The Beauty of Basic Knowledge: A Survival Guide to Musculoskeletal Imaging

E³ 25C
Bone tumours

Moderator:
V.N. Cassar-Pullicino; Oswestry/UK

A-485 12:30
Bone tumours
K. Wörtler; *Munich/DE (klaus.woertler@tum.de)*

The diagnosis of a bone tumour is based on clinical findings, the age of the patient, the location of the lesion, its radiologic appearance, and if imaging does not allow for a specific diagnosis, its histopathologic features. Radiography remains the initial imaging modality for evaluation of the localisation of the lesion with respect to the longitudinal and axial planes of the involved bone, for the depiction of matrix mineralisation, and for estimation of biologic activity by analysing the patterns of bone destruction and periosteal response. CT is typically used to obtain “radiographic” information in regions of complex skeletal anatomy such as the skull, spine, pelvis and shoulder girdle. MR imaging is best suited to determine the local extent of a bone tumour (local staging), but can also be helpful to narrow the differential diagnosis in specific lesions such as cysts and cartilage-forming tumours. With a clear emphasis on conventional radiography, this course will review the basic imaging features of the most common benign and malignant bone tumours. Important radiographic findings, such as bone destruction patterns, types of periosteal reactions and matrix mineralisation, will be explained step by step in correlation with histopathology as well as advanced imaging techniques.
Learning Objectives:
1. To become familiar with the imaging features of benign and malignant bone tumours.
2. To appreciate their imaging characteristic hallmarks on plain film radiography.
3. To learn how best to use imaging modalities in differential diagnosis.

12:30 - 13:30 **Sky High Stage**

Special Focus Session

SF 10
Artificial intelligence (AI) applications

A-990 12:30
Chairperson's introduction
A. Brady; *Cork/IE (adrianbrady@me.com)*

As artificial intelligence increases its penetration into all aspects of life, radiology will change in the future. Radiology reports will become more standardised in format and language, and will become rich sources of information for teaching, research and machine learning, feeding back into a loop of continuing improvement of technological tools. This session will explore how these processes will operate, how radiology report data will be mined and utilised in the future, and what issues this will highlight in terms of data ownership and protection.
Session Objectives:
1. To explain the likely future development of structured reporting.
2. To highlight the opportunities which will arise from availability of radiological data in formats which can be searched and used as imaging biobanks.
3. To discuss the data protection issues which arise from these developments.

A-991 12:35
Imaging biobanks
B. Gibaud; *Rennes/FR (bernard.gibaud@univ-rennes1.fr)*

Significant progress in computer-aided or even automated image interpretation are expected in the near future. Machine learning and assessment of the performances of these new tools will require large quantities of annotated image data. The development of imaging biobanks should be able to provide such data. The presentation will summerise the challenges of gathering large sets of image data, either from past clinical research studies, or from large cohorts and population studies. Particular emphasis will be put on the definition of consensual ontological models to guarantee a good standardisation of semantics borne by image annotations. Indeed, the latter must cover a wide scope from general characteristics of the clinical cases (e.g. known pathology, patient sex and age) up to quantitative image biomarkers derived from the images. The issue of relating image data to other biological data (e.g. genetic / genomic) will be underlined, justifying a strategy of designing information models for imaging biobanks that are consistent with those used in biobanking (e.g. BBMRI-ERIC).
Learning Objectives:
1. To discuss the role that the imaging biobanks can play in providing the data necessary for machine learning and for the assessment of the performances of diagnostic tools.
2. To understand the role ontologies play in the standardisation of image annotations in imaging biobanks.
3. To understand the need to collaborate with the domain of (specimen) biobanking.

A-992 12:50
Big data and structured reporting
D. Pinto dos Santos; *Cologne/DE*

There has been a tremendous increase in interest towards artificial intelligence and machine learning applications in radiology. In order for such systems and algorithms to perform sufficiently well, large amounts of training data are required. These data need to be either standardised and of adequate quality or available in large enough amounts, that enough relevant information can be extracted. However, in current clinical and radiological IT ecosystems access to relevant pieces of information is difficult. This is mostly due to the fact, that a large portion of information is handled as a collection of narrative texts and interoperability is still lacking. This lecture will give an overview on how structured reporting can help to facilitate research in artificial intelligence and in the context of big data. Potential approaches to implementing structured reporting will be discussed, focusing also on interoperability and standardisation.
Learning Objectives:
1. To discuss the data requirements for artificial intelligence and big data.
2. To understand how structured reporting can facilitate research in machine learning.
3. To become familiar with informatics standards, relevant to structured reporting.

A-993 13:05
Data control in the era of AI: man or machine?
P.M.A. van Ooijen; *Groningen/NL (p.m.a.van.ooijen@umcg.nl)*

Recent years has shown an explosive growth in the use of Artificial Intelligence (AI) and Deep Learning not in the least for medical applications. These new technological developments have started a whole new discussion on privacy of data processed by these computerised systems. Especially those applications in health care demand a high level of patient privacy and patient data security. The actual ownership of medical data is also part of this discussion where we can have different situations with original, de-identified, anonymised and processed data. Questions like what data is still personal data for an individual patient or participant in a clinical trial and who actually owns the data that is produced with self-learning computer systems. This educational course will discuss these issues with respect to ownership, intellectual property and the different aspects that are involved in this when moving towards the era of AI.
Learning Objectives:
1. To understand the current and future role of data.
2. To understand the issues surrounding data control and ownership.
3. To discuss the role of AI in the future of radiology.

Discussion

14:00 - 15:30 **Room K**

EFRS meets Switzerland and Portugal

EM 4

EFRS meets Switzerland and Portugal

Presiding:
J. McNulty; Dublin/IE
M. Mordasini; Berne/CH
J. Santos; Coimbra/PT
Moderators:
J. McNulty; Dublin/IE
I. Gremion; Lausanne/CH
J. Santos; Coimbra/PT

A-493 14:00

Introduction
J. McNulty; *Dublin/IE (jonathan.mcnulty@ucd.ie)*

Introduced for the first time for ECR 2013, the 'EFRS meets' sessions follow the tradition of the 'ESR meets' sessions and give the European Federation of Radiographer Societies (EFRS) the opportunity to highlight the contribution of one of their member societies to the profession of radiography each year. Having met Spain (2013), Russia (2014), Germany (2015), Sweden (2016), and Belgium (2017), all of which were the home countries of the congress presidents in the respective years, the EFRS will meet both Portugal and Switzerland, which are two of the 'ESR meets' countries for 2018. Both the Portuguese society, Associação Portuguesa dos Técnicos de Radiologia, Radioterapia e Medicina Nuclear (ATARP), and the Swiss society, Schweizerische Vereinigung der Fachleute für Medizinisch Technische Radiologie (SVMTRA) were founding members of the EFRS in 2008. We also now count five Portuguese and two Swiss educational institutions among the affiliate members that make up our Educational Wing. Portuguese and Swiss radiographers alike come from strong organisational and educational backgrounds; they contribute to radiography research and continue to contribute to the activities of the EFRS.
Session Objective:
1. The introductions will give a very short overview of the aim and history of the Meets sessions (EFRS president) and the characteristics of Portugal and Switzerland (association presidents).

A-494 14:05

Introduction: Across Switzerland
M. Mordasini; *Berne/CH (michela.mordasini@insel.ch)*

Although not member of the European Union, Switzerland is closely integrated with the EU by bilateral sectoral agreements, known as Bilateral one and Bilateral two. By these contracts, free movement of persons between Switzerland and EU (and vice versa) is warranted and certifications and diplomas in the field of medicine, esp. also in the field of radiological technicians are recognised on both sides as long as the training has been similar to the equivalent Swiss qualification, which means, that the content and duration of training must be comparable. With respect to the four Swiss-national languages the bilateral exchange of technicians comes to pass mainly between Ticino and Italy, Bern/Basle/Zürich with Germany and Austria and Lausanne/Geneva with France, whereas the official language of Romance is used in the small southeastern Swiss canton Grisons mostly alongside with German, French or Italian. The radiographer qualification in Switzerland is based on a 3 or 4 year training in an advanced technical college and covers special courses in Diagnostic Radiology, Radio-Oncology and Nuclear Medicine. Most of the radiographers, working in one of about 630 radiological institutes (including radio-oncology and nuclear medicine) of swiss hospitals or in one of about 150 private radiological practices have been trained in a university of applied medical science or a college of higher education in Switzerland, which train and certify about 125 technicians each year. This is not enough, thus about one third of the 3,496 technicians, working in Switzerland at the moment have been trained abroad.
Learning Objective:
1. The introductions will give a very short overview of the aim and history of the Meets sessions (EFRS president) and the characteristics of Portugal and Switzerland (association presidents).

A-495 14:10

Introduction: Across Portugal
J. Santos; *Coimbra/PT (presidente@atarp.pt)*

Portugal is a European Union country with the 10 millions of habitants. The total land area is 91,590 Km2 with 850 Km of splendid beaches bathed by the Atlantic Ocean. Per year Portugal has around 3000 hours of sun however 66.3% of the population is urban. The number of medical imaging equipment's is higher than the Organisation for Economic Co-operation and Development (OECD) recommendations. Structurally the supervisory authorities in the area of ionising radiation for medical exposures in Portugal are Regional Health Administrations, the Nuclear Technological Institute and the Health Authorities. The Portuguese health system is divided in five Regional Health Administrations (ARS). These government agencies ensure the efficiency of health care and manage the human and technical resources. They are responsible for the enforcement of the provisions of the Portuguese law regarding the facilities to radiology practice. Portugal has three dedicated Paediatric Hospitals and three further sites with specialised paediatric services, which have a 24 hour service, a large proportion of paediatric medical imaging examinations are performed in adult hospitals. The National Health Service (Serviço Nacional de Saúde) meets Portuguese healthcare needs. The majority of health care institutions are public but the number of private institutions had increased on the last decades.
Learning Objective:
1. The introductions will give a very short overview of the aim and history of the Meets sessions (EFRS president) and the characteristics of Portugal and Switzerland (association presidents).

A-496 14:15

Radiographers in Switzerland: challenges and chances
Y. Jaermann; *Vevey/CH (yves.jaermann@hopitalrivierachablais.ch)*

Our profession is relatively new in Switzerland. It remains largely unknown by the general population as well as by other health professionals. The current political and economical context obliges us to explore ways in which to defend the position of our profession in the health community. While certain professions seek to take over important areas of established radiography skills, an update of our training system is absolutely indispensable. At the same time, it is vital for us to develop new areas of activity that will allow the profession to acquire the recognition that it deserves.
Learning Objectives:
1. To understand the curriculum of the Swiss radiographers' education and CPD.
2. To acknowledge the competition with other professions and the need for new skills and activities.
3. To evaluate the next steps to professional independence.

A-497 14:30

The Portuguese NHS: the structural pillar that strengthens Portuguese democracy
G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

Over four decades Portugal has been governed under a dictatorship system, leading our country into one of less developed in Europe, specially in the education and health system. On the 25th of April of 1974 a military-led coup put an end to the 40 years of dictatorship, through what is called the "revolução dos cravos", named to the fact that from one day to another, and without a civil war or any kind of deaths, Portuguese went to bed in a dictatorship regime and woke up in a Democracy. One of the main pillars on which the Portuguese democracy has been raised is the SNS (Serviço Nacional de Saúde): Portuguese NHS. The SNS guaranties equal rights and equal access to all Portuguese, independently of age, gender, race, religion, with no social or economic discrimination. Due to the qualitative and civilisational improvement raised from the creation of the Portuguese SNS, Portugal, in the last 38 years, has passed from one of the countries with the worse health indicators to one of the top 10 WHO ranking. The quality of the education of radiographers and radiologists is highly recognised, honouring the Portuguese Nobel prize in Medicine, Egas Moniz (1949), that aside from several achievements in the field of neurosurgery was the pioneer of the cerebral angiography. Medical imaging in Portugal had an important role in the national program against the incidence and prevalence of tuberculosis. Portugal was also one of the first European countries to successfully implement a national mammography screening program.
Learning Objectives:
1. To learn about the development of the Portuguese NHS.
2. To understand the impact of the Portuguese NHS in the social development.
3. To learn about the role of radiology in improving the Portuguese health indicators.

A-498 14:45

(Helv)ethic: from a project to a new culture

F. Riondel; *Geneva/CH (francois.riondel@hcuge.ch)*

At the University Hospital of Geneva, the radiographers collectively produced a document to improve the recognition of their profession within their institution. A reflexion spanning several years with the aim of clarifying their autonomy and responsabilities, and written as an ethical code, presented as a charter. Different elements of this charter reflect themes that are debated in the french speaking part of Switzerland or elsewhere in the country. It covers the development of a radiographer's expertise and recognition of the necessity for access to continuous professional education, centered around the patients needs. New ways of positioning the radiographer in the inter-professional partnership, increasing their autonomy and their independence for certain medicotechnical acts.

Learning Objectives:

1. To learn about a team building philosophy able to promote our profession and build new career opportunities.
2. To understand the central role of radiographers within the growth and promotion of the professional environment and within the profession itself.
3. To acknowledge the importance of patient care and human relationships in radiography.

A-499 15:00

MRI, the image modality for the future: hybrid, diagnostic and therapeutic

V. Silva; *Porto/PT (vitorsoft@gmail.com)*

Magnetic resonance (MR) is a medical imaging modality in permanent evolution. Nowadays, MR is becoming a hybrid technique, functioning for diagnostic and therapeutic considering the superb soft tissue contrast. Dedicated hybrid positron emission tomography (PET) combined with MR - PET/MR have been recently introduced and these equipments have the potential to combine the molecular and functional information of PET with MR excellent soft tissue contrast, perceiving better the localization of pathologies. PET/MR offers opportunities for more efficient, accurate and safe diagnoses. MR can be used to therapeutic methods when combined to a hybrid linear accelerator (linac). MR will provide optimal soft tissue contrast for image guidance in multiple sites in human body providing diagnostic quality images during treatment delivery, and, consequently, permitting very accurate image guided adaptive radiotherapy. Associated to these new paradigms on MR hybrid imaging, the knowledge of MR safety issues and considerations are fundamental for better practices. Knowing how a MR scanner works and its inherent physics is vital. For its functioning, MR has three different types of electromagnetic fields: (i) a static magnetic field; (ii) time varying gradient fields; and (iii) radiofrequency fields. These have different risks and hazards. The MR potential for improving the health care provided to patients is proved by the combination with other diagnostic and therapeutic imaging modalities.

Learning Objectives:

1. To recognise MRI as an image modality with great clinical potential for diagnosis.
2. To learn about MRI/PET opportunities, challenges and new directions in clinical practice.
3. To understand the MRI potential to improve radiotherapy planning and treatment.
4. To be aware of MRI safety considerations and risks to promote best practices.

EuroSafe Imaging Session

EU 3

Clinical diagnostic reference levels for x-ray medical imaging

A-500/A-501 14:00

Chairpersons' introduction and update on the project on clinical DRLs for x-ray medical imaging

J. Damilakis[1], G. Frija[2]; *[1]Iraklion/GR, [2]Paris/FR (damilaki@med.uoc.gr)[1], (guy.frija@aphp.fr)[2]*

Different image quality is needed for different clinical indications of the same anatomical area. Kidney stone evaluation, for instance, can be performed using lower radiation doses than those used in evaluation of appendicitis because detection of high-contrast structures is affected less by high image noise than low contrast structures. Clinical indications dictate the main parameters that affect patient dose from CT such as scanning length, collimation and number of phases. The EC launched the 'European study on clinical diagnostic reference levels for X-ray medical imaging' (EUCLID) project to provide up-to-date clinical DRLs. The main objectives of the project are to; (a) conduct a European survey to collect data needed for the establishment of DRLs for the most important, from the radiation protection perspective, X-ray imaging tasks in Europe; and (b) specify up-to-date DRLs for these clinical tasks. This introductory presentation will provide a brief update on EUCLID project.

Session Objectives:

1. To understand the general concept of diagnostic reference levels (DRLs), in particular clinical DRLs and the project on clinical DRLs for x-ray medical imaging.
2. To learn about the current status of DRLs in paediatric imaging.
3. To become familiar with the concept of local DRLs.

A-502 14:05

The concept of diagnostic reference levels (DRLs)

E. Vaño; *Madrid/ES (eliseov@med.ucm.es)*

Diagnostic reference Levels (DRLs) were introduced by the International Commission on Radiological Protection (ICRP) as a tool to help optimise medical imaging in diagnostic and interventional procedures. ICRP has published a new set of recommendations on DRLs (ICRP Publication 135; 2017). Several issues have been updated: definitions of the terms used in previous guidance, determination of the DRLs values (including multimodality procedures), the appropriate interval for re-evaluating these values, appropriate use of DRLs in clinical practice and application of the DRL concept to newer imaging technologies. Weight bands are recommended for establishing paediatric DRLs. Concerning medical imaging tasks, the DRL values should be tied to defined clinical and technical requirements. The assessment of clinical image quality or the proper diagnostic information when multiple images are used should be performed as part of the optimisation process. ICRP has also included recommendations on establishing regional (for several countries) DRL values that can be based on either a representative sample of health facilities or on national DRL values. Regional DRL values may provide guidance on how to optimise the protection of neighbouring countries with no DRL surveys of their own. When relatively few national DRL values exist for the countries within a region, regional DRL values may be derived through a consensus of the region's competent authorities. ICRP suggested that the problem to combine large and small countries could be dealt with by weighting national DRL values according to the population of each participating country.

Learning Objectives:

1. To understand the concept of DRLs in general.
2. To learn about the International Commission on Radiological Protection's (ICRP) work and perspective.

A-503 14:20

The concept of clinical diagnostic reference levels (DRLs)

G. Frija; *Paris/FR (guy.frija@aphp.fr)*

Diagnostic reference levels (DRLs) are an important tool for optimisation. They are usually established for specific anatomical locations, although some countries established also DRLs based on clinical indications. This talk will highlight the advantages of this latter approach, and will briefly introduce the EUCLID project (European Study on Clinical DRLs), a European Commission tender project aimed at establishing DRLs on clinical indications.

Learning Objectives:

1. To become familiar with the concept of clinical DRLs.
2. To learn about the EUCLID project.
3. To learn about practical implications and advantages of clinical DRLs.

A-504 14:30

An update on current European diagnostic reference levels (DRLs) in adult imaging

J. Damilakis; *Iraklion/GR (damilaki@med.uoc.gr)*

The clinical indication is the main determinant of patient radiation dose. Therefore, DRLs should be specified for a given clinical indication. The 'European study on clinical diagnostic reference levels for X-ray medical imaging' (EUCLID) project aims to specify up-to-date DRLs for the most important, from the radiation protection perspective, X-ray imaging tasks in Europe. A comprehensive review has been carried out to identify the status of existing clinical DRLs for CT, interventional radiology and radiography in

Europe and beyond by analysing recent studies, standards and publications. Information about existing clinical DRLs has also been collected from national competent authorities and other organisations involved in the project. A few national radiation protection authorities, only, have defined a limited number of DRLs for different clinical indications, so far. Although a large number of studies on doses from X-ray imaging are available, there is very limited information about clinical-indication specific DRLs.

Learning Objectives:

1. To learn about methodological requirements for establishing DRLs.
2. To learn about the current status of DRLs in adult imaging in Europe and beyond.
3. To understand why clinical DRLs are needed in adult imaging.

A-505 14:45

An update on current paediatric diagnostic reference levels (DRLs)

C. Granata; *Genoa/IT (cgranata@sirm.org)*

Particular attention should be paid to using diagnostic reference levels (DRLs) in paediatric radiology, as children are at higher risk compared to adults of being affected by the detrimental effects of radiations in some organs and body areas. However, only a few European countries have established paediatric DRLs, mostly for a limited set of examinations. The existing DRLs are often derived from old European Commission (EC) recommendations or from surveys conducted in other countries with inconsistent methodology and rarely updated. Furthermore, DRLs are still largely based on age and not on size, which can be very different among children of the same age. Recently, an EC project on new European guidelines for DRLs in paediatric Imaging (PiDRL) was assigned to a consortium directed by ESR with the involvement of ESPR, EFRS, EFOMP, and STUK. This project resulted in a series of recommendations concerning the appropriate methods to establish new paediatric DRLs. These recommendations define what is intended for local, national, and European paediatric DRLs, the set of examinations for which paediatric DRLs should be established, patient subdivision into groups, dosimetric parameters to be considered, and instructions on how to make good use of paediatric DRLs.

Learning Objectives:

1. To become familiar with paediatric DRLs.
2. To learn about the European Guidelines on DRLs for Paediatric Imaging (PiDRL).
3. To learn about recent work undertaken by the ESR to establish paediatric DRLs.

A-506 15:00

The concept of local diagnostic reference levels (DRLs)

N. Saltybaeva; *Zurich/CH (Natalia.Saltybaeva@usz.ch)*

Diagnostic reference levels (DRLs) are an important dose optimization tool endorsed by many professional and regulatory organizations. National DRLs (NDRLs) are commonly set by the local health authority at the third quartile values (75%) of the dose distribution determined for representative examinations conducted across different healthcare facilities. Besides NDRLs, local DRLs (LDRLs) can be also established for a single center or group of healthcare facilities and used as a baseline for quality control and dose optimization. The invited speaker will give an overview of how LDRL should be defined; which dose tracking tools can be used for this purpose and how the DRLs can be adjusted to the specific needs of the individual healthcare facility.

Learning Objectives:

1. To become familiar with the concept of local diagnostic reference levels (LDRLs).
2. To understand the key factors affecting LDRLs.
3. To learn how the LDRLs can be established and used for dose optimisation; what action should be taken if LDRLs are exceeded.

Radiology will survive, but will the radiologist still be there?

Moderators:
P. Leander; Malmö/SE
S. Morozov; Moscow/RU

A-507 14:00

The landscape in radiology is changing: the radiologists need to adapt

P. Leander; *Malmö/SE (peter.leander@med.lu.se)*

Diagnostic imaging is of great importance and will become even more so with addition of new techniques. In the western world, annual growth-rates of imaging are around 10%. Not only the number of examinations increase also are the studies more complex requiring highly specific reports and more quantitative measurements. To respond to the growing demands radiologists try to run faster, but may have reached the limit of capacity when working in a traditional way. If other strategies not are implemented the increasing workload cannot be handled and requests from clinical colleagues may be turned down. In many countries, workload is handled partly by external reading from teleradiology companies. However, teleradiology is also controversial as it shifts radiology from being an interactive specialty to a commodity that can be ordered and delivered as a common laboratory service. In radiology, traditionally examinations have been performed by technicians and presented to a radiologist for reading. Throughout development of new potent modalities as CT, MRI and PET-CT and filmless departments using RIS and PACS that has not changed. Do we now stand in front of a big paradigm shift? Now the radiologist may become a conductor of several systems performing reading, i.e., machine learning, artificial intelligence (AI), reading radiographers and teleradiology. The technical development may give more opportunities in radiology than ever for giving the radiologist help with the right tasks in the right time.

Learning Objectives:

1. To understand the worldwide trends in workload change.
2. To appreciate the development of teleradiology and commoditisation of the radiology.
3. To become familiar with the role of information technologies in radiology.

Author Disclosure:

P. Leander: Board Member; Spago Nanomedical MRI contrast media research company, Lument, contrast media research in the area of oral CT contrast.

A-508 14:23

Big-data, artificial intelligence, machine learning, deep learning etc.: what radiologists should know

K.J. Dreyer; *Boston, MA/US (kdreyer@partners.org)*

As computers outperform humans at complex cognitive tasks, disruptive innovation will increasingly remap the familiar with waves of creative destruction. And in healthcare, nowhere is this more apparent or imminent than at the crossroads of Radiology and the emerging field of Clinical Data Science. As leaders in our field, we must shepherd the innovations of cognitive computing by defining its role within diagnostic imaging, while first and foremost ensuring the continued safety of our patients. If we are dismissive, defensive or self-motivated - industry, payers and provider entities will innovate around us achieving different forms of disruption, optimised to serve their own needs. To maintain our leadership position, as we enter the era of machine learning, it is essential that we serve our patients by directly managing the use of clinical data science towards the improvement of care—a position which will only strengthen our relevance in the care process as well as in future federal, commercial and accountable care discussions. In this session, we will explore the state of clinical data science in medical imaging and its potential to improve the quality and relevance of radiology as well as the lives of our patients.

Learning Objectives:

1. To learn the basic principles of artificial intelligence.
2. To appreciate the current and future applications of artificial intelligence in radiology.
3. To become familiar with available tools of artificial intelligence in clinical and research radiology.

A-509 14:45

How to cope with the new IT developments: the developer's perspective

S. Tolle; *Galway/IE (Steven.Tolle1@ibm.com)*

It is humanly impossible for radiologists these days to keep up with the sheer volume of medical images generated and the huge reporting workloads, complicated by shrinking radiologist workforce in Europe. Thus, radiology departments and radiologists need to embrace technology that helps make things more efficient and improve their job satisfaction. Through advanced image analysis, machine and deep learning as well as a robust knowledge base, AI can revolutionise healthcare. The power AI can quickly sort abnormal from normal, compare sequential datasets to show changes, detect abnormalities, speed up reporting, and increase capacity. Ultimately, AI in radiology can bring greater confidence in diagnostic decisions, improved workflows, optimised reporting times and better connect people, medical images as well as unstructured and structured data.

Learning Objectives:

1. To understand the market trends of IT and AI in healthcare.
2. To appreciate the clinical needs for IT, AI, machine learning and big-data analysis tools.
3. To understand the current business models and future trends of IT/AI products in healthcare.

A-510 15:08

The value of the radiologist in the evolving digital environment: challenges for leadership

C.D. Becker; *Geneva/CH*

The radiologic profession is at the forefront of digitisation in medicine, and had to adapt continuously to many disruptive changes over the past few decades. Today, images and image processing tools are no longer owned by radiologists but readily accessible for all authorised physicians. Patients may have direct access to medical information via digital platforms and may wish to participate in diagnostic and therapeutic decisions and procedures that are based on radiologic images. The diagnostic radiologist must be able to act as an imaging consultant, with expert knowledge dedicated to a subspecialty area. Although there is a general trend towards a value-based health system, the radiologist's role as guarantor of the quality chain of medical imaging is often underestimated or even taken for granted. Recent advances in data science such as machine-learning algorithms for automated image interpretation, quantitative image processing tools for mathematical texture analysis in the context of advanced oncology, and automated data extraction by means of big data processing tools are on the horizon, heralding new disruptive changes for the radiologic profession. The leadership challenges in radiology for the next decade include the questions how these new tools can best be harnessed and how the clinical relevance of the radiologist can be ensured in this rapidly changing digital environment.

Learning Objectives:

1. To review the impact of the digital environment on the radiologist's role.
2. To examine strategies to ensure the clinical relevance of the imaging specialist in the future.
3. To discuss the challenges for leadership in radiology.

14:00 - 15:30 **Room M 4**

E³ - ECR Academies: State-of-the-Art and Advanced MR Imaging of the Musculoskeletal system

E³ 1119
Small joints

A-511 14:00

Chairperson's introduction

M. Zanetti; *Zurich/CH (marco.zanetti@hirslanden.ch)*

This state of the art course will address how MR imaging can be improved in the assessment of the small joints in the fingers, forefoot, midfoot, temporomandibular joint, and in the pubic symphysis. Optimized MR protocols will be suggested. Based on the challenges to assess the anatomical structures in the small joints the use of contrast media may be considered by some radiologists, but the general use is debated. Thus, this use of contrast media in small joints will be specifically discussed.

A-512 14:05

A. Fingers

E. Llopis; *Valencia/ES (evallopis@gmail.com)*

The purpose of this educational lecture is to become familiar with imaging of the fingers. We will review the anatomy based on a compartmental approach: flexor, extensor, supportive structures, and bones. We will list the most common ligament and tendon traumatic injuries, and the more frequent tumors where imaging can be specific and the role of the different modalities. To finalize we will give a structured report.

Learning Objectives:

1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and how to optimise protocols with and without contrast administration.

A-513 14:26

B. Forefoot and midfoot

N. Mamisch-Saupe; *Zurich/CH (nsaupe@hotmail.com)*

Many disorders produce pain in the forefoot and the metatarsal region. Sometimes it is difficult to establish a diagnosis only on the clinical findings. MRI with its excellent soft tissue contrast and multiplanar imaging capability can often reveal a specific diagnosis. MRI allows a specific diagnosis based on the localization, signal intensity characteristics as well as morphologic features of the lesion. Commonly present disorders include trauma related lesions such as stress fractures or stress reactions of the bone as well as sesamoiditis or Freiberg infraction. Traumatic soft tissue lesions include plantar plate tears which occurs more often in women with increased weight bearing load and hyperextension forces involving the lesser metatarsal joints compared to the turf toe involving the greater metatarsal joint after hyperextension arm more commonly in men. There are additionally many non-neoplastic soft tissue masses to differentiate such as Morton neuroma, ganglia, bursitis or pseudobursae leading to chronic pain. Additionally, other chronic diseases such as gout and rheumatoid arthritis often affect the metatarsal joints. An additional value of contrast-enhanced MRI over standard MRI and STIR sequences exists in imaging mid- and forefoot. There is a slightly more added value for soft tissue lesions compared to bony lesions. Especially in detection of lesser metatarsophalangeal joint plantar plate tears a substantial portion of the lesions becoming only visible or after the administration of gadolinium or leading to change the diagnosis in many cases.

Learning Objectives:

1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and how to optimise protocols with and without contrast administration.

A-514 14:47

C. Temporomandibular joint

G. Andreisek; *Münsterlingen/CH (gustav@andreisek.de)*

The temporomandibular joint (TMJ) is one of the small joint of the body which usually gets only little attention by radiologists. It is also often covered clinically by dentists. Unfortunately, the interaction between dentists and radiologists is usually limited and as such there is also little knowledge among radiologists regarding TMJ disorders. However, the incidence of TMJ joint disorders is fairly high with subsequent problems for the patients. They typically complain about pain or tenderness in the face, jaw joint area, neck and shoulders, and in or around the ear when chewing, speaking, or opening the mouth wide. Patients also describe jaws that get "stuck" or "lock" in the open- or closed-mouth position, clicking, popping, or grating sounds in the jaw joint when opening or closing the mouth or chew. Patients may also develop toothaches, headaches, neck aches, dizziness, earaches, hearing problems, upper shoulder pain, and ringing in the ears (tinnitus). In my lecture, I will review the normal anatomy of the TMJ as well as normal appearance on MR imaging. In addition, comments on a proper imaging protocol which fulfil both the needs for sufficient image quality, but also time-and-cost efficient. Results from own research on ultra-high filed MR imaging of the TMJ will also be presented. Finally, typical acute and chronic TMJ disorders will be discussed.

Learning Objectives:

1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and how to optimise protocols with and without contrast administration.

A-515 15:08

D. Pubic symphysis

P. Robinson; *Leeds/UK (philip.robinson10@nhs.net)*

This lecture will describe the anatomy and function of the symphysis pubis and surrounding soft tissues and how this can vary between the sexes and during pregnancy. Proposed mechanisms of injury will be presented. Primary stresses during athletic activity are thought to be shearing in nature while in pregnancy distraction predominates. Post-partum 'osteitis pubis' is thought to be due to residual instability, but rarely requires surgical intervention. Athletic pubalgia has a more controversial aetiology, but more consistent MRI findings involving and surrounding the symphysis pubis. However, in both areas imaging abnormalities can exist in asymptomatic patients and therefore, clinical context and correlation is vital.

Learning Objectives:

1. To identify the most common post-traumatic entities.
2. To identify the most common entities leading to chronic pain.
3. To know the role of MR imaging and how to optimise protocols with and without contrast administration.

Author Disclosure:

Imaging of the chest

A-516 16:00

A. Fibrosing lung diseases

F. Molinari; *Lille/FR (francescomolinari.dr@gmail.com)*

The diagnostic approach to patients with fibrosing interstitial lung disease (FILD) is often complicated even when clinical history and physical findings are correctly assessed at presentation. In fact, many disorders of known and unknown etiology may result in lung fibrosis and have overlapping clinical and radiographic features. Surgical lung biopsy is a viable tool for establishing the diagnosis. However, the procedure is associated to morbidity and mortality risks. HRCT remains the most important noninvasive modality for the diagnosis and management of patients with FILD. HRCT findings such as parenchymal reticulation, ground-grass attenuation, traction bronchiectasis and bronchiolectasis, architectural distortion, and honeycombing indicate the presence of FILD. Honeycombing also indicates that lung fibrosis is irreversible and potentially progressive. To differentiate the most commonly encountered FILDs, current guidelines recommend to considered the presence of subpleural and basilar reticulation associated with honeycombing, altogether as the "UIP pattern". In the absence of known causes of lung fibrosis, a "definite" UIP is consistent with a diagnosis of idiopathic pulmonary fibrosis and does not require lung biopsy. The forms of FILD that manifest at HRCT as "possible" UIP and for which an alternative diagnosis of NSIP exists require lung biopsy. Finally, if the FILD manifests with HRCT findings that are inconsistent with UIP, the potential diagnosis of chronic HP is considered and lung biopsy is usually not indicated. This clinical-HRCT interpretative algorithm facilitates the assessment of HRCT scans that show the presence of lung fibrosis and provides guidance in the management of patients with FILD.

Learning Objectives:

1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

A-517 16:45

B. Pleural disease

C. Beigelman; *Lausanne/CH*

Diffuse or focal pleural disorders are commonly encountered in routine practice, including pleural effusions, pleural thickenings, calcified or not, pneumothoraces or masses. Differential diagnosis must be known. In particular, focal pleural thickening (PT) may be related to typical pleural plaques, but also to normal structures, previous tuberculosis, pleural metastasis, silicosis, or other rarer conditions. Furthermore, postero-basal PT in supine examination may be reversible on prone position. Any atypical shape, location or change of a PT should suggest a pleural metastasis in a context of malignancy. In all cases, a careful analysis of other CT findings, previous imaging studies and clinical history are determinant for the final diagnosis. Parenchymal bands or rounded atelectasis are helpful for the diagnosis of benign diffuse pleural thickening. Features suggestive of malignancy include circumferential pleural thickening, nodular pleural thickening, parietal pleural thickening greater than 1 cm, and mediastinal pleural involvement. Atypical aspects such as pleural effusion even without plaque and pleural irregularity may be observed in mesothelioma, and slight changes in the mediastinal or interlobar pleura should be considered as suspicious of this diagnosis. Mistakes may be related to the difficult recognition of features such as in case of pneumothorax in supine position or to atypical features such as loculated effusions or atypical presentations of malignant pleural involvement, that may lead to a delayed diagnosis.

Learning Objectives:

1. To identify the key imaging findings.
2. To become familiar with the differential diagnosis.

16:00 - 17:30 **Room B**

Special Focus Session

SF 12a
My three top tips for abdominal imaging

A-518 16:00

Chairperson's introduction

D.J.M. Tolan; *Leeds/UK (djmtolan@doctors.org.uk)*

A rapid review of the key areas for professional learning and development will be provided from a group of expert radiologists for a full range of gastrointestinal conditions. This will provide opportunities for both the general radiologists and specialists to improve the services they offer patients and clinicians dealing with abdominal diseases.

Session Objectives:

1. To learn how to avoid common mistakes in abdominal radiology.
2. To understand how to get over an area of difficulty through the clinical expertise of selected abdominal radiologists.

A-519 16:05

Postoperative abdomen

D.J.M. Tolan; *Leeds/UK (djmtolan@doctors.org.uk)*

Anastomotic leaks on CT are heralded by a number of signs including increasing free gas and free fluid in the abdomen, localised fluid around the anastomosis and in particular the extravasation of positive contrast from the bowel lumen. This is recommended for routine use in the post operative evaluation of patients wherever possible. Surgeons utilitise haemostatic agents in the intraoperative management of bleeding. These can cause confusion in imaging interpretation and can mimic an abscess. Radiologists should have a heightened awareness of this appearance and discuss such cases with the surgical team for clarification. Similarly retention of surgical swabs remains a substantial cause of morbidity for patients in the post operative period. Such swabs are readily identifiable by a radiolucent marker and in such cases the surgical team needs immediate notification to allow a return to theatre for swab retrieval.

Learning Objectives:

1. To learn how to optimise detection of anastomotic leaks on CT using radiological signs and positive luminal contrast.
2. To recognise material in the abdomen surgeons may leave deliberately.
3. To recognise material in the abdomen surgeons may leave by accident.

A-520 16:11

Appendicitis

J.B.C.M. Puylaert; *The Hague/NL (dr.jbcmpuylaert@wxs.nl)*

Abdominal ultrasound plays a pivotal role in the imaging workup of patients with suspected appendicitis. It should be the primary modality, and only in case of a negative or inconclusive examination should it be followed by CT or MR. The specific advantages of US over CT are: US has an image definition in the close range which is much higher than that of CT. US is more interactive than CT. The patient's history as well as the painful area or palpable mass can directly be correlated with the US findings. US is real time and shows peristalsis, pulsations and blood flow. US also shows the effects of respiration, Valsalva manoeuvre, gravity and compression with the probe, allowing to assess whether the appendix or other organs such as the bowel and gallbladder are soft or rigid. US allows immediate US-guided puncture of intraperitoneal fluid and drainage of pus. US in appendicitis should be performed with graded compression. Compression is necessary to displace or compress bowel to eliminate the disturbing influence of bowel gas and to approach the pathological structure closely. This allows the use of a high-

frequency transducer with a better image quality. The final US report should be integrated with the clinical findings, laboratory data, CT-scan and possible other radiological examinations. It is clear that the US examination, as described here, should not be performed by a technician or by a clinician, but by an experienced (abdominal) radiologist.

Learning Objectives:

1. To learn that US has a pivotal and unique role in appendicitis and should be done prior to CT.
2. To learn that US in acute abdomen allows the radiologist to get closer to the patient than CT and MRI.
3. To learn that US should be performed by abdominal radiologists, and not by clinicians or technicians.

A-521 16:17

Bile duct stones

J.A. Guthrie; *Leeds/UK (Ashley.Guthrie@nhs.net)*

The first investigations in patients with suspected gallstone disease, especially if stones within the common bile duct (CBD) are suspected, are US and liver function tests (LFTs). On the basis of this, the risk of CBD stones can be estimated and the decision whether or not to perform the next test, MRCP, can be made. In the presence of stones in the gallbladder, the risk increases with a CBD of > 8 mm and increasing abnormal LFTs. My preference is for 2D T2 sequences without fat saturation in two planes. Breath-hold when possible is preferred in the interests of time, but can be gated in those that struggle. HASTE/SS-FSE/FSE-ADA/FASE is the first set of sequences, followed by FISP/GRASS/FFE/SARGE if a diagnosis is not made as stones vary in their conspicuity between the sequences. The examination can be terminated as soon as a positive diagnosis is made. T1-weighted images occasionally help.

Learning Objectives:

1. To learn that in patients with a high index of clinical suspicion of bile duct stone, MRCP should be employed early.
2. To know that 2D HASTE/SS-FSE/FSE-ADA/FASE without fat saturation in two planes (oblique coronal and axial) will establish a diagnosis in most cases and are the "work horse" sequences in most patients.
3. To understand that FISP/GRASS/FFE/SARGE (which can be gated) are a useful adjunct especially in those patients that have difficulty holding their breath.

Author Disclosure:

J.A. Guthrie: Speaker; Bayer Healthcare, Siemens AG. Other; Attended a symposium organised and at the expense of Bayer Healthcare.

16:23

Questions and discussion

A-522 16:29

Dilated pancreatic duct

R. Manfredi; *Rome/IT (riccardo.manfredi@unicatt.it)*

The prognosis of pancreatic adenocarcinoma is very poor, and little improvement has been reported in the past several decades. Only a low percentage of patients in whom pancreatic cancer is detected at an early stage without local infiltration have the potential for long-term survival after surgical resection. The earliest possible diagnosis may be the most effective way to improve the prognosis. Dilatation of the main pancreatic duct may represent a secondary sign of pancreatic adenocarcinoma. Therefore, the diagnosis of dilated main pancreatic duct may be a predictive sign of pancreatic adenocarcinoma; therefore, careful follow-up in people with such signs and eventually prompt treatment have been recommended. Pancreatic endocrine neoplasms are relatively rare, with an incidence rate of approximately five cases per one million person-years. Some pancreatic endocrine neoplasms release hormones into the blood stream that cause clinical syndromes, whereas others are non-syndromic and present as a mass lesion. At diagnostic imaging, pancreatic endocrine neoplasms typically produce hyperenhanced well-demarcated lesions that are best seen on arterial phase images. Pancreatic endocrine neoplasms may be responsible for pancreatic duct stenosis, even when they are small in size (<2 cm) and be responsible for marked dilatation of the main pancreatic duct and/or marked atrophy of the upstream pancreas. Intraductal papillary mucinous neoplasm (IPMN) originates from the ductal epithelium and overproduce mucin which is responsible for the dilatation of the main pancreatic duct and/or the side branches. Diagnostic imaging is helpful in the diagnosis and follow-up of these patients.

Learning Objectives:

1. To learn how to diagnose and manage adenocarcinoma of the pancreas mimickers: autoimmune pancreatitis and paraduodenal pancreatitis.
2. To appraise how to manage incidental cystic lesions of the pancreas.
3. To learn how to diagnose and manage neuroendocrine neoplasms of the pancreas.

A-523 16:35

Liver biopsy

V. Vilgrain; *Clichy/FR (valerie.vilgrain@aphp.fr)*

Liver biopsy is the most common invasive procedure of the liver. Indications of biopsy in diffuse liver diseases have declined due to improvements in noninvasive assessment of fibrosis and steatosis. On the contrary, biopsy of liver tumours is still indicated mostly for diagnostic purpose and to a lesser extent for assessing the prognosis or the prediction of tumour response. Three keys are important. First, check the indication. There are very few contraindications (mostly related to coagulation disorders) and the most important is to ensure that there is a good indication for liver biopsy. Second, use ultrasound guidance, which is faster, easier and more accurate than CT. It allows real-time control. Third, if a primary tumour liver is considered, always perform a biopsy in the adjacent liver. This will help the pathologist in the diagnosis.

Learning Objectives:

1. To understand the risk/benefit of liver biopsy.
2. To know the absolute contraindications.
3. To be aware of the most important technical tricks.

A-524 16:41

Bowel ischaemia

M. Zins; *Paris/FR (mzins@hpsj.fr)*

Acute mesenteric ischaemia (AMI) is defined by inadequate blood supply through the mesenteric vessels resulting in intestine injury and carries a high mortality rate. A combination of two phenomena is needed to generate AMI: vascular insufficiency and intestinal injury. The diagnosis of AMI should be made as soon as possible, since early stages of ischaemia are reversible if properly treated. The three main messages for the radiologist are: 1) CT angiography (CTA) should use a triple-phase protocol (unenhanced, arterial and portal venous phase), 2) assessment of bowel wall abnormalities at CTA (decreased enhancement, increased attenuation on pre-contrast phase, wall thickening, wall thinning) is a major step in the interpretation of CT scans and 3) always carefully check the mesenteric vessels (for thrombus, embolism, dissection) in patients with acute abdominal pain of unknown origin.

Learning Objectives:

1. To understand the limited value of isolated mesenteric pneumatosis.
2. To learn about the added value of unenhanced scan.
3. To understand the crucial role of vascular assessment at CT angiography.

16:47

Questions and discussion

A-525 16:53

Colon polyp

F. Iafrate; *Rome/IT (francoiafrate@gmail.com)*

"no abstract submitted"

Learning Objectives:

1. To quickly review different morphological aspects and "weapons" in the hand of radiologist to detect colonic polyps with CT colonography with small focus on correct preparation and the use of CAD.
2. To define large, small and intermediate polyp size and to review polyp pathology including the risk of cancer and high-grade dysplasia moreover in small and intermediate polyps.
3. To summarise the current debate with regard to intermediate polyps (conservative management vs polypectomy) and the rational for non-reporting of diminutive polyps.

A-526 16:59

Acute pancreatitis

W. Schima; *Vienna/AT (wolfgang.schima@khgh.at)*

For diagnosis of acute pancreatitis, at least two of the three following criteria, (1) abdominal pain consistent with pancreatitis, (2) increase (≥ 3-fold) in serum amylase or lipase levels and (3) imaging findings of acute pancreatitis, have to be fulfilled. According to the Revised Atlanta Classification, the disease is categorized as interstitial oedematous or necrotizing pancreatitis. Development of necrosis may take some time, so that CT imaging should be performed not earlier than 2-3 days after clinical onset. Imaging too early may lead to underestimation of disease severity. Necrotizing pancreatitis presents with either combined pancreatic and peripancreatic necrosis (most common) or with pancreatic necrosis or with peripancreatic necrosis alone. Acute necrotic collections (ANC) in the early phase may evolve into walled-off necrosis (WON) in the late stage (≥ 4 weeks). A WON containing chunks of digested fat and

parenchyma must not be confused with a pseudocyst containing enzymatic fluid (requiring different therapy). They may appear similarly hypodense at CT, but US or MRI will show the predominantly solid nature of a WON. Secondary infection of necrotizing pancreatitis usually occurs in the 3rd week after onset or later. Diagnosis of infection is difficult based on imaging alone. Infection is more likely if collections have broad contact with bowel. Gas within a collection is not a sensitive sign, but quite specific. In case of infection, percutaneous aspiration is sought, followed by drainage in positive cases. However, necrotic collections with large proportions of debris require a more aggressive approach for clearance.

Learning Objectives:

1. To learn about the proper timing of imaging studies in acute pancreatitis.
2. To learn about the imaging manifestations of necrotising pancreatitis.
3. To understand the different nature of fluid collections with regard to further therapy.

A-527 17:05

Crohn's disease

J. Rimola; *Barcelona/ES (jrimola@clinic.ub.es)*

My three top tips for Crohn's disease. In this session we are going to highlight the MUSTs in the assessment of Crohn's disease using cross-sectional imaging techniques: (1) What to look for first: thickness and enhancement, and T2 sequences. (2) What to look after: complications- all sequences. (3) Not forget to look at: other sequences, and areas other than the bowel.

Learning Objectives:

1. To learn about useful signs indicating active Crohn's disease.
2. To understand the changes which occur after treatment of intestinal inflammation.
3. To become familiar with complications related to Crohn's disease.

Author Disclosure:

J. Rimola: Advisory Board; TiGenix, Gilead. Consultant; Takeda, Robarts Clinical Reserach. Research/Grant Support; Abbvie. Speaker; BMS, Takeda.

A-528 17:11

Liver metastases follow-up

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

Follow-up of liver metastases relies mostly on imaging. The need for standardisation was initially prompted by clinical trials. Several systems, from WHO to RECIST, have been proposed, allowing better intra- and interobserver reproducibility and guiding treatment strategy. However, the need for follow-up might be different according to clinical situations, like neo-adjuvant, palliative or adjuvant therapy. The standard might also be adapted to the type of drug, cytotoxic, targeted or immune therapies. Therefore, the radiologist needs to be aware of the clinical situation and learn to identify the drug, to perform a personalised evaluation.

Learning Objectives:

1. To learn how to quickly identify three most common systemic treatments of liver metastases (cytotoxic, targeted and immune), and to understand why knowledge of the regimen is essential for the radiological report.
2. To understand the rationale of international standards for the evaluation of response to treatment, and how to build accordingly a useful report.
3. To appraise the respective objectives of neoadjuvant and palliative chemotherapy, and to be able to explain the specific endpoints for each clinical situation.

16:00 - 17:30 **Room C**

Chest

RC 1204

Pneumonia

A-529 16:00

Chairperson's introduction

I.E. Tyurin; *Moscow/RU (igortyurin@gmail.com)*

Pneumonia is a major health-care and economic problem because of high morbidity and mortality rate, and due to direct and indirect costs of its management. The most common cause is community-acquired pneumonia, caused by common bacteria like *S. pneumoniae* as well as different viral agents. Tuberculosis is one of the most important respiratory infections in developing countries and in immune-compromised patients with AIDS everywhere. Tuberculosis pneumonia can easily mimic bacterial CAP and other pulmonary infections. Viral and mycotic infections represent a common course of febrile neutropaenia in immune-compromised patients under aggressive therapy. In most of all these patients, a diagnosis is made on the basis of a combination of clinical, radiographic, and laboratory findings. High-resolution CT is usually performed in patients with nonspecific clinical and radiologic findings and in patients with progression of disease despite therapy. A large number of acute and chronic infectious and noninfectious diseases may also result in parenchymal lung disease in both immune-competent and immune-compromised patients. Thin-section CT is also performed in patients with noninfectious causes of acute parenchymal lung disease such as organizing pneumonia, acute interstitial pneumonia, hypersensitivity pneumonitis, acute eosinophilic pneumonia, and pulmonary haemorrhage. These diseases often have clinical and functional features similar to one another, but obviously requiring different treatment. Therefore, the differential diagnosis of these entities is important in daily clinical practice.

Session Objectives:

1. To review the role of imaging in infectious lung diseases.
2. To understand the key role of multidisciplinary approach to diagnosis of lung infections.

A-530 16:05

A. Community-acquired pneumonia

I. Hartmann; *Rotterdam/NL (i.j.c.hartmann@gmail.com)*

Community-acquired pneumonia (CAP) refers to pneumonia acquired outside of hospitals or extended-care facilities and is one of the most common infectious diseases. CAP is an important cause of mortality and morbidity worldwide. According to the IDSA/ATS/AAFP guidelines, a chest radiograph is required for the routine evaluation of patients with suspected CAP to exclude conditions that mimic CAP (e.g. acute bronchitis) and to confirm the presence of an infiltrate compatible with the presentation of CAP. Although chest radiography findings usually do not allow identifying the causative organism, they may be helpful in narrowing down the differential diagnosis, prognosis, and detection of associated conditions. Serial chest radiography can be performed to observe the progression of CAP. CT scanning is increasingly used in clinical practice. Performing CT should be considered if any of the abnormalities at presentation or at follow-up are not consistent with the diagnosis of pneumonia, or if concomitant disease is suspected such as an underlying bronchogenic carcinoma, for the confirmation of pleural effusion and for the detection of pulmonary complications. The aim of the presentation is to provide an overview of the imaging findings of the most common aetiologic organisms in patients with CAP. In addition, imaging findings that may help in the differentiation between pneumonia and other common non-infectious causes of abnormal chest radiographs in patients with suspected CAP will be discussed.

Learning Objectives:

1. To appreciate the role of imaging in the management of community-acquired pneumonia.
2. To consolidate knowledge of how to discriminate from noninfectious diseases.

A-531 16:28

B. Tuberculosis

E. Castañer; *Sabadell/ES (ecastaner@tauli.cat)*

Pulmonary tuberculosis (TB) remains a common worldwide infection that produces high mortality and morbidity, especially in developing countries. In 2013, an estimated 9.0 million (360 000 of whom were HIV-positive) people developed TB and 1.5 million died from the disease. Chest radiographs play a

major role in the screening, diagnosis, and response to treatment of patients with TB. However, the radiographs may be normal or show only mild or nonspecific findings in patients with active disease. We will review the chest radiographs findings of TB, which vary widely in the function of several host factors, age, prior exposure to TB, and underlying immune status. CT is useful in detecting TB incidentally, in resolving cases with inconclusive findings on chest radiographs, and in assessing disease activity. Cavities, centrilobular nodules, and tree-in-bud appearance are the most common CT findings of active pulmonary tuberculosis. We will discuss the classic, and some not-so-classic, signs that should suggest the diagnosis of TB.

Learning Objectives:

1. To appreciate typical and atypical tuberculosis manifestations on imaging.
2. To differentiate between acute and chronic tuberculosis infection.

A-532 16:51

C. Fungal pneumonia in immunocompromised hosts

C.P. Heussel; *Heidelberg/DE (heussel@uni-heidelberg.de)*

The radiological characterisation of infiltrates gives a first and rapid hint to differentiate between different types of infectious (e.g. typical bacterial, atypical bacterial, fungal) and non-infectious aetiologies. Follow-up investigations need careful interpretation according to disease, recovery, concomitant treatment and eventually vessel arrosion requiring contrast-enhanced angio-CT. Due to a high incidence of fungal infiltrates in immunicompromised hosts, interpretation of the follow-up of an infiltrate must use further parameters besides the lesion size.

Learning Objectives:

1. To learn the patterns of fungal lung infection depending on the type of immune depression.
2. To become familiar with CT signs suggesting angioinvasive fungal infection.

17:14

Panel discussion: What is the role of radiologists in the diagnosis and management of lung infections?

16:00 - 17:30 **Room X**

E³ - ECR Master Class (Abdominal Viscera)

E³ 1226

Dual-energy CT of the abdomen: the time is now

Moderator:
P. Vock; Berne/CH

A-533 16:00

A. Basic principles and different approaches

L.S. Guimaraes; *Toronto, ON/CA (luis.s.guimaraes@gmail.com)*

Dual-energy CT (DECT) refers to the use of CT data from two different energy spectra to differentiating and classifying tissue composition, in addition to displaying anatomy and pathology. DECT data can be obtained using various hardware solutions (dual-source, fast kilovolt peak-switching, 2-rotation fast kV-mA switch, dual-layer detector and split filter). An explanation on how each of these solutions works, as well as the advantages and disadvantages of each, will be presented. Abdominal DECT has as main advantages the ability to identify/quantify certain materials (iodine, calcium, urate, etc.), as well as to increase the possibility of performing low kV imaging in a wider range of patients, which in turn is associated with an increased conspicuity of enhancing structures and lesions. The background and reasons for each of these advantages will be reviewed. Several challenges remain for full implementation of Dual Energy CT in routine clinical abdominal practices. These challenges, including absence of standardised post-processing (which may be time-consuming), lack of well-defined advantageous routine applications and limitations in terms of patient size/radiation dose will be discussed.

Learning Objectives:

1. To learn about the types of dual-energy scanners and principles of dual-energy CT.
2. To understand issues of radiation dose and image quality in comparison with single-energy CT.
3. To appreciate the possible advantages of this technology with its many post-processing applications.

Author Disclosure:

L.S. Guimaraes: Research/Grant Support; Institutional Research Grant from Toshiba Medical Systems.

A-534 16:30

B. Applications for genitourinary system

H. Ringl; *Vienna/AT (helmut.ringl@meduniwien.ac.at)*

Dual energy CT is increasingly becoming an important diagnostic tool for the non-invasive assessment of the genitourinary system, with a wide range of applications and several advantages over conventional single-energy CT, as detailed below: (1) The use of dual-energy CT with optimised spit-bolus protocols enables considerable dose savings by eliminating two scan phases. However, using virtual non-contrast images, this protocol provides the same information as an unenhanced, an arterial, a venous, and a urographic phase; (2) Virtual non-contrast images and iodine maps enable better characterisation of renal cysts with dense content, which often pose a diagnostic dilemma in single-energy CT, and which might require MRI or CT follow-up examinations; (3) The reconstruction of low kV mono-energetic images results in a higher iodine contrast, and, therefore, in better lesion conspicuity in the kidneys and the bladder wall; (4) Dual-energy CT enables the quantification of iodine-uptake, and may, therefore, be used for therapy monitoring of cancer of the urinary tract; and (5) The material decomposition algorithms of dual-energy CT are able to discriminate urate from non-urate stones in the case of nephrolithiasis in the clinical routine, making this method a game-changer in therapy.

Learning Objectives:

1. To learn about the role of dual-energy CT in the genitourinary system.
2. To understand the value of determination of renal stone composition with dual-energy CT.
3. To appreciate the ability of dual-energy CT to exactly quantify the iodine uptake in renal lesions.

Author Disclosure:

H. Ringl: Research/Grant Support; Siemens.

A-535 17:00

C. Applications for abdominal organs

M. Karcaaltincaba; *Ankara/TR (musturayk@yahoo.com)*

Dual-energy CT (DECT) is increasingly used for abdominal applications. DECT can be performed by dual-source CT, fast kVp switching and dual-layer detector CT. The major advantage of DECT is availability of virtual non-contrast (water) images in every patient. Spectral CT images can allow the diagnosis of a low amount of of fat (normally invisible on CT) within lesions similar to in-out of phase T1-weighted MR images. DECT can allow diagnosis of calcification or haemorrhage within lesions encountered during routine abdominal CT. Low kV images obtained by DECT are more sensitive to hepatic and pancreas hypervascular lesions compared to standard kV images. DECT can also be helpful in differentiation of colonic polyp/mass from stool detected during routine abdominal CT. In the future, all CT scanners will be most likely produced with DECT capability.

Learning Objectives:

1. To learn about the current applications of dual-energy CT in evaluating the abdominal viscera.
2. To understand the role of dual-energy CT for characterisation of incidental lesions discovered during routine abdominal CT.
3. To appreciate how dual-energy CT increases sensitivity for detecting both hypervascular and hypovascular liver and pancreatic lesions.

Author Disclosure:

16:00 - 17:30 **Room O**

Special Focus Session

SF 12b
Imaging of the brain in preterm infants

A-536 16:00
Chairperson's introduction
P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

In this session, focus will be on ultrasound and MR and their role in investigating the brain in preterms, and the use of these techniques for clinical outcome prediction and measures as well as for diagnostic decision-making.
Session Objectives:
1. To learn about different imaging techniques to study the preterm brain.
2. To understand the clinical importance of assessing the preterm brain.
3. To become familiar with novel imaging techniques and their clinical value.

A-537 16:05
The role of cerebral ultrasound
M.I. Argyropoulou; *Ioannina/GR (margyrop@cc.uoi.gr)*

Ultrasound (US) represents the imaging modality with which to start the evaluation of the neonatal brain in premature babies. A state-of-the-art technique should be applied using appropriate transducers (linear and sectorial) and different acoustic windows such as the anterior, the posterior and the mastoid fontanelle. Familiarisation with the normal US appearance of the brain as a function of gestational age is important to detect brain abnormalities. In very premature babies peri-occipital hyperechogenicity may represent a normal appearance and should be differentiated from periventricular leukomalacia. Increased echogenicity of the basal ganglia is a normal finding and should be differentiated from severe hypoxia lesions. Colour Doppler should be used and offers important additional information not only on blood flow, but also on the presence of subarachnoid haemorrhage. In the context of intraventricular haemorrhage, the disappearance of the normal flow at the level of the terminal vein represents a sign of pending venous infarct. Alternating red and blue colour signals at the level of the aqueduct of Sylvius represent an early finding of the presence of blood into the CSF spaces. The delta resistivity index (RI) evaluated at the anterior cerebral artery is calculated from the RI before and after compression of the anterior fontanelle and is very useful for treatment decision of post-haemorrhagic hydrocephalus.
Learning Objectives:
1. To learn about the technique and typical findings of cerebral ultrasound in preterm infants.
2. To understand indications for cranial ultrasound in neonates.
3. To discuss potential adverse effects and added value of US Doppler.

A-538 16:30
The role of cerebral MRI: morphology and beyond
F.M. Triulzi; *Milan/IT (Fabio.triulzi@policlinico.mi.it)*

Preterm birth with subsequent brain injury is an increasing public health concern. Advances in neonatal intensive care have significantly improved survival rates among very-low-birth-weight infants, but survivors are still at considerable risk of developing cognitive, behavioural, neurosensory, and motor disabilities. The most common preterm brain injury patterns are white matter (WM) injury; germinal matrix-intraventricular haemorrhage and its correlates periventricular haemorrhagic venous infarction and post-haemorrhagic ventricular dilation. Diffuse non-cystic types of WM injury, the so-called "punctate" WM lesions, are the most frequent lesions seen on MRI and the leading cause of disturbed brain growth. Although MR imaging is superior to cranial sonography in detecting diffuse WM injury, conventional MR studies fail to exactly predict outcome. Advanced MR imaging acquisition sequences and post-processing techniques, such as DTI, volumetric MR imaging measurements, and proton MR spectroscopy may contribute to a better understanding of subtle microstructural, volumetric and metabolic abnormalities in preterm newborns, allowing a more precise prognosis at term-equivalent age. Early MR imaging, though of great interest to obtain very precocious biomarkers and enabling an early counselling to the parents, has still too many limitations to be considered a standard of care.
Learning Objectives:
1. To learn about protocol and typical findings in premature babies.
2. To understand indications and timing for MR exams in preterm infants.
3. To discuss the prognostic value of performing advanced MR techniques.

A-539 16:55
US screening in preterm infants: prognostsic value from a clinical point of view
J.-P. Schenk; *Heidelberg/DE (jens-peter.schenk@med.uni-heidelberg.de)*

Preterm (born before 37 weeks of gestational age) and especially very premature infants (gestational age 32 weeks and less) have a great risk for intraventricular haemorrhage (IVH) and periventricular leukomalacia (PVL). Because of the possibility of a poorer neurodevelopmental outcome, the detection of IVH, PVL and subsequent hydrocephalus is mandatory. Due to the possibility of an examination inside the incubator with a high resolution, transfontanellar ultrasound is the method of choice for routine examination and follow-up studies. Typical ultrasound findings and pathology will be presented in context to follow-up findings, especially the postheamorrhagic hydrocephalus and postischaemic cystic PVL. Therefore, the rationale of a US screening will be discussed and the in-Heidelberg-used screening scheme will be presented. US findings of blockage of cerebrospinal fluid pathways and obliterative arachnoiditis will be demonstrated. In context to the literature, the advantages of US screening will be discussed and in case studies the extended imaging with MRI will be demonstrated to see the limitations of US examinations and screening. The evaluation of periventricular echogenicity in PVL typically presents the difficulty of differential diagnosis in single US and demonstrates the necessity of repeated examinations in a screening system. Imaging at multiple time points improves the detection of cystic PVL. US findings in anomalies and tumours complete the range of differential diagnosis.
Learning Objectives:
1. To learn about the rationale for routine follow-up of the premature brain.
2. To understand the clinical impact of US findings in preterm infants.
3. To discuss the prognostic value of routine ultrasound screening of preterm infants.

17:15
Panel discussion: Can we afford the extensive screening programmes proposed today?

16:00 - 17:30 **Room N**

Special Focus Session

SF 12c
Head and neck emergencies

A-540 16:00
Chairperson's introduction
R. Kohler; *Sion/CH (romain.kohler@hopitalvs.ch)*

In this session, traumatic, infectious and inflammatory as well as vascular emergencies of the head and neck will be discussed. In the head and neck, multiple anatomical structures are confined in a small area in which run the airway and major vessels. Moreover, the neck is connected with the brain and thorax. These anatomical factors and the diversity of pathologies explain why emergencies may rapidly lead to potential major complications and disabilities or may even be lethal especially when the diagnosis is wrong or delayed. Besides the medical history, clinical examination and biological tests, imaging therefore plays a crucial role as many pathological processes may extend to adjacent structures, deeper structures or even outside of the head and neck area. Fractures of orbits, temporal bone, face or larynx may for example lead to compromise of the airway or meningitis. All structures of the head and neck may contract infection that can propagate to the surrounding spaces or even outside the head and neck. More rarely, patients present with bleeding which can be secondary to trauma, tumour or vascular malformation. Computed tomography and echography are the first techniques used in the emergency setting. MRI is rarely the first-line technique and is only reserved for selected patients with protected airway that are medically stable. Finally, angiography is reserved nowadays only for endovascular treatments. During this session, participants will become familiar with the most frequent emergencies of the head and neck and learn which imaging technique should be used for a given indication.
Session Objectives:
1. To become familiar with most emergencies of the head and neck in clinical routine.
2. To understand which imaging technique to use for a given indication.

A-541 16:05

What is broken?

E. Loney; *Darlington/UK (elizabeth_loney@hotmail.co.uk)*

Radiological assessment is critical in the management of skull base and facial trauma. CT is the preferred imaging technique, combining detailed visualization of bony and soft tissue injuries with the ability to perform 3D reconstructions and aid surgical planning. The scope of this presentation is broad and therefore we will concentrate on producing useful reports by differentiating Le Fort injuries from naso-orbitoethmoid and zygomaticomaxillary fracture patterns. We will consider orbital and temporal bone injuries and briefly touch upon laryngeal trauma, which in itself could account for a whole session. If attendees feel more comfortable reporting a facial trauma scan by the end of the presentation than they did at the start, our aims will have been achieved!

Learning Objectives:

1. To know which imaging techniques to use in case of trauma.
2. To become familiar with base of skull fracture (including temporal bone and orbit).
3. To learn about maxillofacial fractures.
4. To get acquainted with the traumatic lesions of the larynx.

A-542 16:28

It is red and swollen ...

M. Becker; *Geneva/CH (minerva.becker@hcuge.ch)*

Computed tomography (CT), magnetic resonance imaging (MRI) and occasionally ultrasonography (US), play a major role for the correct diagnosis of a variety of infectious head and neck conditions seen in the emergency situation. The purpose of this lecture is to familiarise the radiologist with the most common types of infectious emergencies in the head and neck. A systematic review will include key radiologic features of these potentially life-threatening conditions. The following entities are discussed: otomastoiditis, complicated sinusitis and sialadenitis, suppurative lymphadenitis, paratonsillar, retropharyngeal, parapharyngeal and other neck abscesses, cellulitis, myositis, necrotising fasciitis, osteomyelitis, thrombophlebitis and septic deep venous thrombosis. Associated complications affecting the mediastinum and lung, meninges and brain will be discussed with emphasis on the early detection of lesions. Typical spread patterns of infection within the neck will be summarised. The detection of foreign bodies as a cause of secondary infection, as well as pitfalls and limitations of individual imaging techniques will also be addressed. Major emphasis will be put on what is the most appropriate imaging modality in which clinical situation, how should imaging be performed in an optimal fashion and how to report the findings in a structured and comprehensive way.

Learning Objectives:

1. To learn which imaging techniques to use in the case of an infection and inflammation in the emergency setting.
2. To become familiar with the infections of the base of skull.
3. To understand the diversity of infection patterns of soft tissues.
4. To appreciate the pathologies of the salivary glands that may present in the emergency setting.

A-543 16:51

It is bleeding ...

D.-A. Varoquaux; *Marseille/FR (arthur@varoquaux.com)*

Arterial embolisation is the preferred treatment for refractory epistaxes and for certain hemorrhages of the ENT area. When carried out by trained radiologists, it proves to be an efficient method that presents little risk of complications. Hemorrhages of the ENT area are of different nature and etiology. Their approach should be considered according to specific clinical context. The treatment of hemorrhages of venous origin does not fall under the competence of interventional radiology; endovascular or percutaneous embolization treatment of vascular malformations will not be treated in this article. According to circumstances, several types of arterial hemorrhages of the ENT sphere can be distinguished: (1) Hsemorrhages of nasal origin (epistaxes). They can be essential or symptomatic (2) Life threatening ENT haemorrhages in oncology, pre- or postoperative by hemostasis disorders or secondary bleeding specifically after a laryngectomy or a tonsillectomy devascularisation of hypervascular tumours (paragangliomas and nasopharyngeal fibromas) by preoperative embolisation. (3) Carotid blow out, linked to the presence of a progressive tumour, or post-radiation, or traumatic. In some cases, these haemorrhages are cataclysmic and require extreme emergency care. In all cases, close collaboration with the ENT surgery department, the presence of an anaesthetist, and at least a sedation are determining factors in the improvement of care and therefore in the success of the embolisation. Every patient and/or family is to be given true, clear and appropriate information

Learning Objectives:

1. To learn about the vascular blunt and penetrating traumatic injuries.
2. To appreciate the role of the interventional radiologist in the treatment of epistaxis and tumours (juvenile angiofibroma and squamous cell carcinoma) in the emergency setting.
3. To have notions of vascular malformations and their complications.
4. To acquire basic notions of endovascular treatments.

17:14

Panel discussion: Is the radiologist an essential component of the emergency team

16:00 - 17:30 **Studio 2018**

Genitourinary

MRI for gynaecologic imaging: how I do it

A-544 16:00

Chairperson's introduction

B. Ahuja; *Agra/IN (drbahuja@gmail.com)*

Ultrasound is the imaging modality of choice for the female pelvis. It is widely available and is relatively inexpensive. However, there are some shortcomings with this modality, such as limited field of view, obscuration of pelvic organs by bowel gases, inherent limitations due to patient size and dependence on operator skills. With its high contrast resolution, ability to provide good tissue characterisation and its multiplanar capabilities, MRI is increasingly used to evaluate pelvic pathology. Standard MRI protocol includes coronal single shot fast spin echo (FSE), sagittal T2W FSE fat suppressed sequences, axial T2W FSE sequence, axial in phase and opposed phase T1W gradient recall echo and axial diffusion weighted sequence using a dedicated pelvic phased array coil. GRE imaging is done to detect haemorrhagic foci in case of deep infiltrative pelvic endometriosis. Diffusion weighted imaging play a pivotal role in detection & staging of gynaecological malignancies and to see the response of therapy. Fat suppressed T1W sequences following intravenous administration of 10 ml of gadolinium contrast are routinely obtained. For pelvic floor imaging, dynamic 2D GRE imaging may be performed with and wthout the valsalva maeuver.

Session Objectives:

1. To learn how to optimise MRI of the female pelvis.
2. To understand the diagnostic benefit of integration of advanced techniques.

A-545 16:05

A. Basics of patient preparation and T2W-imaging

N.M. deSouza; *Sutton/UK (nandita.desouza@icr.ac.uk)*

T2-W MR imaging provides exquisite soft tissue contrast for evaluation of pelvic pathology. Maximising contrast and spatial resolution is fundamental to achieving a high diagnostic accuracy. Adequate signal-to-noise ratio with sufficient T2-weighting requires appropriate consideration of available hardware and software. Patient-related factors that result in image degradation can be reduced by careful patient preparation. Motion from bowel peristalsis may be controlled with antiperistaltic agents (Buscopan [hyoscine butylbromide] 20mg or glucagon 1mg); intramuscular administration is crucial as intravenous delivery produces a short period of antiperistalsis insufficient to last through the scanning period. Bladder filling during the scan also can substantially degrade image quality, and therefore an empty bladder at the outset is essential. To minimise diuresis during scanning, caffeine-containing drinks should be avoided and fluid intake limited for 4 hours prior to scanning. Images dedicated to the uterus should be acquired along the long and short axis of the organ, with as small a field of view as feasible without compromising signal-to-noise ratio. For large field-of-view images, T2-W scans in true orthogonal planes to the B0 field are preferred. The sagittal plane is best for visualising the uterus, while the transverse plane is ideal for assessing parametria, adnexae and pelvic sidewall. For the ovaries, the coronal plane may be helpful. 3D acquisitions provide high spatial resolution with the flexibility of multiplanar reconstruction. High-quality T2-W images in orthogonal planes are usually sufficient for detecting, characterising and staging pelvic malignancy, monitoring treatment response and assessing disease recurrence in a range of gynaecological pathologies.

Learning Objectives:

1. To understand the value of patient preparation.
2. To learn how to optimise and tailor protocols in female pelvic imaging.
3. To understand the role of T2WI, and how and when to use 3D techniques.

A-546 16:28

B. Contrast agents

R.A. Kubik-Huch; *Baden/CH (rahel.kubik@ksb.ch)*

Gadolinium-based contrast material is not usually necessary for evaluating benign uterine disease, but is recommended in fibroid evaluation. Gadolinium-enhanced sequences are performed for staging endometrial carcinoma, being useful in the assessment of the depth of myometrial tumour invasion. The optimal tumour/myometrial contrast timing was reported between 90 and 150 seconds. Thus, the utility of dynamic acquisition has been debated. Contrast-enhanced imaging will not be routinely performed in cervical carcinoma, but can be valuable in selected cases. It is recommended in the MR assessment of sonographically indeterminate adnexal masses and mandatory for staging ovarian carcinoma. Dynamic contrast-enhanced MRI may provide quantitative information about tumour perfusion, being useful for monitoring the therapeutic effects and predicting the therapeutic outcome. MR angiography should be performed in patients scheduled for fibroid embolisation or in suspected pelvic congestion syndrome. Gadolinium-based contrast agents will cross the placenta and enter the foetal bloodstream. The agents are excreted into the amniotic fluid and will not be removed effectively from the foetal environment. Contrast agents should be avoided in the pregnant patient. Only a small amount of gadolinium is excreted into the breast milk and absorbed by the infant, without any adverse effects being reported. Therefore, breast feeding can be continued, but it might be the preference of the mother to discard the breast milk in the 24 hours after contrast medium. If contrast agents need to be administered in these patients, linear gadolinium chelates should be avoided.

Learning Objectives:

1. To become familiar with the safety considerations and guidelines for the use of gadolinium with a special focus on imaging pregnant and lactating patients.
2. To learn why, how and when to use IV contrast-enhanced imaging in MRI of the female pelvis.
3. To understand different gadolinium T1W techniques and their clinical value in routine imaging, as well as to become familiar with quantification techniques.

A-547 16:51

C. Diffusion and ADC

R. Forstner; *Salzburg/AT (r.forstner@salk.at)*

Diffusion-weighted Imaging (DWI) has become a powerful imaging technique in the female pelvis providing functional information. It improves tissue characterisation and facilitates lesion depiction. This is based on visualisation of differences of random motion of water molecules within tissues, changes of tissue cellularity, and altered cell membranes. DWI is typically assessed in conjunction with findings obtained by conventional MR imaging sequences. Although several *b* values may be used, at least two *b* values (low <100 and high ≥800-1000mm^2/sec) will provide visual information as well as quantitative analysis, the apparent diffusion coefficient (ADC). DWI has emerged as an available complementary sequence in staging gynaecological cancers, in differentiation of benign from malignant masses, and in imaging recurrent disease. DWI has also been linked to lesion aggressiveness and emerges as an imaging biomarker for tumour response. In pregnancy or in impaired renal function, DWI serves also as an alternative to i.v. contrast media. The main clinical applications include assessment of depth of myometrial invasion in endometrial cancer and identification of local tumour extent in small size or in diffusely growing cervical or endometrial cancers difficult to depict on T2WI. It also aids in characterisation of adnexal masses and facilitates identification of metastatic spread in advanced gynaecologic cancers, particularly to the peritoneum or to lymph nodes. The added value of DWI in various applications in clinical practice will be highlighted and the pitfalls will be demonstrated.

Learning Objectives:

1. To understand the technical principles of DWI.
2. To learn how to optimise and integrate DWI in pelvic imaging.
3. To illustrate the added diagnostic value of DWI in female pelvic imaging.

17:14

Panel discussion: Multiparametric MRI of the female pelvis: should it replace tailored protocols?

16:00 - 17:30 **Room L 8**

E³ - Rising Stars Programme: EFRS Radiographers' Basic Session

BR 1

Radiography research: a how to guide

A-548 16:00

Chairperson's introduction: Why is radiography research important

M. Hardy; *Bradford/UK (M.L.Hardy1@bradford.ac.uk)*

Increasing the capacity, volume and quality of radiography research is essential to professional credibility and standing. Research forms the foundation upon which evidence-based decisions are made and enables clinical practice and service delivery innovation. As a result, it is imperative that we are all comfortable with the research processes and understand the sometimes confusing language and terminology adopted, to ensure that our practice is relevant and research informed. This starts with being clear about what research is and the ethical dilemmas that need to be tackled in designing competent and achievable research programmes. A further building block is developing the skills of criticality, understanding the limitations of a piece of work and, importantly, the gaps in the evidence base that need to be plugged to ensure a coherent knowledge base. Finally, it is important to appreciate the responsibility of researchers to disseminate their findings to ensure they are adopted in practice and the necessary skills required to construct high-quality scientific abstracts for conference presentations and posters. This session has some exciting speakers who will guide, inform and inspire you to take forward your research aspirations, whether as a research user or as a future research leader, and I look forward to facilitating this session to enhance your learning.

Session Objectives:

1. To become familiar with common ethical issues arising in radiography research.
2. To understand the value of critical appraisal when reading research publications.
3. To identify good practices for constructing quality scientific abstracts and posters.

Author Disclosure:

M. Hardy: Board Member; British Institute of Radiology. Employee; University of Bradford. Grant Recipient; National Institute of Health Research.

A-549 16:05

How to avoid ethical issues

B.T. Andersson; *Lund/SE (bodil-t.andersson@med.lu.se)*

Good research practices. Consent from a research ethics committee. Ethical principles: respect, autonomy, non-maleficence, beneficence, justice. Fundamental principles of research integrity: reliability, honesty, respect, accountability. Research environment: research procedures, documentation, data protection and archiving information to participants about the value and confidentiality. The right to integrity. The right to decline participation. The right to withdraw from the study. Informed consent. Ensuring confidentiality. Risks-causing harm, violation or suffering to the participant.

Learning Objectives:

1. To understand the importance of ethics in medical research and the role of research ethics committees.
2. To become familiar with common ethical pitfalls in research design.
3. To appreciate strategies for avoiding ethical problems in research.

A-550 16:23

How to critically appraise a research article

B. Kraus; *Vienna/AT (barbara.kraus@fh-campuswien.ac.at)*

To appreciate the role of literature reviews in the research process, students first of all have to find reading strategies for scientific text and particularly for non-native speakers to read an English scientific text. Different methods of reading, e.g. the shopping centre strategy or SQ3R technique (Survey, Question, Read, Recite, Review), are useful for guiding through research articles. Reading the title and abstract of an article is the first selection step with "the quick review", followed by the process of "the detailed review" to get an assessment about not just the quality of the study design, but also the quality and applicability of the results. The aim is to find strengths and weaknesses in each section of a research report and it is necessary to identify the research method (quantitative/qualitative), the methodology with all pros and cons and to screen the questions using the PICO (population, intervention, comparison and outcome) system. Was the study design appropriate to address the research question? How precise are the results and are they

appropriately presented? Also, the relevant expertise of the author(s) should be clear. Another important point is to figure out clearly in the discussion or conclusion about any conflicts of interest and any acknowledgement of limitations. The presence of an ethics committee approval must also be declared. Finally, knowledge of and the proper use of guidelines/checklists and scoring systems are important key factors that help in the critical appraisal of research work.

Learning Objectives:

1. To appreciate the role of the literature review in the research process.
2. To identify strengths and weaknesses in each section of a research report.
3. To critically appraise the overall value of a research report.

A-551 16:41

How to write a good scientific abstract

R. Decoster; *Brussels/BE*

Writing an abstract is the art of delicately luring your reader into exploring your research. The abstract, 250 words of carefully selected text, consists of a web built from ideas and findings that pinpoint why someone should spend time on your article or talk. During this presentation, I will dissect an abstract to illustrate the universal backbone of each abstract. We will explore how different science branches put other accents in their carefully woven bait. While reading between the lines of some examples, we will steal like an artist in the search for success.

Learning Objectives:

1. To understand general qualities of good scientific abstracts.
2. To be aware of typical formats of scientific abstracts.
3. To consider tips for success.

A-552 16:59

How to produce a high-quality scientific or educational poster

L.A. Rainford; *Dublin/IE (louise.rainford@ucd.ie)*

This presentation will firstly discuss the many types of posters and the key matters a prospective presenter must consider in relation to the variation in poster submission processes across national and international conferences. The importance of reading the poster submission guidelines will be highlighted. Suggestions will be proffered with respect to the poster design under a number of key headings. The material covered will include: choosing the correct title, institutional identification, author affiliations and ordering of affiliations, designing sections of the poster to facilitate the reader with an opportunity to logically progress through the material provided in the poster and the importance of clear, scientific language, accurate grammar, spell checks and appropriate labelling of images and figures. The use of appropriate scientific language will be discussed and examples of good practice supplied. Accurate formatting cannot be overstressed and the presentation will include examples of potentially avoidable poster errors. The overall recommendations and design suggestions incorporated in this presentation are aimed at supporting radiographers in achieving high-quality scientific poster submissions, and the content will be appropriate for both radiography students and radiographers.

Learning Objectives:

1. To become familiar with poster formats and layouts.
2. To consider good practices in poster design.
3. To appreciate important considerations when designing a poster.

17:17

Panel discussion: Ask the experts

16:00 - 17:30 **Room E1**

Breast

RC 1202

MRI for early detection, staging and management of breast cancer

A-553 16:00

Chairperson's introduction

J. Camps Herrero; *Valencia/ES (juliacamps@gmail.com)*

This Masterclass will tackle three issues that are currently at the forefront of the breat MRI debate: imaging biomarkers, preoperative staging and the so-called “overdiagnosis”. Breast MRI should have already passed the phase of diagnostic validation and must now head towards the definition of imaging biomarkers that are capable of sampling the whole cancer in its entire heterogeneity as well as allowing serial measures in response evaluation. Imaging biomarkers must be solid, reproducible and standardised. This lecture will define common imaging biomarkers in the clinical setting as well as set the path for their further development in the future. Preoperative breast MRI is still being questioned as a valid indication and the MIPA study has been designed to answer the questions raised by published evidence on the contrary (excess mastectomies, no significant difference in mastectomy rates, etc) tainted by methodological biases which will be highlighted during this session. The number of high-risk (B3) lesions has increased after the use of breast MRI, being considered traditionally false-positive diagnoses, when in fact they have underlying prognostic implications. This lecture outlines these implications and lets us see breast MRI under a different light, when pathology correlates are considered.

Session Objectives:

1. To understand the contribution of MRI to preoperative staging and the context within it should be recommended.
2. To learn about the different MRI biomarkers and in which clinical setting they are of value.
3. To recognise the steps required to move to abbreviated MRI for high-risk screening.

Author Disclosure:

J. Camps Herrero: Consultant; Bayer, Bard. Speaker; Bayer.

A-554 16:05

A. Preoperative staging with MRI: did the MIPA trial solve all issues?

F. Sardanelli; *San Donato Milanese/IT (f.sardanelli@grupposandonato.it)*

Preoperative breast MRI is a highly debated modality. New evidence has been emerging from the MIPA study, an ongoing prospective observational multicentre study, enrolling two concurrent groups with a newly diagnosed first breast cancer, not candidate to neoadjuvant therapy, receiving or non-receiving MRI before surgery. Up to October 2017, over 6,000 patients were recruited. The data from 2,425 patients were as follows: 1,201 (49.5%) with MRI and 1,224 (50.5%) without. Of these 1,224 MRIs, 210 (17%) were performed for screening (4%) and for diagnostic purposes (13%). Of 1,014 preoperative MRIs, 595 (59%) were ordered by radiologists alone and 321 (32%) by surgeons alone; radiologists and surgeons were involved in the request in 68 and 40% of cases, respectively. Mastectomy rate planned at mammography/ultrasound was 185/1201(15.4%) in the non-MRI-group and 245/1224 (20.0%) in the MRI-group (p<0.001). In the MRI group, 21 additional mastectomies (1.7%) were planned after MRI, while 25 patients planned to have mastectomy shifted to conservative surgery (CS). Of the 1,004 patients planned for CS before MRI, MRI did not indicate a change in performing surgery in 733 (73%), while it prompted a wider CS in 143 (12.5%) and a less extensive CS in 128 (12.7%). Mastectomy rate was 192/1201(16%) in the non-MRI-group and 257/1224 (21%) in the MRI-group (p<0.001). Per-patient reoperation rates for close/positive margins were 135/1009 (13.4%) and 80/967 (8%), respectively (p<0.001). Most mastectomies were already planned at mammography/ultrasound, using MRI as a confirmation tool. This patient selection also contributed in determining a lower reoperation rate in women undergoing MRI. Conversely, CS was modified by MRI according to disease extent, balancing increased and decreased tissue removal.

Learning Objectives:

1. To learn about the evidence for and against the use of MRI in preoperative staging.
2. To understand the background, design and early results of the MIPA trial.
3. To be able to explain the role of preoperative MRI during multidisciplinary tumour board meetings.

Author Disclosure:

F. Sardanelli: Advisory Board; Bracco, General Elecric. Research/Grant Support; Bracco, Bayer, Real Imaging.

A-555 16:28

B. MR imaging biomarkers for the clinical setting

E.A. Morris; *New York, NY/US (morrise@mskcc.org)*

Background parenchymal enhancement is related to vascular flow and it has been proposed that this may represent an imaging biomarker of the underlying proliferation of fibroglandular tissue. Investigations have shown that there is an extremely strong association between BPE and risk of breast cancer, at least as strong as the association between mammographic density and breast cancer. It has been observed that background parenchymal enhancement is also affected by treatment changes and hormonal manipulation. Radiation therapy to the breast causes marked reduction in background parenchymal enhancement. MRI can further stratify women at high risk for developing breast cancer on the basis of background parenchymal enhancement. Rim enhancement MRI phenotypic features can predict the aggressiveness of breast cancer. For example, we know that spiculation on MRI is associated with a lower histologic grade and lower ki67 expression and is more commonly

seen in ER+ cancer. Rim enhancement has been shown to be associated with cancers that are higher in grade and ER-. Rim enhancement is associated with a worse distant metastatic survival. It has been shown that triple negative tumours without rim enhancement are associated with tumour-infiltrating lymphocytes. High TIL levels are associated with pCR, following NAC and improved survival in TNBC. Peritumoural oedema is caused by increased vascular permeability and release of cytokines. It is seen in <10% of breast cancer and is associated with early distant metastases (<2.5 y). In TNBC peritumoural oedema was a significant independent predictor of worse recurrence-free survival.

Learning Objectives:

1. To learn about the different biomarkers that are available and the evidence for using them in patients with breast cancer.
2. To understand in which clinical settings biomarkers might be of value.
3. To appreciate the newer techniques that are being developed and tested clinically.

Author Disclosure:

E.A. Morris: Advisory Board; Delpjinus, Hologic, GE, Avon. Research/Grant Support; GRAIL, Hologic, Komen.

A-556 16:51

C. Screening with abbreviated protocols

C.K. Kuhl; *Aachen/DE (ckuhl@ukaachen.de)*

Early diagnosis improves survival of women with breast cancer. Mammographic screening improves early diagnosis of breast cancer. Yet, there appears to be room for improvement. The major shortcomings of mammographic screening are overdiagnosis of prognostically unimportant cancer, as well as underdiagnosis of cancers that are indeed relevant. Failure to detect biologically relevant breast cancer with mammographic screening is driven by host-related factors, i.e. breast tissue density, but also tumour-related factors: Biologically relevant cancers may exhibit imaging features that renders them indistinguishable from normal or benign breast tissue on mammography. These cancers will then progress to become the advanced-stage interval cancers observed in women undergoing mammographic screening. Since breast cancer continues to represent a major cause of cancer death in women, the search for improved breast cancer screening method continues. Abbreviated breast MRI has been proposed for this purpose because it will greatly reduce the cost associated with this method, due to a greatly reduced magnet time (down to 3 minutes), but especially also due to a greatly abridged image interpretation time, i.e. radiologist reading time. This lecture will review the current evidence and present the EA1141 trial designed to investigate the utility of abbreviated breast MRI for screening average-risk women with dense breast tissue.

Learning Objectives:

1. To learn about the evidence for abbreviated MRI and the comparison with standard protocols.
2. To understand the different protocols for abbreviated MRI and the merits of each sequence used.
3. To appreciate the advantages and limitations for abbreviated MRI.

17:14

Panel discussion: Why are some recommendations not adopted and how can we change practice?

16:00 - 17:30 **Room E2**

Neuro

RC 1211

Inflammatory and infectious CNS pathology

A-557 16:00

Chairperson's introduction

E.T. Tali; *Ankara/TR (turgut.tali@gmail.com)*

Clinical presentation and imaging features of infectious and noninfectious inflammatory diseases of the spinal cord are variable and usually nonspecific. Differentiating these conditions from the other spinal cord lesions (neoplasms, degenerative disorders, etc.) is still challenging. For both groups, early and accurate diagnosis is important because of the different treatment protocols as well as to decrease neurologic complications. Spinal cord infections are clinically important because of the high rates of morbidity and even mortality. The symptoms are usually nonspecific, which can delay the diagnosis. A combination of clinical history, neurologic examination, laboratory data, spinal fluid analysis, serological studies, and imaging findings are the main tools for making a correct diagnosis. Spinal inflammatory diseases can be caused by autoimmune, granulomatous, and idiopathic conditions. Demyelinating diseases (multiple sclerosis (MS) and neuromyelitis optica (NMO)) are the most common inflammatory conditions. Transverse myelitis, acute disseminated encephalomyelitis (ADEM) and Guillain-Barré syndrome (GBS) should be thought as differential diagnoses. Demyelinating lesions may also be seen in autoimmune diseases such as sarcoidosis, systemic lupus rrythematosus and Sjögren's syndrome. Vascular malformations, arachnoiditis, and even neoplastic diseases may also produce inflammation. For the radiologist, it is crucial to be aware of different imaging features of spinal infections and inflammatory diseases. Comprehensive evaluation of the imaging features associated with the clinical presentation, laboratory data, spinal fluid analysis, and serological studies helps to make the final diagnosis.

Session Objectives:

1. To understand the role of imaging in the diagnosis and monitoring of inflammatory and infectious diseases of the central nervous system.
2. To learn basic principles of the use of imaging in neuroinfection and neuroinflammation.
3. To appreciate the added value of imaging in addition to the clinical findings and laboratory tests including CSF analysis.

A-558 16:05

A. Autoimmune encephalitis

P. Demaerel; *Leuven/BE (philippe.demaerel@uzleuven.be)*

Autoimmune encephalitis (AE) is emerging as a more common cause of encephalopathy than previously thought. AE is a difficult clinical diagnosis and occurs both in adults and in children. The presence of antibodies (Ab) in the CSF confirms the diagnosis, but the results can take several weeks to obtain and negative results do not exclude AE. Therefore, MR imaging plays an important role in these patients, who often present with nonspecific neurological symptoms. Subacute encephalopathy, new adult-onset seizures or psychiatric symptoms should raise the suspicion of a possible AE. AE consists of a large number of Ab-related diseases. They are usually divided into three groups: (1) Ab to cell-surface antigens, (2) Ab to intracellular synaptic proteins and (3) Ab to intracellular antigens. The imaging-related findings will be reviewed in this course. The most common imaging finding consists of uni- or bilateral FLAIR hypersignal in the hippocampus, amygdala and/or parahippocampal area. It is important to emphasize that these signal changes can be very subtle. Extratemporal lesions in the cerebral cortex, the grey nuclei, the cerebellum and the brainstem have been reported too and can support the clinical suspicion of AE. But Brain MR can also remain normal and FDG-PET is certainly recommended in these patients. MR imaging is also used to exclude or confirm other autoimmune diseases, e.g. MS, neuromyelitis optica, ADEM and lupus. Finally, MR imaging is helpful to exclude other diseases that can have a similar clinical presentation, e.g. lymphoma, carcinomatous meningitis and Wernicke encephalopathy.

Learning Objectives:

1. To learn about the imaging pattern of autoimmune encephalitis.
2. To understand the limited role of conventional MRI and the need for advanced imaging techniques in the diagnostic process and for follow-up purposes.
3. To appreciate the role of imaging in a multidisciplinary and multimodality approach.

A-559 16:28

B. Infectious encephalitis

K.D. Kurz; *Stavanger/NO (kurk@sus.no)*

Encephalitis is a potentially fatal disease occurring at any age. The most common types of encephalitis are caused by viral infections, with herpes simplex virus (HSV) encephalitis the most known type. It is critical to make a rapid and correct diagnosis to tailor the treatment with the goal of better outcome of the disease. MRI is a powerful tool for the fast detection of typical imaging patterns in CNS caused by viral infections and helps to grade the severity of the disease, especially by using diffusion weighted imaging. In this refresher course, we would like to summarize the current understanding of MRI findings of viral encephalitis, especially related to HSV, varicella zoster, rabies, influenza viruses and haemorrhagic encephalitis. We also discuss the typical CNS complications of the infections. In addition, we would also like to discuss the imaging features of subacute cerebral infections such as Rasmussen encephalitis, HIV, progressive multifocal leukoencephalopathy (PML), and Creutzfeldt-Jakobs disease.

Learning Objectives:

1. To learn about the correct choice of imaging modalities and image acquisition parameters for the detection and monitoring of infectious diseases of the central nervous system.
2. To understand the benefits and challenges of image pattern recognition for

diagnostic purposes.
3. To appreciate the heterogeneity of the disease spectrum and challenges to interpret imaging findings in the context of the clinical presentation and possible comorbidities.

A-560 16:51

C. Inflammatory and infectious myelitis
M.M. Thurnher; *Vienna/AT (majda.thurnher@meduniwien.ac.at)*

Transverse myelitis (TM) is an "umbrella term" used to describe inflammatory disorder of the spinal cord that can be idiopathic or associated with central nervous system (CNS) autoimmune inflammatory diseases, connective tissue autoimmune diseases, or post-infectious neurological syndromes. Myelitis can present either as monophasic or recurrent disease. The most common monophasic diseases causing TM are idiopathic transverse myelitis and acute disseminated encephalomyelitis (ADEM), whereas recurrent disorders include multiple sclerosis (MS), neuromyelitis optica spectrum disorder (NMOSD), vasculitis (Behcet disease, SLE, Sjögren syndrome) and neurosarcoidosis. The recent discovery of multiple novel neural-specific autoantibodies accompanying autoimmune and demyelinating disease has improved the current understanding and classifications. This lecture will provide an overview of radiological, clinical, serological, and prognostic differences of inflammatory and infectious spinal cord diseases.
Learning Objectives:
1. To learn about the spectrum of infectious diseases of the spinal cord level and their most characteristic imaging features.
2. To understand the difficulties in image acquisition and image interpretation.
3. To appreciate the clinical relevance of early diagnosis and therapeutic intervention.

17:14
Panel discussion: Ask the expert: Is imaging the key diagnostic modality for an early and specific diagnosis of infectious diseases, leading to a better functional outcome?

Cortical anatomy and primary functional areas
T.A. Yousry; *London/UK*

The anatomy of the brain is often perceived as being complicated. Especially the cortex is seen as an irregular arrangement of variable structures, which are difficult to differentiate and to identify. We will review the overall subdivision of the brain into lobes and describe their boundaries and their major gyri and sulci. We will then describe the location of specific functions. (1) Primary sensorimotor cortex: Motor is located in the precentral gyrus, sensory in the postcentral gyrus around the central sulcus (CS), hence the importance of always correctly identifying the CS. We will present 4 interlocked methods to identify the CS in the axial plane a) Knob, b) lateral axial, c) medial axial, d) gyral/cortical thickness and 3 to identify it in the sagittal plane a) lateral sagittal, b) hook, c) medial sagittal. (2) Primary auditory cortex (A1): Centred at the postero-medial part of Heschl's gyrus (HG), we will present simple landmarks in each of the 3 planes: a) axial: adhaesio interthalamica, b) sagittal: omega/heart shape of HG, c) coronal: omega shape of HG. (3) Primary visual cortex (V1): Centred on the calcarine sulcus, we will discuss the characteristic shape that allows the identification of this structure in all 3 planes. At the end of this lecture, you will know the subdivision of the cortex; the methods and landmarks necessary to identify the primary sensorimotor, speech, auditory, and visual areas.
Learning Objectives:
1. To understand the basic concepts of cortical subdivision.
2. To be able to identify critical cortical structures.
3. To learn to localise primary functional areas.

A-562 16:30

Vascular distribution territories: arterial and venous
T. Engelhorn; *Erlangen/DE (Tobias.Engelhorn@uk-erlangen.de)*

After a short overview on the vascular anatomy of the brain with a focus on vascular distribution territories, the main focus of this talk is to present neurovascular pathologies closely associated with arterial and venous vascular distribution territories. One focus is also put on acute stroke and subsequent patient selection for interventional stroke therapy. Another aim is to provide a better understanding of the pathophysiology of different neurovascular diseases in an interactive matter. In addition, the advantages and limitations of CTA, flat-panel CTA and MRA compared to conventional angiography are presented.
Learning Objectives:
1. To become familiar with a comprehensive vascular anatomy of the brain.
2. To recognise patterns of various pathologies attributed to vascular distribution territories.
3. To recognise the different imaging patterns in stroke and their prognostic value.

A-563 17:00

The basal ganglia of the brain revisited
D. Zlatareva; *Sofia/BG (dorazlat@yahoo.com)*

The term "basal ganglia" refers to caudate nucleus, putamen, globus pallidus, substantia nigra and subthalamic nucleus. They are paired symmetric structures located in the telencephalon, diencephalon and mesencephalon. The lenticular nucleus includes putamen and globus pallidus. Together with caudate nucleus, these structures are named corpus striatum. Being part of the extrapyramidal system, the basal ganglia have wide connections not only with each other, but also with the midbrain, thalamus and cerebral cortex. The striatum is the main recipient of afferents from the entire cerebral cortex and thalamus. The information is then processed and integrated with other inputs and transmitted to the globus pallidus internal segment and the substantia nigra pars reticulate. Those are major output structures of the basal ganglia and make GABAergic, inhibitory connections on their targets. According to current concepts in the motor regions of the basal ganglia, there is a motor homunculus similar to that in the primary motor cortex. The basal ganglia and thalami have five functional divisions that are sensorimotor, supplementary motor, premotor, association and limbic territories. Very complex functional cortical-basal-ganglial-thalamocortical circuits enable the execution of automatic and semi-automatic motor programmes, modulation of muscle tone and the harmonisation of movement. If one or more of these regulatory circuits are disrupted, the result will be either a net removal of inhibition, leading to excessive movement like tremor or dystonia, or a net decrease in motor activation causing impaired movement (e.g. rigidity, akinesia).
Learning Objectives:
1. To recall the basal ganglia nuclei and their topography.
2. To identify the classic functional organisation of the basal ganglia and its current concepts.
3. To elucidate the pathophysiology of various movement disorders.

16:00 - 17:30 **Room F2**

Oncologic Imaging

RC 1216
Cancer screening

A-564 16:00

Chairperson's introduction: Screening for cancer: lessons learned and future challenges
S. Törnberg; *Stockholm/SE (Sven.Tornberg@ki.se)*

Cancer is a lethal disease. The purpose of screening is to find cancer in an early, still curable, phase. Population based screening is a strategy aiming to, in a systematic and organised way, find early cancers in a population at risk, related to sex, age, or risk behaviour. The benefit (of not dying) can't, for obvious reasons, be experienced by the individual person, only a confirmation of not having a cancer (which is not the purpose of screening). Harms of screening are unnecessary exposure to radiation, worry, false negative and false positive results, and over-diagnosis leading to unnecessary and invasive treatment. The balance between harms and benefit needs to be evaluated before recommending population based screening. EU recommends screening for breast cancer, colorectal cancer and cervix cancer. EU has also published guidelines on how to ensure the quality of the entire screening process by using indicators as surrogate measures. If participation rate, cancer detection

rate, interval cancer rate, and stage distribution is equal to the levels experienced in the RTC's, it reflects a similar effect. EU has defined acceptable levels of performance. Individual data needs to be recorded in order to measure the quality and the effect of the screening. EU's 2nd screening report (2017) compared the extent, and the quality of the recommended cancer screening programs between the EU member states. During the session, the above mentioned aspects will be discussed for, lung-, colorectal-, and breast cancer, all three being leading causes of cancer deaths in Europe.

Session Objectives:

1. To understand the basic idea behind cancer screening protocols.
2. To learn about potential harms and benefits of screening protocols.
3. To explain why epidemiological data are so important for successful screening programmes.

A-565 16:05

A. Lung cancer screening: the evidence

H.-U. Kauczor; *Heidelberg/DE*

Lung cancer is the most common and most fatal cancer in Europe and worldwide, with a 5-year survival of only 13%. The by far most important risk factor for lung cancer is cigarette smoking. In 2011, the results of the largest randomized controlled screening trial (NLST) using low-dose CT (LDCT), performed in the USA showed a significant 20% reduction of lung cancer mortality in elderly (55-74 years) and heavy smokers (> 30 packyears), but has not been replicated by any other trial so far. Although lung cancer screening (LCS) using LDCT was established in the USA in 2015, the introduction of such screening programmes in Europe remains controversial. For a successful LCS programme using LDCT the pretest probability has to be high, while the numbers of false-positive screens and overdiagnosis are low. Thus, a risk model and dedicated nodule management algorithms must be strictly followed. The radiation exposure from LDCT should be < 1 mSv if not obese. The whole workup of positive screens requires strict SOPs at experienced high-throughput centres with clinical audits established. A smoking cessation programme should be a mandatory component of LCS. Furthermore, LCS in the future should tackle the "Big Three" killers associated with cigarette smoking, i.e. lung cancer, COPD and cardiovascular diseases, at the same time. Cost-benefit analyses should be performed on a national basis. All data from comprehensive LCS programmes should be stored in a central registry and undergo independent review to confirm the quality and benefits of LCS for high-risk smokers.

Learning Objectives:

1. To learn about risk populations for lung cancer screening.
2. To understand the benefits and potential drawbacks of a lung cancer screening programme.
3. To appreciate the already existing clinical evidence for lung cancer screening programmes.

A-566 16:28

B. Colorectal cancer screening: what is the radiologist's role?

S. Halligan; *London/UK*

The speaker will describe the role of the radiologist in colorectal cancer screening. There will be an emphasis on effective and efficient population-based screening, and on the high-level evidence base for this. Examples of current population screening programmes will be given, and the way in which radiological techniques intergrate with these will be described.

Learning Objectives:

1. To learn about already existing clinical screening tools for CLC.
2. To understand the concept of radiological screening tools for CLC.
3. To appreciate the benefit and clinical applications for new imaging-based screening tools.

Author Disclosure:

S. Halligan: Research/Grant Support; Holder of multiple competitive peer-reviewed research grants.

A-567 16:51

C. Breast cancer: to screen or not to screen

P. Skaane; *Oslo/NO (per.skaane@outlook.com)*

Screening includes "non-programme screening" (opportunistic) and "organised", with higher degree of management, target groups, defined intervals, and specified management procedures. Organised screening is "population based" when women in the target group are individually identified and personally invited, and all steps adequately coordinated. European Guidelines recommend biannual screening for women 50-69 years old. Full-field digital mammography, the "gold standard" for screening women at average risk, has inherent limitations including low specificity and low sensitivity in women with dense breasts. Supplementary annual MRI in addition to mammography is offered for high-risk women with lifetime risk over 20% and BRCA mutation carriers. Supplementary ultrasound is in general not recommended when MRI is carried out. To maximise the benefits while minimising the harms, there has been much focus on moving from "one-size-fit-all" to personalised screening. Due to economical and practical reasons, reduced screening for women with fatty breast has occasionally been suggested. However, caution is necessary since it is problematic to identify subgroups of women with nondense breasts with less frequent screening. The costs and availability prevent implementation of many new modalities with high accuracy in high-volume screening, including molecular breast imaging (MBI), contrast-enhanced spectral mammography (CESM), and dedicated breast CT. The most promising new technique for population-based screening is digital breast tomosynthesis (DBT). The main challenges of DBT include longer reading time and overdiagnosis. The problem of radiation dose using mammography plus DBT is solved by synthetic 2D images. DBT has reduced sensitivity in women with very dense breasts. However, cost-effectiveness studies on DBT screening programmes should be carried out.

Learning Objectives:

1. To learn about the existing mammography screening programmes.
2. To understand the potential add-on of MR for breast cancer screening (e.g. MR).
3. To balance harm/cost against benefit for new screening programmes.

Author Disclosure:

P. Skaane: Equipment Support Recipient; Tomosynthesis equipment for the Oslo Tomosynthesis Screening Trial was provided by Hologic.

17:14

Panel discussion: Cancer screening: a success story?

16:00 - 17:30 **Room D**

Musculoskeletal

RC 1210

Shoulder MRI: mastering technique and making my report relevant

A-568 16:00

Chairperson's introduction

I. Boric; *Zabok/HR (igor.boric1@zg.t-com.hr)*

For a successful MRI of the shoulder, certain conditions should be met. It is necessary to perform the examination in a standardised manner using generally accepted protocols. The applied protocols should be geared towards providing a response to a clear clinical question. Knowledge of the advantages and disadvantages of MRI techniques is the guiding node in choosing the optimal technique: specific protocol, normal positioning or ABER position of the patient, native or contrast-enhanced MR, standard MR examination or MR arthrography. Understanding of normal shoulder anatomy: rotator cuff muscle, other shoulder muscles and its tendons, labrum and ligaments, shoulder bursas, bones and articular cartilage, neurovascular bundles as well as normal variants is crucial for a quality finding interpretation and to make the report relevant. In the case of postoperative shoulder evaluation, knowledge of the applied surgical techniques and the expected anatomical changes is necessary. The analysis of shoulder changes should take into consideration the specificity of each patient: age, gender, occupation, existence of previous injuries and shoulder diseases, and degree of sport activity. Information on the mechanism of injury is helpful in assessing the site and extent of lesions. To improve the quality and reliability of shoulder MRI evaluation, feedback from the clinician and the patient is extremely useful. An experienced MSK radiologist is crucial for a good and reliable MRI of the shoulder.

Session Objectives:

1. To understand the level of expertise that patients expect for adequate performance and reading of shoulder MRI.
2. To gain insight into differentiating normal age-related changes from clinical relevant MR features.

A-569 16:05

A. The normal MRI: techniques and anatomy

E. Llopis; *Valencia/ES (evallopis@gmail.com)*

MRI is the primary diagnostic imaging modality when of the shoulder joints is suspected. For an accurate evaluation, it is essential to know the normal anatomy and the complex biomechanics with a wide range of motions and variants, to avoid misdiagnosis and to understand which ones are clinically relevant. We will divide shoulder anatomy into static and dynamic structures:

the bone structures, labrum and ligament as static structures, and rotator cuff muscles as dynamic ones.
Learning Objectives:
1. To become familiar with MRI techniques for imaging the shoulder.
2. To understand normal MRI shoulder anatomy, and normal variants seen.

A-570 16:28

B. Rotator cuff tears: what are they and what do they look like?
K.-F. Kreitner; *Mainz/DE (Karl-Friedrich.Kreitner@unimedizin-mainz.de)*

Rotator cuff (RC) disease is common and maybe a significant cause of shoulder pain. The tendons of the rotator muscles are highly organised structures with five distinct histologic layers. Over the last decade, the rotator cable has received increasing attention, as it acts as a supporting limb of the cuff. The cable is adjacent to the crescent zone of the RC and can be seen on most MR imaging studies. Pathologically, tendinosis/tendinopathy can be differentiated from partial- and full-thickness tears of the cuff. Whereas tears at the rotator crescent are often due to ischaemia and degeneration, tears of the footprint have obtained increased attention as they affect younger patients and have implications on the appropriate operative procedure. Partial-thickness tears can be described as articular, bursal or intrasubstance partial tears and should be further characterised with regard to the degree of tendon involvement. Full-thickness tears allow communication between the glenohumeral joint and the subacromial-subdeltoid bursa and can be pinhole in size or involve an entire tendon. It is further of utmost importance to assess atrophy or fatty infiltration in case of an RC tear, as these findings influence the therapy and outcome of the affected patients. Tears of the subscapularis tendon typically begin in the cranial part of the tendon and are often associated with lesions of the long biceps tendon and the rotator interval. “Novel lesions” of the RC most commonly affect the infraspinatus tendon at the musculotendinous junction and represent a delamination that may be missed at arthroscopy.
Learning Objectives:
1. To become familiar with the anatomical basis of rotator cuff tears.
2. To learn about the MRI findings of rotator cuff pathology.

A-571 16:51

C. Patterns of instability: what does the MRI show?
A.J. Grainger; *Leeds/UK (andrewgrainger@nhs.net)*

Two patterns of injury are seen in patients dislocating their shoulder. Younger patients will tend to disrupt the labroligamentous complex, whereas the older population tends to disrupt the integrity of the rotator cuff. In this latter group, tears of supraspinatus are seen along with tears of subscapularis and avulsion fractures of the greater tuberosity. Rotator cuff disruption forms the subject of other talks and so will not be discussed further here. Anterior dislocation leading to avulsion of the anteroinferior labral ligamentous complex from the glenoid is termed the Bankart lesion, or bony Bankart if accompanied by a fracture. Avulsion occurs due to the pull of the anterior band of the inferior glenohumeral ligament (AIGHL) at its attachment to the anteroinferior labrum. The AIGHL is the primary restraint to movement when the arm is abducted and externally rotated. Avulsion of the labrum is well shown on MR arthrography and a number of variants exist which will be discussed. Posterior dislocation will produce a reverse pattern of shoulder injury which will also be discussed.
Learning Objectives:
1. To become familiar with patterns of abnormality seen in shoulder instability.
2. To learn about the MRI findings of shoulder instability.

17:14
Panel discussion: How are the indications for MR arthrography of the shoulder changing?

16:00 - 17:30 **Room G**

New Horizons Session

NH 12

Radiomics: what is it and how can we use it?

A-572 16:00

Chairperson's introduction
O. Clément; *Paris/FR (olivier.clement@aphp.fr)*

The term "Radiomics" has emerged a few years ago and is attracting a lot of attention as a tool to extract quantitative information out of the images. Several softwares are on the market that provide a large amount of quantitative features from medical images using data-characterisation algorithms.These features, termed radiomic features, have the potential to uncover disease characteristics that fail to be appreciated by the naked eye. The goal of the New Horizon session is to review the concepts behind the name and appreciate the potential clinical applications in radiology.
Session Objectives:
1. To understand what radiomics is.
2. To appreciate the clinical potential of radiomics in radiology.
3. To address the professional challenges of radiomics.

A-573 16:03

Radiomics: what is it and how does it work?
L.S. Fournier; *Paris/FR (laure.fournier@aphp.fr)*

Radiomics is a new 'data-driven' approach for extracting large sets of complex descriptors from routine (or not) clinical images, based on the assumption that there is a relationship between the imaging features of tumours and their underlying gene expression patterns and biology. The radiomics process aims to establish links between the imaging phenotype and genotypic and phenotypic characteristics of a tumour governed by its molecular substratum. Advanced methods of image processing are applied to images to extract a large number of descriptors, such as texture analysis from histograms, co-occurrence matrices, and fractal analysis. This large set of data can be analysed using bioinformatics and biostatitics methods into clusters defining metadata sets describing combinations of imaging features, or imaging 'profiles'. Finally, these data can be correlated to gene expression profiles, often called radiogenomics, or to outcomes, such as treatment response or survival.
Learning Objectives:
1. To learn about new methods of image analysis derived from '-omics' methods.
2. To understand processing of big data derived from images.
3. To become familiar with new vocabulary such as radiomics, radiogenomics, clusters, heat map, etc.
Author Disclosure:
L.S. Fournier: Advisory Board; Keosys. Grant Recipient; Invectys. Research/Grant Support; Philips, Ariana Pharma, Evolucare.

A-574 16:21

Radiomics: technical validation
R. Leijenaar; *Maastricht/NL (ralph.leijenaar@maastro.nl)*

Radiomics is increasingly more important in cancer research; the high-throughput mining of quantitative image features from standard-of-care medical imaging that enables data to be extracted and applied within clinical decision support systems to improve diagnostic, prognostic, and predictive accuracy. The field of radiomics is emerging rapidly. However, this field lacks standardized evaluation of both the scientific integrity and the clinical significance of the numerous published radiomics investigations resulting from this growth. With the prospect of multicentre clinical applications, it has become clear that variation in, for example, software implementations, feature nomenclature, mathematical definitions and methodology, makes reproducibility and validation of studies in radiomics a major challenge. For radiomics to mature as a discipline, there is a clear need for rigorous evaluation criteria, reporting guidelines and tools to facilitate standardization, interoperability and advancement of the field.
Learning Objectives:
1. To learn about the robustness and reproducibility of radiomics features.
2. To understand the differences and similarities between radiomics software.
3. To understand that quality of big data is the key.

Author Disclosure:
R. Leijenaar: Employee; Health Innovation Ventures / OncoRadiomics. Founder; co-founder of OncoRadiomics. Shareholder; OncoRadiomics.

A-575 16:39

Radiomics: biological correlation
E. Sala; *Cambridge/UK (evis.sala@gmail.com)*

Tumour heterogeneity in cancers has been observed at the histologic and genetic levels, and increased levels of intra-tumour genetic heterogeneity have been reported to be associated with adverse clinical outcomes. In oncologic imaging, phenotypic heterogeneity between and within tumours of a given patient is readily apparent and various imaging features are routinely described subjectively in radiology reports. However, recently, imaging research has focused increasingly on the newly emergent field of radiomics, which involves a high-throughput process in which a large number of shape, edge and texture metrics are extracted and quantified objectively and in a reproducible form. These quantitative metrics can provide important insights into tumour phenotype as well as the interaction of the tumour with its microenvironment, referred to as “habitat imaging”. In the effort to delineate the biological and clinical implications of these new quantitative metrics, radiomic metrics obtained from MRI including diffusion-weighted and dynamic-contrast-enhanced MRI sequences, computed tomography and FDG-PET/CT have been further correlated with genomics data, a process intrinsic to the field known as radiogenomics. Radiogenomics and outcome data can be meaningfully mined with the goal of developing robust biomarkers that may potentially aid cancer diagnosis, improve assessment of treatment response and better predict patient outcome.

Learning Objectives:
1. To understand how radiomics features relate to the underlying biology.
2. To learn what information radiomics can give on tumour heterogeneity.
3. To become familiar with potential added value of radiomics in predicting treatment response and outcome.

A-576 16:57

Radiomics: clinical challenges
T. Penzkofer; *Berlin/DE (tobias.penzkofer@charite.de)*

Radiomics, either as feature classifiers or in the form of machine intelligence, is poised to play an increasing role in clinical imaging. It offers ample potential to extend the current practice of oncological and non-oncological imaging: currently around the corner are automatic anatomy annotation, next-generation CAD systems, lesion tracking and tumour heterogeneity analysis. More complex systems with an integrated understanding of a wider range of pathologies seem markedly further down the road. Before radiomics can be implemented and used to enrich our well-tested and robustly working workflows, a number of prerequisites need to be met: it is important to understand who wants and accepts semiautomated and/or fully automated decision-making systems in radiology. Patients, insurance companies and health-care provides are important stakeholders and might or might not be drivers of the implementation of radiomics. Additionally, current laws governing regulation of medical devices are drafted with monolithic, invariable products in mind. This could be impracticable for continuously self-improving machine learning systems. Lastly, quality control measures will certainly play an important role in tackling these issues, including the liability in case of "algorithmic malpractice". Is seems reasonable to assume, that future generations of radiologists, instead of being replaced, will have a wider range of quantitative information at their disposal. Knowledge in data science to better understand, maintain and extend the systems will be a prime skill, just as technological understanding of imaging is part of every radiological curriculum.

Learning Objectives:
1. To understand the potential role in oncological and non-oncological clinical settings.
2. To define prerequisites for the integration into clinical workflows, including: patient acceptance, legal challenges and quality control.
3. To appreciate the future roadmap and its impact on training of young radiologists.

Author Disclosure:
T. Penzkofer: Employee; Charité University Hospital, Berlin, Germany. Grant Recipient; Berlin Institute of Health, Berlin, Germany.

17:15
Panel discussion: Radiomics, the new holy grail in radiology?

16:00 - 17:30 **Room K**

Special Focus Session

SF 12d

Radiographers' challenge: informing patients about radiation risk

Moderator:
J.N. Vassileva*;* Vienna/AT

A-577 16:00

Chairperson's introduction: The European BSS (Basic Safety Standards) Directive and current legal requirements
S. Geers-van Gemeren; *Utrecht/NL (s.geers@nvmbr.nl)*

It is necessary that patients understand the risks of radiation associated with medical imaging examinations. Few studies have been conducted to assess patient knowledge of and attitudes towards radiation and only some have focused on the general population. Additionally, these studies showed that although computed tomography (CT) is estimated to be responsible for more than 70% of the collective radiation dose received by patients, most of them lack information about the reasons behind the medical imaging examination prescribed (the benefits) and the associated radiation dose (the risks). There are new requirements in the BSS for informing patients, recording patient doses, and recording, reporting and follow-up of accidental and unintended exposures. The patient or their representative is provided with adequate information relating to the benefits and risks associated with the radiation dose from the medical exposure. Similar information as well as relevant guidance shall be given to carers and comforters. A collaborative approach between referrers, radiologists, medical physicist and radiographers is suggested to help explain these risks to patients. Challenges for all professionals involved, especially for radiographers. Radiographers are the interface between the patient and the technology.

Session Objectives:
1. To learn about the requirements within the BSS Directive for the different healthcare professionals in informing patients.
2. To learn about the important role of radiographers in informing patients.
3. To understand patients' need related to the information about radiation risk.

A-578 16:05

So whose role is it? What different professionals can and should do
G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

Teamwork is needed wherever multiple individuals with multiple skills are required to work interdependently to achieve a favourable outcome. This means that teamwork is absolutely critical in the management of patients, since health care is a complex activity, which needs many different types of professionals, with different knowledge, skills and competences and with specific roles. One individual working alone cannot achieve the target of taking care of a patient, and from the concept defined in 1926 by Francis Peabody that “the secret of the care of a patient is caring for the patient” we have moved nowadays to: “the real secret of the care of a patient is teamwork”. An increasing volume of medical imaging procedures combined with a demand for more rapid access to diagnostic services is putting high pressure on radiographers, who, by being the final point of contact for the patient, have the responsibility of providing the best and correct procedure to the patient. Departments should adopt communication strategies to explain the procedure in an understandable manner, adapted to patient social and economic characteristics, giving adequate information for him/her to be able to make a proper decision. Radiographers are, according to the BSS Directive, responsible for the practical aspects of medical imaging procedures, defined as: “means the physical conduct of a medical exposure and any supporting aspects, including handling and use of medical radiological equipment, the assessment of technical and physical parameters (including radiation doses), calibration and maintenance of equipment, preparation and administration of radio-pharmaceuticals, and image processing”.

Learning Objectives:
1. To understand the importance of teamwork to improve communication skills when informing about radiation risk.
2. To learn about the importance of the radiographers' role in the healthcare setting.
3. To become familiar with the European Basic Safety Standards challenges for the different health professionals involved in patient clinical pathway.

A-579 16:30

What do patients want to hear and need to be told?

J. Portelli; *Msida/MT (jonathan.portelli@um.edu.mt)*

Recent years have seen an ever-growing movement towards the importance for health-care delivery to be more patient centred, particularly since this has been associated with improved outcomes and quality of care. In effect, the drive towards patient-centred care should compel health professionals to invest more time and consideration to reflect upon and amend their practices, as necessary, so as to ensure that they are always providing care that is respectful of, and responsive to the needs, values and preferences of each individual patient, their families and/or representatives. In the context of medical imaging and radiotherapy, a patient-centred care approach therefore necessitates that radiographers are not only knowledgeable about how to identify the different information, emotional and social needs of each individual patient, but also need to be able to have and master the necessary skills to satisfy such needs in a manner that is meaningful and valuable to each patient. In this regard, this lecture will seek to outline and discuss possible information and communication needs of different patient groups attending medical imaging examinations. Additionally, this lecture will seek to highlight the different expectations, perceptions and concerns patients may have when attending a medical imaging examination and how such factors need to be considered holistically so as to further enhance patients' experiences in medical imaging and radiotherapy departments.

Learning Objectives:

1. To learn about the information and communication needs of patients attending for a medical imaging examination.
2. To appreciate that patients may have different expectations, perceptions and concerns when attending for a medical imaging examination.

A-580 16:55

How to effectively communicate radiation risks

L.R. O'Hora; *Dublin/IE (lohora@mater.ie)*

The quantification of patient dose and communication of associated risk is now a legislatively mandated function of radiology departments. The practical delivery of this essential service is sometimes lacking in clinical practice. This talk aims to suggest simple steps all diagnostic departments can use to quantify, interpret and communicate diagnostic doses and associated risks to patients.

Learning Objectives:

1. To understand dose metrics.
2. To appreciate the difference between diagnostic dose metrics and effective dose.
3. To understand the concept of "lifetime risks" associated with specific effective doses.
4. To become familiar with relating specific procedure dose to understandable concepts such as equivalent periods of environmental radiation.

17:20

Cardiac hybrid imaging indications: case-based

C. Rischpler; *Munich/DE (christoph.rischpler@tum.de)*

Molecular imaging modalities such as positron emission tomography (PET) and single photon emission computed tomography (SPECT) are usually combined with morphological imaging techniques such as computed tomography (CT) or magnetic resonance imaging (MRI). These hybrid cardiac imaging approaches allow the beneficial combination of radioactive, molecular imaging probes with the detailed assessment of cardiac function and anatomy. As a consequence, hybrid cardiac imaging plays an increasing role in the work up in various clinical scenarios. Possible indications include the workup of coronary artery disease (perfusion and viability), inflammatory diseases and cardiac tumours. This case-based talk discusses the application of hybrid imaging in various cardiac diseases with a special focus on hybrid PET/MRI.

Learning Objectives:

1. To learn about indications of hybrid imaging in cardiology.
2. To appreciate cardiac indications of different hybrid imaging modalities.

A-582 16:30

Non-oncological intracranial indications for hybrid imaging: case-based

A. Drzezga; *Cologne/DE*

"no abstract submitted"

Learning Objectives:

1. To understand non-oncological indications of hybrid imaging in the brain.
2. To become familiar with non-oncological radiopharmaceuticals for brain imaging.

A-583 17:00

Hybrid imaging in inflammation: case-based

A. Signore; *Rome/IT (alberto.signore@uniroma1.it)*

In the field of infection, early diagnosis of infection extent and severity is crucial. In some cases the location of the infection is also unknown. The use of hybrid imaging modalities, such as SPECT(CT, PET/CT and PET/MRI has enormously increased the possibility to identify and quantify the severity and extent of an occult infection. The main role is to be attributes to the choice of radiopharmaceutical, followed by the possibility to visualise the anatomy of patient by CT or MRI. In this presentation I will show several example about how to correctly apply different radiopharmaceuticals and what can be the added value of CT and/or MRI in the diagnostic approach. Cases of osteomyelitis, diabetic foot, spondylodiscitis and vascular graft infections will be presented.

Learning Objectives:

1. To learn about indications of hybrid imaging in inflammatory diseases.
2. To appreciate hybrid imaging for therapy response assessment in inflammatory diseases.

Value-based radiology

Moderators:
P. Mildenberger; Mainz/DE
G. McGinty; New York, NY/US

A-584 16:00

Basic concepts of value-based radiology: US perspective

J.A. Brink; *Boston, MA/US*

The value of radiology care may be defined from both the patient's and provider's perspective, including their views about quality and cost. Both perspectives demand image-derived information that is simple to understand, precise and actionable. Traditional quality metrics are informed well by these attributes, providing better pathways to health, risk mitigation and disease avoidance. Non-traditional quality metrics centre on patient experience, care coordination, and integration in care teams with clinical imaging pathways. Both traditional and non-traditional quality systems enable meaningful participation in new health-care delivery systems including accountable care and population health models. Cost models must consider both tangible and intangible costs, from both the patient's and provider's perspective. Tangible patient costs include out-of-pocket expenses as well as lost wages. Tangible provider costs include variable and fixed direct costs as well as indirect costs and overhead. Measuring costs can be particularly challenging, as top-down approaches may be overly simple while bottom-up approaches may be time consuming and difficult to maintain.

Learning Objectives:

1. To understand basic concepts of value-based radiology.
2. To be informed of the current state of value-based radiology in the US.
3. To explain professional implications of value-based radiology.

A-585 16:20

Basic concepts of value-based radiology: European perspective

L. Donoso; *Barcelona/ES (ldonoso@clinic.ub.es)*

Value-based health care (VBH) is a concept that was primarily developed to address the challenges resulting from the ever-increasing demand on health-care systems coupled with financial constraints. These trends also affect the

radiology profession, and the ESR established a working group on value-based imaging (VBI WG) in response to these developments and to shape them. The ESR's concept paper on value-based radiology (VBR) sets out the ESR's approach to this topic. At the conceptual level, the ESR argues that the diagnostic process should be included in the VBH framework, which focuses on outcomes but starting only at the point of treatment. However, an accurate and timely diagnosis is the first outcome that matters to patients. In this context, VBR should be a concept not only by and for radiologists, and the ESR plans to engage in this debate with the wider medical community. The focus on outcomes and value also requires organisational changes. The organisation of health-care delivery should be centred on the patient, and the structure must functionally follow the multidisciplinary management of medical conditions. In this new setting, radiologists need to demonstrate the value they provide to referrers, treating physicians, administrators and patients. The ESR proposes different metrics that can help change the perception of radiology from a volume-based cost to a value-driven asset. The metrics focus on five key aspects for a high-quality diagnosis: appropriateness of requests, radiation protection measures, quality of the radiology report, relationship between radiologists and patients, and education, research and innovation.

Learning Objectives:

1. To discuss possible concepts of value-based radiology in the European environment.
2. To discuss possible strategies leading from volume-based to value-based radiology in Europe.
3. To explain implications of value-based radiology on quality.

A-586 16:40

New metrics are required for value-based radiology

G. McGinty; *New York, NY/US (geraldinemcginty@gmail.com)*

This session will provide participants with an understanding of how quality and resource use metrics are currently developed and implemented in the US, both for radiology and the health-care system in general. I will discuss how data are collected and submitted around these metrics and give an overview of the ways in which metrics are used by payers, both governmental and private, in the US health-care system. I will also explore the degree to which existing metrics have succeeded or failed in shaping value-based imaging care as well as the costs associated with demonstrating and reporting compliance.

Learning Objectives:

1. To understand the limitations of current metrics.
2. To understand how to effectively develop metrics around value-based radiology.
3. To understand the connection between metrics and payment.

17:00

Interventional Radiology

RC 1209

Pulmonary embolism: a joint challenge for diagnostic and interventional radiology!

A-587 16:00

Chairperson's introduction

A.G. Ryan; *Waterford City/IE (jackoriain@yahoo.ca)*

Venous thrombo-embolism (VTE) is an enormous health-care issue, resulting in more deaths in Western Europe than AIDS, breast cancer, road traffic accidents, and prostate cancer, all combined. This session focuses on the state of the art in the diagnosis and management of pulmonary embolus (PE). All radiologists need to know how to diagnose and interpret the findings in this important condition, and Dr. Ghaye will describe in detail the optimal clinical and imaging algorithm to diagnose and stratify the condition, and its imaging follow-up. Dr. Uberoi will expand on the risk stratification and optimal management strategies based on current evidence. Once the diagnosis has been established, interventional radiologists have a major role in its treatment via aggressive catheter-based therapy and Dr. Spiliopoulos will discuss the Interventional techniques, outcomes and evidence supporting their use in the treatment of massive and sub-massive pulmonary emboli.

Session Objectives:

1. To appreciate the value of imaging in therapy planning and follow-up.
2. To learn about patient selection and evidence in catheter directed therapies for PE.
3. To learn about recent and ongoing trials in the endovascular treatment of PE.

A-588 16:05

A. Imaging algorithm for pulmonary embolism

B. Ghaye; *Brussels/BE (benoit.ghaye@uclouvain.be)*

The diagnosis of pulmonary embolism (PE) is difficult, since the clinical signs and symptoms are non-specific. Unstable patients usually undergo thrombolysis following demonstration of right ventriclular (RV) dysfunction at echocardiography. Diagnostic algorithm strategies in stable patients have been developed to limit the number of patients requiring an imaging test. The first step includes the assessment of the clinical probability of PE and D-dimers testing. Patients with either a high clinical probability or a positive D-dimers test should undergo further imaging test. Incompliance to such diagnostic algorithms has been demonstrated to increase the rate of PE recurrence and the rate of false-positive CT pulmonary angiographies. In patients not at high risk of mortality (i.e. without clinical findings such as cardiogenic shock or persistent arterial hypotension), signs of RV dysfunction (at echocardiography or CT pulmonary angiography) are used together with clinical prognostic scores, such as the PESI, and cardiac biomarker dosage to discriminate patients with intermediate or low risk. This is usually performed by measuring the ratio between the diameters of RV and the left ventricle (RV/LV). More recent and potentially more powerful predictor CT findings have been reported, including among others RV/LV surface and volume ratios, the severity of "perfusion" defect and cardiac function parameters as calculated from ECG-gated acquisition. Evidence concerning the follow-up of unselected patients after treatment is still limited in literature. Short-term follow-up after systemic thrombolysis or endovascular treatment has been performed using various techniques, including RV/LV dimensions, pulmonary arterial obstruction scores or pulmonary perfusion comparison.

Learning Objectives:

1. To learn how clinical findings influence the selection of the imaging strategy in PE.
2. To learn about the follow-up after treatment.
3. To learn how imaging may predict the outcome of the patient.

A-589 16:28

B. What is new in the recently published guidelines for pulmonary embolism treatment?

R. Uberoi; *Oxford/UK (Raman.Uberoi@ouh.nhs.uk)*

PE is a major cause of mortality, morbidity, and hospitalization in Europe. 317 000 deaths related to VTE were reported in six countries of the European Union (with a total population of 454.4 million) in 2004. 34% presented with sudden fatal PE and 59% postmortem. Only 7% who died early were correctly diagnosed with PE before death. Following diagnosis, patients should undergo risk stratification using a scoring system such as the pulmonary embolism severity index and patients stratified into high-, intermediate- and low-risk groups based on the clinical status of the patient, i.e. shock , hypotension, signs of RV dysfunction and cardiac biomarkers. Patients with scores of PESI of III-IV will have a 30-day mortality of 24.5%. High-risk and intermediate high-risk patients should undergo consideration for rapid primary pharmacologic treatment or surgery and, where available, interventional treatment to rapidly clear thrombus. Acute right ventricular dysfunction is a critical determinant of the outcome, and persistent arterial hypotension and cardiogenic shock carry a high risk of early death. Primary reperfusion treatment, particularly systemic thrombolysis, is currently the treatment of choice. This can result in the early reduction of pulmonary resistance and improvement in RV function. The maximum benefit is in the first few days , ideally within 48 hours with 90% of patients showing improvement, with no benefit at one week. Low-risk patients, i.e. with PESI scores I-II or sPESI 0, should be considered for early discharge and outpatient treatment with anticoagulation.

Learning Objectives:

1. To learn about the recently published guidelines for PE treatment in stable patients.
2. To learn about the recently published guidelines for PE treatment in unstable patients.
3. To learn about recent therapeutic algorithms in PE treatment.

A-590 16:51

C. Updates on the endovascular treatment of massive and submassive pulmonary embolism

S.C. Spiliopoulos; *Athens/GR (stavspiliop@med.uoa.gr)*

Minimal invasive percutaneous endovascular treatment of massive and submassive pulmonary embolism (PE) offers the benefit of low-risk, more aggressive management than systemic anticoagulation and has been correlated with reduced morbidity and mortality rates. Traditional endovascular methods include thrombus dissolution using standard pigtail catheters or balloons, presenting reasonable technical success rates of approximately 86%. Local low-dose catheter-directed thrombolysis combined with thrombectomy (e.g. pharmacomechanical thrombolysis) seems to improve outcomes, without increasing the risk of bleeding. The rationale of recent and ongoing trials is based on the fact that systemic thrombolysis, although more effective than anticoagulation alone, increases by 5-fold the risk of major bleeding and 10-fold that of haemorrhagic stroke, while it is contraindicated in many patients mainly due to recent surgery or intracranial haemorrhage. On the other hand, the majority of evidence for catheter-based interventions is based on few single-centre case series and prospective trials. Over the past few years, several prospective, multi-centre, randomised trials and large registries have investigated novel pharmacological and pharmacomechanical thrombectomy techniques, such as ultrasound-accelerated thrombolysis, providing a high level of evidence regarding the safety and efficacy of endovascular treatment options in acute PE. Nonetheless, studies comparing various endovascular modalities versus systemic fibrinolysis are missing, while additional large-scale, well-designed randomised trials are required to improve the level of evidence of currently available interventional radiology techniques. In this lecture, the outcomes of all available and ongoing clinical data will be presented and future developments will be discussed.

Learning Objectives:

1. To learn about the rationale of recent and ongoing trials.
2. To learn about the level of evidence for interventional radiology techniques in PE treatment.
3. To learn about clinical results and possible further developments.

17:14

Panel discussion: Appropriate diagnosis and risk stratification in the management of acute massive and acute submassive pulmonary embolism

Pros & Cons Session

PS 1227

Gadolinium: image wisely

Moderators:

P.M. Parizel; Antwerp/BE

A. Rovira-Cañellas; Barcelona/ES

A-591 16:00

A. Intracranial gadolinium deposition: update and perspectives

H.A. Rowley; *Madison, WI/US (hrowley@uwhealth.org)*

Trace quantities of gadolinium are retained in the brain and other body tissues after intravenous administration of all gadolinium-based contrast agents (GBCAs), even in patients with normal renal function. This phenomenon has been known since pre-clinical studies, but only recently 'rediscovered' when Kanda et al. reported intrinsic T1 hyperintense signal in the dentate and globus pallidus on brain MRI in patients who had received multiple doses of certain linear agents. Subsequent autopsy studies have shown that gadolinium is primarily retained in or near the endothelial walls of these deep grey nuclei. Routine histopathology shows no evidence for gliosis or neuronal injury, even when there is clear-cut visible signal hyperintensity on MRI. Clinical series and population-based studies have not verified any neurologic deficits related to this phenomenon. Certain linear agents (e.g. gadodiamide, gadopentate) show the greatest visible signal changes on MRI, while the high relaxivity linear agent (gadobenate) shows a lower likelihood at similar exposure, perhaps accentuated when there is concomitant radiation or chemotherapy. Macrocyclic agents show lower propensity for visible changes on T1-weighted images, but deposition in brain and other tissues (e.g. bone, spleen, liver) is confirmed for these agents when using techniques such as MR relaxometry and direct tissue assays. Body tissues show about 10- to 100-fold higher concentrations than in brain, in some instances higher for macrocyclic than linear agents. While the EU has largely banned linear agents, the USA and most other countries have suggested new GBCA label warnings, and all agree that more research is needed.

Learning Objectives:

1. To evaluate intracranial gadolinium deposition with direct assessment of gadolinium accumulation in neuronal tissues of patients previously exposed to multiple doses of intravenous gadolinium.
2. To explore the relationship between intracranial gadolinium deposition, the type of contrast agent and renal function.

A-592 16:20

B. Do we need gadolinium in imaging MS? Pros and cons (part 1)

C. Lukas; *Bochum/DE (carsten.lukas@ruhr-uni-bochum.de)*

Magnetic resonance imaging (MRI) plays a key role in the diagnostic setup and follow-up of patients with multiple sclerosis (MS). The high sensitivity of the MRI enables the detection of focal inflammatory disease involvement in vivo, contributing substantially to an early diagnosis of MS. The intravenous administration of gadolinium-based contrast agents (GBCAs) in the diagnostic workup provides important information for fulfilling the concept of widely accepted and established diagnosis criteria. Subclinical MRI activity, e.g. detected by enhancing MS lesions, can substitute for a clinical relapse, allowing the diagnosis of MS from one single MRI after the first relapse. Furthermore, regular brain MRI scans play an essential role in monitoring disease progression in treated MS patients. Currently available treatment approaches differ in respect to efficacy and associated risks, stressing the importance of paraclinical tools to individualize the choice of disease-modifying therapy and closely monitor treatment efficacy and drug safety. MR Imaging exhibits a higher sensitivity to inflammatory disease activity than clinical relapses alone and provides valuable information for guiding escalating immunotherapy. Furthermore, its ability to detect early signs of side effects such as progressive multifocal leucoencephalopathy (PML) makes it an indispensable tool to closely monitor patients at risk. Although gadolinium-enhanced MRI can increase the confidence of disease activity in the follow-up setting in MS patients, referring clinicians and radiologists should be aware of certain limitations and consider limiting the amount of serial GBCA administration to dedicated situations to reduce the number of unnessessary enhanced MRI scans.

Learning Objectives:

1. To review the role of Gd-enhanced follow-up MRI for management of patients with multiple sclerosis.
2. To explore alternative imaging techniques for assessment of disease progression in order to avoid gadolinium deposition.

A-593 16:35

B. Do we need gadolinium in imaging MS? Pros and cons (part 2)

W. Van Hecke; *Antwerp/BE (wim.vanhecke@icometrix.com)*

Gadolinium (Gd)-based contrast agents have been used for many years for the diagnosis and follow-up of patients with multiple sclerosis (MS). Post-Gd T1-weighted scans provide the unique ability to assess lesion activity and inflammation through the breakdown of the blood-brain barrier. Gd-enhacing lesions therefore are part of the standard diagnostic critaria in MS. Recently, there have been findings that there might be some Gd retention in the brain for some agents. This has led to a discussion on the use of frequent Gd injections and comments and recommendations by different bodies (CMSC, FDA, etc.). This is especially relevant for patients with MS, as they typically undergo an annual MRI scan for therapeutic monitoring. In addition to the possible Gd retention in the brain, and the unknown impact on the patient's well-being, the clinical need of the use of Gd for follow-up scans can be questioned, as it is known that Gd-enhancing lesions only show this Gd enhancement for a few weeks. Furthermore, some alternative quantitative measures of MS disease activity based on non-contrast MRI scans have been emerging.

Learning Objectives:

1. To review the role of Gd-enhanced follow-up MRI for management of patients with multiple sclerosis.
2. To explore alternative imaging techniques for assessment of disease progression in order to avoid gadolinium deposition.

A-594/A-595 16:50

C. Do we need gadolinium in imaging vestibular schwannomas? Pros and cons

B. Verbist[1], F.B. Pizzini[2]; [1]*Leiden/NL,* [2]*Verona/IT*
(b.m.verbist@lumc.nl)[1], (francescabenedettapizzini@gmail.com)2

Vestibular schwannoma (VS) is a benign nerve sheath tumour that may occur in the cerebellopontine angle cistern, internal acoustic meatus and in the inner ear. Patients will present with unilateral sensorineural hearing loss (SNHL), tinnitus, balance problems and - when tumours become large - cranial nerve palsy of the trigeminal and/or facial nerve. According to the most recent American College of Radiology (ACR) Appropriateness Guidelines, magnetic resonance imaging (MRI) of the head and internal auditory canals with and without contrast is the most appropriate imaging modality in patients with SNHL to evaluate for a possible VS. However, since the 1990s several studies have been conducted to compare the diagnostic accuracy of non-contrast-enhanced sequences with post-contrast MRI, mainly for reasons of cost-effectiveness, but more recently also inspired by concerns about the safety of MR contrast agent. The use of contrast-enhanced MRI during observation of a known VS or surveillance after surgical or radiotherapy treatment has also been questioned. In this lecture, the controversies on the use of gadolinium for the diagnosis of a VS will be discussed based on current literature and clinical experience. The aim of the follow-up studies is to evaluate growth (during a wait and scan policy and after irradiation) or to pick up recurrent disease early (after surgical removal). A literature review of possible follow-up strategies and the results of an own patient review will be presented.

Learning Objectives:

1. To determine whether Gd-enhanced MRI offers advantages in the initial diagnosis and follow-up of patients with (suspected) vestibular schwannoma.
2. To assess the diagnostic accuracy of high-resolution T2-weighted scans as an alternative to Gd-enhanced T1-weighted scans.

16:00 - 17:30 **Room M 5**

Special Focus Session

SF 12e

Memorable cases in cardiovascular imaging: how to avoid common mistakes

A-596 16:00

Chairperson's introduction

K. Nikolaou; *Tübingen/DE (Konstantin.Nikolaou@med.uni-tuebingen.de)*

In this session special and memorable cardiovascular cases will be presented and discussed by experts in cardiovascular imaging. Cardiac imaging modalities covered and discussed will comprise cardiac MRI and cardiac CT imaging, and the potential role of multimodality diagnoses, incorporating information from several examination techniques. Clinical entities will include inflammatory, congenital and ischemic heart disease.

Session Objectives:

1. To learn how to avoid common mistakes in cardiac imaging.
2. To understand how to systematically review complex cardiac cases.
3. To appreciate the importance of clinical context and clinical knowledge for solving differential diagnoses in cardiac imaging.

A-597 16:06

Coronary fistula mimicking a cystic paracardial tumour

C. Loewe; *Vienna/AT (christian.loewe@meduniwien.ac.at)*

Coronary fistulas represent a rare type of coronary anomalies. They are classified as abnormal coronary drainage (coronary anomaly group C). Coronary fistulas show a broad variation in the abnormal anatomical areas they could drain into including the atria, the superior vena cava, the pulmonary arteries and many more. The changes in haemodynamics could lead to volume overload, and huge coronary fistulas might even cause heart failure due to this volume overload if they are not treated on time. Additionally, the feeding vessel (=coronary artery) can dilate significantly as well, whereas the distal part of the feeding coronary artery might become hypoplastic due to steal effect, which can cause signs of ischaemic heart diseases and severe problems during surgical repair of the fistula. However, most of the coronary fistulas remain asymptomatic for a long period of time and are diagnosed usually by chance. In such a situation, the diagnosis can be challenging since the coronary fistula can mimic other diseases, and non-invasive diagnosis had been difficult in the past. With the introduction of non-invasive coronary CT angiography, the diagnosis of coronary fistula has become easy and straightforward, since this technique can provide a detailed anatomical overview. In case treatment is of indicated, coronary CT angiography is able to provide all information for treatment planning as well. In the presentation, a memorable case will be presented that was initially diagnosed as cystic paricardial tumour, but finally confirmed as aneurysmatic coronary fistula.

Learning Objectives:

1. To learn how to avoid the most common pitfalls in image interpretation of the coronary arteries.
2. To understand how to systematically review (complex) coronary artery anatomy/disease.
3. To appreciate the importance of clinical context for solving differential diagnoses in coronary imaging.

C. Loewe: Speaker; GE Healthcare, Bracco, Siemens.

A-598 16:20

Right ventricular myocarditis diagnosed with CMR: the great imitator

M. Francone; *Rome/IT (marco.francone@uniroma1.it)*

Isolated right ventricular (RV) involvement in acute myocarditis is an uncommon event, sharing overlapped clinical and morphological manifestations with arrhythmogenic right ventricular dysplasia (ARVC). The common features associated with both affections may be the presence of RV regional wall motion abnormalities and volumetric enlargement, impaired ejection fraction and late gadolinium enhancement of the free wall. The condition has shown to be misdiagnosed with cardiac magnetic resonance in approximately 50% of cases with relevant clinical implications on patient's prognosis and therapeutic management, posing a possible source of misdiagnosis in clinical pratice.

Learning Objectives:

1. To learn how to avoid the most common pitfalls in image interpretation of myocarditis and inflammatory heart diseases.
2. To understand how to systematically review (complex) inflammatory myocardial cases.
3. To appreciate the importance of clinical context for solving differential diagnoses in myocardial imaging.

A-599 16:34

Congenital elastic band of the aortic valve: a "multimodality" diagnosis

K. Pagonidis; *Iraklion/GR (kpagonidis@yahoo.de)*

Aortic stenosis due to supravalvular membrane (elastic band) usually presents in children. It may be associated with fusion of the left coronary leaflet and the supravalvular membrane, causing obstruction of the left coronary ostium and resulting in myocardial ischaemia. Despite the immobilization of the left coronary leaflet, these patients present in childhood with aortic stenosis, with or without accompanying myocardial ischaemia. The case is about an adult patient with supravalvular aortic membrane presenting with turbulent flow due to fusion of the left coronary leaflet with the supravalvular membrane and left ventricular hypertrophy with mild obstruction in the LVOT and apical aneurysm.

Learning Objectives:

1. To learn how to avoid the most common pitfalls in image interpretation of the valves.
2. To understand how to systematically review (complex) valvular cases.
3. To appreciate the importance of clinical context for solving differential diagnoses in valvular imaging.

A-600 16:48

Dyspnea with an abnormal right ventricle: role of MR imaging

A. Jacquier; *Marseille/FR (alexis.jacquier@ap-hm.fr)*

MRI is an accurate and reproducible method to assess right ventricular function and characterise phenotype. Specific protocol and methods are used to estimate the RV function, volume, segmental abnormality and late enhancement. Learning curve for right ventricular assessment is longer than for the left side. MRI is increasingly playing a central role in diagnosis, prognosis and patient management. MR with its ability to assess cine, flow and late enhancement represents the first line exam to assess right ventricular pathologies. Pulmonary hypertension, arrythmogenic RV dysplasia, tricuspid regurgitation, congenital abnormalities are the main disease that could affect the right ventricle but more rare disease could be encountered.

Learning Objectives:
1. To learn how to avoid most common pitfalls in image interpretation of the right ventricle.
2. To understand how to systematically review right heart function and morphology.
3. To appreciate the importance of clinical context for solving differential diagnoses in the right heart.

Author Disclosure:
A. Jacquier: Research/Grant Support; Guerbet.

A-601 17:02

Misleading CMR LGE artefact in cardiomyopathies

M. Gutberlet; *Leipzig/DE*

"no abstract submitted"

Learning Objectives:
1. To learn how to avoid the most common pitfalls in image interpretation of LGE images.
2. To understand how to systematically review (complex) LGE datasets.
3. To appreciate the importance of clinical context for solving differential diagnoses in myocardial and LGE imaging.

A-602 17:16

Hypertrabeculation vs non-compaction of the left ventricle: treat or don't touch?

K. Gruszczynska; *Katowice/PL (kgruszczynska@poczta.onet.pl)*

Left ventricular non-compaction (LVNC) according to ESC classification belongs to unclassified cardiomyopathies. It is defined by the two-layer structure of the myocardium with thin compacted subepicardial and thick non-compacted subendocardial layer with deep recesses and thick trabecula. Two forms of LVNC have been reported: non-familial-isolated and familiar-inherited. LVNC was thought to develop due to the arrest of coalescence of foetal myocardial trabeculae in utero, and was linked to different genetic findings. However, hypertrabeculation can also occur in adult life. Clinically, LVNC has been linked to LV failure and increased risk of thromboembolic events. Radiological diagnostic criteria have defined LVNC as the index of NC/C layer >2.3 in LA EDD images or trabecular mass >20% of total LV mass in ED. According to recent publications, these criteria could be fulfilled by a substantial percentage of the asymptomatic population. Moreover, LV hypertrabeculation was not of higher clinical prognostic value than EF, LV volume or myocardial fibrosis. So, the question that arises is: what is the clinical value of excessive LV trabeculation visible on MRI and CT, both in patients with reduced and preserved cardiac function, as the common mistakes in diagnosis can have tremendous impact on the patient's life.

Learning Objectives:
1. To learn how to avoid most common pitfalls in image interpretation of left ventricular function and morphology.
2. To understand how to systematically review the causes of reduced cardiac function.
3. To appreciate the importance of clinical context for solving differential diagnoses of the left ventricle.

Saturday, March 3

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1321
Oncologic imaging

A-603 08:30
A. Lung cancer: key signs in the new TNM
A.R. Larici; *Rome/IT (annarita.larici@unicatt.it)*

Lung cancer is a leading cause of cancer-related mortality worldwide. A correct staging is the prerequisite for an adequate management of patients with lung cancer. Recently, the 8th edition of the TNM classification introduced relevant changes to the descriptors T and M. Regarding T, it has been demonstrated by survival analyses that from 1 to 5 cm of diameter every centimetre counts, and that larger tumours are best aligned with either T3 (tumour size of more than 5 to 7 cm) or T4 (tumour size of more than 7 cm). This finding further confirms the common intuition that the larger the tumour, the worse is the prognosis. Regarding M, the category of extrathoracic lesions has been distinguished in M1b and M1c to indicate, respectively, one (oligometastatic disease) and more than one lesion. In this context, it is advisable that radiologists report the number of lesions if only one organ is involved and the number of organs if many are involved. This approach has a relevant clinical impact because oligometastatic disease nowadays is managed and treated differently with respect to an extensive M stage disease. Several limitations still remain, such as classification of a tumour adjacent to the chest wall, mediastinum and diaphragm, as well as the categorization of lymphangitic carcinomatosis as an independent descriptor and the evaluation of multiple lung lesions. Certainties and controversies on the topic will be argued in this session, taking into account that cancer staging should be always considered a multidisciplinary process.

Learning Objectives:
1. To learn about the new staging system for lung cancer.
2. To highlight the differences in the meaning of CT findings between the new system and the previous one.

A-604 09:15
B. Incidental findings in oncologic patients
M.-P. Revel; *Paris/FR (marie-pierre.revel@aphp.fr)*

Incidentalomas are frequently found during CT follow-up of oncologic patients. Unsuspected pulmonary embolism (UPE) prevalence is reported to be as high as 5%. Symptoms, which had been erroneously attributed to cancer, are often retrospectively found. UPE more often involves distal arteries. The recurrence rate is the same as for suspected PE, around 20%. Up to 30% of UPEs are not initially reported. Incidental pulmonary nodules are very frequently found in oncologic patients. At the initial staging, it is of major importance to distinguish between lung metastasis and other cause of lung nodule. The nature of the primary malignancy must be taken into account, and a histologic assessment might be required if there are implications on treatment. Adrenal masses are also frequently found. An attenuation below 10 UH on unenhanced CT is the best criterion for benign adenoma. If not, 40% relative washout on CT or 20% drop of signal on out-of-phase MR sequences suggests a benign lesion. In case of increased FDG uptake on PET-CT, percutaneous biopsy might be performed after having excluded pheochromocytoma by a dosage of catecholamine metabolites.

Learning Objectives:
1. To recognise the importance of different incidental findings in patients with cancer.
2. To learn how to manage patients with incidental findings.

08:30 - 10:00 **Room B**

GI Tract

RC 1301
Difficult challenges in imaging the acute abdomen

Moderator:
S.K. Puri; New Delhi/IN

A-605 08:30
A. Perforation of the GI tract
V. Maniatis; *Aabenraa/DK (vmaniatis67@gmail.com)*

Perforation of the GI tract represents an emergency and life-threading condition. The causes of perforation may be traumatic (endoscopy, blunt trauma, ingested foreign body), inflammatory (peptic ulcer disease, diverticulitis, appendicitis, Crohn's disease or other enteritis), bowel schema or neoplasms. Clinical diagnosis may be difficult and patients may be first radiologically evaluated with plain radiographs or ultrasound, but with limited information in cases of perforation. CT scanning is by far the imaging method of choice in these patients. CT findings of GI tract perforation can be direct or indirect. Direct findings include free air or/and oral contrast either intra- eller retroperitoneal. Indirect findings comprise inflammatory mass surrounding an appendicolith or a radiopaque foreign body. Non-specific findings include bowel wall thickening, mesenteric infiltration, interloop free fluid and abnormal bowel wall enhancement. With the use of both direct and indirect findings, the sensitivity of CT in diagnosing GI tract perforation is up to 92%. False-positive results usually occur in post-operative patients, where free air as a result of previous operation can be misdiagnosed as a sign of anastomotic leak or iatrogenic bowel trauma. CT is also able to depict the site of perforation with an overall accuracy between 82 and 90% and the cause of perforation in up to 67% of cases. It is well documented that CT plays a crucial role in the assessment of patients with GI tract perforation, by offering fast and accurate essential information to the clinicians and enabling the most correct therapeutic choice.

Learning Objectives:
1. To learn about the main causes and clinical symptoms of GI tract perforation.
2. To become familiar with the imaging methods used to detect GI tract perforation and with relevant diagnostic algorithms.
3. To appreciate the important imaging appearances indicative of GI tract perforation. What should radiologists not miss?

A-606 09:00
B. Bowel obstruction
A.J.B.S. Madureira; *Porto/PT (ajbmadureira@gmail.com)*

Bowel obstruction is responsible for a considerable number of surgical admissions for acute abdominal pain in the emergency department. It has a high morbidity and mortality if left untreated. The diagnosis can be suggested by plain abdominal films, but CT, and particularly contrast-enhanced CT, plays a crucial role in the diagnosis and management of these patients. Not only can CT confirm the diagnosis, but it can also grade the severity of the obstruction, locate it, and provide the aetiology. A dedicated technique is necessary and multiplayer reconstructions in the coronal and sagittal planes are mandatory. The causes of small bowel obstruction can be divided into intrinsic (inflammatory diseases, neoplasia), extrinsic (adhesions, hernias), and intraluminal (gallstones, bezoars). The three most frequent causes of large bowel obstruction are neoplasm, volvulus, and diverticulitis. The imaging findings vary according to the cause, and some are very specific. CT can provide a quick diagnosis and allow an early and optimal management of these patients, contributing to better patient care and improved survival.

Learning Objectives:
1. To learn about the different types and causes of bowel obstruction.
2. To become familiar with relevant imaging signs in both small and large bowel obstruction including complications.
3. To appreciate the most widely used imaging approach for detection and evaluation of bowel obstruction.

A-607 09:30
C. Acute biliary conditions
C.D. Becker; *Geneva/CH*

Acute cholangitis is a serious condition which occurs most commonly in the context of bile duct obstruction due to stone disease or strictures. Unless diagnosed and treated correctly, acute cholangitis may lead to liver abscess

formation, septicaemia and multiorgan failure. The role of noninvasive imaging is to determine the presence of obstruction of the biliary tree., as well as its level and its cause. Although ultrasonography or computed tomography are most commonly used in the emergency situation, magnetic resonance imaging offers the most detailed diagnostic results, especially with regard to the cause of obstruction. Depending on the level and the cause of bile duct obstruction, decompression of the biliary tree may be done by means of minimally invasive interventional techniques via the endoscopic- retrograde or the percutaneous - transhepatic approach. Acute gallbladder disease is most often associated with calculus disease and obstruction of the cystic duct. Depending on the clinical situation, a diagnostic workup may be required to exclude the simultaneous presence of bile duct stones.

Learning Objectives:

1. To learn about the most common pathologies leading to acute biliary conditions.
2. To become familiar with the relevant multimodality imaging appearances in this group of patients.
3. To appreciate the role of interventional radiology in the management of these conditions.

08:30 - 10:00 **Room C**

Special Focus Session

SF 13a

Chest imaging of cystic fibrosis: from infants to adults

A-608 08:30

Chairperson's introduction

M.O. Wielpütz; *Heidelberg/DE (wielpuetz@uni-heidelberg.de)*

Chronic progressive lung disease in cystic fibrosis (CF) is the major life-limiting factor of this autosomal-recessive genetic disorder. CF newborn screening programmes in Western countries allow for an early diagnosis even before pulmonary symptoms occur. Imaging provides detailed information on the regional distribution of CF lung disease. Chest x-ray (CXR), computed tomography (CT) and, most recently, magnetic resonance imaging (MRI) are now available as routine modalities, each with individual strengths and drawbacks, which need to be considered when choosing the optimal modality adapted to the clinical situation of the CF patient. At the same time, novel treatment strategies with CFTR modulators have revolutionized treatment in CF, starting early to prevent irreversible lung damage. Thus, radiologists are now faced with an increasing demand for imaging to monitor the course of CF lung disease from birth to adult ages. The hallmarks of the CF lung are bronchiectasis as one early sign of lung damage, airway wall thickening, consolidations and atelectasis, as well as emphysema in advanced stages of lung disease. Mucus plugging as well as air trapping and perfusion impairment are linked to basic pathophysiology and potentially reversible under therapy. Bronchiectatic destruction of lung lobes, dilatation of bronchial arteries and pulmonary haemorrhage are sequelae, which may require invasive treatment and lung transplantation. This session aims at teaching the most important imaging findings in CF lung disease and how these are depicted by chest x-ray, CT and MRI.

Session Objectives:

1. To learn about the imaging appearance of cystic fibrosis lung disease.
2. To appreciate the advantages and drawbacks of available imaging modalities.
3. To appreciate the role of repeated surveillance imaging in cystic fibrosis.
4. To understand the current developments in cystic fibrosis lung imaging.

Author Disclosure:

M.O. Wielpütz: Advisory Board; Boehringer Ingelheim.

A-609 08:35

X-ray: is there still a value in CF?

C. Owens; *London/UK (owensc@gosh.nhs.uk)*

The so-called “cutting edge” imaging research in cystic fibrosis suggests the use of computed tomography-generated measurements of bronchial wall thickness and airway tapering, sometimes using spirometer-guided CT or hyperpolarised gas MRI measures of regional ventilation, and even computed fluid dynamics based on individual patient airway geometry. But what is the real evidence base for this being reliable, reproducible, scientifically specific and robust? How does this really influence the patients’ management and well-being? What of the humble chest radiograph? What other imaging modality provides relatively non-invasive, robust, repeatable diagnostic images in patients ranging from the neonate to a 40-year-old, and even post-lung transplantation? In the presence of good clinical examination and detailed pulmonary function tests, for annual follow up, or in the presence of acute clinical deterioration, there is no need to provide a potentially "oversensitive' view of the anatomy. Subtle (possible transient/ reversible) mucos plugging and airway thickening may be overread. Clearly if the patient is on an expensive drug trial, CT is more sensitive, but what do we know about how reliable (or reversible) the CT images are in reflecting the patients' real clinical status. The future of advanced airways imaging is extremely bright, but it is not yet time to put the simple chest radiograph to bed.

Learning Objectives:

1. To learn about the typical imaging appearance of cystic fibrosis on radiography.
2. To become familiar with semi-quantitative scoring methods.
3. To appreciate radiography's role in imaging of the cystic fibrosis lung.

A-610 08:55

CT: information content vs dose?

P. Ciet; *Rotterdam/NL (p.ciet@erasmusmc.nl)*

Computed tomography (CT) remains the cornerstone of pediatric thoracic imaging. This holds true also for Cystic Fibrosis (CF) lung disease. Chest-CT has proved to be more sensitive than chest radiographs (CR) and lung function to detect disease progression in patients with CF. Chest-CT enables high-quality and diagnostic images both in non-collaborative and collaborative children. In non-collaborative children, fast acquisition CT protocols can be used to avoid sedation or anesthesia without compromising image quality. Specific CF-CT findings can be assessed with CT to monitor CF lung disease progression. The ability to recognize these findings on CT and to summarize them in a radiology report is important for the management of the CF patient. Nonetheless, the main limitation of Chest-CT remains radiation exposure, which always conveys a risk of developing cancer related to its stochastic nature. However, dose reduction measures have been introduced to minimize this risk and nowadays chest-CT can be performed at the same radiation dose of a CR. Further radiation dose reduction might be achieved through Chest-CT protocol standardization across vendors, which is still lacking. Finally, chest-CT has enabled to shift from qualitative to quantitative radiology. Newly developed imaging analysis techniques allows today to extract numbers from CT images that can be used to assess treatment’s efficacy or to determine patient’s prognosis. This presentation will be a summary of the state of the art of CT imaging in CF lung disease, with description of the CT technique, CF-CT imaging findings, semi-quantitative and quantitative scoring methods, and clinical examples.

Learning Objectives:

1. To learn about the typical imaging appearance of cystic fibrosis on CT.
2. To become familiar with semi-quantitative scoring and quantitative CT.
3. To appreciate CT's role in imaging of the cystic fibrosis lung.

Author Disclosure:

P. Ciet: Consultant; Vertex Pharmaceutical.

A-611 09:20

MRI: value of routine MRI?

F. Doellinger; *Berlin/DE (felix.doellinger@charite.de)*

Substantial technical improvements during the last fifteen years have provided a basis for the routine use of chest MRI in the assessment of lung disease in cystic fibrosis. Typical pulmonary disease manifestations, such as bronchial wall thickening, bronchiectasis, and mucus plugging are easily assessable, as they come along with an increase of protons, thereby giving signals. The disadvantages of MRI compared to CT, which is the faster technique and still offers better spatial resolution, are overwhelmed by the fact that MRI is a radiation-free modality and by the possibility of perfusion imaging, which can give important additional information. Morphofunctional MRI scores allow for a reproducible quantification and surveillance of lung changes. Successful response to antibiotic drugs in patients with infectious exacerbations goes along with a decrease of MRI scores. Recent studies have shown that MRI scores can even be helpful in the detection of cystic fibrosis in asymptomatic infants.

Learning Objectives:

1. To learn about the typical imaging appearance of cystic fibrosis on MRI.
2. To become familiar with semi-quantitative scoring and quantitative MRI.
3. To appreciate MRI's role in imaging of the cystic fibrosis lung.

09:50

Panel discussion: X-ray, CT or MRI, or a combination?

To appreciate the different strengths and weaknesses of each modality.

08:30 - 10:00 **Room Z**

Joint Session of the ESR and the BBMRI-ERIC (Biobanking and BioMolecular resources Research Infrastructure - European Research Infrastructure Consortium)

Linking imaging biobanks to -omics: the role of BBMRI and ESR

Moderators:
A. Van der Lugt; Rotterdam/NL
E. Steinfelder; Graz/AT

A-612 08:30

Introduction to BBMRI biobanking and biomolecular resources research infrastructure

E. Steinfelder; *Graz/AT (erik.steinfelder@bbmri-eric.eu)*

The way biobanks see it, researchers have no alternative than to connect and partner up with them when looking for high-quality samples and associated data. In other words, researchers cannot go find a better alternative because there is none. The researchers themselves, however, are often convinced that there are many alternatives to biobanks, which is mainly due to the fact that sample collections hosted by biobanks lack visibility, findability and accessibility, or simply because researchers have a strong desire to have their own collections of specific material. To bridge this gap between biobanks, the research community and the different stakeholders, BBMRI-ERIC's focus will be on building and strengthening value-added sustainable biobanking. The set of services offered by BBMRI-ERIC to support the various stakeholders will be continuously developed and improved. Quality Management will continue to expand its self-assessment survey, launch a quality grade and develop a concept paper for an audit programme. The Common Service IT will focus on improving and supporting the Directory, the Negotiator, the Connector and BIBBOX. The Common Service ELSI will centre it efforts around a number of services and support, including optimising the recently launched help desk, adapting the ethics check and drafting the code of conduct.

Learning Objectives:
1. To learn about biobanking and BBMRI.
2. To understand the diversity of human disease, biological samples and corresponding data.
3. To appreciate the benefits provided by biobanks for personalised medicine.

A-613 08:40

Secondary use of existing data: ethical issues, sharing and data protection

M.T. Mayrhofer; *Graz/AT (michaela.th.mayrhofer@bbmri-eric.eu)*

In the context of research, the secondary use of data refers to the processing of already existing medical data for a purpose different from the originally intended and for which it was initially collected. Secondary use of data is a common practice in medical research and poses ethical, legal and organisational challenges, among others. To seemingly simplify secondary use, is often recommended or even required to anonymise the data. Leaving aside the fact that anonymisation is a challenged concept in the era of big data, it can (a) deprive research projects from producing meaningful results, (b) to share incidental findings with research participants and (c) deny research participants their right to withdraw. Despite European and international efforts on harmonising practices of re-use of data, substantial differences remain across countries due to legal frameworks and cultural sensibilities. Moreover, appropriate safeguards (e.g., k-anonymity) are only as successful as constantly improved and lived as part of organisational culture. This presentation provides an overview of the challenges of secondary use of data (especially with regard to data sharing and data protection), how our concepts of privacy are challenged by scientific progress and discusses potential solutions (e.g. the Code of Conduct for Health Research initiative).

Learning Objectives:
1. To understand the rationale for patient rights the Code of Conduct for responsible use of human biomaterial and data.
2. To consolidate knowledge about the implementation of anonymization and pseudonymisation.
3. To learn about the sharing data and the General Data Protection Regulation.

A-614 09:00

Types of biobanks in the BBMRI network

P. Holub; *Graz/AT (petr.holub@bbmri-eric.eu)*

BBMRI-ERIC is a pan-European research infrastructure facilitating access to quality-defined biobanking and biomolecular resources. As such, it comprises heterogeneous partner biobanks ranging from clinical biobanks, disease-specific biobanks, population biobanks or rare diseases biobanks. Recently as a part of the collaboration with ESR, BBMRI-ERIC is being extended to improve findability of imaging biobanks, too. This presentation provides an overview of types of existing biobanks and biological material and data collected. Ability to asses quality of the biological material and data, i.e., ability to assess fitness for given research purpose and method, has become a paramount and resulted in increasing deployment of quality procedures inside the biobanks. Different present and upcoming quality standards will be discussed, namely CEN and ISO standards, including current standardisation work on provenance information management. The presentation will also cover basic principles of access procedure as implemented by BBMRI-ERIC and showcase how they are practically implemented in a distributed heterogeneous research infrastructure.

Learning Objectives:
1. To learn about the aims of BBMRI and the existing biobanks.
2. To understand how to offer and obtain easy access to samples, data and images.
3. To learn about quality assurance in biobanks.

Author Disclosure:
P. Holub: Employee; BBMRI-ERIC. Founder; Comprimato Systems. Shareholder; Comprimato Systems.

A-615 09:20

Radiomics: enhancing the value of images by standardised feature extraction

S. Trattnig; *Vienna/AT (siegfried.trattnig@meduniwien.ac.at)*

The need to improve cancer survival rates continuously motivates scientists to uncover the genetic and molecular composition of tumours and use this information to develop more effective cancer therapies. Since tumours differ in their biological makeup, treatments can now often be tailored towards individual patients, in a strategy termed 'personalised medicine'. Radiomics uses computer algorithms to process the data collected by different imaging techniques and is becoming increasingly popular in cancer imaging research. One of its key characteristics is that radiomics recognises that digital medical images are not only pictures, they are also complex data. Radiomic analyses, extracts and measures an array of "features" that describe the image texture and distributions of individual voxel values, the units that make up a 3D image, within a tumour. Features can be descriptive terms derived from radiology reports or mathematical quantities. Feature extraction requires several complex steps in a defined pipeline: defining the regions of interest and segmenting three-dimensional images, extracting features and converting images into "mineable" data. Finally, data from imaging techniques, and from biofluids and tumour tissue, are combined into models to predict patient prognosis or benefit from a specific therapy. One of the main benefits is that medical imaging data acquired in routine health care can be used in a new way to inform clinicians about the biology of a tumour and provide potential prognostic or predictive information. However, several challenges need to be overcome before radiomics, such as statistical problems, standardisation of terminology and PACS integration.

Learning Objectives:
1. To learn how image features can be extracted.
2. To discuss how radiomics can be integrated in "omics" analysis.
3. To explore the potential of radiomics analysis in care.

A-616 09:40

Integrating an imaging biobank in a BBMRI biobank

B. Gibaud; *Rennes/FR (bernard.gibaud@univ-rennes1.fr)*

Biomedical research related to the development of personalised medicine requires more and more imaging data. Moreover, clinical decision in personalised medicine involves more and more the use of both biological biomarkers and imaging biomarkers, derived from image data through image processing. Besides, the ultimate validation of results in medical image processing often requires a histopathologic diagnosis, which needs to access and analyse the corresponding specimen. In this context, researchers need infrastructure and services to search, locate, and retrieve the bioresources they need for their research (e.g. images, biospecimen, histopathologic diagnosis, genomic data). Such service is being implemented by the BBMRI-ERIC infrastructure which coordinates the sharing of biospecimen throughout Europe. Such infrastructure does not exist for imaging biobanks yet. The presentation will introduce the basic requirements for clinical imaging biobanks. It will analyse the main differences between biobanks and imaging biobanks. Specifically, it will underline the commonalities and differences between image collections and biospecimen collections. It will provide an introduction to the Minimum Information About BIobank data Sharing (MIABIS) model, and to its ontological version OMIABIS. The presentation will discuss how MIABIS/OMIABIS can be extended to facilitate image description and sharing,

in a way that enables native interoperability between biobanks and imaging biobanks data infrastructure.
Learning Objectives:
1. To understand the requirements for a clinical imaging bank.
2. To learn about the intra-operability of clinical image biobank and other data repositories.
3. To consolidate knowledge about "Minimum Information About Biobanking Sharing" (MIABIS) 2.0.

08:30 - 10:00 **Room O**

E³ - ECR Master Class (Cardiac)

E³ 1326a
Cardiac MRI: from sequence to bedside

A-617 08:30
Chairperson's introduction
L. Natale; *Rome/IT (luigi.natale@unicatt.it)*

In this session, three main topics will be addressed by speakers: flow, metabolism and myocardial deformation. Flow imaging has been recently enriched by 4D techniques, that demonstrated to be promising either for diagnosis or for prognosis. Metabolic assessment of cardiac diseases has been relegated to research field for a long time, due to time consuming techniques, costs and relatively low clinical impact. However recent advances in metabolic assessment of some cardiomyopathies seems to be promising. Finally, myocardial deformation evaluation and strains calculation are actually hot topics, due to introduction of a new approach, i.e. feature tracking, that allows qualitative and quantitative approach to myocardial function. Differently from tagging techniques, feature tracking is applied on cine-MR data sets, without any additional time and is more robust.
Session Objectives:
1. To understand the current clinical challenge for cardiac MRI in flow, metabolism and myocardial deformation.
2. To understand how the process evolves from method development to clinical application for flow, metabolism and myocardial deformation.

A-618 08:35
A. 4D flow imaging: how and when can it help?
A.A. Azarine; *Paris/FR*

"no abstract submitted"
Learning Objectives:
1. To learn about technical requirements to perform 4D flow imaging.
2. To understand what the strength and limitations of 4D flow are compared to 2D flow assessment.
3. To learn about potential clinical applications of 4D flow imaging.

A-619 09:00
B. Spectroscopy: implications of myocardial metabolism?
H.J. Lamb; *Leiden/NL (h.j.lamb@lumc.nl)*

Recently, the concept of the 'metabolic syndrome' was introduced, which is a constellation of risk factors of metabolic origin that are accompanied by increased risk for cardiovascular disease and type 2 diabetes. The two major underlying risk factors for the metabolic syndrome are obesity and insulin resistance. Metabolic imaging and total body fat distribution may be used to determine if obese subjects are at an increased risk for developing type 2 diabetes. In this situation, more intensive lifestyle intervention can be advised and monitored. MR techniques, including MR spectroscopy, offer unique possibilities for monitoring the effects of new dietary strategies. Whole-body imaging may also allow one to study the interaction between different organs. For example, initial results show that high liver triglyceride content in type 2 diabetes is associated with decreased myocardial perfusion, glucose uptake and high-energy phosphate metabolism, in conjunction with impaired whole-body insulin sensitivity. Multi-organ imaging in a single patient opens interesting possibilities to study the interaction between key organs involved in the metabolic syndrome, such as liver, pancreas, kidney and heart, in relation to vascular morphology and function. In summary, metabolic MR imaging, including MR spectroscopy and total body fat distribution, may be used in the future for risk assessment and personalized medicine in patients with the metabolic syndrome. Furthermore, multi-organ MR imaging and spectroscopy are promising for evaluation of the interaction between different organs in metabolic syndrome.
Learning Objectives:
1. To learn about technical requirements and how to perform proton spectroscopy and multinuclear spectroscopy.
2. To understand what has been learned from cardiac spectroscopy.
3. To learn about potential clinical applications of spectroscopy.

A-620 09:25
C. Feature tracking: what to conclude from strain and torsion?
J. Lotz; *Göttingen/DE (Joachim.Lotz@med.uni-goettingen.de)*

Quantification of wall motion has ever been an unresolved issue in cardiac imaging. Tagging techniques have been employed by MR-imaging in different field strengths and sequence designs to define myocardial features that can be tracked by specific software. However most of these techniques fell short of adequately defining diastolic myocardial wall motion. Diastolic dysfunction however has emerged as a key element in the detection of early stage myocardial disease. Myocardial feature tracking based on SSFP-sequence images has evolved as a reasonably reliable alternative to the classical myocardial tagging techniques in MRI. Similar developments have enriched echocardiography imaging for myocardial characterisation. Myocardial strain and torsion represent quantitative parameters that allow an in depth characterisation of myocardial wall motion. Quantitative myocardial dys-synchrony is a secondary parameter based on the strain and torsion values of left and/or right ventricle. There are numerous reports on the clinical benefit of these parameters for early diagnosis of diastolic heart failure and monitoring therapeutic interventions in cardiomyopathies. They may be helpful in defining the success of electrophysiological interventions in cardiac arrhythmias. This talk gives a comprehensive overview on the status and clinical usability of quantitative myocardial strain and torsion.
Learning Objectives:
1. To learn about a new MRI method to assess myocardial deformation.
2. To understand the strength of MRI feature tracking compared to other methods.
3. To learn about potential clinical applications of feature tracking.

09:50
Panel discussion: Is it time to include these MRI techniques in routine practice?

08:30 - 10:00 **Room N**

Head and Neck

RC 1308
Post-treatment imaging of the head and neck

A-621 08:30
Chairperson's introduction
H.B. Eggesbø; *Oslo/NO (h.b.eggesbo@medisin.uio.no)*

Head and neck cancer in the Western countries accounts for 3-4% of all cancers. the worldwide incidence is estimated to be 500,000, and in Europe 250,000. There are three times as many men as women that are affected. Squamous cell carcinoma constitutes more than 80% of the cancer. At the time of the diagnosis, one-third is in stage I/II, and two-thirds are in stage III/IV. The recurrence rates for stage I/II are relatively low, with 5-year-survival of 70-90%. Therefore, the risk of a secondary primary cancer after radiation therapy (RT) may be higher than the risk of recurrence. For stage III/IV, the local recurrence rates vary from 25 to 80%, and metastases from 10 to 30%, and the 5-year-survival is 10-55%. For stage I/II, the treatment options are surgery and/or RT, while for stage III/IV chemo- and RT are the main options. Common for all treatments are major alterations to the tissue that challenge the post-treatment imaging interpretation, independent of the modality. This session will focus on the expected changes after RT and surgery, including the most frequent surgical procedures, and when and how to perform post-treatment imaging, to depict early cancer recurrence.
Session Objectives:
1. To become familiar with different ways of treatment.
2. To understand post-surgical and post-RT complications.
3. To know how to follow-up patients in order to depict early recurrence.

A-622 08:35

A. Normal findings after radiotherapy

R. Hermans; *Leuven/BE (Robert.Hermans@uzleuven.be)*

After radiotherapy, imaging may be used to monitor tumour response and to detect recurrent or persistent disease before it becomes clinically evident. Early tumour recurrence may be difficult to distinguish from treatment-induced tissue changes. Therefore, the expected imaging changes after radiotherapy of a head and neck cancer should be well known. These tissue changes depend on the radiation dose, the irradiated volume, and the time elapsed since treatment. Reticulation of fat layers, retropharyngeal space oedema, postirradiation sialadenitis, lymphatic tissue atrophy, and thickening of the pharyngeal and laryngeal structures may be seen. These expected tissue changes often appear symmetrical, unless asymmetric radiation portals were used. However, at the site of a bulky tumour, scar tissue may cause an asymmetric appearance also after successful treatment. Therefore, obtaining a baseline CT or MR study after therapy for a neoplasm with a high risk for recurrence is recommended, best 3-6 months post-treatment. By comparing subsequent studies with this baseline study, tumour recurrences or treatment complications can be detected with more confidence. Some recommend PET-CT as the initial baseline study, as this technique has a high negative predictive value; the positive predictive value is lower, as therapy-induced inflammatory changes may cause false-positive results. Tissue necrosis is a rare complication of radiotherapy in the head and neck region, usually appearing late after treatment. Both soft tissue, cartilage and bone necrosis may be encountered; differentiation from tumour recurrence at an early stage may be difficult. Other long-term complications may occur, such as development of a secondary tumour.

Learning Objectives:

1. To get acquainted with changes in tissues during and after radiotherapy.
2. To understand expected changes after radiotherapy in CT and MR imaging.
3. To recognise treatment complications from expected tissue changes after radiotherapy.

A-623 08:58

B. Normal findings after surgery

A. Trojanowska; *Lublin/PL (agnieszka30@yahoo.com)*

Nowadays, the management of head and neck cancer involves multidisciplinary evaluation and treatment, which usually includes surgery, radiation therapy and chemotherapy. The various approaches to surgical resection and tissue reconstruction, the types of neck dissection, different radiation therapy techniques and the addition of concurrent and neoadjuvant chemotherapy regimens may complicate imaging findings. Differentiating post-treatment changes from tumour recurrence with the use of different imaging modalities is challenging because of the presence of altered anatomy secondary to resection, flap reconstructions, oedema, inflammation and the presence of scar tissue. Therefore, it is essential to be familiar with normal findings after surgery and radiotherapy, to distinguish these characteristics from tumour recurrence and treatment-related complications.

Learning Objectives:

1. To get acquainted with most frequent surgical procedures in head and neck.
2. To understand how to evaluate post-surgical patients.
3. To learn how to assess microvascular flaps.

A-624 09:21

C. Treatment monitoring for early detection of recurrence

A.D. King; *Hong Kong/CN (king2015@cuhk.edu.hk)*

Head and neck tumour recurrence occurs in ~ 15-50% (depending on the initial stage at diagnosis) of patients with squamous cell carcinoma treated by chemoradiotherapy. The majority of recurrences occur in-field and are detected either on the post-treatment assessment or within 2-3 years of follow-up. The role of MR and CT imaging is not only to identify early recurrence amenable to curative salvage surgery, but also to avoid unnecessary biopsy or surgery. Reported size criteria for recurrence include ≥ 1cm primary focal mass and ≥1cm nodal short axis, or for nodes < 75%-90% size reduction. However, size criteria have limitations, notably in HPV+ disease which is associated with large sterile post-treatment nodes. Extracapsular tumour spread and persistent necrosis are also inaccurate signs of persistent nodal disease. The main advantages of MRI over CT are the T2-weighted and diffusion-weighted images (DWI). Tumour recurrence has similar signal intensity to the pre-treatment tumour, T2 intermediate signal intensity and restricted diffusion (b-1000 high + ADC map low signal intensity), compared to inflammation (high signal intensity) or mature scar tissue (low signal intensity) on the T2 images and ADC maps. Contrast enhancement tends to be moderate in recurrence and between that of mature scar tissue (mild/absent) and granulation tissue/inflammation (marked), but there is overlap on the conventional T1W post-contrast images. DWI is also complementary to FDG-PET, helping to reduce the FDG-PET false-positive results for recurrence caused by inflammation. False-negative findings arise from microscopic disease such as that found at tumour margins or in pre-treatment occult nodal metastases, and also from small/infiltrating tumours mixed with benign post-treatment change. False-positive findings arise from post-treatment changes, especially granulation tissue/inflammation, sterile component of necrotic node (ADC map low signal intensity) and complications such as radionecrosis, radiation-induced tumours and granulomatous polyps.

Learning Objectives:

1. To get acquainted with problem of recurrence in imaging studies.
2. To understand how to estimate signs of recurrence on CT and MRI.
3. To learn about false positive and false negative findings.

09:44

Panel discussion: What are the challenges in differentiating post-treatment changes from tumour recurrence?

A. Adrenals

L.E. Derchi; *Genoa/IT (derchi@unige.it)*

Adrenal gland abnormalities are unexpectedly identified in 5%-8% of abdominal imaging studies. Most of them are benign and source of little or no concern; others are potentially fatal. Clinical and imaging criteria make differentiation between benign and malignant lesions possible in most cases. When there is no history of malignancy, adrenal lesions are almost always non-malignant (usually an adenoma). On the contrary, in patients with a history of malignancy, up to 50% are malignant and mostly metastatic. Imaging criteria based on macroscopic appearance of these lesions can easily identify those containing mature fat (myelolipomas), the hyperdense haematomas and the fluid-filled cysts. However, when lesions have non-specific appearance, it is necessary to analyse their structure with lipid-sensitive techniques (density measurement on unenhanced CT; chemical shift evaluation at MR), using perfusion/washout imaging after contrast injection, or with metabolic imaging during PET and CT/PET studies. This presentation will discuss how to behave when an unexpected adrenal lesion is encountered and how to perform its diagnostic workup.

Learning Objectives:

1. To understand the definition of incidental findings in adrenal pathology.
2. To learn about the imaging characteristics of common adrenal incidental masses.
3. To become familiar with the algorithm approach and evidence-based recommendations for management of adrenal incidentalomas.

A-626 09:00

B. Kidneys

H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

Cystic and small solid renal masses are frequently detected as incidental renal lesions with increasing incidence in the elderly population. Therefore, renal cell carcinomas are also increasingly detected as incidental findings on imaging. Nephron-sparing surgery has been the method of choice for the treatment of small solid renal masses. However, a large percentage of these solid renal lesions are benign and most of the incidentally detected malignant renal tumours such as renal cell carcinomas (RCCs) are smaller, with lower stage and are less aggressive than symptomatic RCCs. In addition, a correlation with size of the solid lesion and growth rate has been described ranging from 0.13-0.31 cm per year. Therefore, active surveillance is now a more frequently applied approach to deal with these incidentally detected small solid renal lesions (<3-4cm). Whereas in solid enhancing lesions < 1cm in diameter, active surveillance is the treatment of choice at any age, in larger lesions, management mainly depends on clinical factors including the age and the performance state of the patient. The role of the radiologist is to exclude benign lesions such as Bosniak I and II cysts and angiomyolipomas as well as non-neoplastic conditions mimicking a tumour (infection, infarct, vascular anomalies and aneurysms). In patients with small solid renal lesions stratified

for active surveillance, close follow-up with note of the growth rate has to be performed in order not to miss the time point of delayed treatment in case of a fast growth rate or clinical progression.
Learning Objectives:
1. To understand the definition of incidental findings in renal pathology.
2. To learn about the imaging characteristics of common renal incidental masses, namely cystic.
3. To become familiar with the algorithm approach and evidence-based recommendations for management
of renal incidentalomas.
Author Disclosure:
H.C. Thoeny: Advisory Board; Guerbet SA.

A-627 09:30

C. Adnexa
C.S. Balleyguier; *Villejuif/FR (Corinne.BALLEYGUIER@gustaveroussy.fr)*

Incidental adnexal lesions are non symptomatic lesions diagnosed on ultrasound, CT or MRI performed for an unrelated reason. They have increased in frequency with increased use of crosssectional imaging. The majority are benign, even in patients with known malignancy or postmenopausal women. However it is important to reliably differentiate malignant from benign lesions to avoid delays in treating ovarian cancer and prevent unnecessary interventions in benign lesions. To try to characterise these findings, age, menopausal status, previous medical and family history and tumour marker such as CA 125 have to be known. Further management will depend on whether the lesion is clearly benign or malignant, or indeterminate. Specific diagnoses have to be suggested in case of fatty content (teratoma, lipoid cell tumour, etc), calcified content (ovarian leiomyoma, teratoma, brenner struma, etc), and in extra-gynecological origin (lipoleiomyoma, pelvic teratoma, liposarcoma, etc). Diagnostic algorithms in cystic and solid incidentaloma will be presented in this session, including differential diagnoses. A specific focus will be made on diagnostic strategy in post menopausal cystic ovarian lesions. Treatment strategy wil also been described.
Learning Objectives:
1. To understand the definition of incidental findings in adnexal pathology.
2. To learn about the imaging characteristics of common adnexal incidental masses.
3. To become familiar with the algorithm approach and evidence-based recommendations for management of adnexal incidentalomas.

08:30 - 10:00 **Room L 8**

E³ - Rising Stars Programme: EFRS Radiographers' Basic Session

BR 2
Radiation protection from A to Z

A-628 08:30

Chairperson's introduction: The radiographers' role in radiation protection
D. Catania; *Milan/IT (cataniadiego@hotmail.com)*

This EuroSafe Imaging session will incorporate four important aspects of radiation protection for consideration by the audience. The session will be opened by an update on radiographers' responsibilities with regard to the EU Basic Safety Standards Directive. This is critically important information that all professionals with radiation safety responsibilities in clinical practice should be aware of. The session will progress to include discussion of justification for radiographic examinations, which is an important aspect of all radiographers' daily work practice. As the technology used by radiographers advances, so must our knowledge of how to best use the technology. It is essential that radiographers remain up to date with respect to optimisation techniques in radiography practice. The third presentation in this session will provide the audience with important updates. The focus will be on conventional radiography which remains a core activity in all radiology departments. The final presentation will discuss the radiographers' role in benefit-risk communication. Once more, this professional matter is of high importance to all radiography professionals. The variety of core radiography matters, as included in this EuroSafe session, offers updates to our continuing professional development and are aimed at supporting our professional practice.
Session Objectives:
1. To understand radiographers' current legal responsibilities regarding radiation protection.
2. To consider the role radiographers play in application of the justification principle.
3. To review recent optimisation techniques for projection radiography.
4. To appreciate how radiographers can best communicate risk-benefit information to patients.
Author Disclosure:
D. Catania: Board Member; EFRS, European Federation of Radiographer Societies. Founder; AITRI, Italian Association of Interventional Radiographers.

A-629 08:35

The Basic Safety Standards Directive: all you need to know
S.J. Foley; *Dublin/IE (shane.foley@ucd.ie)*

The European Commission issued its most recent radiation protection Directive in December 2013 which will repeal five other Directives (including 97/43/Euratom) and must be transposed by all Member States of the EU by February 2018. Therefore, this presentation is timely in coinciding with the European-wide adoption of the new Directive, which takes into account new recommendations from the ICRP in light of new scientific evidence and is hoped to strengthen the culture of radiation safety throughout Europe. While the Directive remains faithful to and maintains the already well-accepted pillars of radiation protection - justification, optimization and dose limitation - these are further strengthened in this Directive. Further new requirements under the Directive will also be discussed, including obligations related to recording dose information and communicating benefit/risk to patients. Additional responsibilities have also been designated to a number of professionals which will impact the work of both radiographers and radiologists alike; so, all imaging staff need to be aware of its implications. This will ensure that the true ethos of the Directive will be effectively implemented into routine clinical practice.
Learning Objectives:
1. To familiarise attendees with the European BSS Directive (2013/59).
2. To discuss the additional responsibilities of radiographers and radiologists under the Directive.
3. To consider how the BSS Directive can improve the culture of radiation safety in clinical practice.

A-630 08:53

The importance of justification
D. Katsifarakis; *Athens/GR (dikatsifarakis@gmail.com)*

Justification derives from the safety culture. It is a crucial procedure in diagnostic radiology, considered as one of the of the cornerstones of radiation protection. We currently carry out practices of justification appropriate to an era of examinations with minimal radiation dose. The majority of radiological examinations are performed by radiographers. They greet the patient and receive the medical referral simultaneously. Hence, radiographers can easily detect an inappropriate examination, particularly those arising from systems' inconsistencies. Also, according to their education-professional culture and expertise, they can recognize whether the prescribed examination will satisfy the diagnostic requirements. Radiographers bear the responsibility of delivering doses of ionizing radiation to patients and during research applications. Therefore, they must have the authority to exercise their judgement in accepting a referral for medical exposure. This must include an adjusting technique to minimize the exposure to patients, staff and the public whilst optimizing a diagnostic or therapeutic outcome. Radiographers must engage in effective gatekeeping and clinical audits by: reinforcing knowledge and communication skills to facilitate the 3As of justification (awareness, appropriateness, audit), complying with referral guidelines and employing clinical decision support systems. The ISRRT promotes the scope of practice of a team approach to authorization and justification as safe and best practice for diagnostic imaging services.
Learning Objectives:
1. To appreciate the key role of justification within radiation protection.
2. To be familiar with the role radiographers can play in justification.
3. To consider initiatives for improving adherence to the principle of justification.

A-631 09:11

The latest optimisation techniques in conventional radiography
P.H. Hogg; *Salford/UK (P.Hogg@salford.ac.uk)*

In the clinical routine, demand for medical imaging continues to grow and conventional radiography, comprising DR and CR technologies, enjoys significant utility. Given the moral and legal requirements to minimise radiation dose to patients, optimisation techniques must be used. Methodologically speaking, these techniques must evolve constantly because of technological and philosophical advances. Overall, optimisation seeks to reduce dose without compromising pathology detection/characterisation. Optimisation techniques need robust estimates of patient dose and pathology detection/characterisation performance to determine which interventions are

fruitful. With relevance to conventional radiography, this review will address important philosophical and practical optimisation issues. One philosophical issue will consider the merits and limitations of pathology detection/characterisation in contrast to assessing image quality; it is worth remembering that the latter is often used as a 'proxy' for the former. Following on from this, a critical review of visual and physical image quality measures will be presented. Consideration will also be given to different measures of radiation dose, from 'simple to make', but relatively unhelpful in optimisation (e.g. DAP), to 'complex to make', but potentially more helpful (e.g. effective risk and effective dose). A proposal will be offered on why dose reference levels are of limited value in the absence of pathology detection/characterisation or even image quality data. Finally, I will offer some practical suggestions on what steps might be taken to reduce dose in the clinical setting while maintaining image quality levels fit for pathology detection/characterisation.

Learning Objectives:

1. To discuss the limitations of image quality as a parameter for use in optimising dose in medical imaging examinations.
2. To discuss a range of visual and physical techniques that can be used to assess medical image quality.
3. To discuss a range of practical measures which might be implemented to minimise radiation dose whilst maintaining a level of image quality that is fit for purpose.

A-632 09:29

The radiographers' role in benefit-risk communication

J. Portelli; *Msida/MT (jonathan.portelli@um.edu.mt)*

By February 2018, each EU Member State is required to transpose Council Directive 2013/59/EURATOM into national legislation, thereby laying down revised basic safety standards for the protection against dangers arising from exposure to ionising radiation. Amongst the changes noted in these revised regulations, apart from the responsibilities relating to the justification and optimisation of each medical radiation exposure, referrers and/or practitioners will now be legally obliged to provide each patient with adequate information relating to the benefits and risks associated with the radiation dose to be received from a proposed medical imaging procedure. While many referrers and practitioners may already be fulfilling this 'new' responsibility in their daily practice, the decision to have such a responsibility well defined within the regulations can be interpreted as a way to oblige more health professionals to realise their duty in delivering patient-centred care and to duly respect each patient's right to information. In this regard, this lecture will seek to highlight the importance of radiographers having a sound understanding of radiation-related concepts, particularly those relating to the benefits and risks of medical imaging procedures they perform. Furthermore, the need for radiographers to develop and have effective communication skills will also be highlighted, since these are necessary to allow them to convey adequate benefit-risk information in accordance to the needs and preferences of different patient groups and their families, as well as to other health professionals that may be involved in the patient's care.

Learning Objectives:

1. To understand new legislative requirements under the BSS Directive.
2. To be aware of the key role radiographers play in benefit-risk communication.
3. To understand key principles for appropriate benefit-risk communication.

09:47

Panel discussion: Teamwork in radiation protection

08:30 - 10:00 **Room E1**

Breast

RC 1302

Rethinking ductal carcinoma in situ (DCIS)

Moderator:
C. Van Ongeval; Leuven/BE

A-633 08:30

A. New radiologic-pathologic knowledge on DCIS

A. Frigerio; *Turin/IT (alfonso.frigerio@gmail.com)*

A modern rethinking of ductal carcinoma in situ must take off from the awareness of the utter inadequacy of the terminology currently in use. Already in 1976, Jensen, Rice and Wellings remarked that "ductal carcinoma in situ of the human breast is of lobular (acinar) origin". While the latest (2012) WHO Classification decided to omit the name 'ductal' from the definition of the most common type of invasive breast carcinoma, it still fails to recognize the inconsistency of this descriptor for its intra-epithelial counterpart. It is time to move to a new inter-disciplinary approach where a mutually respectful interaction between radiologists and pathologists should take full advantage of new imaging techniques and new pathologic methods to achieve better characterization of the different types of breast lesions and their clinico-biological potential. A new classification and terminology based on the site of tumour origin (acinar vs ductal), as best displayed by diagnostic imaging paired with modern pathologic techniques as large-format histologic sections, should open the way to a better understanding of the lesion biology, eventually improving treatment planning decisions. This lecture will include a discussion of: different subtypes of in situ lesions; neoductgenesis as an important feature that should be recognized and reported; the potential of mammographic tumour features as synergistic prognostic factors alongside classical pathological and modern molecular patterns. Overcoming long-lasting barriers to effective communication would be the prerequisite to a new professional setting where all specialists involved mutually enhance the benefits of their clinical knowledge.

Learning Objectives:

1. To learn about different types of DCIS.
2. To become familiar with risk of developing cancer.
3. To appreciate radiologic-pathologic correlations.

A-634 09:00

B. Diagnosing DCIS

S. Schrading; *Aachen/DE (sschrading@ukaachen.de)*

The presentation gives an overview over the current role and recent data of dynamic contrast-enhanced (DCE) breast MRI for diagnosis ductal carcinoma in situ (DCIS). Special attention is paid on the description and illustration of typical imaging features as well as pitfalls and difficult differential diagnosis of DCIS at MRI. In addition, the impact of DCE MRI on DCIS treatment and recent discussion on overdiagnosis and overtreatment of DCIS are discussed.

Learning Objectives:

1. To understand the evidence on MRI for evaluating DCIS.
2. To become familiar with different imaging appearances of DCIS.
3. To appreciate the value added of MRI for diagnosis.

A-635 09:30

C. Reducing overtreatment of DCIS

M.G. Wallis; *Cambridge/UK (matthew.wallis@addenbrookes.nhs.uk)*

Breast screening has led to an inexorable rise in the number of women living with a diagnosis of DCIS predominantly but not exclusively as a result of the detection of microcalcification. It is clear from long-term follow-up that conventional treatment fails the 15 to 20% who develop invasive disease, a few of whom then die from breast cancer. There is a larger group that never progresses within their life time which means we have either cured them or overtreated them. Traditional pathology and genetics suggest that there is a low-risk group that either never progress or if they do develop 'low-risk' invasive disease. I will describe the three international randomised controlled trials: LORIS (The LOw RISk DCIS trial), LORD (LOw Risk DCIS), COMET (Comparison of Operative versus Medical Endocrine Therapy for Low Risk DCIS) and LORETTA a single-arm confirmatory study of endocrine treatment only. I will describe PRECISION that aims to identify markers for progression from retrospective data sets and then prospectively validated these on the three randomised trials. Using LORIS, I will discuss how we have attempted to resolve the hurdles of setting up a 'no treatment trial' and talk about some of the lessons learnt from successfully steering LORIS from feasibility to full trial. Anecdotally, patient views have been more entrenched than those of surgeons and to my surprise the radiology second opinion service set up to reduce the risks of 'active monitoring' up by annual VAB has not been overwhelmed.

Learning Objectives:

1. To learn about the risk of overdiagnosis and overtreatment.
2. To become familiar with the risk of avoiding surgery.
3. To appreciate the level of evidence required to change future practice.

08:30 - 10:00 **Room E2**

Neuro

RC 1311
Altered mental state

A-636 08:30
Chairperson's introduction
M.A. van Buchem; *Leiden/NL*

Session Objectives:
1. To learn about the complex spectrum disease entities presenting with cognitive decline.
2. To understand the role of standardised imaging and reporting in the context of diagnosis and monitoring of patients with neurocognitive disorders.
3. To appreciate importance of multimodal imaging approaches in the diagnosis of neurocognitive disorders.

A-637 08:35
A. Patterns of referrals
N.N.

Learning Objectives:
1. To learn about the broad spectrum of clinical presentation of cognitive decline.
2. To understand the role of imaging in the context of the clinical presentation and other biomarkers (e.g. CSF) in the diagnosis of cognitive impairment.
3. To appreciate the heterogeneity of primary and secondary pathologies presenting to the memory clinic.

A-638 08:58
B. Imaging in altered mental state
A.J. Bastos-Leite; *Porto/PT (ajbastosleite@gmail.com)*

The most common causes of altered mental state (AMS) encompass neurological and psychiatric conditions, as well as pharmacological, toxic, infectious, metabolic, or even traumatic disorders. Neuroimaging became a very relevant tool for the diagnosis of AMS, especially for the diagnosis of dementia (major neurocognitive disorder), a clinical syndrome, rather than a single nosological entity, characterised by deficits in one or more cognitive domains, and the most serious consequence of pathological brain ageing. Over the past decades, the role of neuroimaging has revolutionised the diagnosis of neurocognitive disorders by positively predicting the diagnosis rather than just excluding disorders that may mimic dementia. This change has been possible both by visually assessing the extent, pattern and severity of brain volume loss and cerebrovascular pathology, as well as by increasingly using computer-aided techniques, potentially advantageous at the very early stages of pathology progression. Functional neuroimaging techniques, such as arterial spin labelling, represent added value in this setting as well. In addition, cerebrospinal fluid biomarkers (Beta-amyloid- and tau-mediated injury markers) also support the clinical diagnosis of Alzheimer's disease. The challenge, however, persists in other mental conditions, such as psychiatric disorders. A key example here is schizophrenia, in which there are subtle—microscopic—abnormalities involving functional brain networks. This precludes the diagnosis by means of visual inspection, and currently limits the usefulness of neuroimaging. Nevertheless, novel techniques and methods for the assessment of effective (i.e., directed) brain connectivity seem to provide a very promising lead.
Learning Objectives:
1. To learn about the role of imaging in the diagnosis of neurocognitive diseases: from the exclusionary approach to the inclusionary approach.
2. To understand the challenges to diagnose neurocognitive disease in a very early stage using imaging.
3. To appreciate the complexity of differential diagnosis of neuroimaging in cognitively affected individuals and the crucial need for other biomarkers to support the clinical diagnosis.

A-639 09:21
C. MRI in the diagnosis of Alzheimer's disease
A. Krainik; *Grenoble/FR (akrainik@chu-grenoble.fr)*

As the most common cause of neurodegenerative dementia, Alzheimer's disease (AD) is a diagnosis and therapeutic challenge. In clinical practice, diagnosis remains probabilistic without pathological proofs, relying on clinical and neuropsychological examinations, CSF biomarkers, and brain imaging. Multidisciplinary collaborations and recent technical advances deliver now more accurate and relevant information, to better diagnose AD. Indeed, imaging data provide evidence to step forward and to refine AD diagnosis, based on homogeneous imaging subgroups of patients, despite similar clinical and biological profiles. Additionally, advanced MR techniques investigate new tools to demonstrate supplementary abnormalities, that could be used in clinical practice and suggest new paths for therapeutic research. Imaging of dementia is now far from ruling out neurosurgical aetiologies, only. Clear and reproducible cerebral images allow quantitate assessment to estimate severity, to discuss differential diagnoses, and to monitor evolution. We, radiologists, have to carefully analyse our images to provide the most probable diagnosis and to maximise the value of our work. The present lecture gives you tips and tricks for your daily practice.
Learning Objectives:
1. To learn about the imaging features and possible comorbidities of Alzheimer's dementia.
2. To understand the complexity of differential diagnosis.
3. To appreciate the crucial and so far unmet medical need to use quantitative MRI techniques in the diagnosis of Alzheimer's disease.

09:44
Panel discussion: Ask the expert: How can I standardise my image reading and reporting in order to support the clinical process in cognitively impaired patients?

08:30 - 10:00 **Room F1**

E³ - European Diploma Prep Session

E³ 1323
Cardiac and vascular

A-640 08:30
Chairperson's introduction
R. Vliegenthart; *Groningen/NL (r.vliegenthart@umcg.nl)*

This European Diploma Prep session covers essential knowledge regarding radiological techniques in cardiovascular imaging, cardiovascular anatomy and highlights of cardiovascular pathology. Radiologists have an increasingly important role in the evaluation of cardiac and vascular diseases, due to the fact that CT/MRI can provide a diagnosis in a non-invasive, more detailed, more reproducible and/or more tissue-specific way than other modalities. In this session, a general basis is provided regarding the technique of cardiovascular imaging with CT and MRI, anatomical depiction in CT/MRI, and the main disorders of the myocardium, pericardium, valves and aorta.
Session Objectives:
1. To understand the basic principles and techniques of cardiovascular imaging including CT and MRI of the heart and great vessels.
2. To become familiar with the imaging presentations of disorders of the endocardium, the pericardium and the cardiac valves.
3. To understand the MR imaging presentation of disorders of the myocardium.

A-641 08:36
A. Cardiovascular imaging: the basics
M. Gutberlet; *Leipzig/DE*

"no abstract submitted"
Learning Objectives:
1. To understand the anatomy, normal variants and abnormalities of the heart and great vessels.
2. To describe the technical aspects and methodology of cardiac and vascular CT.
3. To describe the technical aspects and methodology of cardiac and vascular MRI.

A-642 09:04
B. Cardiovascular imaging: valves, endocardium and aorta
C. Loewe; *Vienna/AT (christian.loewe@meduniwien.ac.at)*

The new possibilities provided by means of non-invasive cardiac imaging moved the heart back into the interest of radiology, and radiologists play an increasing role even in the management of patients suffering from non-coronary cardiac diseases. Despite the outstanding role of echocardiography in the diagnosis and follow-up of valvular diseases in clinical routine, cardiac MR plays an important and CT an increasing role in the management of patients suffering from valvular diseases. The most common and most important valvular diseases including aortic regurgitation and stenosis will be introduced.

The role of imaging for diagnosis, treatment decision-making and treatment planning will be discussed as well. After valvular repair, CT evolved as the method of choice to assess possible infectious complications providing exact information about local and systemic manifestations of endocarditis. The importance of early diagnosis and treatment of endocarditis will be clarified and the value of modern imaging will be underlined. In the third part of the presentation insight into the role of CT angiography in the diagnosis and management of acute and chronic aortic diseases will be provided, focusing on aortic dissection and aneurysm. Within this presentation, a short overview about the most important diseases of valves, endocardium and aorta will be provided while defining the most important questions to be answered by imaging. Based on this, current and possible future role of CT and MR in these fields will be explained and basic tips for optimised imaging will be provided.

Learning Objectives:

1. To recognise the imaging presentation of the different forms of valvular disease.
2. To understand the causes and imaging presentations of endocarditis.
3. To describe the diagnostic evaluation and imaging presentation of common diseases of the great vessels, including aortic dissection and aneurysms.

Author Disclosure:

C. Loewe: Speaker; GE Healthcare, Bracco, Siemens.

A-643 09:32

C. Cardiovascular imaging: myocardium and pericardium

J. Bogaert; *Leuven/BE (Jan.Bogaert@uz.kuleuven.ac.be)*

Cardiovascular magnetic resonance (CMR) provides substantial, often unique, information in the evaluation of myocardial and pericardial diseases. This talk summarizes how CMR can be used to comprehensively study the pericardium and myocardium including tissue characterization, deep phenotyping, assessment of myocardial strain, and ventricular function, as well as the interaction between the pathologic pericardium and the remainder of the heart. The aim is to make the audience familiar with current use of CMR in daily clinical practice to assess this group of cardiac patients.

Learning Objectives:

1. To describe the diagnostic evaluation and imaging presentation of ischaemic heart disease.
2. To understand the diagnostic evaluation and imaging presentation of myocarditis.
3. To become familiar with the causes and imaging presentations of pericardial effusion.

08:30 - 10:00 **Room F2**

Emergency Imaging

RC 1317
Imaging of 'foreign bodies'

A-644 08:30

Chairperson's introduction

M. Pezzullo; *Brussels/BE (martina.pezzullo@erasme.ulb.ac.be)*

The presentation starts with an introduction of myself. Foreign bodies could be introduced in human body cavities voluntarily or accidentally. All the medical devices usually belong to the first category and to be familiar with their names, use and radiolgraphic appearance is mandatory to recognise proper positioning and prevent displacement or migration. Accidental introduction of foreign bodies usually happens due to ingestion of food particles or small objects, especially in early childhood or in mentally impaired subjects. These objects can cause gastrointestinal tract complications due to impact or perforation, and a high level of suspicion is required to look for subtle signs as the presence of a foreign body is often unexpected.

Session Objectives:

1. To be familiar with names and image characteristics of commonly used surgical, and orthopaedic devices and materials.
2. To learn their proper positioning and early signs of postoperative complications.
3. To understand the imaging pathway in management of ingested foreign bodies.

A-645 08:35

A. Surgical and orthopaedic devices: are they really properly positioned?

E. Dick; *London/UK (elizabeth.dick@imperial.nhs.uk)*

This session will address the common surgical and orthopaedic devices that we encounter in everyday radiology practice. What do the clinicians consider to be optimal placement of each device? How can we assess if positioning is suboptimal? What kind of language should we use to describe devices? It will cover: (1) Lines and tubes: how to evaluate whether endotracheal tube and chest and abdominal drains are correctly placed, including: assessing the position of ETT beyond the vocal cords and satisfactory inflation of the ETT balloon. (2) Surgicel (surgical packing used in damage control surgery): how to evaluate the post-operative trauma abdomen even with Surgicel in place. (3) Neurosurgical devices: cervical and thoraco-lumbar spinal fixation: principles of stabilisation, how to evaluate whether correctly positioned, what language to use, complications including epidural haematoma and collections. (4) Orthopaedic devices: rib and pelvic fixation devices: how to assess the stability and considerations of neurovascular compromise.

Learning Objectives:

1. To become familiar with different types of commonly used surgical, neurosurgical and orthopaedic devices in clinical practice.
2. To understand how to evaluate their proper positioning.
3. To be familiar with imaging signs of incorrect implementation of neurosurgical and orthopaedic devices.

A-646 09:00

B. Foreign bodies in the gastrointestinal tract: the role of radiographs, US and CT

J.B.C.M. Puylaert; *The Hague/NL (dr.jbcmpuylaert@wxs.nl)*

Did I swallow that?!: US and CT of sharp foreign bodies penetrating stomach and bowel. Accidental ingestion of sharp foreign bodies is a potentially life-threatening event with a reported mortality of 18%. If a sharp foreign body gets stuck in the oesophagus, the patient usually will notice its presence and seek medical help rapidly. However, when it reaches the stomach or bowel and penetrates the wall there, the ensuing symptoms are atypical and treacherous and serious delay may ensue. Perforating foreign bodies in the stomach and bowel are increasingly recognised by the use of US and spiral CT with multiplanar reconstructions and may be of great help in guiding minimal invasive treatment. The most frequently encountered penetrating sharp foreign bodies are chicken bones, fish bones and wooden sticks such as toothpicks. Most patients do not recall having swallowed such an object. Some patients wear denture plates rendering their palatum insensitive and the phenomenon is reported to be more frequent in mentally retarded patients. However, the majority of our patients were otherwise healthy. Over two-thirds have a history of a previous operation with kinking of bowel loops caused by adhesions, which locally inhibit the foreign body to “take the corner”. Once a sharp object penetrates the wall of the stomach or bowel, the omentum and mesentery will try to wall-off the ensuing perforation. Often an abscess develops in the peritoneal cavity, in the liver or in the abdominal wall. Eventually, significant migration of the object may be the result. If the sharp foreign body is beyond reach of the endoscope, patients usually undergo laparotomy for removal of the foreign body and drainage of the abscess. This presentation will emphasise the role of US and CT in the diagnosis and in the minimal invasive treatment of these sharp foreign bodies.

Learning Objectives:

1. To be familiar with characteristics of commonly ingested abdominal foreign bodies.
2. To understand which imaging modalities are best suited for detection of foreign bodies in different clinical scenarios.
3. To recognise the first signs of early complications resulting from ingested abdominal foreign bodies.

A-647 09:25

C. Body packing: what to know about imaging and when should we suspect early complications?

M.K. Scherr; *Munich/DE (michael.scherr@bgu-murnau.de)*

Body packers, pushers and stuffers incorporate a variable amount of packs containing illicit drugs such as heroin and cocaine by ingestion or insertion vaginally or rectally. Every pack usually contains a lethal dose of narcotic. Due to increased luggage controls and body checks at customs and airports, this practice has a steady increase. Radiologists and emergency departments get confronted with body packers in two different ways. There is the forensic indication when suspects are presented by the authorities or the more familiar medical indication in cases of bowel obstruction or mainly severe intoxication. In both scenarios, the radiologist should know the legal issues and be prepared to perform the adequate examination and proper image interpretation to detect the body packs with a high degree of certainty. Already occurred or potential

complications like complete obstruction, package rupture or leakage have to be clinically and radiologically perceived. The diagnostic limitation of applied conventional x-ray is already known and increasingly replaced by (dose-reduced) computer tomography with its very high sensitivity. In some cases, already the CT scout view gives the clue. It is crucial to know about the CT presentation of packages depending on the manufacturing process and ingredients, where liquid packs become a diagnostic challenge. Attempts have been made to analyse body pack drug content by CT density or dual-energy appearance for further treatment planning. The treatment options are conservative under surveillance, laparotomy and intensive care with or without targeted antidote administration.

Learning Objectives:

1. To be familiar with the phenomenon of drug smuggling by body packing and its medical/legal issues.
2. To learn about imaging modalities and their limitations in case of body packing and variants.
3. To recognise potential or manifested complications in body packing.

09:50

Panel discussion: Common language with clinicians: how to report 'foreign bodies' presence

08:30 - 10:00 **Room D**

Special Focus Session

SF 13b

Paediatric MRI: can we make gadolinium superfluous?

A-648 08:30

Chairperson's introduction

M. Alison; *Paris/FR*

Session Objectives:

1. To learn about the risk of gadolinium injection in paediatric patient.
2. To learn about the alternative sequences to study vessels or perfusion.
3. To appreciate the indication of intravenous gadolinium in common paediatric diseases.

A-649 08:35

Safety issues of intravenous gadolinium in children

F.E. Avni; *Lille/FR (favni@skynet.be)*

A latest report (2017) estimates the adverse drug reaction (AdR) rate between 0.05 and 0.5%. AdR tends to be more frequent with linear GBCA. AdR is mostly mild to moderate and includes nausea, vomiting and urticaria. At approved doses, there is no evidence of renal toxicity even in neonates. 23 cases of nephrogenic systemic fibrosis (NSF) have been reported up to 2012 in children. All (most) cases were related to linear GBCA. No case has been reported in recent years. In the last 3 years, several studies have reported evidence of gadolinium deposits after repeated injections in various tissues, especially in the brain and bones. Most cases are related to the injection of linear GBCA. The rate of AdR and tissue deposits seems influenced by the thermodynamic and kinetics stability of GBCA. This rate is further influenced by pre-existing renal impairment or immaturity. All these data have generated a precautionary approach: (1) The necessity of injection should be evaluated case by case. (2) Exceeding the doses advised or repeating examinations with injections should be avoided, especially in patients with renal impairment. (3) Injecting GBCA in neonates or patients with significant renal impairement should be avoided. (4) Many hospitals should shift from linear to macrocyclic GBCA. (5) The EMA recommends withdrawing the acceptance of linear GBCA. Still, the need to test renal function previous to GBCA injection is presently not confirmed. (6) It is recommended to keep a record of cumulative contrast dose. (7) In general, it is advised to follow adults' recommendations.

Learning Objectives:

1. To learn about the existing literature on potential side effects of intravenous contrast in children.
2. To understand how underlying conditions may influence the risk for side effects.
3. To discuss the implications of the new knowledge for clinical practice in paediatric radiology.

A-650 08:53

The role of intravenous gadolinium in paediatric oncology

P.D. Humphries; *London/UK (humphriespaul@gmail.com)*

Imaging plays a central role in the diagnostic pathway for children with cancer, being used to investigate clinically apparent lesions, screen children with cancer predisposition syndromes, stage known cancers and monitor treatment response. Magnetic resonance imaging has become a mainstay in the imaging of children with cancer, not only for CNS malignancies, but also for body tumours, owing to a move away from anatomical imaging using ionizing radiation. Intravenous MR contrast agent administration is frequently used as part of MR imaging protocols in paediatric oncology. With respect to body tumour imaging, there is a paucity of literature or systematic investigation of the diagnostic benefit of this, with practice being driven largely by expert opinion. Lesion characterization, anatomical boundary definition and relationships to vascular structures may all benefit from contrast administration, and dynamic-enhanced MR may be used to assess the effects of anti-angiogenic agents. Increasing utility of high-resolution unenhanced MR sequences and diffusion-weighted imaging enable MR protocols to be optimized such that IV contrast administration can be reduced. Additionally, other imaging modalities such as CE-US now provide a broader repertoire of imaging modalities to assess the vascular enhancement characteristics of lesions.

Learning Objectives:

1. To learn about the existing literature on the usefulness of intravenous MRI contrast in paediatric oncology.
2. To understand how protocols can be optimised to avoid the use of intravenous gadolinium in the diagnosis and follow-up of children with cancer.
3. To discuss how non-enhanced MRI sequences could replace gadolinium-enhanced sequences.

Assessment of musculoskeletal disorders: when is intravenous gadolinium necessary?

M. Maas; *Amsterdam/NL (m.maas@amc.nl)*

Intravenous use of gadolinium in MSK is mostly seen in the diagnosis of oncology, infection and inflammation. It aids in detecting and characterising pathology, enhances depicting subtle areas of residual disease, and might make a contribution in assessing the response to therapy. Also, dynamic biomarkers might be beneficial and can be added to protocols. For some pathologies, gadolinium is described to be essential to delineate the diseased tissue (i.e. the synovial membrane in juvenile idiopathic arthritis); however for other diseases, this need might not be so prudent. Indications will be discussed during the lecture and will be illustrated with MR images. Novel techniques that might replace intravenous gadolinium-enhanced sequences should at least be equal in defining the presence or absence of pathology. In this lecture, special focus will be given to DWI as a non-contrast alternative: what is the rationale behind using DWI? What are the possible applications of imaging the synovial membrane using DWI? can DWI be used in bone tumour assessment? Literature regarding non-contrast MRI of synovitis, including DWI and inversion recovery techniques, will be addressed and images of our experience as well as images of other authors in the field will be shared.

Learning Objectives:

1. To discuss what are the indications of gadolinium injection in musculoskeletal disorders.
2. To understand how novel techniques may replace intravenous gadolinium-enhanced sequences for some indication (i.e. depiction of synovitis or ischaemia).
3. To discuss current knowledge and future potential of non-enhanced MRI techniques in detecting and grading of synovitis.

A-652 09:29

Brain imaging: when is intravenous gadolinium necessary?

K. Karli Oguz; *Ankara/TR (karlioguz@yahoo.com)*

Since their first availability for clinical use, Gd-based MR contrast agents have been widely applied in neuroimaging. Apart from nephrogenic systemic fibrosis, there has been an increasing concern about Gd retention in the brain and its possible, yet unravelled, clinical effects among the physicians, patients and parents. Since we have an obligation not to harm paediatric patients, we have to review our contrast material usage policy carefully, present our indications strictly and fully take over the responsibility. By doing so, we should consider using techniques that do not necessitate administration of contrast material (such as arterial spin labelling-ASL instead of T2*EPI perfusion studies, non-contrast-enhanced angiography techniques) or supplementing

routine non-enhanced MRI sequences with other techniques to get more information on focal lesions such as diffusion-weighted imaging, ASL, SWI and MR spectroscopy . Cutting-edge imaging techniques including chemical exchange saturation transfer glucose imaging and magnetic particle imaging that do not need Gd injection will also be mentioned very briefly in this session. The indications such as infections, tumours and vascular diseases will be reviewed and contrast material use, especially on demyelinating and degenerative diseases, will be discussed.

Learning Objectives:

1. To learn about the indications of intravenous gadolinium for brain imaging.
2. To understand the role of non-enhanced sequences for brain vascular imaging.
3. To understand the role of non-enhanced sequences for brain perfusion imaging.

09:47

Panel discussion: How can we reduce our use of intravenous gadolinium in children?

08:30 - 10:00 **Room G**

Physics in Medical Imaging

RC 1313

Motion artefacts and their management in medical imaging

A-653 08:30

Chairperson's introduction

T. Beyer; *Vienna/AT*

Session Objectives:

1. To learn about the origins of motion management in medical imaging.
2. To understand motion-related artefacts in medical imaging.
3. To learn about solutions and work-arounds.

A-654 08:35

A. Managing motion in CT: conventional approaches and motion compensating techniques

M. Kachelrieß; *Heidelberg/DE (marc.kachelriess@dkfz.de)*

Diagnostic CT provides highly quantitative images with very high spatial resolution (0.3 mm isotropic) for complete anatomical areas in scan times as short as about 1 s. CT further routinely achieves an unprecedented temporal resolution of 63 ms, which is one-quarter of the rotation time, for complete anatomical regions. In many cases, this is sufficient to freeze patient motion. For quickly moving organs, even 63 ms may introduce motion blurring. Given the spatial resolution of 0.3 mm, objects moving at a speed of about 4 mm/s or faster will introduce blurring. Velocities of up to 70 mm/s occur in the heart. Typical methods to manage cardiac motion are prospectively or retrospectively gated single breath-hold scans. Recently, new algorithms that have the ability to compensate for the motion during image reconstruction are being developed: they have the potential to significantly increase the temporal resolution or to improve the dose usage. For lung imaging, the intrinsic temporal resolution of CT is sufficient. However, when 4D images are required, as it is the case for radiation therapy planning, the problem arises of how to generate moving images with a CT that freezes motion. The solution is to use respiratory gated scans with a very low pitch value. These methods, however, suffer from artefacts and high patient dose. Although dedicated motion compensation techniques for 4D CT could remove the artefacts and decrease the dose, the manufacturers provide no implementations. The lecture discusses the methods in use and those that are currently being developed.

Learning Objectives:

1. To learn about conventional techniques for motion compensation in CT.
2. To learn about new methods for motion compensation in CT.
3. To contrast the available and up-and-coming motion compensation methods in CT.

A-655 08:58

B. Managing motion in cone-beam CT (CBCT): conventional approaches and motion compensating techniques

P. Paysan; *Baden–Dättwil/CH (Pascal.Paysan@varian.com)*

Motion management and motion-induced image artefacts in cone-beam CT (CBCT) imaging differ from CT due to inherent technical limitations of CBCT systems. While CT vendors have the possibility of increasing rotation speed to acquire complete slices within one motion state (e.g. breathing phase), the rotation speed is limited on CBCT systems. The major limiting factors are the readout frequency of a flat panel detector and the design-dependent absence of a slip ring (e.g. on C-Arm systems). Understanding the technical differences between CBCT and CT explains the different visual appearance of image artefacts and how motion management can be addressed on CBCT systems. One can distinguish two strategies that are to either reduce (freeze) the motion or in case of periodic motion to collect data from subsequent phases. Methods for motion reduction (immobilization) are fixations such as head frames, bite blocks, abdominal compression and breath-hold acquisitions, and also corrective methods for e.g. rigid (global and local) motion often applied on head scans. Periodic motion can be dependent on the use case, either handled by applying e.g. (prospective) gated CBCT or can be time-resolved reconstructed (4D CBCT). Time-resolved 4D CBCT reconstruction implies optimized acquisition parameters as well as the different algorithms to obtain the 4D reconstruction. Recent research explores new 4D reconstruction techniques such as HDTV or motion-compensated reconstruction that show very promising results in terms of image quality and dose usage. Knowing the technical differences of CBCT over CT helps to understand patient motion-induced image artefacts and the variety of technical solutions to reduce or resolve this motion.

Learning Objectives:

1. To learn about conventional techniques for motion compensation in CBCT.
2. To learn about new methods for motion compensation in CBCT.
3. To contrast the available and up-and-coming motion compensation methods in CBCT.

A-656 09:21

C. Motion compensation in MR and PET imaging

C. Kolbitsch; *Berlin/DE (christoph.kolbitsch@ptb.de)*

MRI provides images with excellent soft tissue contrast and a wide range of diagnostic parameters. Physiological organ motion (e.g. breathing, heartbeat or swallowing) can strongly impair image quality and hence diagnostic accuracy. Advances in MR hardware, plus novel image acquisition and reconstruction approaches, have strongly decreased MR scan times. Nevertheless, still up to 20% of MR scans experience severe motion artefacts and require repeated data acquisition. A wide range of techniques to minimise motion artefacts has been developed for different MR applications. In clinical practice, this is commonly motion prevention (e.g. asking a patient to hold their breath) and motion gating (i.e. restricting data acquisition to a certain motion state). More advanced motion correction approaches measure displacement of organs due to physiological motion and utilise this information to reduce motion artefacts during image reconstruction. PET images are affected by motion in two ways. Movement of organs can lead to blurring of the imaged structures and impair detectability, particularly of small features. In addition, motion can lead to a mismatch between attenuation correction maps and PET image data, resulting in severe errors in PET quantification. The recent introduction of simultaneous PET-MR now offers us the possibility to improve PET image quality and accuracy by utilising MR-based motion information. In addition, PET and MR data can also be combined to improve motion estimation and motion correction.

Learning Objectives:

1. To learn about motion measurement and compensation in MR.
2. To understand how patient motion affects PET images.
3. To learn about how MR data can be used to motion-compensate PET images, in MR/PET.

Professional Challenges Session

PC 13

Closing the gap between education and clinical practice for radiographers

A-657 08:30

Chairpersons' introduction (part 1)

K.G. Vikestad; *Oslo/NO (karivi@hioa.no)*

This session, professional changes, focuses on the gap between education and clinical practice in radiography. At the end of the session, we will discuss the challenges and aim to come up with suggestions to reduce this gap. Three speakers are invited; they will present their perspective on the topic to open the minds of the audience and provide some new thoughts. The speakers are: Anne Bjørnstad, Norway; Eric Wolker Van Der Weij, the Netherlands; and Louise Rainford, Ireland. The speakers represent both the clinical and educational field of radiography. Anne will present how the clinical field views the competence level of the newly graduated radiographers when they start working at Oslo University Hospital and what kinds of competence are important for the clinical field right now. She will also provide some reflections on whether or not specialisation should be part of the bachelor's degree. Eric will give a presentation about a new method for preparing students for clinical practice. They have starting using this method at his university, and he will share his thoughts and experiences in using this method. The title of the presentation by Lousie is “Tools for success - academic and clinical practice working together”. Her focus will be on how to emphasize variation of combined education and training, how to explore collaboration between hospitals and universities, and finally how undergraduate research can enhance academic/clinical relationships.

Session Objectives:

1. To understand the need for updated methods of training radiographers in the context of modern technology.
2. To discuss existing differences and controversies in the education system and teaching methods.
3. To explore possible ways of collaboration between academic institutions and hospitals for optimal education.

A-658 08:33

Chairpersons' introduction (part 2)

M. Raissaki; *Iraklion/GR (mraissaki@yahoo.gr)*

Competence refers to what a health specialist is capable of doing in his/her daily clinical practice. To achieve competence, a health specialist in a radiology department should acquire sufficient knowledge of various aspects of anatomy, physiology, physics, radiography and medicine. Performance refers to what a health specialist actually does. Performance is associated with much more than knowledge including ethics, interpersonal relationships, clinical skills, empathy for patients and ability to perform diagnostic tests as safely and efficiently as possible. Living in the era of evidence-based medicine, personalized medicine and ALARA has enhanced the role of the radiographer into a highly-skilled health specialist coping with multiple tasks in demanding environments. Academic activity composes a triangle formed by research, teaching and clinical practice. Teaching is considered one of the most challenging and endangered aspects of academic activities because of continuous changes in the methods of education, technology and patient management. Excellence in performance is the ultimate goal of education throughout pre- and postgraduate teaching programmes, and the possibility of new learning platforms might prove useful in the effort to close the gap between education and clinical practice for radiographers.

Session Objectives:

1. To understand the need for updated methods of training radiographers in the context of modern technology.
2. To discuss existing differences and controversies in the education system and teaching methods.
3. To explore possible ways of collaboration between academic institutions and hospitals for optimal education.

A-659 08:35

Education vs clinical practice

A. Bjørnstad; *Oslo/NO (Anne.Bjornstad@oslo-universitetssykehus.no)*

Newly qualified diagnostic radiographers’ knowledge, skills and competencies do not comply with the expectations and demands of the health care sector in Norway. Continual developments in technology and the changing role of the radiographer create a need for restructuring of radiography education.To ensure that newly qualified diagnostic radiographers meet the expectations of the clinical site , the Learning outcomes of radiography education should be reevaluated. The level of clinical competencies diagnostic radiographers are expected to have achieved on completion of their education should be revised. This process cannot be initiated without a closer evaluation of the employer´s role and responsibility. The employer should consider how the training of both students and newly qualified radiographers is organized. The evaluation of the required competencies of a clinical diagnostic radiographer should be an ongoing and dynamic process. To Ensure satisfactory quality of both the academic studies and the clinical training, the collaboration between the educational institutions and clinical placement locations should be improved. Also, the competence of the clinical practice supervisors should be strengthened. Technological advances and the increasing complexity of radiographic procedures demand a continuous increase in competencies beyond the bachelor education. This raises the question; should the bachelor degree include specialization in specific areas within the field of diagnostic radiography or should this remain as a mandatory part of continuing professional development.

Learning Objectives:

1. To understand the different perspectives of theoretical education and practical training of radiographers.
2. To appreciate means of rapid acquisition of clinical skills during education.
3. To discuss the possibility and potential of sub-specialisation during education.

A-660 08:58

How can new teaching methods be implemented?

E. Wolters van der Weij; *Groningen/NL (e.m.wolters.van.der.weij@pl.hanze.nl)*

Serious Gaming! Didactics is the scientific discipline that deals with the question of how teachers can train knowledge, practical skills and attitude to students. Thirty years ago, education was more teacher controlled which is often associated with passive learning. Currently, activating or self-directed learning are the didactic methods which place the student more in a central position. Self-directed learning is a process in which the student himself takes the initiative for the learning process: the student plans, tests, evaluates and reflects with or without the help of others. Recent scientific literature indicates that contemporary or present-day young people (the so-called network generation) learn in a different way. Authenticity, multitasking, interactivity and gaming are some key concepts. Education does not have to be entirely different, but could be better adapted to this generation of students by new forms of education like serious gaming. The department of Medical Imaging and Radiation Therapy (MIRT) of the Hanze University of Applied Science has started implementing serious gaming in their educational programme in 2015. How and to what extent can serious gaming be used in the Dutch education system for radiographers as a new didactic instrument whose implementation may lead to improvement,or complement or replace current traditional approaches and methods?

Learning Objectives:

1. To understand the different pedagogical methods available for the education of radiographers.
2. To discuss the advantages and disadvantages of expert lectures for education.
3. To demonstrate how EBP can be integrated into the training curriculum.

A-661 09:21

Tools for success: academic and clinical practice working together

L.A. Rainford; *Dublin/IE (louise.rainford@ucd.ie)*

This presentation will address the three learning outcomes listed; the principal focus of the talk will be on undergraduate radiography education. An overview will be provided on how education and clinical training of radiography students vary across academic institutions, both within Europe and also internationally, and the implications of these variations upon the profession. The presenter will explore potential best practice models for collaboration between clinical centres and universities in the delivery of radiography training. Reflection upon day-to-day considerations required to run local and national training programmes will be included. Practical difficulties will be discussed and possible mechanisms for enhance into radiography training proffered. A discussion of how undergraduate research activity could possibly support and enhance academic /clinical relationships will be offered to the audience to stimulate further conversation. Reference will be made to initiatives currently employed across a number of training programmes with the permission of the academic institutions.

Learning Objectives:

1. To emphasise variation of combined education and training among different academic institutions.
2. To explore collaboration between hospitals and universities for the

preparation of radiographers.
3. To discuss how undergraduate research can enhance academic/clinical relationships.

Vascular

RC 1315
US and vascular disease: a perfect match

A-662 08:30
Chairperson's introduction
T. Jargiello; *Lublin/PL (tojarg@interia.pl)*

Ultrasound is widely used in the diagnosis of vascular diseases. The technique is unique, as it provides not only imaging of vascular structures morphology but also haemodynamic information (Doppler technique). Its availability, safety and ability to examine real-time blood flow changes makes it very useful in a wide range of vascular pathology investigations. Among the disadvantages, high dependence on operator's personal skills and used equipment are the most important. Additional technical drawback, coming from limitations of ultrasound penetration in tissues (i.e. bones or gas) is also a negative casus. That is why the right placing of ultrasound in a diagnostic algorithm is so important. US examination usually goes first to make initial diagnosis of vascular pathology and to give the information of which modality should be the next. In some cases when US study excludes suspected vascular disorder, the diagnostic process may be stopped. A similar situation arises with vascular evaluation after treatment. US examination is a routine procedure after majority of open surgery or endovascular operations. Its outcome determines further diagnosis.
Session Objectives:
1. To review advantages and disadvantages of US.
2. To identify the role of imaging modalities in vascular disease.
3. To understand the role of US in post-treatment follow-up.

A-663 08:35
A. Abdominal aorta
D.A. Clevert; *Munich/DE (Dirk.Clevert@med.uni-muenchen.de)*

Abnormalities of the abdominal aorta and the visceral vessels may represent a diagnostic challenge in patients with acute or chronic clinical symptoms. In addition to the primary diagnosis in colour-coded duplex ultrasound, contrast-enhanced ultrasound (CEUS) with low mechanical index (low MI) is a new promising method in the diagnosis and follow-up of pathological aortic lesions. Colour code duplex ultrasound and CEUS with SonoVue® allows a more rapid and noninvasive diagnosis, especially in critical patients because of its bedside availability. This course describes the visceral vessels and focuses on the aetiology and the meaning of abdominal aortic pathologies. These pathologic findings were compared with colour-coded duplex ultrasound, CEUS and multi-slice computed tomography angiography (MS-CTA).
Learning Objectives:
1. To learn how to perform the examination and its role in diagnostic assessment.
2. To learn about US findings in AAA treatment planning and post-treatment evaluation.
3. To appreciate the role of CEUS and technological innovations in routine practice.
Author Disclosure:
D.A. Clevert: Advisory Board; Siemens, Samsung, Philips, Bracco. Speaker; Siemens, Samsung, Philips, Bracco.

A-664 08:58
B. Upper and lower limb: arterial district
B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

B-mode ultrasound enables evaluation of arterial anatomy and of the vessel wall, detects early atherosclerotic changes, and allows detection of stenosis and occlusions, but tends to overestimate the degree of stenosis and should not be used for stenosis grading. Colour duplex Doppler ultrasound (CDUS) enables fast visualization of the vessel to be examined. It demonstrates haemodynamic changes, including velocity increase. Underestimation of disease is likely if only colour is used and the precise assessment of haemodynamic disturbances is impossible without a spectral analysis. In general, CDUS has a high diagnostic accuracy, it is cheap and widely available, and there is no exposure to ionizing radiation and no contrast media injection. However, the examination is time consuming and requires high operator dependence. The thorough understanding of haemodynamics and physics is needed for adequate interpretation of Doppler findings. The factors influencing spectral morphology will be discussed in the lecture and the different types of spectra presented. Waveform changes will be presented in stenosis and occlusion. The typical findings of pseudoaneurysms and arteriovenous fistulas will be presented. Findings in acute occlusion and collateral flow will be discussed, both for native arteries and bypass grafts. The role of ultrasound in endovascular recanalizations will be discussed, both in planning and performing of the procedure and in the follow-up. Several clinical examples will be presented.
Learning Objectives:
1. To understand how to perform the examination and its role in diagnostic assessment.
2. To understand US findings for diagnosis and follow-up.
3. To underline tips and tricks to start your activity.

A-665 09:21
C. Upper and lower limb: venous district
H. Hoppe; *Berne/CH (hanno.hoppe@web.de)*

Duplex ultrasound is the initial imaging modality of choice evaluating upper and lower extremity veins. For upper extremity veins, most frequent indications are evaluation for thrombosis and vessel patency, pre- and postoperative mapping of arteriovenous fistula or graft, and venous access procedures. For lower extremity veins, duplex ultrasound is an adequate modality diagnosing venous valvular incompetence. Usually, this study is performed with the patient in an upright position and in addition manual compression manoeuvres are used to initiate reflux. Previously, cutoff values for reflux have been defined. Routinely, perforating veins are identified and the flow direction during compression is recorded. Duplex ultrasound is utilized to examine the extremity veins for venous outflow obstruction including chronic changes in deep or superficial veins post-venous thrombosis. However, additional imaging studies such as magnetic resonance imaging or computed tomography venography are increasingly used for reliable noninvasive identification of post-thrombotic changes and venous outflow obstruction and for treatment planning. In general, anatomic variations in superficial and deep veins are quite frequent and should be identified. Reporting should rely on a proper classification of venous disease including current anatomic description.
Learning Objectives:
1. To understand how to perform the examination and its role in diagnostic assessment.
2. To understand US findings for diagnosis and follow-up.
3. To underline tips and tricks to start your activity.

09:44
Panel discussion: When do we need additional imaging and which modality is best suited for the scenario?

08:30 - 10:00 **Room M 2**

E³ - ECR Master Class (Neuro)

E³ 1326b
Stroke: emergent large vessel occlusion (ELVO)
Moderator:
M. Pavia; Brescia/IT

A-666 08:30
A. Selecting ELVO patients for endovascular therapy
T. van der Zijden; *Antwerp/BE (thijsvanderzijden@hotmail.com)*

Endovascular treatment of large vessel occlusions in acute ischaemic stroke has proven to be effective. In an effort to achieve the best clinical outcome, and optimal cost-effectiveness as well, potential candidates for recanalization procedures should be triaged correctly. Besides a proper clinical workup, an adequate neuroradiological workup should be performed. On the one hand, selection of patients with a potential target for endovascular treatment (large vessel occlusion) should be done. On the other hand, exclusion of patients, who are not eligible for recanalization therapy, should be done as well. Imaging should not only be focused on exclusion of haemorrhage and/or stroke mimickers and on structural imaging of craniocervical arteries, but also give an idea about the extent of potential salvageable brain at risk versus already

infarcted brain. During the last years, in addition to plain CT and CT angiography of the brain, CT perfusion techniques and multiphase CT angiography have increasingly been used. Implementing these more advanced imaging tools in addition to basic neuroradiological workup enables theoretically a better prediction of clinical outcome after a potential recanalization procedure in a given patient, using qualitative and quantitative perfusion-based cutoffs and assessment of collateral vessel status. Advanced imaging techniques can also be used in the setting, immediately or early after recanalization, in an attempt to predict potential complications and/or clinical outcome.

Learning Objectives:

1. To learn about the correct indication/patient for endovascular therapy.
2. To understand the importance of clinical and neuroradiological work-up prior to the intervention.
3. To appreciate clinical relevance in terms of outcome measures applying state of the endovascular treatment for the right patient.

A-667 09:00

B. Advanced thrombectomy techniques

O. Jansen; *Kiel/DE*

Neurothrombectomy has been shown to be the primarily choice of treatment in acute stroke-patients with large intracranial vessel occluison. While the great randomised trials were performed mostly with the use of stent-retrievers or aspiration devices alone more recent papers have shown better recanalisation results in experimental and/or clinical studies. These so called advanced thrombectomy techniques mostly combine retrieval and aspiration techniques to result in fewer recanalisation maneuvers, shorter recanalisation time and less fragmentation of the embolus. While the choice of the best recanalisation technique is important for the recanalisation result periprocedural techniques (anaesthesia, stenting, medication) also show an important impact on clincal outcome. Additonal endovascular or medical treatment is also requested in more rare stroke cause like underlying intracranial arterial stenosis or acute dissection of the extra- or intracranial arteries. Recent studies and secondary analysis have also shown that dedicated patient selection with advanced stroke imaging is less important in patients with short time window (<8hrs) but may extend the individual treament window up to 24hrs.

Learning Objectives:

1. To learn about the spectrum of new and upcoming thrombectomy techniques.
2. To understand the importance of applying correct technique in individual patients.
3. To appreciate the increasing role of thrombectomy in ischaemic stroke therapy.

Author Disclosure:

O. Jansen: Consultant; Rapid Medical. Speaker; Stryker, Medtronic.

A-668 09:30

C. Is endovascular thrombectomy and medical therapy better than medical therapy alone?

S. Bisdas; *London/UK (s.bisdas@ucl.ac.uk)*

A tipping point has been reached in acute stroke management from evidence provided in recent clinical trials studying the efficacy of thrombectomy in ischaemic stroke. Almost the entire literature has studied anterior proximal occlusion, some studies have performed sub-analyses to clarify if the site of the clot can be used as outcome predictor. The evidence on the endovascular thrombectomy seems still heterogenous in method and underpowered for secondary outcomes. Interestingly, endovascular thrombectomy treatment is advocated in elderly patients whom will have a higher number of co-morbidities. Notably, the majority of studies looking at the recanalisation rate in patients who had prior IV thrombolysis against those who had direct thrombectomy revealed that thrombectomy was more likely to successfully recanalise if IV thrombolysis had been administered first. Currently, some of the large 2015 trials and subsequent trials patients have often received a thrombolysis infusion whilst the thrombectomy is being undertaken. In patients with tandem occlusions, any endovascular treatment offered could be the best available treatment since IV thrombolysis has showed no significant benefit. Recent results have shown excellent long term outcomes, with no evidence of delayed complications or restenosis. Additionally, the quality of life score measured between the endovascular treatment and conventional therapy group showed a significant difference in favour of the treatment arm. This advocates the appropriate use of mechanical thrombectomy; however, the specific details about best clinical practise in these patients have yet to be answered.

Learning Objectives:

1. To learn about the current data and medical evidence of the available therapies.
2. To understand the role of individualised therapy concepts.
3. To appreciate the importance of interdisciplinary approach for ischaemic stroke therapy.

08:30 - 10:00 **Room M 3**

Special Focus Session

SF 13c

Drug elution or drug illusion in vascular disease

A-669 08:30

Chairperson's introduction

R.W. Günther; *Berlin/DE*

Advances of coronary artery recanalization have essentially influenced the treatment of peripheral artery disease (PAD). Following coronary PTA (1977) and bare metal stents (1988), the concept of local drug delivery was realized using drug-eluting stents (DES) in 2001 and drug-coated balloons (DCB) in 2006. The drugs used for local delivery were the cytotoxic paclitaxel and the immunosuppressive agent sirolimus and its derivatives, which prevent or inhibit vascular restenosis due to suppression of cell proliferation. The pharmacokinetics after different drug applications varies and the mechanism of cellular inhibition differs. In the treatment of PAD, we saw the stepwise development from exclusive mechanical techniques to additional local drug delivery using DCB, DES or bare metal stents combined with DCB before or after stent placement. Also, debulking procedures like percutaneous atherectomy plus DEB have been described. Apart from peripheral artery disease, the problem of restenosis can be approached by DEB also in other areas such as renal arteries, haemodialysis fistulas and transjugular intrahepatic porto-systemic shunts (TIPS). The basic aspects of drug release, biological reaction, clinical evidence and practical consequences in different vascular areas will be presented in this session, which is dedicated to a critical appraisal by showing the clinical evidence of current data as well as the pros and cons.

Session Objectives:

1. To learn more about drug elution and biological reaction.
2. To show the pros and cons of drug elution devices in coronaries, infrainguinal arteries and haemodialysis fistulas.
3. To critically analyse the published data and summarise the current evidence and indications regarding treatment.

A-670 08:35

Drug-eluting balloons and stents, technology and biological interaction: lessons learned from the coronaries

F. Kleber; *Berlin/DE (post@fxkleber.de)*

Dilatation of arterial vessels leads to an increase in luminal and overall vessel dimensions, only partly counteracted by elastic recoil and dissection. Unfortunately, this effect is often short-lived since healing leads to vessel shrinkage. Stents, especially drug-eluting stents, can overcome recoil and shrinkage, but induce intimal hyperplasia, which in turn leads to late luminal loss. Also, late stent malapposition has been found in a sizeable number of treated segments promoting vessel thrombosis. Foreign body reaction and a persisting small thrombosis rate lead to a 5-year target lesion failure (TLF) rate of 13 to 26% . Stents with thinner struts seem to have better long-term results. To avoid such high TLF rates, drug-coated balloons (DCBs) were developed and clinically used to treat in-stent restenosis as well as de novo lesions. It could be shown experimentally and clinically that the most often used drug paclitaxel can induce late luminal gain, which after stenting is a untoward side effect, but without stenting helps to achieve good long-term results. Therefore even in small coronary arteries treated with DCBs, the target lesions revascularisation rate is very low (2.5%) and thrombosis is almost absent on dual antiplatetet therapy. However, excipients for drug-eluting ballons are different and have different efficacy. New drugs are in a late developmental stage and compete with paclitaxel. Future trials will shed light on which excipients and which drugs show the best results. However, even now, in many situations, DCBs are equal or even superior to stents in not jeopardizing the further course by foreign body reaction to the implants and thrombosis.

Learning Objectives:

1. To learn about the individual components of drug-coated balloon catheters and their importance.

2. To summarise key messages from non-clinical studies with coronary balloons and stents.
3. To gain an overview of the key lessons from randomised clinical trials in coronary.

Drug-eluting balloons and stents in femoropopliteal and crural lesions: pro

F. Fanelli; *Rome/IT (fabrizio.fanelli@uniroma1.it)*

Drug-eluting stents-DES and drug-eluting balloons-DEB represent “two sides of the same coin” for the ability to deliver locally anti-proliferative drugs. The main goal of drug is to inhibit the neo-intimal reaction. DES and DCB have been evaluated in different studies, both showing a significant increase in primary patency (PP) rate when compared to standard devices. Three randomised trials, using different DCBs, were performed to compare DCB vs. angioplasty (PTA) in de-novo femoro-popliteal lesions. PP at 1-year ranged between 73.5% and 89.0%; the 4-year data of In.Pact SFA trial showed a PP of 69.5% (DCB) vs. 45.1% (PTA) p<0.001, and freedom from clinically-driven target lesion revascularisation (CD-TLR) of 76.8% (DCB) vs. 70.4% (PTA) p=0.039. Many other studies have been performed in different setting such as diabetic patients, in-stent restenosis, long lesions, chronic total occlusions and all of them showed always a better outcome using DCB. The efficacy of DES, in the femoro-popliteal region, was confirmed by the Zilver-PTX trial were PP after 5-year is 64.9% compared to a low 19% for PTA. This study showed also a superior PP when provisional DES was compared to provisional bre metal stent (BMS): 72.4% vs 53.0% respectively. These superior results have been also supported from several other studies. In the infrapopliteal region DCB has not yet demonstrated their superiority in comparison to the standard PTA, but several randomised controlled trials (RCT) are ongoing. DES sowed their efficacy in several studies with a PP at 1 year comprised between 75% and 86%.
Learning Objectives:
1. To learn about the difference between the various drug-eluting platforms and medication.
2. To understand the difference between technical success, patency and clinical outcome in patients treated with endovascular technologies.
3. To understand the advantages of drug-eluting balloons and stents in femoropopliteal and crural lesions.
4. To learn which patients and which lesions derive the most benefit from their use.
Author Disclosure:
F. Fanelli: Speaker; Medtronic, Cook, WL Gore & Associates, Spectranetics.

A-672 09:10

Drug-eluting balloons and stents in femoropopliteal and crural lesions: contra

J.A. Reekers; *Amsterdam/NL (j.a.reekers@amc.uva.nl)*

Restenosis after balloon angioplasty or stenting has been a major drawback of angioplasty. Depending on the vessel area and length of the lesion, restenosis due to intimal hyperplasia is 20%-60% in the first 12 months. Inhibition of intimal proliferation with local drug administration, either with a drug-eluting stent or a drug-releasing balloon, looks like a promising solution to this problem. Paclitaxel and sirolimus have both been shown to be able to inhibit local intimal proliferation and thereby to prevent or reduce local intimal hyperplasia after angioplasty. Drug elution therefore seems, and is also marketed accordingly, the way forward. Unfortunately, there has been no study to show the clinical benefit of local drug elution. Prevention of intimal hyperplasia is a pseudo end point. The real end points are: improvement of walking distance in a patient with intermittent claudication or prevention of amputation in a patient with critical limb ischaemia. Until this has been proven in a prospective randomised trial, drug elution is still an illusion.
Learning Objectives:
1. To understand the limitations of drug-eluting balloons and stents in femoropopliteal and crural lesions.
2. To be familiar with potential complications from their use.
3. To become familiar with a critical review of the current literature and to understand how marketing of new endovascular technologies works.

A-673 09:30

Effect of drug-eluting balloons and stents in haemodialysis access lesions: where is the evidence?

K. Katsanos; *Patras/GR (katsanos@med.upatras.gr)*

Creation of hemodialysis access in the form of either an autologous arteriovenous fistula or prosthetic arteriovenous graft is one of the commonest vascular procedures and serves as the "lifeline" for dialysis patients. Percutaneous techniques are widely practised for salvage of failing native or synthetic arteriovenous shunts. Nonetheless, balloon angioplasty is frequently associated with recurrent, aggressive, vessel restenosis and early failure. The pathobiology of arteriovenous stenoses is completely different from arterial atherosclerosis, and is typically characterised by aggressive venous neointimal hyperplasia associated with adventitial myofibroblast proliferation and striking fibrosis on the background of repeated endothelial injury, altered hemodynamic shear stress, systemic uremia and oxidative stress. Cutting or high pressure balloons, covered stents or stent-grafts, and paclitaxel-coated balloons have been extensively tested and investigated with the aim to improve immediate anatomical and long-term clinical results. There is high quality of randomised evidence that placement of covered stents for the treatment of draining vein stenosis may prolong the patency of failing synthetic arteriovenous grafts. There is also evidence from mostly proof-of-concept pilot studies that paclitaxel-coated balloons may inhibit restenosis and improve mid-term patency of failing arteriovenous fistulas and grafts when applied in combination with adequate mechanical dilatation of the underlying stenosis. The results of different clinical studies for each device category will be reviewed and a good practice algorithm for percutaneous salvage of failing arteriovenous shunts will be proposed based on anatomical and procedural parameters.
Learning Objectives:
1. To understand the pathophysiology of restenosis and mode of failure of haemodialysis circuits.
2. To analyse amassed clinical evidence about drug-coated balloons and stents in haemodialysis fistulas.
3. To learn about the limitations of current drug-coated balloon technologies.

E³ - ECR Academies: Tips and Tricks in Pancreatic and GI Tract Imaging

E³ 1322
New challenges of pancreatitis

A-674 08:30

Chairperson's introduction

G. Zamboni; *Verona/IT (gzamboni@hotmail.com)*

The 2012 Revised Atlanta Classification categorizes acute pancreatitis as interstitial oedematous or necrotizing, introducing a uniform terminology for describing its imaging features and fluid collections. Collections are defined based on their timing (early phase <4 weeks from onset; late phase ≥4 weeks). Interstitial pancreatitis may present with acute pancreatic fluid collections in the early phase, which can later either resolve or evolve into pseudocysts. Necrotizing pancreatitis presents with necrosis (pancreatic, peripancreatic, or combined pancreatic and peripancreatic); the acute necrotic collections may later evolve into walled-off necrosis. Autoimmune pancreatitis (AIP) is increasingly recognized, accounting for ≤6% of cases of chronic pancreatitis. Type 1 AIP, more common, is a systemic IgG4-associated disease with elevated IgG4-positive cells in the serum, pancreas, and other organ. Type 2 AIP involves primarily the pancreas, without IgG4-positive cells. On MR, the affected pancreas appears enlarged, either focally or diffusely, hypointense on T1 and hyperintense on T2, with a hypointense capsule-like rim. MPD shows diffuse or focal stenosis. The parenchyma has reduced and delayed enhancement. Pancreatic cystic lesions include neoplastic and non-neoplastic cysts. A combination of imaging findings and demographic, clinical and laboratory data is necessary for a correct diagnosis. MR has higher diagnostic accuracy than CT in lesion identification, characterization and differentiation between benign and malignant lesions. Findings useful for characterization include lesion site, cystic pattern, presence of septa, wall thickness, calcifications and their morphology, mural nodules, communication with the ductal system and dilation of the MPD. Several international guidelines address their diagnosis and management.

A-675 08:35

A. Understanding the Atlanta 2012 classification of acute pancreatitis

W. Schima; *Vienna/AT (wolfgang.schima@khgh.at)*

According to the Revised Atlanta Classification of 2012, acute pancreatitis is categorized as interstitial oedematous or necrotizing pancreatitis. In interstitial oedematous pancreatitis, approximately 50% of patients develop acute peripancreatic fluid collections early (< 4 weeks from onset). In the late phase (≥ 4 weeks), these either resolve or evolve into pseudocysts, which are hypodense on CT and hyperintense on T2w MRI. Treatment of pseudocysts is only indicated in symptomatic patients or if complications (gastric outlet obstruction, cholestasis or haemorrhage) develop. Necrotizing pancreatitis may present either with combined pancreatic and peripancreatic (most common) or with pancreatic necrosis or with peripancreatic necrosis alone. Acute necrotic collections may evolve into walled-off necrosis (WON) in the late stage. A WON containing digested fat and parenchyma must not be confused with a pseudocyst. They are similar on CT, but US/MRI reveals the predominantly solid nature of WON. Secondary infection of necrotizing pancreatitis results in high mortality. Imaging diagnosis of infection is difficult. Gas within a collection is specific, but not sensitive. If feasible, CT-guided abscess drainage is recommended. Necrotic collections with debris require a more aggressive approach. In general, MDCT for diagnosis of pancreatitis should be performed no less than 2-3 days from clinical onset, because development of necrosis may take some time. In case of suspected biliary pancreatitis, early MRCP guides further treatment (endoscopic stone removal). The Revised Atlanta Classification system introduced a uniform terminology for imaging features of pancreatitis. Contrast-enhanced CT is the primary tool of diagnostic imaging and image-guided therapy. MRCP characterizes fluid collections and delineates ductal abnormalities.

Learning Objectives:

1. To be aware of the new terminology for the evaluation of acute pancreatitis.
2. To learn about how to report imaging findings.
3. To understand the relationship between imaging findings and prognosis.

A-676 09:03

B. Autoimmune pancreatitis and its relatives

G. Morana; *Treviso/IT*

"no abstract submitted"

Learning Objectives:

1. To understand the various forms of autoimmune pancreatitis, especially cases that are associated with extra pancreatic disease.
2. To learn about the usual and unusual appearance of autoimmune pancreatitis.
3. To understand the principles of the follow-up.

A-677 09:31

C. Tough clinical cases of cystic pancreatic lesions

M.A. Bali; *Sutton/UK (mantoniettabali@icr.ac.uk)*

Pancreatic cystic lesions (PCL) include epithelial and non-epithelial neoplasm and non-neoplastic cysts and are classified as benign, potentially malignant and malignant, according to WHO. Imaging has a key role in detection and characterization; however, the final diagnosis is provided by the integration of imaging findings with demographic, clinical and laboratory data, including cystic fluid analysis obtained by EUS. MR has higher diagnostic accuracy than CT for detection and characterization. At imaging, several findings, such as the localization, the cystic pattern (unilocular, multilocular), the presence of septa, wall thickness, calcifications (central or peripheral, thin or thick), mural nodules, communication with the pancreatic ducts and the concomitant dilatation of the main pancreatic duct (MPD) may allow the differential diagnosis between PCLs and may also be suggestive of malignancy. However, lesions smaller than 3 cm may lack specific morphological features. Neoplastic cysts such as serous cystadenoma (most common with benign behaviour) followed by mucinous cystic and intraductal papillary mucinous neoplasms (potentially malignant or malignant neoplasm) must be differentiated from non-neoplastic cysts such as pancreatitis-associated pseudocysts (most common) to provide the most adequate treatment and to avoid unnecessary surgery. For the mucinous neoplasm, imaging findings highly suggestive of malignancy are: for brunch-duct IPMN, mural nodules and dilatation of the MPD; for main duct-IPMN, MPD larger than 1cm, mural nodules and symptoms; for mucinous cystic neoplasm, large lesion (>4cm), mural nodules, mass-forming lesions and peripheral calcifications. Guidelines (Fukuoka Guidelines 2012, European Guidelines 2013 and American Gastroenterology Association Guidelines 2015) are available to assist in decision-making.

Learning Objectives:

1. To understand how to report a cystic pancreatic lesion, including recommendation for imaging strategy.
2. To become familiar with the most common cystic neoplasms of the pancreas.
3. To learn how to differentiate neoplasms and inflammatory cystic lesions of the pancreas.

Upper extremity sports injuries

Moderators:
L.W. Bancroft; Orlando, FL/US
A.J. Grainger; Leeds/UK

A-678 08:30

A. Shoulder injuries in the throwing athlete

L. Steinbach; *San Francisco, CA/US (lynne.steinbach@ucsf.edu)*

Overhead throwing athletes develop significant abnormalities as a result of acquired adaptations to the extremes of motion in the dominant shoulder. These abnormalities may eventually result in an inability to throw with the same velocity, the so-called “dead arm” syndrome. These abnormalities involve tendons, ligaments, labrum, muscles, nerves, vessels, and bones. This presentation will review the biomechanics of throwing forces as they relate to the shoulder. The MR imaging characteristics of the resultant abnormalities in the labroligamentous structures and the rotator cuff will also be highlighted. This will be followed by a brief discussion of pathologic and normal developmental changes in the shoulders of skeletally immature throwing athletes.As a prototype, the throwing motion in baseball occurs over a period of approximately 2 seconds and is divided into six stages: wind up, cocking, early and late acceleration, deceleration, and follow through. The late cocking, acceleration, and deceleration phases produce the greatest stress on the glenohumeral joint structures. As with other throwing sports, the superior labrum and rotator cuff are often affected by these extreme forces.

Learning Objectives:

1. To understand the biomechanics of throwing forces as they relate to the shoulder.
2. To become familiar with rotator cuff and labroligamentous injury patterns caused by overhead sports.
3. To appreciate pathologic and normal developmental changes in skeletally immature throwing athletes.

A-679 09:00

B. Soft tissue wrist injury in the athlete

C.W.A. Pfirrmann; *Zurich/CH*

Wrist injuries account for 5 % of sports injuries. In the young athlete, fractures are the most common injuries. The hand and wrist are the most common sites for fracture in the young athlete. Physeal injuries are typical overuse injuries in gymnasts. Chronic stress reactions with widening of the growth plate are seen in the distal radial and less common in the ulnar growth plate. Injuries to the TFCC in the athlete occur in acute trauma and with overuse. TFCC injuries are an important cause for ulnar-sided wrist pain. The differential diagnosis includes ulnar sytloid impaction syndrome, ulnar impingement syndrome and tenosynovitis of the extensor carpi ulnaris tendon. Injury to the interosseous ligaments may lead to carpal instability. Chronic injury of the intrinsic or extrinsic ligaments of the wrist may cause ganglion cyst formation.

Learning Objectives:

1. To learn about the patterns of injury seen at the wrist in athletes.
2. To understand the advantages and disadvantages of different modalities for imaging the athlete's wrist.
3. To recognise the imaging appearances of cartilage and ligamentous injury at the wrist.

A-680/A-681 09:30

C. Interactive case discussion

L. Steinbach[1], C.W.A. Pfirrmann[2]; *[1]San Francisco, CA/US, [2]Zurich/CH*
(lynne.steinbach@ucsf.edu)[1], (christian.pfirrmann@balgrist.ch)[2]

This session will show cases related to upper extremity sports injuries of the shoulder.

Learning Objectives:

1. To appreciate common patterns of athletic injury in the shoulder and wrist.
2. To become familiar with the techniques available and imaging appearances of shoulder and wrist athletic injury.
3. To consolidate the knowledge gained from the session with interactive cases of upper limb athletic injury.

E³ 1421

Brain tumours

A-682 10:30

A. Paediatric brain tumours

M.I. Argyropoulou; *Ioannina/GR (margyrop@cc.uoi.gr)*

Primary brain tumours in childhood are the second most common malignancy after leukaemia. The presenting symptoms depend on age with macrocephaly and failure to thrive in infants, and headache, morning vomiting, diplopia, ataxia motor and sensory deficits, seizures and endocrinological symptoms in older children. Brain tumours may be of glial origin (astrocytomas ependymomas), neuronal or neuroglial (gangliogliomas, gangliocytomas, DNET), embryonal (PNET, ATRT) and from germ cells (germinomas, teratomas). Tumours arising in the sellar and parasellar region (craniopharyngiomas, hypothalamic hamartomas and pituitary adenomas) may also occur. Neurinomas and meningiomas are rare in children arising mainly in the context of neurofibromatosis type II. Secondary brain tumours arise mainly from CSF seeding, while haematogenous metastases are rare. MRI is the modality of choice for the diagnostic workup of brain tumours. Imaging protocols may include T2W, T1W plain and contrast-enhanced images, diffusion tensor imaging, dynamic susceptibility-weighted contrast-enhanced perfusion imaging (DSC), functional MRI (fMRI) and MR spectroscopy (MRS). Brain tumours may be heterogeneous with cystic and solid components. The latter appears with low signal on T1W and high signal on T2W images. A low signal intensity on T2W images, associated with restricted diffusion and increased perfusion indexes on DSC, may be suggestive of a more aggressive tumour. Increased choline and lactate and decreased N-acetyl aspartate in MRS are also suggestive of malignant tumours. Tractography and f-MRI are useful for preoperative evaluation to assess major white matter tracts and eloquent areas of the brain related with the tumour.

Learning Objectives:

1. To become familiar with different paediatric brain tumours.
2. To learn the imaging criteria for differentiation.

A-683 11:15

B. Adult brain tumours

P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

Glioblastomas are the most common malignant neoplasms and together with metastatic tumours comprise half of all malignant tumours in the adult population. The latest WHO classification is from 2016 and several changes have occurred with respect to the classification of brain tumours. The grading of tumours presumes biological behaviour or phenotype of a lesion and is of high importance clinically by guiding therapy selection: adjuvant radiation, chemotherapy, or surgical or palliative treatment of brain tumours. MRI is considered the standard modality for the diagnosis and prognosis of brain tumours, based primarily on gadolinium (Gd) enhancement. However, this concept has become more and more challenging due to the fact that not all high-grade gliomas demonstrate Gd enhancement, while low-grade tumours might enhance in up to 30% of the cases. This lecture will review the more common primary and secondary brain tumours in adults and their imaging characteristics on CT and MRI. The use of advanced imaging for diagnosis and treatment follow-up will be discussed.

Learning Objectives:

1. To become familiar with the different types of brain tumours.
2. To learn the imaging criteria for differentiation.

Author Disclosure:

P.C. Maly Sundgren: Investigator; I conduct research on advanced MR appilcations on brain tumors and brain metastasis. Research/Grant Support; I have grants from Swedish Research Council, Swefish Cancer Foundation adn reginal Research Funds for Advanced MR imaging techniques in brain tumors and ttreatment effects. Speaker; i speak at international meeting on advanced imaging brain tumor treatment effects.

10:30 - 12:00 **Room B**

ESR meets Portugal

EM 2

Discovering Portuguese radiology: past, present, future

Presiding:
F. Caseiro Alves; Coimbra/PT
B. Hamm; Berlin/DE

A-684 10:30

Introduction: SPRMN President address

F. Caseiro Alves; *Coimbra/PT (caseiroalves@gmail.com)*

A brief presentation of the past and present history of Portuguese Radiology will be made on behalf of SPRMN. Relevant contributions to angiography will be highlighted as well as a brief overview of the Portuguese Society and its main activities. The future will be presented by the three chosen young lecturers on topics of their research domain.

Session Objectives:

1. To revisit the major Portuguese contribution for radiological sciences.
2. To provide a selection of present and future clinical research on imaging.
3. To explain and display the musical heritage through the Portuguese guitar.

A-685 10:35

Imaging biomarkers for diffuse liver disease

M.M. França; *Porto/PT (mariamanuela.franca@gmail.com)*

Fat, iron deposits and fibrosis can be found in different diffuse liver diseases. Because liver biopsy has several limitations, MR imaging biomarkers have been developed for fat and iron quantification, and to stage liver fibrosis. Quantification of proton density fat fraction (PDFF) can be accurately performed with multi-echo chemical shift-encoded (MECSE) gradient echo MR sequences, corrected for T1 relaxation, T2* decay effect, noise and fat spectral complexity. Quantification of liver iron content is needed to detect and stage iron overload, and also to monitor iron-reducing treatments. Iron MR quantification may be performed with R2/R2* relaxometry techniques. Simultaneously, quantification of hepatic fat (PDFF) and iron (R2*) can be achieved with MECSE sequences, which are advantageous in diffuse liver diseases, as fat and iron frequently coexist in the liver parenchyma. MR elastography can detect and stage significant or advanced fibrosis and cirrhosis, with high accuracy, in different diffuse liver diseases. All of these MR imaging biomarkers are increasingly being used for the non-invasive assessment of hepatic steatosis, siderosis and fibrosis for evaluating and monitoring diffuse liver diseases.

Learning Objectives:

1. To understand the need for non-invasive imaging biomarkers to accurately detect and quantify hepatic steatosis, iron overload and fibrosis, in different diffuse liver diseases.
2. To review the different MR imaging techniques to evaluate and to quantify imaging biomarkers of liver steatosis, iron overload and fibrosis.
3. To discuss the role and clinical relevance of MR imaging biomarkers for the evaluation of diffuse liver diseases, in different clinical scenarios.

A-686 10:55

Prostate artery embolisation (PAE) for benign prostate obstruction (BPO): the paradigm shift

T. Bilhim; *Lisbon/PT (tiagobilhim@hotmail.com)*

Prostate artery embolisation (PAE) has been proven to be safe and effective to relieve lower urinary tract symptoms (LUTS) related to benign prostate obstruction (BPO). Knowledge of the anatomy of the prostate arteries (PAs) is cornerstone to PAE. Pre-procedural CT-angiography (CTA) and intra-procedural cone-beam CT (CBCT) have been proven to be reliable tools to study the PAs. Identification of the PAs is generally performed under fluoroscopy. Developing alternatives are the use of fusion imaging with the pre-procedural CTA images, overlay with the intra-procedural CBCT images and

the use of vessel-tracking software that automatically identifies the PAs. Up to 25% of patients may have clinical failure after PAE. Most of these patients are nonresponders, with a minority being relapsers. Thus, it is very important to define the predictors of clinical outcome to help exclude those patients less likely to respond to PAE. Predictors of better clinical outcome that have been identified include: younger age; lower baseline LUTS severity; patients under acute urinary retention; and adenomatous-dominant BPO. Bilateral PAE has been proven to be better than unilateral PAE. MR-detected ischaemia after PAE, PSA values 24 hours after PAE, prostate volume reduction and clinical outcome have been shown to be correlated. Prognostic quantification with perfusion imaging of the prostate, developing catheters and embolic agents/sizes are some of the future directions in the investigative field of PAE on the path to inclusion in the guidelines for the management of patients with symptomatic BPO.

Learning Objectives:

1. To learn about the anatomy of male pelvic arteries relevant for selective embolisation of the prostate.
2. To understand what imaging modalities can be used for guidance inside the pelvis to find the prostate arteries.
3. To become familiar with clinical outcome and predictors of treatment response after prostate artery embolisation.

Cardiac CT from anatomy to functional information: comprehensive CAD evaluation

H. Marques; *Lisbon/PT (h919741379@gmail.com)*

Coronary CTA has been a fast growing imaging technique to assess the coronary arteries non-invasively. Recently, some guidelines consider it to be the first-line test in patients with non-acute chest pain of possible cardiac origin, regardless of the pre-test probability of CAD. Intense research preceded and accompanied its evolution, from a rule-out test to an all-in-one coronary disease assessment with prognostic validation. We will follow this route and the scientific evidence behind it: from stenosis to plaque presence, segment involvement and plaque characteristics; transluminal gradient,"first-pass" perfusion CT and dual-energy "perfusion" CT; virtual fraction flow reserve (FFR);- evaluation of myocardial viability with CT. Finally, we will focus on artificial intelligence and machine learning techniques applied in this context and how they will be disruptive.

Learning Objectives:

1. To learn and understand the different anatomic information regarding CAD derived from coronary CTA and its prognostic relevance.
2. To review different cardiac CT techniques to access functional relevance from anatomic stenosis and its clinical evidence.
3. To integrate cardiac CT derived data for a comprehensive CAD evaluation.

The soul of Portugal: Facts and sounds of the Portuguese guitar

F. Caseiro Alves, B. Costa, R. Silva, N. Botelho; *Coimbra/PT (caseiroalves@gmail.com)*

A historical perspective of the Portuguese guitar will be presented focusing on its construction and structure. Emphasis will be put on the differences between the Lisbon Guitar and the Coimbra Guitar concerning sound and purposes. The explanation will be accompanied by a live performance where players will try to show the audience the major sound differences. The session will end with a live performance of an instrumental theme for each of the two types of guitars. We hope to offer an educative and enjoyable moment of musical détente.

Routine cartilage evaluation and novel approaches

V. Salapura; *Ljubljana/SI (salapura@siol.net)*

The mechanical properties of cartilage provide repetitive frictionless movements across joint surfaces. Cartilage is constituted of chondrocytes and extracellular matrix (ECM) mainly composed of water (65-80%), collagen (15-20%) and negatively charged proteoglycans (PG) (3-10%). The cartilage's four layers (superficial, transitional, deep and calcified) differ in the shape and orientation of the chondrocytes and the distribution of collagen. The biochemical changes of the damaged cartilage include the reduction of proteoglycans concentration, the elevation of water content, and degradation of matrix macromolecules. Magnetic resonance (MR) imaging is considered to be the best noninvasive method for evaluation of cartilage morphology and its biochemical changes. Routinely used techniques for morphological evaluation are two-dimensional turbo-spin-echo sequences with fat suppression (PDW,T2W), and traditional (FLASH, DESS) or novel (SSFP) 3D gradient-echo sequences. 3D TSE sequences have been recently developed for 3T scanners (SPACE) with capability of contrast properties similar to 2D TSE, allowing better tissue contrast. New MR imaging techniques for detection of ECM have been developed. The delayed gadolinium-enhanced MR imaging of cartilage (dGEMRIC) and Na23 MR imaging use similar principles with Na+ ions attraction to the negative glycosaminoglycans chains. The T1ρ time constant displays a relationship between motion-restricted water molecules and the macromolecular environment and is most sensitive to the changes of PG content. T2 mapping reflects proton movements in the tissue and is affected by the density of collagen fibres and free water content. In healthy articular cartilage, an increase in T2 values from deep to superficial cartilage layers can be observed and therefore zonal evaluation is important in T2 analysis.

Learning Objectives:

1. To learn about normal cartilage morphology and structure.
2. To understand the principles of cartilage imaging.
3. To learn about standard imaging techniques of cartilage.
4. To investigate novel approaches to cartilage imaging.

A-690 11:00

Non-occlusive mesenteric ischaemia: CT diagnosis and signs of reperfusion

M. Mazzei; *Siena/IT (mmazzei@sirm.org)*

Non-occlusive mesenteric ischaemia (NOMI) is an abdominal emergency that accounts for 20-30% of all intestinal ischaemic events and is the most lethal form of acute mesenteric ischaemia (AMI) (58-70%) because of the delayed diagnosis related to the non-specific symptoms and signs at imaging. Among various mesenteric ischaemia presentations, the early phase of NOMI is not easy to diagnose via CT, because it can reveal a different appearance at imaging dependent on the time in which the CT examination is performed and on the presence of reperfusion, meaning the re-establishment of normal mesenteric blood supply after an ischaemic event is more frequent than in an occlusive ischaemic condition. However, the event of reperfusion could be further worsened if the initial damage was caused by ischaemia, when it occurs in an advanced condition of ischaemia. This entity is known as ischaemia/reperfusion injury and in many cases can progress into shock, multiple organ failure and death. Drawing a distinction between NOMI with or without reperfusion, is necessary to ensure correct treatment (medical or surgical). The analysis of not only vessel features, but also of mesenteric, bowel and peritoneal CT findings propose a potentially useful method to distinguish NOMI with reperfusion (absent or present) and, in addition, any possible prognostic value. Therefore, the introduction of CT in the decision tree of NOMI treatment may bring the benefit of a prompt diagnosis and subsequent early and efficient initiation of therapy in the emergency setting, which may improve the mortality rate.

Learning Objectives:

1. To investigate imaging/pathological and experimental model correlation in NOMI with and without reperfusion.
2. To gain awareness about the CT findings of NOMI with and without a reperfusion event.

3. To learn where to look for reperfusion signs.
4. To understand the potential clinical impact of imaging in treatment planning.

A-691 11:30

Imaging of paediatric gastrointestinal emergencies

D. Baleva; *Mistelbach/AT (dilianabaleva@yahoo.com)*

In the newborn and infant age groups, the gastrointestinal pathology manifests often as an emergency condition, which requires a prompt and correct diagnosis to be made. In choosing the most appropriate imaging modality, the higher radiation sensitivity of the paediatric patients, the inability of voluntary follow-of commands and the sparse abdominal fat tissue must be taken into consideration. Thus, ultrasound and conventional x-ray modalities are the main imaging tools to solve paediatric gastrointestinal emergencies. The imaging findings of the most common gastrointestinal emergency entities in the young paediatric patient are presented: necrotising enterocolitis, congenital diaphragmatic hernia, malrotation and volvulus, proximal and distal congenital GI obstructions, intussusception, and hypertrophic pyloric stenosis. Special attention has been paid to the specific clinical hallmarks and age predilection of each entity.

Learning Objectives:

1. To discuss the relevant imaging approach and modalities in the setting of acute gastrointestinal pathology.
2. To review the imaging findings in the most common and important emergencies of the paediatric GIT.
3. To specially emphasise upon the typical clinical setting of the different entities.

10:30 - 12:00 **Room L 8**

ESR Patient Advisory Group (ESR-PAG)

PA 1

Patient-doctor relationship and interdisciplinary communication in the radiology department

A-692/A-693 10:30

Chairpersons' introduction

N. Bedlington[1], M.H. Fuchsjäger[2]; *[1]Vienna/AT, [2]Graz/AT (michael.fuchsjaeger@medunigraz.at)*

This session will offer insights not only into the patient-radiographer-radiologist relationship in general, but specifically into communication between patients and health-care professionals (radiographers and radiologists) in the radiology department. The impact of good as well as bad communication on patient journey and well-being will be reported. Effective communication strategies required to avoid miscommunication and misunderstandings will be discussed. The radiology report which is another centre piece of communication between the patient and radiologist should express and generate confidence, be consistent and avoid confusion. Specific focus will be laid on information overload, which might be equally detrimental to a safe feeling as no information at all, as well as on timely information, which is so critical in radiology.

Session Objectives:

1. To understand the patient-doctor relationship and influencing factors, as well as how to improve the relationship.
2. To learn basic principles of communication between the patient and the radiologist or radiographer, as well as the impacts of good and bad communication.

A-694 10:40

A radiologist's point of view

D.-G. Carrié; *Toulouse/FR (dominiquecarrie@wanadoo.fr)*

Only in the practice of a few of our specialities (ultrasound, interventional...) does the radiologist enter de facto into a direct relationship expressly with the patient. In other domains (CT, MR), patients are informed (or not) about their imaging by the doctor who prescribed, our secretaries, information searched on the internet, informed consent forms, or even technicians-nurses during their stay in the imaging unit. In each European country, the situations are of course very disparate, but in most cases the patient cannot see the radiologist if the latter decides that it is necessary to consult with the patient (to request some elements necessary to an interpretation, or to announce a diagnosis that seems necessary, or if he has the time). Our patients endure this existing situation. Practical solutions can and must be proposed to facilitate and improve patient-radiologist communication (for example, systematically offer each patient as much access as possible to the radiologist who will take care of his case, physically organise the imaging department: consultation room located between interpretation offices and waiting rooms, better understand patient expectations by implementing satisfaction questionnaires). Our businesses, increasingly technical and standardised, should not distance us from the very foundation of medicine: helping our patients better understand their disease to better accept treatments that modern medicine is likely to offer them. Radiologists are part of this chain of communication, and it is in their interest to not remain indifferent and to retain their visibility to their patients.

Learning Objectives:

1. To understand the patient-doctor relationship from a radiologist's view.
2. To learn about effective communication and how to avoid miscommunication and misunderstanding.
3. To understand the impact of good communication strategies for the patient's journey.

A-695 10:55

A radiographer's point of view

B.T. Andersson; *Lund/SE (Bodil-T.Andersson@med.lu.se)*

Communication is a vital part of the encounter between the radiologist and the patient. Patients require physical and psychological support when undergoing a radiographic examination or a complex radiological intervention. The rapid growth of technical and scientific knowledge has changed not only the environment but also the requirements on competence for all professionals and the health care system as whole. High technology has transformed the physical appearance of the diagnostic radiology department and influenced its social structure. Along with caring for the patient, technology has affected radiologists' as well as radiographers' everyday life in that it allows less human control in the organisation. When a patient attends the hospital to undergo a radiographic examination or intervention, he/she expects the encounter to involve humane and dignified care, irrespective of how difficult the circumstances may be. Provision of information concerning the examination/intervention is central, as well as communication to ensure that the information provided is accurate and complete and the patient has understood. Communication helps the patient to stay involved and participate in the examination/intervention, and detailed information about what is going to happen next can be of great value to patients experiencing fear and panic. It is important to have an understanding of other professions working inside and outside a diagnostic radiology department to offer a person-centred care and climate, to increase patient safety, including effective communication.

Learning Objectives:

1. To understand the patient-doctor relationship from a radiographer's view.
2. To learn about effective communication and how to avoid miscommunication and misunderstanding.
3. To understand the impact of good communication strategies for the patient's journey.

A-696 11:10

Patients' point of view (part 1)

J. Birch; *Poole/UK (judy_b@dsl.pipex.com)*

This presentation will look at: examples of discussion with the radiologist, as well as the lack of it, and the implications from the patients' perspective. Avoiding assumptions: what information is helpful and in what form - verbal or written? The procedure itself, the report, the follow-up.

Learning Objectives:

1. To understand the patient-doctor relationship from patients' view.
2. To learn about effective communication and useful information for patients.
3. To learn that an overload of information is equally detrimental to a safe feeling as no information.

A-697 11:20

Patients' point of view (part 2)

D. Walsh; *Dublin/IE (executivedirector@efna.net)*

This presentation will explore the perspective of the neurology patient in terms of what is perceived as useful information and the challenges in communicating this effectively. It will also look at how the radiology department and the patients it serves, can work together to ensure that these barriers are overcome. This will encompass a discussion on the theory of good doctor-patient communication, but also consideration of the structures of health service delivery which may create an environment in which effective communication cannot take place.

Learning Objectives:

1. To understand the patient-doctor relationship from patients' view.
2. To learn about effective communication and useful information for patients.

3. To learn that an overload of information is equally detrimental to a safe feeling as no information.
Author Disclosure:
D. Walsh: Advisory Board; Pfizer Patient Centricity Board. Grant Recipient; The European Federation of Neurological Associations, who I represent as Executive Director, is a patient organisation which is funded by unrestricted grants from a consortia of industry partners..

A-698 11:30

The radiologist as a patient
R. Stern Padovan; *Zagreb/HR (rpstern@mef.hr)*

I was working the whole career as academic radiologist and I was for almost 20 years chair of the large academic radiology department. My prinicpal field of work was abdominal and urogenital radiology and I was not directly involved in breast imaging. Shortly after retirement, I was diagnosed with breast cancer and had to undergo complete surgical and oncologic treatment. Imaging is part of diagnosis and follow-up. Suddenly, I have seen the medical system from the side of the patient and understood more than before the importance of communication between patients and physicians. Radiologists often lack communication skills which render them invisible to patients. In the case of breast cancer patients, radiologists are the first among doctors who should very carefully communicate with patients, inform them of all relevant facts and further steps and demonstrate compassion. Doctors and radiologists require the same as patients from other doctors as non-professional patients. Actually, doctors know much more and should be informed in detail, and with great care. Being aware of the clinical course and potential complications of my disease, which eventually occurred, I was even more vulnerable and needed complete information and an even more tailored approach by all managing physicians. Radiologists need to communicate with patients much more and the importance of that cannot be overemphasized. I strongly believe that radiologists should receive training in this area which is largely neglected.
Learning Objectives:
1. To understand the patient-doctor relationship from patients' view.
2. To learn about effective communication and useful information for patients.
3. To learn that an overload of information is equally detrimental to a safe feeling as no information.

11:40
Panel discussion: How can we improve communication in the department and avoid misunderstanding?

10:30 - 12:00 **Room F1**

E³ - European Diploma Prep Session

E³ 1423
Head and neck

A-699 10:30

Chairperson's introduction
M.G. Mack; *Munich/DE (m.mack@radiologie-muenchen.de)*

During this session, the participants will learn the most common variants and pathologies of the temporal bone, the skull base, the nose, the paranasal sinuses and the nasopharynx as well as the oral cavity, the oro- and hypopharynx and the larynx. Normal anatomy, variants, inflammatory disease as well as benign and malignant tumours will be presented.
Session Objectives:
1. To become familiar with the anatomy and imaging presentation of the most common disorders of the temporal bone and skull base.
2. To understand the imaging presentation of common inflammatory and neoplastic disorders of the nose, paranasal sinuses and nasopharynx.
3. To describe the typical imaging features of the most common neoplastic disorders of the oral cavity, oropharynx, hypopharynx and larynx.

A-700 10:36

A. Temporal bone and skull base
A. Trojanowska; *Lublin/PL (agnieszka30@yahoo.com)*

During the lecture we will first discuss the complex anatomy of the temporal bone with special regards to conductive and sensorineural hearing loss. Next, we will go through most common causes of conductive hearing loss, with emphasis on middle ear tumours including cholesteatoma, and chronic inflammation. Afterwards we will focus on sensorineural hearing loss, including acquired inner ear pathology and developmental anomalies. During second part of this lecture we will go through most important tumours of anterior, middle and posterior skull base. We will discuss the features of different malignancies on CT and MRI images, focusing on providing an informative report for the clinician
Learning Objectives:
1. To differentiate the anatomy, normal variants and congenital disorders of the temporal bone.
2. To understand the causes and imaging features of hearing and vestibular disorders.
3. To describe the imaging presentation of the most common tumours of the skull base.

A-701 11:04

B. Nose, paranasal sinuses and nasopharynx
C. Czerny; *Vienna/AT (christian.czerny@meduniwien.ac.at)*

Radiological imaging of the nose, paranasal sinuses and the nasopharynx is applied in patients with inflammatory or suspected benign or malignant tumours. The knowledge of the normal anatomy and its variants is necessary to understand the pathways of inflammatory and tumourous pathologies and to establish the correct diagnosis. Multidetector-spiral-CT (MDCT) and MRI are the methods of choice for radiological imaging. Additionally, positron emission-computed tomography (PET-CT) is an extremely valuable imaging tool in patients with malignant disease. It is a combination of MDCT and PET. A contrast-enhanced CT is performed - in most cases for staging covering the whole body - and a PET scan after the intravenous application of a tracer (in most cases, fluorodeoxyglucose). Malignant tissues take up the tracer and with the CT-scan the pathology can be exactly anatomically localised. In recent times, positron emission-magnetic resonance tomography (PET-MR) has been introduced. The normal anatomy and its variants as well as the importance of close neighbouring anatomical structures, which can be involved in inflammatory and tumourous disease, will be described. Pathology consists of inflammation and tumours. Inflammation can be differentiated into acute and chronic. Tumours can be either benign or malignant. It is important to describe the exact localisation and extension of the different pathologies. Imaging characteristics and involvement of the surrounding structures may help to differentiate between benign and malignant disease. Uptake of contrast material and tracer - especially when using PET-CT or PET-MR - may well differentiate benign from malignant disease and additionally enable a whole-body scanning with the exact radiological staging.
Learning Objectives:
1. To describe the anatomy and normal variants of the nose, paranasal sinuses and nasopharynx.
2. To differentiate the imaging features of acute and chronic inflammatory changes of the nose and paranasal sinuses.
3. To understand the imaging features of benign and malignant tumours of the nose, paranasal sinuses and nasopharynx.

A-702 11:32

C. Oral cavity, oro- and hypopharynx and larynx
M. Becker; *Geneva/CH (minerva.becker@hcuge.ch)*

The purpose of this lecture is to review common pathologic conditions of the oral cavity, oropharynx, hypopharynx and larynx, to describe the key anatomic structures relevant to tumour spread and to discuss the clinical implications of CT and MRI in the pre-therapeutic work-up of neoplastic lesions, in particular squamous cell carcinoma of the head and neck. A systematic review will include key radiologic features and characteristic patterns of submucosal tumour spread and implications of cross-sectional imaging for staging and treatment. The lecture will also review the characteristic aspect of less common tumours and tumour-like conditions affecting this area. Typical radiologic features will be discussed with an emphasis on potential pitfalls and on how to avoid them. Imaging aspects of Human papilloma Virus (HPV) positive and HPV- negative squamous cell cancers will be addressed and the impact of the new TNM classification on radiologic reporting will be discussed. Emphasis will be put on what the clinician needs to know and how to report the findings in a systematic way.
Learning Objectives:
1. To describe the normal imaging anatomy of the oral cavity, oropharynx, hypopharynx and larynx.
2. To understand the imaging features of tumours of the oral cavity and oropharynx.
3. To describe the imaging features of tumours of the hypopharynx.
4. To understand the imaging features of tumours of the larynx.

10:30 - 12:00 **Room M 4**

E³ - ECR Academies: Tips and Tricks in Pancreatic and GI Tract Imaging

E³ 1422
Pancreatic tumours

A-703 10:30
Chairperson's introduction
R. Pozzi-Mucelli; *Verona/IT (roberto.pozzimucelli@univr.it)*

Pancreatic tumours represent a major challenge to the radiologist, in detection, characterisation and staging. Imaging techniques perform well in the diagnosis of typical forms of ductal adenocarcinoma, However, a multimodality imaging approach is essential in equivocal and difficult cases. A variety of imaging studies, including CT, endoscopic ultrasound (EUS), MRI and positron emission tomography with 18F-fluorodeoxyglucose (FDG PET), have important roles in the diagnosis, staging and follow-up of pancreatic tumours. Primary epithelial neoplasms of the pancreas arise either from the exocrine parenchymal tissue or endocrine islet cells. The differential diagnosis among these different tumours is essential, since these tumours require different therapeutical approches. Although a great improvement has been achieved in the diagnosis of pancreatic diseases by modern imaging modalities, a number of challenging lesions are still difficult to be characterised. This occurs with neoplastic and inflammatory diseases, which, in a limited number of cases, may present with similar imaging features that can be misdiagnosed and subjected to unnecessary surgical treatment. To make a correct differential diagnosis, clinical, morphological and structural (i.e. density and signal intensity) findings have to be evaluated at the same time. The value of the integration of imaging modalities to reach the correct diagnosis will also be discussed in this course.

A-704 10:35
A. Staging adenocarcinoma
N. Kartalis; *Stockholm/SE (nikolaos.kartalis@me.com)*

Pancreatic cancer is a disease with very dismal prognosis. The 5-year survival is around 5% and has been stable over the last decades. The only potential curative treatment is surgical resection combined with adjuvant and/or neoadjuvant medical therapy. However, at diagnosis less than 20% of patients have a resectable tumour, while the rest have tumours that are locally advanced and/or have distant metastases. In order to improve survival, there is a need to increase the number of patients that undergo surgery. However, for the surgical removal to be meaningful, the goal is to achieve complete macroscopic and microscopic removal of tumour (R0-resection). For the identification of patients who will benefit from surgery, the so-called “resectability status” was developed. It is based on the presence and extent of tumour contact with the major peripancreatic vessels such as portomesenteric axis (PV/SMV), hepatic artery, celiac artery and superior mesenteric artery. Depending on the degree of the circumferential tumour-vessel contact the tumours are classified in one of the three categories: resectable, borderline resectable and unresectable. The criteria of the various existing classification systems will be discussed and their differences outlined. Furthermore, the role of CT, MRI and PET-CT in the evaluation of these patients will be analysed and, finally, important aspects of the post-operative imaging follow-up will be presented.
Learning Objectives:
1. To understand the rationale behind local staging of pancreatic adenocarcinoma.
2. To learn about the respective role of CT, MRI and PET/CT.
3. To become familiar with the principle of postoperative follow-up.

A-705 11:03
B. Neuroendocrine tumours
R. Manfredi; *Rome/IT (riccardo.manfredi@unicatt.it)*

Neuroendocrine tumours account for 1.2%-1.5% of all gastrointestinal neoplasms, with an incidence of 1.6-2.0 new cases per 100,000 persons per year. The majority of neuroendocrine tumours occur sporadically; that is, they are non-familial. However, they sometimes occur as part of complex familial endocrine cancer syndromes such as type 1 multiple endocrine neoplasia (MEN 1) and neurofibromatosis type 1. Immunohistochemical staining has played an important role in the diagnosis of neuroendocrine tumours. The neuroendocrine cells of the diffuse neuroendocrine system are characterized by the expression of certain marker proteins, such as chromogranin, synaptophysin, and neuron-specific enolase (NSE). Clinically, neuroendocrine tumours of the pancreas are classified into functioning and non-functioning tumours, according to the symptoms. Non-functioning, hormonally silent, neuroendocrine tumours (NF-NET) represent 68-80% of all NETs, and are diagnosed because of the mass effect exerted by the tumour. Abdominal pain is the most frequent presenting symptom (35-78%), followed by weight loss (20-35%), anorexia and nausea (45%), palpable mass (7-40%), and jaundice (17-50%). According to the 2010 WHO classification, neuroendocrine neoplasms are classified according to the percentage of Ki67, a protein index of cell replication, on the pathologic specimen. There are three categories: G1, Ki-67 index ≤2%; G2, Ki-67 index between 3% and 20%; G3, with Ki-67 index >20%. At diagnostic imaging, neuroendocrine neoplasms are hypervascular compared to the adjacent pancreas in 74% of the cases. Hyper- or isovascularity represents the most suggestive feature of neuroendocrine neoplasms that are helpful in the differential diagnosis with adenocarcinoma.
Learning Objectives:
1. To understand the basics of histological classification of neuroendocrine tumours.
2. To learn about the natural history of these tumours.
3. To become familiar with the usual appearance and imaging specificities of neuroendocrine tumours.

A-706 11:31
C. Tough clinical cases
T.C. Lauenstein; *Essen/DE (thomas.lauenstein@evk-duesseldorf.de)*

The ability to non-invasively diagnose and characterise pancreatic tumours has vast therapeutic implications. However, there are several aspects that may impede a reliable characterisation of a pancreatic lesion. While some pancreatic tumours exhibit typical imaging findings, there is often an overlap of imaging findings between different lesions, e.g. pseudotumours due to chronic pancreatitis and adenocarcinoma of the pancreas. We often face the same dilemma as far as cystic pancreatic lesions are concerned, since some cystic tumours have a potential for malignant transformation including IPMN or mucinous cystadenomas. Furthermore, there is a large variety of diagnostic tools available for the assessment of pancreatic disease, including ultrasonography, endosonography, CT, MRI and PET. It is important to understand the strengths and weaknesses of these diagnostic modalities, particularly in equivocal cases of pancreatic lesions. Eventually, biopsy samples are often needed either to establish a diagnosis or to allow for a more profound histopathological analysis of tumour tissue. Several challenging cases of pancreatic tumours will be presented in this lecture. Differential diagnoses will be discussed and a diagnostic algorithm for each case will be proposed.
Learning Objectives:
1. To be able to define diagnostic probabilities when facing an unknown case of solid mass in the pancreas.
2. To understand the role of multimodality approach, including endosonography and biopsy.

10:30 - 12:00 **Room M 5**

Transatlantic Course of ESR and RSNA (Radiological Society of North America): Sports Imaging

TC 1428
Lower extremity sports injuries
Moderators:
L.W. Bancroft; Orlando, FL/US
A.J. Grainger; Leeds/UK

A-707 10:30
A. Sports-related injuries of the knee: what does the orthopaedic surgeon need to know?
T.T. Miller; *New York, NY/US (millertt@hss.edu)*

MRI has become the workhorse of musculoskeletal imaging, and in most practices the knee is the most commonly imaged joint. We will review examples of cruciate ligament and meniscal injuries (with attention to diagnostic pitfalls and post operative appearances), patterns of injury, osteochondral injuries and repair, and periarticular tendinous and ligamentous injuries. We will also discuss features of these injuries that help the surgeon decide whether to operate.
Learning Objectives:
1. To learn about what to include in knee MRI dictation templates.
2. To understand the most common sports-related injury patterns in the knee.
3. To appreciate which specific orthopedic indications should prompt additional information in the dictation.

A-708 11:00

B. Multimodality imaging of foot and ankle injuries in the athlete

A.J. Grainger; *Leeds/UK (andrewgrainger@nhs.net)*

Ankle injuries are common in many sports, and the complicated anatomy of the ankle joint can be challenging to the reporting radiologist. The ankle joint itself is a synovial hinge joint, but important movement for ankle function also occurs at the joints of the hind and midfoot which are also susceptible to injury. In addition to conventional radiographs, CT, MRI and ultrasound all have important roles to play in the diagnosis of foot and ankle injuries in the athlete. The ligamentous and tendon structures about the ankle are generally superficial in nature and readily amenable to assessment with ultrasound, where assessment can be enhanced due to the dynamic capabilities of the technique. While MRI also demonstrates these structures, it has advantages for assessing deeper joint structures such as the chondral surfaces and bones. The complex 3D anatomy of the foot and ankle means that conventional radiographs can struggle to demonstrate bone injury which means CT also has an important role to play. This lecture will focus on the use of these imaging modalities for the assessment of acute and chronic ligamentous and tendon injury. Emphasis will be put on the mechanisms of injury and how they determine the resultant patterns of injury and the imaging appearances.

Learning Objectives:

1. To appreciate the different and often contributory roles that imaging modalities have in the foot and ankle.
2. To recognise the most common ligamentous and tendon injuries in the ankle.
3. To understand how common patterns of injury relate to the mechanisms involved.

A-709/A-710 11:30

C. Interactive case discussion

T.T. Miller[1], A.J. Grainger[2]; *[1]New York, NY/US, [2]Leeds/UK (millertt@hss.edu)[1], (andrewgrainger@nhs.net)[2]*

Several cases of knee MRI will be shown, demonstrating examples of various abnormalities such as internal derangement (cruciate ligament and meniscal injuries), osteochondral injuries, abnormalities of the extensor mechanism, collateral ligamentous injuries, and patterns of injury. These cases will be examples of what the orthopedic surgeon wants to know.

Learning Objectives:

1. To appreciate common patterns of athletic injury in the knee.
2. To become familiar with the techniques available and imaging appearances of knee, foot and ankle athletic injury.
3. To consolidate the knowledge gained from the session with interactive cases of lower limb athletic injury.

12:15 - 12:45 **Room A**

Headline Session

HL 3

Josef Lissner Honorary Lecture

Presiding:
B. Hamm; Berlin/DE

A-714 12:15

Human papilloma virus and head and neck cancer: the new face of malignancy

A. Trojanowska; *Lublin/PL (agnieszka30@yahoo.com)*

Head and neck cancer is a commonly encountered pathology. Oropharyngeal location of the disease is increasing rapidly, affecting young people and its relation with oropharyngeal infection by oncogenic type-16 human papillomavirus (HPV) has been proven. The clinical and biologic profile of HPV-positive patients is distinct from any other head and neck squamous cell cancer patients, however, it is not possible to differentiate the HPV status based on imaging studies. HPV-positive patients have a tendency towards early lymph nodes metastasis, more frequent distant metastatic disease and much better response to non-surgical treatment, comparing to HPV-negative ones. Detection of intratumoral oncogenic HPV DNA seems to be mandatory now, since it determines prognosis in terms of long-term survival and locoregional control. A policy of vaccination for both girls and boys may be the key answer to a growing number of this particular cancer

Learning Objectives:

1. To describe the behavior of human papilloma virus.
2. To understand the specific biology and imaging features of HPV - positive cancer of the head and neck.
3. To become familiar with effective diagnostic imaging procedures, treatment and follow-up of these tumour.

12:30 - 13:30 **Room C**

E³ - The Beauty of Basic Knowledge: Cardiovascular and Interventional Radiology

E³ 24D

CT of the heart made easy

Moderator:
C. Loewe; Vienna/AT

A-718 12:30

Cardiovascular risk estimation made easy: CA-scoring

R. Vliegenthart; *Groningen/NL (r.vliegenthart@umcg.nl)*

Evaluation of the extent of atherosclerotic plaque may improve cardiovascular risk stratification in primary prevention. Among the non-invasive measures of atherosclerosis, focus has turned to assessment of coronary calcification by non-contrast-enhanced computed tomography (CT). The calcium score increases with age, and is generally higher for men than for women. The calcium score is divided into 4 categories: 0 (none), 1-99 (mild), 100-399 (moderate), and at least 400 (severe coronary calcification). Another commonly used approach is to calculate an age- and gender-matched percentile. The calcium score is predictive of coronary events in men and women, and in younger and older populations. The relative risks for increasing calcium scores are much higher than those reported for cardiovascular risk factors or other measures of atherosclerosis. Additionally, the absence of coronary calcification indicates a very low risk of cardiovascular disease. According to latest guidelines, calcium scoring should be considered in asymptomatic individuals at intermediate risk based on risk factors. In this group, calcium scoring leads to more appropriate risk classification, into the low- or high-risk group. There is increasing interest in a zero calcium score in patients with chest pain. The presence of >50% coronary stenosis and coronary events was found to be very unlikely in case of a zero calcium score, in both acute and non-acute patients. It seems likely that calcium scoring will play a role in the diagnostic algorithm of patients with chest pain in the future, especially to exclude coronary artery disease.

Learning Objectives:

1. To learn about importance of risk estimation in coronary artery disease.
2. To understand the principle of CA-scoring quantification.
3. To appreciate the value of “zero calcium” as well as of “high calcium”.

R. Vliegenthart: Research/Grant Support; Institutional grant Siemens.

A-719 13:00

Non-invasive coronary (CT) angiography made easy

F. Bamberg; *Tübingen/DE (fabian.bamberg@uni-tuebingen.de)*

Cardiac CT angiography has undergone a tremendous development over the last two decades and is diffusing into current medical practice substantially. On the one hand, this can be attributed to emerging scientific evidence demonstrating the incremental value of implementing cardiac CT angiography in diagnostic strategies; on the other hand, the technique itself has become very robust and broadly applicable. Still, performing a cardiac CT angiography requires some basic understanding of the underlying technical principles, physiological circumstances, and the coronary anatomy. The presentation will review available protocols and techniques and provide a straightforward approach to cardiac CTA acquisitions. Practical tips and tricks as well as limitations of the technique will be covered.

Learning Objectives:

1. To learn about optimised examination technique of non-invasive coronary CT angiography.
2. To understand the need for structured approach to coronary CT angiography.
3. To appreciate clinical value of non-invasive coronary CT angiography.

Author Disclosure:

F. Bamberg: Research/Grant Support; Siemens Healthineers, Bayer Healthcare. Speaker; Siemens Healthineers, Bayer Healthcare.

12:30 - 13:30 **Room D**

E³ - The Beauty of Basic Knowledge: A Survival Guide to Musculoskeletal Imaging

E³ 25D

Acute trauma: patterns in the peripheral skeleton

Moderator:
V.N. Cassar-Pullicino; Oswestry/UK

A-720 12:30

Acute trauma: patterns in the peripheral skeleton
J. Teh; *Oxford/UK (jamesteh1@googlemail.com)*

A systematic approach to analyse trauma imaging of the peripheral skeleton is presented. Typically, imaging begins with x-rays. A stepwise approach may reveal subtle abnormalities that should prompt further action. For example, the presence of a Segond fracture on x-ray suggests an ACL injury and thus should lead to an MRI scan. It should be recognized that in trauma, certain injuries cannot occur in isolation; therefore, a dislocated radial head on elbow x-ray should prompt imaging of the whole forearm, as Monteggia fracture-dislocation may be present. Understanding the mechanisms of injury allows the radiologist to predict the patterns of injury. So if bone bruising is present on MRI in the lateral femoral condyle and medial patella, a lateral patellar dislocation should be suspected and a specific search for an injury of the medial retinaculum should be made. Conversely, recognizing classic patterns of injury can allow the mechanism of injury to be deduced. This lecture will focus on the classical patterns of acute trauma in the peripheral skeleton.

Learning Objectives:
1. To become familiar with the imaging manifestations of common important injuries in the upper and lower limb.
2. To understand the underlying mechanism that result in combination of injuries.
3. To learn how to best employ imaging modalities in their diagnosis.

12:30 - 13:45 **Room M 1**

New Horizons Session

NH 14

The new horizon for radiology

A-721/A-722 12:30

Chairpersons' introduction
L. Donoso[1], B. Hamm[2]; *[1]Barcelona/ES, [2]Berlin/DE*

Session Objectives:
1. To become familiar with the challenge and opportunities of artificial intelligence.
2. To become familiar with the Department of Diagnostics of the future.
3. To learn from experts how to organise integrated diagnostics.
4. To learn about integrated diagnostics from the European and American experience.

A-723 12:35

What will the radiologist's job look like in 2025?
W. Kim; *Los Angeles, CA/US (woojinrad@gmail.com)*

Today, plenty of fear, hope, and hype encompass the use of artificial intelligence (AI) in radiology. Many AI experts have predicted the demise of radiology by having AI replace radiologists in the near future. These predictions have impacted the career choices of medical students, caused worries for the radiology trainees, and brought concerns to many practising radiologists. However, much of these so-called expert opinions are based on a very simplified view of what we do as radiologists. Furthermore, when it comes to AI in radiology, with media attention and many startups focused on using AI to identify findings within medical images, it is easy for us in the radiology profession to have "tunnel vision" about AI in our field. It is important to widen our view to see the many other ways AI can benefit medical imaging. In 2014, there was a Journal of the American College of Radiology article on something called the "imaging value chain" that described various processes within radiology from ordering to reporting and communication. This value chain illustrates various areas where AI can augment and improve radiology. Throughout history, radiologists have adapted to technological innovations and made adjustments to integrate them into our workflow. AI will soon become an integral part of our lives and our profession. As we learn to integrate AI into radiology, we must have a wider view to take full advantage of this emerging technology and maximise our role in patient care.

Learning Objectives:
1. To appreciate why some radiologists fear artificial intelligence (AI).
2. To learn about the role AI can play beyond interpretation of images.
3. To learn about how AI can augment radiologists and what we can do to maximise its positive potential.

Transforming the integrated diagnosis (ID) opportunity into the Diagnostic Institute (DI) innovative change management
P. Ros; *Cleveland, OH/US (Pablo.Ros@UHhospitals.org)*

In recent years, voices have been calling for tighter integration between radiology, pathology, and genomics. This multidisciplinary convergence is captured by the term Integrated Diagnostics (ID). Now is the right time for a move toward ID, based on current technology advances. One major change is that anatomic pathology is transforming from an analogue (slide and microscope) approach to a digital workflow at a rapid pace, thanks to whole slide imaging scanners and pathology picture archiving and communication systems (PACS) for large scale, clinical use. With digital pathology, the cross-disciplinary IT tools greatly expand. Moreover, there is the strong trend for quantification of image contents to enable large-scale computational analysis. We discuss three pillars for an effective ID practice The first pillar standardizes the pathways through diagnostics that can be quite complex. In our design of an ID practice, the diagnosticians would take on a larger responsibility and would directly decide on follow-up studies when the next step in the pathway is clear. The second pillar is facilitated joint radiology -genomics decision-making. The third pillar is dependent on the service level provided and perceived by the customers—the referring clinicians, patients, and, ultimately,, society. This is essential to ensure the ultimate success of radiology, pathology and genetics. The opportunities described sum up a strong call for focusing on ID as one of the key forefronts of health-care development forming diagnostic institutes.

Learning Objectives:
1. To learn the concept of integrated diagnosis (ID) combining the practices of radiology, pathology and genomics into an innovative diagnostic tool.
2. To understand how the computational resolution provides the technology basis for the cross-disciplinary implementation of ID.
3. To share the early experience of first Diagnostic Institute established in a large Academic Health System in the US in 2017.

A-725 13:05

Medical imaging and clinical laboratories: a fruitful liaison
J.E. Wildberger; *Maastricht/NL (j.wildberger@mumc.nl)*

Setting up a global diagnostic chain offers new opportunities to optimise patient logistics and to become more (cost-)effective. As a first step, all diagnostic departments in our center were clustered into the "division of medical imaging and clinical laboratories" in 2011. In December 2016, the departments of radiology and nuclear medicine were fused. Based on lean principles (operational excellence), a framework of breakthrough objectives has been established. Achievements are shared and updated on a regular basis. From a radiological perspective, the next step to be taken is the implementation of an uniform reporting platform for imaging and pathology. In parallel, all diagnostic laboratory information systems are to be homogenised and clustered. This set-up forms the basis for a deep integration of underlying logistics, shared infrastructure, as well as for optimisation of current management information and reporting. By doing so, bioinformatics can be further developed, not only for the clinics but also in the scientific setting. Standardisation throughout the entire diagnostic chain will guarantee high quality data sets for new insights on a larger scale. Sharing this information openly and cross-disciplinary will help to further optimise patient care.

Learning Objectives:
1. To understand why we should cluster the entire diagnostic chain.
2. To learn how "unity in diversity" can be achieved in a clinical setting.
3. To become familiar with the opportunities of this approach for bioinformatics, data sciences and artificial intelligence.

A. Fractures in children

K.J. Johnson; *Birmingham/UK (karl.johnson@bch.nhs.uk)*

Traumatic injury and fracturing are some of the commonest reasons why children present to hospital and undergo radiological investigation. The anatomy and physiology of the growing skeleton is different from that of adults and, as a consequence, some of the fractures and injuries are unique to children. This presentation will demonstrate the various types of incomplete fracture which occur within the more plastic skeleton of the child. It will detail the different types of Salter-Harris fractures which can occur across the unfused growth plate. The differences in relative strength of bone and ligamental attachments which are seen in children and the consequences of the different types of injuries which can occur will be illustrated. The importance of recognising the normal variants of growth from pathological change will also be highlighted. The importance of understanding the child's development and mobility and how this correlates with the injury patterns seen in normal childhood will be discussed along with an understanding of the injury patterns and fracture types which occur from inflicted physical injury.

Learning Objectives:

1. To become familiar with different traumatic fracture types.
2. To identify possible criteria for child abuse.

A-732 14:45

B. Typical MRI applications in paediatric musculoskeletal imaging

K. Rosendahl; *Bergen/NO (karen.rosendahl@helse-bergen.no)*

Magnetic resonance imaging (MRI) has become exceedingly important in the diagnosis and follow-up of MSK disease, allowing for targeted therapy. MRI uses non-ionising radiation, has a high soft-tissue resolution and discrimination and may provide both morphological and functional information. Correct interpretation depends on extensive knowledge of physical properties and *normal appearances* of the imaged tissue and of the pathophysiological disease processes. Imaging of the paediatric skeleton represents a particular challenge as normal appearances change over time, thus mimicking diseases such as juvenile idiopathic arthritis (JIA), osteomyelitis, malignancies and traumatic changes. All the aforementioned diseases represent typical MRI applications in paediatric MSK imaging. During this lecture, I will discuss imaging strategies, findings and differentials.

Learning Objectives:

1. To learn indications of paediatric MRI.
2. To become familiar with MR imaging findings in children.

14:00 - 15:30 **Room B**

Professional Challenges Session

Artificial intelligence and big data in medical imaging

A-733 14:00

Chairperson's introduction

W.J. Niessen; *Rotterdam/NL (w.niessen@erasmusmc.nl)*

The analysis of big data with artificial intelligence techniques will have an enormous impact on disease prevention, cure and care, and by 2030 it will have dramatically changed the landscape of the health-care system. This session will show examples of possible large benefits of big data analytics in health care from the imaging perspective. Specifically, in this introduction I will provide examples to show that the use of AI and big data should be embraced, as it has a large potential to realizing the potential of precision medicine and precision health, both in dementia and oncology.

Session Objectives:

1. To learn about the disruptive role that big data and artificial intelligence can play in medical imaging.
2. To appreciate that these technologies are key to realise the full potential of precision medicine.
3. To appreciate where the big challenges and opportunities are.

IT infrastructure, data sharing methods and data analysis aspects

A. Alberich-Bayarri; *Valencia/ES (alberich_ang@gva.es)*

Quantitative image analysis solutions and artificial intelligence (AI)-based methods usually find interoperability issues when trying to transfer information with hospital information systems (HIS) and electronic health records (HER). Appropriate quantitative data management would allow for a better understanding of the tissue and organ alterations in the disease and their relationship with patient characteristics and associated clinical or lab data. The image reading process is today in constant improvement, from traditional image reading by the naked eye and free text reporting of the findings, towards the inclusion of new technologies in the loop such as AI computer-aided detection and diagnosis (CAD), imaging biomarker extraction and structured reporting. To cover all clinical needs using AI solutions, quantitative imaging and structured reporting, a technological framework was engineered. The platform is modular and allows the installation both in local and cloud environments. The solution also includes a built-in anonymization module and allows for the incorporation of AI and image processing plug-ins. After the analysis of the images through the different pipelines, a quantitative structured report is generated, which can be integrated with hospital information systems. The platform allows for the mining of quantitative data extracted from patients, a functionality which is not available nowadays in PACS systems and workstations.

Learning Objectives:

1. To understand the importance of creating IT infrastructures for the management of quantitative medical image analysis solutions, both for research and clinical applications.
2. To become familiar with the main storage and computational requirements for high performance infrastructures.
3. To learn about how to move from research to clinical application in the field of quantitative imaging and biomarkers.

Machine learning in the biomedical domain: challenges and opportunities

M. de Bruijne; *Rotterdam/NL (marleen.debruijne@erasmusmc.nl)*

This lecture introduces the current state-of-the-art techniques in machine learning in medical imaging, highlights the potential of these techniques for computer-aided diagnosis and quantitative imaging biomarkers, addresses challenges related to variations in scan protocols and a requirement of annotated data for model training, and presents examples of successful applications of machine learning in radiology.

Learning Objectives:

1. To learn about machine learning concepts used for diagnosis, prognosis, and quantitative analysis of medical imaging data.
2. To understand the challenges to introduce these techniques in clinical practice.
3. To appreciate the potential of machine learning in radiology.

Patterns of pulmonary toxicity

Moderator:
J.E. Roos; Lucerne/CH

A-737 14:00

A. Drug-induced lung disease
C.M. Schaefer-Prokop; *Amersfoort/NL (cornelia.schaeferprokop@gmail.com)*

Drug-induced lung disease is an underreported cause of acute and chronic lung disease. It affects up to 10% of patients receiving chemotherapy for hematological and solid organ malignancies. Two mechanisms are differentiated: lung injury due to direct toxic injury and due to hypersensitivity reactions. Numerous CT patterns are seen in the context of drug induced lung disease ranging from diffuse alveolar damage (DAD) to all forms of acute and chronic interstitial pneumonia but also includes nodules, pleural effusion and airways reactions. The presentation will illustrate the most frequent CT patterns to be encountered in drug induced lung injury and provide keys how to differentiate them from other lung pathology such as infection, edema or underlying malignancy. Drugs, known for potential lung injury will be discussed, including new immunotherapeutic drugs. Further on, case-based discussion of typical clinical scenarios will provide you with practical tools for analysis.
Learning Objectives:
1. To learn about the various CT patterns of lung injury.
2. To understand the role of imaging in their recognition.
3. To discuss differential diagnoses.

A-738 14:30

B. Smoking-related lung disease
S.R. Desai; *London/UK (s.desai@rbht.nhs.uk)*

It is generally accepted that, in addition to the well known consequences of COPD and lung cancer, smoking may cause interstitial lung disease (ILD). The hypothesis that tobacco smoke can cause ILD - and, specifically, pulmonary fibrosis - dates back to the 1960s. The histopathological and radiological features of interstitial lung disease caused by smoking are variable and frequently overlapping, the latter prompting the introduction of the generic term 'smoking-related interstitial lung disease'. The list of interstitial lung disease, in which smoking is believed to have an aetiological role, includes Langerhans' cell histiocytosis, respiratory bronchiolitis/respiratory bronchiolitis-interstitial lung disease and desquamative interstitial pneumonia. There is also evidence which indicates that smoking may be associated with other patterns of pulmonary fibrosis (e.g. nonspecific interstitial pneumonia and smoking-related interstitial fibrosis). In the present session the pathology and imaging of the ILD known to be caused by smoking; the typical appearances and the diagnostic challenges will be discussed.
Learning Objectives:
1. To learn about the classification of smoking-related lung diseases.
2. To understand the most common CT patterns.
3. To highlight newly recognised entities.
Author Disclosure:
S.R. Desai: Board Member; Deputy Editor, European Radiology.

A-739 15:00

C. Inhalation lung injury beyond smoking
J.A. Verschakelen; *Leuven/BE (johny.verschakelen@uz.kuleuven.ac.be)*

Non-smoking-related inhalation lung injury is usually secondary to chronic or repetitive occupational or environmental exposures, but may also result from inhalation of smoke or of chemical products of combustion, a condition that is mostly associated with significant morbidity and mortality. Every year new agents causing pulmonary injury are described, and although many are isolated cases others prove to be clustered or repetitive events with more or less specific imaging features. The clinical and radiological presentation of inhalational lung injury depends, on one hand, on the chronicity of inhalation, the amount and phase of the inhaled agent and its toxicity to the lung and, on the other, on the reaction of the lung to this injury. This presentation will focus on the CT features seen after non-smoking-related lung injury caused by direct chemical toxicity to the bronchial tree and lungs and by chronic or repetitive inhalation of particulates and organic dusts. Attention will also be given to the inflammatory syndrome seen in hypersensitivity pneumonitis.
Learning Objectives:
1. To learn about the various causes of environmental lung diseases.
2. To understand the changes related to acute lung injury.
3. To describe the long-term sequelae of inhalation lung injury.

14:00 - 15:30 **Room O**

Special Focus Session

SF 15a

Hybrid imaging in oncology

A-740 14:00

Chairperson's introduction
M.E. Mayerhöfer; *Vienna/AT (marius.mayerhoefer@meduniwien.ac.at)*

Hybrid imaging has revolutionized the field of oncologic imaging within the last decade. [18F]FDG-PET/CT in particular is now an integral part of the management guidelines for different tumours (e.g. lymphoma), with a particular emphasis on treatment response assessment. Despite the success of [18F]FDG in oncologic imaging, there is a clear trend towards development and clinical application of novel, tumour-specific PET tracers, such as [68Ga]PSMA for prostate cancer. Since PET/CT is only of limited value for local staging of the primary tumour in several malignancies (e.g., rectal cancer and gynaecological cancers), hybrid MR/PET scanners were developed and are presently being compared to PET/CT in an increasing number of studies. Furthermore, the MR component of MR/PET offers additional functional and even quantitative information, derived from techniques such as diffusion-weighted imaging (DWI) and dynamic contrast-enhanced imaging. The combination of PET- and MRI-based parameters may not only improve non-invasive, image-based characterization of tumours (including assessment of tumour heterogeneity), but may also enable better assessment of response to novel types of immunotherapies that have recently become available. Because of this multi-parametric approach, hybrid imaging has the potential to contribute significantly to the success of precision medicine.
Session Objectives:
1. To identify key clinical applications for hybrid imaging in oncology.
2. To compare PET/CT and MR/PET for tumour detection, staging and restaging.
3. To discuss the use of established and novel radiotracers and functional MR sequences for tumour characterisation and treatment response assessment.

A-741 14:05

Role of hybrid imaging in thoracic malignancies
G. Cook; *London/UK (Gary.Cook@kcl.ac.uk)*

18F-FDG PET/CT is now established in the management of solitary pulmonary nodules and the staging of lung cancer and mesothelioma when there is curative intent. Whilst 18F-FDG PET/CT is of undoubted clinical value, there are circumstances when the sensitivity or specificity is limited and therefore efforts have been made to evaluate new radiopharmaceuticals to improve characterisation, treatment stratification and treatment monitoring. These include 18F-FLT for cellular proliferation, 18F-MISO (and other compounds) for measuring tumour hypoxia, and angiogenesis-targeting radiopharmaceuticals and 68Ga-DOTA-peptides for detection of neuroendocrine tumours. As well as the development of new tracers to evaluate underlying buiological characteristics of thoracic malignancy, there is growing interest in the extraction of additional parameters from PET and CT that describe heterogeneity within an image or in a radiomics approach to better characterise lung cancers and improve the predictive and prognostic ability.
Learning Objectives:
1. To become familiar with the PET tracers used in thoracic malignancies.
2. To learn the interpretation of PET/CT in lung cancer, mesothelioma, and neuroendocrine tumours of the lungs.
3. To discuss the possible benefits of tumour heterogeneity assessment on hybrid imaging.

A-742 14:23

Prostate cancer: the "killer application" for MR/PET?
M.R. Makowski; *Berlin/DE (marcus.makowski@charite.de)*

In this lecture, we will give an overview of the potential of MR/PET in the context of prostate cancer. The different available MR/PET acquisition protocols will be introduced. The evaluation and interpretation of datasets acquired during MR/PET acquisitions will be discussed. We will highlight the strengths and weaknesses of MR/PET for the evaluation of patients with prostate cancer and give an outlook regarding the potential of this technique.

Learning Objectives:
1. To learn pelvic MR/PET acquisition protocols, normal anatomy, and pitfalls.
2. To become familiar with interpretation of MR/PET in the settings of prostate cancer.
3. To understand strengths and weaknesses of MR/PET applied to prostate cancer.

A-743 14:41

MR/PET of breast tumours

K. Pinker-Domenig; *Vienna/AT (pinkerdk@mskcc.org)*

Cancer development is characterised by several biological capabilities or so-called hallmarks, which comprise sustaining proliferative signalling, evading growth suppressors, resisting cell death, enabling replicative immortality, inducing angiogenesis, and activating invasion and metastasis. With medicine entering the genomic era, personalised approaches towards treatment, which require a deeper understanding of the hallmarks of cancer, are being explored and ultimately will be implemented in patient care. To match advanced therapeutic strategies in the era of personalised medicine, diagnostic tests must be equally multilayered and complex to identify the relevant underlying processes of cancer development and progression. In this context, multiparametric magnetic resonance imaging (MRI) and positron emission tomography/MRI (PET/MRI), which, in addition to morphologic changes, can simultaneously assess a multitude of functional cancer-related processes, have emerged as exceptionally powerful, versatile, and precise imaging techniques. Multiparametric functional imaging of the breast aims to simultaneously quantify and visualise multiple functional processes at the cellular and molecular levels to further elucidate the development and progression of breast cancer and the response to treatment. There is evidence that multiparametric functional imaging, using different MRI and PET parameters, provides detailed information about the hallmarks of cancer and, thus, improves the diagnostic accuracy and assessment of response to neoadjuvant therapy. Multiparametric functional MRI provides a variety of techniques to assess functional tumour characteristics such as diffusion-weighted imaging, dynamic contrast-enhanced imaging and multi-nuclei magnetic resonance spectroscopic imaging. PET/(MRI) detects and quantifies radiolabelled tracer substances, which allows the measurement of specific functional characteristics of breast cancer such as increased glucose uptake, tumour hypoxia or hormonal receptor expression. This talk aims to summarize the current and emerging applications of PET/MRI in breast tumours.

Learning Objectives:
1. To understand the principle of multimodality multiparametric functional imaging of breast tumours with MR/PET.
2. To identify the potential and challenges of multiparametric breast MR/PET using different quantitative functional parameters.
3. To realise the potential of novel tracers for personalised medicine.

A-744 14:59

MR/PET of pelvic cancers

P.R. Ros; *Cleveland, OH/US (Pablo.Ros@UHhospitals.org)*

PET/MRI raises the hope of providing a comprehensive TNM staging of pelvic malignancies in one single imaging examination. Combining the high diagnostic accuracy from PET with the excellent soft tissue contrast of MR enables accurate assessment of primary tumours and nodal metastases. In our experience, FDG-PET/MR is distinctly helpful in (a) advanced pelvic cancers for staging and treatment planning, (b) in a post-treatment setting of recurrence and (c) in equivocal cases where other methods failed to determine the exact origin and extent of the neoplastic disease. PET/MRI can characterize therapeutic fibrosis and tissue scarring after therapy, which significantly improves the detection of recurrent diseases. FDG-PET/MR plays an important role in ovarian cancer for all stages of disease: (1) the use of DWI in MRI is helpful in detecting small peritoneal deposits, which escape detection on FDG-PET; (2) MRI facilitates the distinction of FDG-avid peritoneal and serosal implants from physiological bowel uptake, and 3) MRI can improve lesion detection and localisation. Another benefit PET/MR provides is a specific GTV (gross tumour volume) which is critical to the treatment of cervical cancer patients. The use of PET/MR for prostatic cancer evaluation with Ga-68 PSMA is the newest application in pelvic malignancies. Several Ga-68-labelled ligands of prostate-specific membrane antigen (PSMA) have recently been developed with promising results. Ga-68 PSMA offers a higher tumour-to-tissue contrast compared to FDG, resulting in an accurate evaluation of the prostate gland, highly sensitive loco-regional staging as well as visualising distant metastases.

Learning Objectives:
1. To learn pelvic MR/PET acquisition protocols, normal anatomy, and pitfalls.
2. To become familiar with interpretation of MR/PET in the settings of pelvic cancers.
3. To understand strengthens and weaknesses of MR/PET applied to pelvic cancers.

15:17
Panel discussion: Does the multiparametric approach have a clinical benefit?

14:00 - 15:30 **Room N**

Cardiac

RC 1503

What a radiologist needs to know about imaging of myocardial viability

A-745 14:00

Chairperson's introduction

C. Peebles; *Southampton/UK (Charles.Peebles@suht.swest.nhs.uk)*

The concept of myocardial viability is central to the investigation and management of ischaemic heart disease (IHD). Viable myocardium is defined as 'dysfunctional myocardium that maintains the potential to return to normal function' e.g. it is alive and not dead. Dysfunctional, but viable myocardium is the end result of ischaemic myocardial injury that can either be acute (stunning) or chronic (hibernating). In the former, a single acute ischaemic injury causes temporary dysfunction that will recover after restoration of myocardial blood flow, but there may be a delay of weeks or months for this to occur. Hibernation is the end result of chronic or repetitive ischaemia causing downregulation of myocyte metabolism and function, which will again recover following revascularisation. Accurate identification of viable myocardium is critical, as revascularisation of non-viable myocardium confers the risks of revascularisation without the benefits of functional recovery. Conversely, failing to revascularise viable myocardium that is ischaemic may place the patient at increased risk. The two general approaches to identifying viable myocardium are functional improvement of a regional wall motion abnormality during low dose stress or identification of myocardial scar that involves less than the full thickness of a myocardial segment. The first approach is adopted by stress echo and dobutamine stress CMR. The second approach requires the use of extracellular contrast agent and is usually performed by CMR with late gadolinium enhancement or CT with iodinated contrast and delayed imaging. This session will compare the standard techniques for viability imaging and discuss their pros and cons.

Session Objectives:
1. To understand what viability means.
2. To understand current state-of-the-art knowledge about the principle of viability.
3. To understand shortcomings of echo and SPECT compared to other techniques.

A-746 14:05

A. MRI

J. Bogaert; *Leuven/BE (Jan.Bogaert@uz.kuleuven.ac.be)*

Ischaemic heart failure is probably the most challenging issue in cardiology today, posing an enormous medical and financial burden on our society. Conceptually, it represents a maladaptive cardiac remodelling due to acute and/or chronic coronary artery disease (CAD) with varying degrees of left ventricular (LV) dilatation and dysfunction. Though therapeutic options have improved overall survival over the years, mortality rates remain high and in daily practice cardiologists not infrequently face the therapeutic dilemma whether a revascularization procedure will lead to symptomatic and prognostic benefit for the patient. Simple, straightforward guidelines are lacking because of the complexity of the disease. Moreover, the issue of viability imaging grounded on observational, and retrospective studies has recently been challenged by the publication of prospective, randomized trials (e.g. STICH and PARR trial) showing no benefit of revascularization or of pre-procedural viability assessment in those patients. These contradictory findings have obliged us to enquire whether viability imaging still is relevant and what is needed to make it more appropriate.

Learning Objectives:
1. To learn about how MR should be performed to assess viability.
2. To understand the strength and weaknesses of MR compared to other techniques.
3. To learn how to report MRI for viability assessment.

A-747 14:28

B. Hybrid imaging

O. Ratib; *Geneva/CH*

Hybrid imaging combining molecular imaging (PET or SPECT) with anatomical and functional imagine (CT and MRI) offers a scope of new clinical applications. Traditional myocardial perfusion scans (SPECT) combined with advanced CT of coronary arteries anatomy and calcium scoring allows a better assessment of the degree of coronary disease and the risk of future events and objective determination of the appropriateness of therapeutics interventions. The development of new radiotracers for PET imaging of myocardial perfusion and viability opens new perspective for more objective evaluation of the efficacy of new treatments. The emergence of hybrid PET-MR imaging offer new perspectives for cardiac imaging. Functional MR allow identifying areas of decreased myocardial perfusion and tissue viability. PET provides more quantitative data on true tissue perfusion and metabolism and quantitative myocardial flow and coronary flow reserve. The combination of both modalities, improve the accuracy and reproducibility of diagnostic procedures. But the true potential of hybrid PET-MR may reside in applications beyond coronary artery disease. It is shown that the combination of both modalities help better characterise atherosclerotic plaques and identify plaques with high risks of rupture. Development of new tracers will allow evaluating myocardial remodeling and assessment of stem cell therapy in myocardial infarction. It will also provide new means for evaluating alterations in cardiac innervation and angiogenesis and even in assessment of reporter gene technologies.

Learning Objectives:

1. To learn about how hybrid imaging should be performed to assess viability.
2. To understand the strength and weaknesses of hybrid imaging compared to other techniques.
3. To understand how hybrid imaging could be developed in clinical practice.

A-748 14:51

C. CT

F. Bamberg; *Tübingen/DE (fabian.bamberg@uni-tuebingen.de)*

Given its high relevance, substantial research efforts have been focused on the development of different cardiac CT methods to obtain information on myocardial viability. Despite a relatively low level of scientific evidence, these approaches are currently initially entering the clinical arena. Analogous to the presence of late gadolinium enhancement on MRI, viability imaging using cardiac CT may be limited to the detection of delayed iodinated contrast enhancement on delayed CT acquisitions. However, from a clinical perspective CT myocardia imaging protocols are generally combined with myocardial perfusion imaging at rest and stress. In general, such a protocol includes as a first step perfusion imaging followed by a second step that includes a low-radiation scan for the detection of DCE. Of note, perfusion imaging by CT can be conducted as a “single-shot” acquisition with or without dual energy or as a dynamic acquisition during rest or stress conditions. The talk will provide an overview of available approaches and protocols, highlight limitation, and review current level of evidence related to the role of CT for assessment of myocardial viability.

Learning Objectives:

1. To learn about the potential of CT to assess viability.
2. To understand the strength and weaknesses of CT imaging compared to other techniques.
3. To understand how to report CT for viability assessment.

Update on functional genitourinary MRI

Moderator:

M. Studniarek; Gdansk/PL

A-749 14:00

A. Kidney

N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Renal physiology is complex with two compartments functioning under highly different conditions. The cortex is highly perfused with a high level of oxygen, whereas the medulla shows a poor perfusion level and works under hypoxic conditions. Water movements are multiple along the nephrons to maintain normal homeostasis. Glomerular filtration rate is a major marker of renal function, but its measurement is complex to be obtained in clinics. All these parameters can be approached using functional MRI with DCE, DWI, and BOLD. However, validation of these tools and their impact on patient management still requires further prospective studies. Some of these techniques may reflect changes within the extracellular matrix of renal tissue during the process of renal scarring.

Learning Objectives:

1. To learn about the renal physiology and the pharmacokinetics of contrast agents.
2. To understand the clinical and imaging features of renal disorders.
3. To appreciate the incremental value of functional imaging in differential diagnosis.

Author Disclosure:

N. Grenier: Advisory Board; Supersonic Imagine, Aix-en-Provence, France.

A-750 14:30

B. Prostate

G.M. Villeirs; *Ghent/BE*

Multiparametric magnetic resonance imaging (mpMRI) of the prostate combines T2-weighted MRI (T2w) with functional techniques such as diffusion-weighted MRI (DWI) as a marker of cellular density, and dynamic contrast-enhanced MRI (DCE) to assess neoangiogenesis. The minimal technical requirements for these techniques have been described in the Prostate Imaging, Reporting and Data System (PI-RADS) by the American College of Radiology and the European Society of Urogenital Radiology. T2w MRI detects prostate cancer as low signal-intensity (SI) areas in the peripheral zone (PZ) or transition zone (TZ). It provides sensitivity up to 85% for overall prostate cancer detection, but lacks specificity. DWI primarily detects higher-grade prostate cancers as areas of restricted diffusion (high SI on high b-value images; low SI on ADC maps) and improves the overall specificity. DCE detects cancers because of their early and rapid enhancement after contrast administration, but is useful for the PZ only, due to false-positive enhancement of benign prostatic hyperplasia in the TZ. Reporting of mpMRI has been standardized using the PI-RADS 5-point assessment scale, estimating the likelihood of clinically significant prostate cancer. Prostate biopsies directed to mpMRI-detected lesions have shown to be able to decrease the overall number of prostate biopsies, to increase detection of clinically significant prostate cancer and to decrease overdiagnosis of clinically insignificant prostate cancer. mpMRI-guided biopsies are currently recommended in the setting of rebiopsy after a previously negative biopsy, but evidence has been accumulating showing that mpMRI-guided biopsies are equally useful in biopsy-naïve men.

Learning Objectives:

1. To understand the clinical and imaging features of prostatic disorders.
2. To appreciate the incremental value of functional imaging in differential diagnosis.
3. To become familiar with MRI-guided prostate biopsies.

A-751 15:00

C. Uterus

E. Sala; *Cambridge/UK (evis.sala@gmail.com)*

The standard MRI uterus protocol includes axial SE T1WI with a large FOV to evaluate the entire pelvis and upper abdomen for lymphadenopathy as well as bone marrow changes and high-resolution FSE T2WI in the sagittal, axial and coronal planes. Other extra planes and imaging sequences are specific and designed to answer a specific clinical question. Functional MRI sequences such as DCE-MRI and DW-MRI are now part of routine protocols. DCE-MRI is very useful for assessment of the depth of myometrial invasion in endometrial

cancer. DW-MRI is now part of routine MRI protocol for evaluation of uterine malignancies. It should be performed at two or more b-values, which include one or more low b-values (50-100 s/mm^2), since perfusion contribution to diffusion is then eliminated, and a very high b-value (750-1000 s/mm^2). Both breath-hold and non-breath-hold DW sequences can be used. However, the type of DW sequence differs among manufacturers and the radiologist should be familiar with the strengths and limitations of their own scanners. A combination of DWI with conventional MRI sequences improves lesion detection and the radiologist confidence in imaging interpretation. DW-MRI can be useful for accurately determining the depth of myometrial invasion in endometrial cancer. In addition, ADC values are inversely related to the cellularity of tumours which may be useful for distinguishing between benign and malignant tissues and for monitoring tumour response to treatment in cervical cancer.

Learning Objectives:

1. To understand the clinical and imaging features of uterine disorders.
2. To appreciate the incremental value of functional imaging in differential diagnosis.
3. To learn about the imaging features of the treated uterus.

14:00 - 15:30 **Room E1**

Special Focus Session

SF 15b

Contrast-enhanced spectral mammography

A-752 14:00

Chairperson's introduction

A. Athanasiou; *Athens/GR (aathanasiou@mitera.gr)*

Mammography is the only imaging modality that has been shown to reduce mortality from breast cancer. Despite technical advances in full-field digital mammography, it is still not a perfect screening tool, especially in women with dense breasts. Contrast-enhanced spectral mammography has emerged several years ago and has been shown to be superior to FFDM for cancer detection. It can depict lesion neovascularity in an analogous manner to breast MRI. The dual-energy technique consists of acquisition of low- and high-energy images after intravenous iodine contrast agent administration in both CC and MLO views. The total acquisition time is about 5 min. Extra radiation dose depends on breast thickness, but still it is acceptable and inferior to the recommended mammographic dose. Recent studies comparing MG, CESM and MRI confirm better lesion detection with CESM and MRI compared to MG alone, both in the screening and diagnostic setting. Further possible indications include pre-operative local staging in case of multifocality/multicentricity, evaluation of response to NACT and possible correlation of enhancement pattern with intrinsic tumour biology/molecular subtype. CESM can be considered as an alternative to MRI in case of contraindications to MRI (limited availability, cost issues, claustrophobia, gadolinium allergic reactions, etc.). Further studies will define the future role of this promising technique.

Session Objectives:

1. To understand the technical principles of contrast-enhanced spectral mammography.
2. To be familiar with the current indications in clinical practice and current published data on overall performance of contrast-enhanced spectral mammography.
3. To appreciate future perspectives in screening and diagnostics setting.

A-753 14:05

Technique and comparative approaches

M.B.I. Lobbes; *Maastricht/NL (marc.lobbes@mumc.nl)*

Contrast-enhanced spectral mammography (CESM) or contrast-enhanced dual-energy mammography (CEDM) is a novel mammographic technique which is superior to full-field digital mammography (FFDM) and matches the performance of breast MRI, not only in terms of breast cancer detection but also in the assessment of disease extent. In a typical CESM exam, an iodine-based contrast agent is administered intravenously two minutes prior to image acquisition. In general, an iodine contrast concentration higher than 300 mg/mL is used, with a dose of 1.5 mL/kg body weight. Preferably, an automated injector should be used with a flow rate of 3 mL/s. Next, the patient is positioned in the mammography unit like a regular FFDM exam, with image acquisition consisting of two views per breast: mediolateral oblique and craniocaudal. The exam consists of a low-energy image, which is similar to FFDM. However, the CESM exam also acquires a high-energy image to enable visualization of the iodine uptake. This image is not for diagnostic purposes, but is used to post-process a recombined image, which shows areas of contrast captation. On a PACS workstation, only the low-energy and recombined images are displayed. The principles behind CESM are similar to those used in breast MRI. Hence, several studies have compared the diagnostic performance of these two. These have shown that CESM has a similar or sometimes even better diagnostic performance than CESM. CESM exams tend to have less false-positive findings than breast MRI and are generally better tolerated by patients that underwent both exams.

Learning Objectives:

1. To understand the technical considerations of contrast-enhanced spectral mammography.
2. To be familiar with the pitfalls and limitations of the technique.
3. To have an overview of different comparative approaches.

A-754 14:30

Evidence for efficacy and implementation

E.M. Fallenberg; *Berlin/DE (eva.fallenberg@charite.de)*

X-ray mammography (MG) has been the gold standard for detection of breast cancer so far. However, the method is limited due to a reduced contrast difference between breast tumours and surrounding breast tissue, especially in dense breasts. In postoperative surveillance exams, scar tissue can compromise the detection of local recurrence due to postoperative architectural distortions mimicking or masking tumour growth. Also in ultrasound, it can be difficult to differentiate scar tissue, postoperative changes or local recurrence. To overcome the limits of mammography and ultrasound, especially in these conditions, dynamic contrast-enhanced breast MRI is very useful, but is limited in availability and reimbursement. The introduction of full-field digital mammography has presented the possibility of developing further technical methods, which are less expensive and widely available. One of these is contrast-enhanced spectral mammography (CESM). CESM is able to increase sensitivity without decreasing specificity, due to higher contrast and better lesion delineation than mammography alone. In this talk, I will present the clinical performance results of CESM versus mammography and ultrasound. I will show the additional value of CESM in screening assessment. The potential of this technique in imaging the response to neoadjuvant chemotherapy will be elaborated. The role in the detection of recurrence during follow-up examinations after breast-conserving therapy will be addressed as well. The potential advantages and disadvantages will be indicated and a sample of clinical cases will be presented to illustrate how CESM contributes to the detection of lesions and how it can be used in daily clinical workflow.

Learning Objectives:

1. To understand current indications for clinical implementation.
2. To appreciate the added value of information provided by contrast-enhanced spectral mammography as a problem-solving tool in every day diagnostic dilemmas.
3. To become familiar with the results of published studies on overall performance of contrast-enhanced spectral mammography comparing to digital mammography.

E.M. Fallenberg: Board Member; EUSOBI. Research/Grant Support; Siemens Healthcare, Guerbet, GE Healthcare. Speaker; GE Healthcare, Guerbet, Bayer Healthcare.

A-755 14:55

Finding the killer cancers? Can it replace MRI?

C. Dromain; *Lausanne/CH (Clarisse.Dromain@chuv.ch)*

Contrast-enhanced digital mammography is a relatively recently introduced imaging technique that uses an intravascular contrast agent to identify breast cancer on the basis of iodine signal enhancement from tumour angiogenesis. CESM is generally used in the diagnostic setting with clinical indications similar to breast MRI. However, while both CESM and MRI are based on the analysis of washing and washout of breast lesions, there are several technical differences potentially influencing the clinical performance and image interpretation. These major differences include 2D vs 3D images, contrast and temporal resolution, type and quantity of contrast agent, acquisition under compression vs free of compression, positioning, additional value of LE image and limited kinetic analysis for CESM interpretation. If MRI remains the most sensitive method for breast cancer detection, published data comparing CESM and MRI have shown a similar rate of primary tumour detection and size measurement. The largest prospective multicentre study conducted in 178 patients found the overall sensitivity of MRI to be better than that of CESM (76% vs 72%, $p < 0.05$), but the overall specificity of CESM was better than that of MRI (94% vs 88%, $p < 0.001$). The difference in sensitivity in favor of MRI was explained by a better sensitivity for additional lesion detection (39% for CESM vs 49% for MRI), while the sensitivity for index lesion detection was identical (95% for CESM versus 94% for MRI). Based on published data including one meta-analysis, CESM can be considered as an alternative to

MRI, in particular in the case of contraindications to MRI as well as difficulty in MRI availability.
Learning Objectives:
1. To understand the association between enhancing pattern information provided by contrast-enhanced spectral mammography and tumour biology.
2. To appreciate the comparison of information provided by contrast-enhanced spectral mammography and breast MRI regarding lesion morphology and enhancement.
3. To become familiar with published data comparing sensitivity and positive predictive value of the two techniques.
Author Disclosure:
C. Dromain: Research/Grant Support; GE Health Care.

15:20
Panel discussion: Is contrast-enhanced spectral mammography the "mammography of the future"? Can it provide relevant morphological and functional information in everyday practice in a simpler manner? Can it replace breast MRI?

14:00 - 15:30 **Room E2**

Special Focus Session

SF 15c
My three top tips for neuroimaging

A-756 14:00
Chairperson's introduction
J. Van Goethem; *Antwerp/BE (johan.vangoethem@uantwerpen.be)*

Despite the vast amount of knowledge that is available in books, at courses and online, sometimes radiologists still miss basic and practical information for use in their daily practice. This session will provide easy-to-understand, easy-to-learn and easy-to-remember tips on neuro-imaging. Each speaker will provide his or her top three tips in their field of expertise. The information will be presented in short 6-minute lectures focusing on these tips.
Session Objectives:
1. To learn practical tips and tricks usable in daily neuroimaging practice.
2. To avoid common pitfalls in neuroimaging.
3. To learn how to tackle common diagnostic problems in neuroimaging.

A-757 14:05
Leukodystrophies
B. Ertl-Wagner; *Munich/DE (Birgit.Ertl-Wagner@med.uni-muenchen.de)*

Leukodystrophies of the brain can be difficult to diagnose. It is important to be familiar with the different imaging patterns of metabolic disorders and with the typical clinical presentations. Crucial clinical information needs to include the age at presentation, the gender, the family history and the type and evolution of symptoms. Symptoms may be progressive or occur in crisis-like deteriorations. When interpreting images of patients suspected of suffering from a leukodystrophy always remember these three tips: (1) Know as much as possible about the clinical symptoms, the onset and time course of the symptoms and associated abnormalities. (2) Look for “gradients” in the images, e.g. anterior to posterior, inner to outer gradients of the white matter abnormalities. (3) Look for imaging patterns, such as zones, tigroid patterns or areas of abnormal enhancement.
Learning Objectives:
1. To learn about imaging protocols for the diagnostic evaluation of leukodystrophies.
2. To become familiar with typical imaging patterns of the most common leukodystrophies.
3. To gather an understanding of typical pitfalls in imaging leukodystrophies.

A-758 14:11
Hydrocephalus
S. Kumar; *Singapore/SG (sumeet.kumar@singhealth.com.sg)*

Hydrocephalus is a disorder of CSF hydrodynamics resulting in dilatation of the ventricular system. Imaging plays an important role in establishing the presence of hydrocephalus and distinguishing communicating hydrocephalus from non-communicating or obstructive hydrocephalus. The cause of hydrocephalus and complications arising from it can often be revealed by imaging. In this lecture, radiological signs of early hydrocephalus and review areas in a patient with hydrocephalus will be discussed. Imaging features distinguishing normal pressure hydrocephalus from age-related atrophy will be explored and the characteristics of DESH pattern of normal pressure hydrocephalus will be explained.
Learning Objectives:
1. To learn to distinguish communicating from non-communicating hydrocephalus.
2. To identify the DESH pattern of chronic communicating hydrocephalus.
3. To discern ventricular dilatation due to atrophy from chronic communicating hydrocephalus.

A-759 14:17
Acute ischaemic stroke
P.M. Parizel; *Antwerp/BE* (*paul.parizel@uantwerpen.be*)

Stroke is now a potentially curable disease, if discovered early enough. Imaging can help to establish an early diagnosis. Radiologists shoulds be familiar with the patient history and understand the neurological signs and symptoms; this information tells us WHERE to look and WHAT to look for. My “top tips” are focused on CT (still the mainstay for detecting acute stroke in most hospitals) and are: (1) Use narrow window-width (high contrast) CT review settings to increase detection of subtle stroke signs on CT. Many radiologists find it difficult to assess the stroke volume and extent on CT. Other tools, such as the ASPECTS score, can also improve sensitivity and specificity, especially for less experienced readers, but narrow window width settings are the first step. (2) Look for the hyperdense vessel sign, which refers to focal increased density in the vessel and reflects the presence of thromboembolic material within the lumen. It is most commonly observed in the middle cerebral artery, and less frequently in other cerebral vessels, e.g. basilar artery tip. (3) Perform CT angiography to look for blocked vessels, in order to decide if the patient is a good candidate for referral the the angiography suite for clot extraction. (4) Perform CT perfusion, to assess potentially viable brain tissue, the so called penumbra. This is the brain tissue at risk, surrounding the infarct core. On CT the penumbra is the area surrounding the core infarct with delayed arrival of contrast and prolonged MTT, and with preserved CBV (reflecting auto-regulation).
Learning Objectives:
1. To learn how to recognise acute infarct on NECT.
2. To know when to use advanced imaging in acute stroke.
3. To learn the indications for thrombectomy depending on NECT findings.

A-760 14:23
Low back pain
M. Muto; *Naples/IT (mutomar2@gmail.com)*

Clinical finding must correlate always with imaging finding before any type of minimal invasive or surgical procedure. This is a mandatory rule to avoid overtreatment and the development of post-treatment complications that are difficult to solve. Low back pain can be related to soft tissue abnormality, DDD or neoplastic lesion, and for this reason an appropriate diagnostic approach is necessary to exclude or include patients in the treatment. The use of multimodality imaging in evaluating low back pain is very important not only in the case of degenerative spine disease, but also in patients with clinical and imaging findings suspicious of primary or secondary spine neoplasm. Integration of MR with CT can have added value in understanding the pain source and excluding neoplasm or clarifying the type of neoplasm. In this case, never forget Nuclear Medicine study for a complete oncologic balance. Once you have excluded or confirmed the presence of a diffuse or solitary oncologic disease, it is possible to decide about a mini-invasive treatment or surgical treatment. The abscence of neurological deficit leads to a mini-invasive approach to disk disease with multiple treatment options.
Learning Objectives:
1. To learn how to match clinical and imaging findings.
2. To understand how to use multimodality imaging in evaluating low back pain.
3. To learn the possibilities of percutaneous treatments in low back pain.

14:29
Questions and discussion

A-761 14:37
Movement disorders
T.A. Yousry; *London/UK (t.yousry@ucl.ac.uk)*

Disease or degeneration of the basal ganglia, cerebral cortex and sometimes the thalamus give rise to disorders of movements (MD) known as dyskinesias (Greek: difficult movement), which can be differentiated into hypokinetic and hyperkinetic syndromes. We will concentrate on the hypokinetic syndromes, which include Idiopathic Parkinson’s disease (IPD), atypical PD (APD): multiple system atrophy (MSA), progressive supranuclear palsy (PSP) and cortico basal

degeneration (CBD). These movement disorders (MD) are often difficult to diagnose and to treat. Up to now the diagnosis is based on clinical criteria. However, despite the fact that imaging plays an increasing role in establishing and confirming the diagnosis of MD, many radiologists are not familiar with the role of the various imaging techniques, in establishing the diagnosis, monitoring disease progression and furthering our understanding of the pathophysiology of MD. We will present on the most salient imaging signs that will allow the diagnosis of the these disorders.

Learning Objectives:

1. To be able to categorise movement disorders.
2. To know the value of MRI in movement disorders.
3. To learn how to differentiate different entities causing movement disorders.

A-762 14:43

Dementia

S. Haller; *Carouge/CH (Sven.Haller@affidea.ch)*

"no abstract submitted"

Learning Objectives:

1. To understand how ASL might improve confidence of diagnosing dementia, notably at early stages.
2. To understand how SWI might contribute to the diagnosis of dementia with Lewy bodies.
3. To understand that in many cases dementia has mixed degenerative and vascular pathology.

A-763 14:49

Multiple sclerosis

A. Rovira-Cañellas; *Barcelona/ES (alex.rovira@idi.gencat.cat)*

In the last few years, techniques and clinical implementation of MR imaging of multiple sclerosis (MS) have markedly evolved based on the relatively large amount of new published data from clinical trials and observational studies, which assessed the value of this tool in the diagnosis and for monitoring and predicting treatment response of this disease. The aim of this presentation is to provide few tips for the clinical implementation of brain and spinal cord MR imaging in the diagnostic and monitoring process of patients with MS, based on an extensive review of recent literature and personal experience. These tips, which include the recommended brain and spinal cord MRI protocol, some key radiological features that help in the accurate diagnosis of this disease, and the role of MR imaging for monitoring and predicting treatment response, should help neuroradiologists in the optimization of the use of MR imaging in MS in clinical practice.

Learning Objectives:

1. To know the recommended brain and spinal cord MRI protocol in multiple sclerosis.
2. To be familiar with the typical radiological features of multiple sclerosis.
3. To learn how to use MRI for monitoring and predicting treatment response in multiple sclerosis.

Author Disclosure:

14:55

Questions and discussion

A-764 15:01

Non-enhancing brain tumours

M. Smits; *Rotterdam/NL (marion.smits@erasmusmc.nl)*

A non-enhancing adult brain tumour is commonly a low-grade glioma, but 30% of non-enhancing lesions prove to be anaplastic on histopathology. Moreover, the current molecular data suggest that 20% of the histologically low-grade tumours carry in fact the glioblastoma-like genotype (7+/10- TERT mutated) with a dismal clinical course similar to glioblastoma. Given this prognostic heterogeneity, the question is even whether tumour grade may retain its clinical relevance. Clearly, in patients with non-enhancing tumours mimicking relatively benign low-grade glioma, but with a molecular profile indicating clinical behaviour and prognosis of glioblastoma, any delay in initiating treatment will be detrimental. At the same time, the policy in patients with non-enhancing tumours is controversial. A watch and wait policy is advocated by many physicians, while others recommend immediate surgery. Surgery, however, carries a risk for peri-operative morbidity in patients that are generally clinically asymptomatic, apart from usually well-controlled seizures. An early recognition of specifically patients with glioblastoma-like non-enhancing glioma by - advanced - MR imaging and analysis will greatly improve and allow for personalised treatment decisions.

Learning Objectives:

1. To learn the differential diagnosis of non-enhancing brain tumours.
2. To learn the added value of advanced imaging techniques in non-enhancing brain tumours.
3. To learn the most important pitfalls in assessing non-enhancing brain tumours.

Author Disclosure:

M. Smits: Consultant; independent reviewer for Parexel Ltd.

A-765 15:07

Ring-enhancing brain lesions

M.M. Thurnher; *Vienna/AT (majda.thurnher@meduniwien.ac.at)*

When ring-like enhancing brain lesion is detected, the following questions arise: a) differentiation between an abscess and a neoplasm, b) bacterial or fungal origin, c) tuberculous lesion, d) parasitic infection, and finally e) demyelinating lesion? Diagnosis will be made using multiparametric MR imaging including conventional and advanced MR techniques (DWI, SWI, MR perfusion). This lecture will teach you how to create a quick road map and how to interpret MR imaging findings on different MR techniques to make a specific diagnosis of a ring-like enhancing brain lesion.

Learning Objectives:

1. To know the top differential diagnosis of ring-enhancing lesions.
2. To recognise less common pathology giving rise to ring-enhancing lesions.
3. To understand the value of advanced imaging in ring-enhancing lesions.

A-766 15:13

Assessment of tumour response/progression

P.C. Maly Sundgren; *Lund/SE (Pia.Sundgren@med.lu.se)*

Clinical information about primary diagnosis, treatment in the form of surgery, chemotherapy and radiotherapy and the time between the treatment and the present images are crucial for the correct differentiation between response and progression. Images alone can be misleading. In addition to the conventional MR sequences pre- and post-contrast administration, additional sequences like diffusion-weighted imaging and perfusion-weighted imaging can be valuable to differentiate between response and progression as well as these sequences can help especially to detect progressive disease before the lesion demonstrates contrast enhancement. All imaging shall be analysed together with the clinical information and previous MR examinations.

Learning Objectives:

1. To understand the importance of appropriate clinical information to be able to comment on response or progression.
2. To understand the indications for diffusion and perfusion imaging in assessing response or progression.
3. To be able to discuss the value of advanced imaging in the assessment of response or tumour progression.

Author Disclosure:

P.C. Maly Sundgren: Investigator; I do research on the use of advanced imaging in brain tumor treatment effects. Research/Grant Support; I have funding from Swedish Research Council, Cancer Foundation and regional funding fro advanced MRI in monitoring brain tumor treatment, treatment effects and tumor grading.

15:19

Gynaecological and obstetrics

A-767 14:00

Chairperson's introduction

K. Kinkel; *Chêne-Bougeries/CH (karen.kinkel@grangettes.ch)*

Imaging of the uterus and the adnexa uses primarly subsequent transabdominal AND transvaginal ultrasound with colour Doppler capabilities to determine the myometrial, endometrial or adnexal origin of gynaecological symptoms. According to the complexity or the size of the anomaly, magnetic resonance Imaging is the first problem-solving imaging tool with excellent soft tissue capabilities. This session will increase the participants' knowledge in learning adequate patient preparation, the appropriate imaging protocol for frequent clinical questions and important diagnostic features and rules for the

most common gynaecological problems. Computed tomography of the abdomen and pelvis is usually indicated in emergency situations when a gynaecological versus urinary or bowel origin of the symptom is unclear. The indications, techniques and imaging findings of foetal imaging will be presented.

Session Objectives:

1. To understand the imaging presentation of the most common benign and malignant disorders of the uterus.
2. To become familiar with inflammatory and neoplastic disorders of the adnexa.
3. To understand the principles of foetal images and the imaging presentation of the most common foetal disorders.

Author Disclosure:

K. Kinkel: Consultant; for Bayer in MRI of the uterus. Speaker; Philips symposium on Breast Ultrasound.

A-768 14:06

A. Imaging of the uterus

R.A. Kubik-Huch; *Baden/CH (rahel.kubik@ksb.ch)*

In this lecture, the current approach to uterine imaging and the advantages and limits of the various imaging modalities will be discussed. Ultrasound, usually using the high-resolution transvaginal approach, is the imaging modality of choice for the uterus. It is widely available and relatively inexpensive. Shortcomings with this imaging test are the limited field of view, obscuration of pelvic organs by the presence of bowel gas, inherent limitations dependent, and its dependence on the experience of the operator. The role of hysterosalpingography has become very limited in recent years. CT has an inferior soft tissue contrast compared to MRI and the disadvantage of ionising irradiation; its role is thus mainly limited to the emergency setting as well as oncologic staging of disease. With its high-contrast resolution, its ability to provide good tissue characterisation, and its multiplanar imaging capabilities, MRI is increasingly used to evaluate pathologies of the uterus. In this lecture, indications and contraindications of MRI will be reviewed. Patient's preparation for pelvic MRI and the imaging sequences, tailored to the specific clinical questions, will be discussed.The audience will learn about the normal zonal anatomy of the uterus, congenital anomalies as well as variations of the uterus during the menstrual cycle and in the postmenopausal phase. The spectrum of normal and pathologic findings and the most important benign and malignant pathologies of the uterus will be reviewed and the role of MRI for staging cervical and endometrial cancer will be discussed.

Learning Objectives:

1. To comprehend the imaging anatomy of the uterus and its changes throughout life and during pregnancy.
2. To understand typical imaging features and the local imaging-based staging of cervical cancer.
3. To become familiar with the typical imaging features of benign disorders of the uterus, especially uterine leiomyomas, adenomyosis and endometriosis.

A-769 14:34

B. Disorders of the adnexa

T.M. Cunha, M. Horta; *Lisbon/PT (tmargarida@gmail.com)*

Adnexal disorders are commonly identified in radiologists' daily practice, mostly after minor pelvic complaints or incidentally. The majority of disorders correspond to benign ovarian lesions of no concern, but the clinical impact in predicting malignancy is crucial for proper patient management. Ultrasonography (US) remains the first-line imaging technique to investigate adnexal disorders, with about two-thirds being correctly characterized using transvaginal US with colour Doppler. Magnetic resonance imaging (MRI) is a second-line technique, with higher accuracy than US, and particularly helpful in the assessment of complex and sonographically indeterminate adnexal masses. An algorithmic MRI approach using basic and problem-solving sequences allows to differentiate benign from malignant tumours, and to ensure a specific diagnosis in the majority of adnexal masses. Solid tissues with intermediate T2 signal, diffusion restriction and time intensity curve type 3 on dynamic contrast-enhanced MRI, as well as peritoneal implants, are important predictors of malignancy. In the emergency setting of acute or subacute pelvic pain of women of reproductive age, inflammatory disorders of the upper gynaecologic tract should be considered. Computed tomography (CT) is often performed to assess gynaecologic disorders and to exclude gastrointestinal and urologic diseases. Tubo-ovarian inflammatory diseases often cause complex cystic masses and simulate malignant adnexal tumours. Bilateral involvement, tubular adnexal masses, perilesional infiltration and endometrial thickening in the appropriate clinical and laboratory context favours pelvic inflammatory disorders.

Learning Objectives:

1. To describe the imaging features of benign tumours of the ovaries.
2. To understand the diagnostic evaluation and imaging features of malignant tumours of the ovaries.
3. To explain the imaging features of inflammatory disorders of the Fallopian tubes.

A-770 15:02

C. Fundamentals of foetal imaging

D. Prayer; *Vienna/AT*

Foetal MRI can be done at 1.5T or at 3T. Body or cardiac coils are used and ultrafast seqeunces are applied, the duration of which does not exceed 20-30 seconds on average. The emphasis of foetal MRI lies on providing information that cannot be received by ultrasound which is still the mainstay of prenatal imaging diagnosis. Cerebral malformations involving cortical development and/or infratentorial regions are among the most frequent indications for foetal MRI, as information on these structures may alter the prognosis of gross malformations considerably and thus change the further management of these pregnancies. Acquired pathologies of the brain comprise infection and/or haemorrhage. The high sensitivity of MRI to visualize parenchymal damage and blood breakdown products allows to give accurate information on such processes. in the foetal body, MRI is used in many centres for the assessment of lung development in a variety of pathologies such as, for instance, congenital diaphragmatic hernia, other lung malformations, or premature rupture of membranes which may also be associated with impaired lung development. Complex malformations including more tha one organ system can be classified , establishing a respective prognosis and sometimes allowing a conclusion on a genetic background. Prerequisites of performing foetal MRI successfully is a wide knowledge on prenaatl cerebral and extracerebral development and deviations thereof. In addition, a training at a foetal MRI centre might be useful to learn the methodical details and troubleshooting, as foetal MRI differs from other MRI methods.

Learning Objectives:

1. To describe the methodology and technical principles of foetal MR imaging.
2. To understand the imaging presentation of common pathologies of the foetal central nervous system.
3. To understand the imaging presentation of common pathologies of the foetal body.

14:00 - 15:30 **Room F2**

Joint Session of the ESR and EU Commission

ESR/EU

eHealth in radiology: policies, practices, pitfalls, potential

A-771 14:00

Chairperson's introduction

K. Riklund; *Umea/SE (katrine.riklund@umu.se)*

eHealth is a priority topic in which the ESR is actively engaged, having been a member of the European Commission's eHealth Stakeholder Group since 2012. A white paper on teleradiology has been published on insight into imaging and an online survey was conducted in 2012. Recently, HIMSS Europe and the ESR launched the Digital Imaging Adoption Model (DIAM) as a benchmarking programme to guide the adoption of IT supported processes in radiology departments. So, radiology is heavily involved in eHealth and at the session we will learn a lot more of policies, practices, pitfalls, and potential.

Session Objectives:

1. To learn about the ESR's eHealth policy positions, initiatives and tools.
2. To understand the European Union's eHealth policies.
3. To understand the complementarity of and tensions between eHealth policy and practice.
4. To learn about the present status and future outlook for eHealth in radiology from the policy makers' and practitioners' perspectives.

Author Disclosure:

K. Riklund: Board Member; Swedish Drug Authority. Speaker; GE, Paris meeting 2016, Nordic Conf in Radiology 2017 Iceland.

A-772 14:05

ESR eHealth SC and eHealth policy positions

E. Neri; *Pisa/IT (emanuele.neri@med.unipi.it)*

The ESR eHealth and Informatics is a subcommitte of the ESR Quality and Safety Committee. The main activities of the subcommittee have been focused on the following: (A) Development of the ESR-RSNA joint Structured reporting initiative. The initiative is ruled by a memorandum of understanding signed in 2015 between RSNA and ESR aimed at promoting the development of structured reports available on the radreport.org website of RSNA. The initiative led to the creation of a Template Library Advisory Board Panel, an editorial board that revises and validates the SR Templates. The eHealth subcommittee produced a ESR position paper on Structure reporting that is under publication in Insight Into Imaging. (B) Impact of the Data Protection Regulation on the Radiology profession. In 2016 the EU delivered the General Data Protection Regulation (GDPR), that provides rules on how to protect the citizens data in the digital era. The eHealth subcommittee has produced a ESR position paper on "What the radiology should know about the GDPR", recently published in Insight Into Imaging. (C) Proper Use of Mobile Devices in Radiology. In the digital single market mobile devices (smartphone, tablets, PCs) are used by multiple physicians as a tool for helping their clinical practice. In radiology mobile devices are used as DICOM user, as eLearning tool, for social media access to improve communication. All these aspects are discussed in the ESR Position paper on the "Use of mobile devices in radiology" under publication in Insight Into Imaging.

Learning Objectives:

1. To learn about the ESR eHealth SC activities.
2. To understand the role of eHealth tools within radiology.
3. To learn about the ESR policy positions on eHealth issues.

Author Disclosure:

E. Neri: Advisory Board; QUIBIM.

2. To understand the links between European Commission and Member State eHealth activities.

A-775 14:45

ESR eHealth tools

B. Brkljačić; *Zagreb/HR (boris@brkljacic.com)*

The adoption of eHealth systems has already revolutionised radiologists' daily routine and, with big data and artificial intelligence, the next revolution appears to be just around the corner. The ESR supports its members caught up in these developments by providing a variety of eHealth tools and materials. CDS: In cooperation with the American College of Radiology and National Decision Support Company, the ESR has developed the clinical decision support system, ESR iGuide. Using the ESR's referral guidelines based on the ACR Appropriateness Criteria, ESR iGuide can be integrated into CPOE systems to provide actionable, evidence-based guidance to help referrers select the most appropriate imaging test at the point of patient care. CDS referrals for the first time enable statistical analysis of incoming requests for radiology departments, and these data can be used to improve performance or be linked with other data sets like dose data or structured reports to understand the correlations between the interrelated tasks in the imaging value chain. The ESR has been working in cooperation with the Radiological Society of North America (RSNA) on a joint structured reporting initiative. The first step in this cooperation is the creation of structured reporting templates for a template library to cover clinical scenarios suitable for structured reporting. To facilitate the adoption of these templates in practice, the ESR is exploring cooperation with PACS and voice recognition systems. In addition, the ESR's eHealth and Informatics Subcommittee is publishing a paper on structured reporting in radiology, setting out the ESR's conceptual approach.

Learning Objectives:

1. To learn about the ESR's clinical decision support initiative ESR iGuide.
2. To learn about the ESR-RSNA cooperation regarding structured reporting.
3. To understand how the ESR views the use of eHealth tools in clinical practice.

A-776 14:55

ESR-HIMSS Digital Imaging Adoption Model

J. Studzinski; *Leipzig/DE (jstudzinski@himss.org)*

The Digital Imaging Adoption Model (DIAM) has been jointly developed by ESR and HIMSS Europe to provide clinical and managerial users of medical imaging technology with a tool to assess the maturity of their Imaging-IT investments and implementations. The model is designed to identify potential gaps in infrastructure and workflow, to monitor technological progress, to enable benchmarking with peer organisations and to provide a roadmap for strategic and operational planning as well as investment decisions. The DIAM, launched in 2016 at ECR, can be used by hospitals with imaging departments or external imaging centres collaborating with hospitals across the globe. The DIAM associates participating organisations with one of 8 stages. Stage 0 indicates a low level of imaging IT maturity and Stage 7 represents advanced maturity. Participants of the session will learn how the DIAM can be used, which organisations have been assessed so far and what benefits they have received from participation. An outlook about future developments will also be provided.

Learning Objectives:

1. To understand the concept of the Digital Imaging Adoption Model (DIAM).
2. To learn about the benefits in participating in the DIAM.
3. To learn about the DIAM stages, survey and certification.

Author Disclosure:

J. Studzinski: Employee; HIMSS Europe GmbH.

Patient perspective on EU eHealth policies

N. Bedlington; *Vienna/AT*

"no abstract submitted"

Learning Objectives:

1. To learn about the ESR-PAG view of eHealth policy in the EU.
2. To understand how patients can benefit from eHealth tools.
3. To learn about concerns about the adoption of eHealth from the patient's view.

15:15

Panel discussion: The role of medical societies in implementing EU eHealth policy

14:00 - 15:30 **Room D**

Emergency Imaging

RC 1517

The latest update in imaging of polytrauma patients

A-778 14:00

Chairperson's introduction: The role of proper imaging and management in patients after severe trauma

M. Stajgis; *Poznan/PL (stajgis@gmail.com)*

The rationale of emergency procedures in severe trauma patients is based on the time factor and adequate selection of patients and proper imaging modalities. The "Golden Hour" concept describes the need for as-fast-as-possible management of these patients very well. The present-day diagnostic workup of polytrauma patients is mostly based on whole body CT (WBCT); however, this method is thought to be overused in some clinical scenarios. Therefore, we should look very carefully again at advantages and limitations of still evolving all modern diagnostic modalities such as ultrasound, CT and MR. All three lectures in this session are dedicated to effective imaging of polytrauma patients, management priorities in different clinical situations and suggested practical approach.

Session Objectives:

1. To understand the role of early and fast diagnostic imaging in patients after severe trauma.
2. To recognise the basic statistics in management of polytrauma patients

which have impact on practical approach regarding selection of proper diagnostic modalities and imaging findings.
3. To be aware of the position and responsibilities of a radiologist in "decision-making team".

A-779 14:05

A. Ultrasound: when, why and by whom?
P.-A. Poletti; *Geneva/CH*

"no abstract submitted"
Learning Objectives:
1. To become familiar with the role of modern ultrasound in polytrauma patients.
2. To comprehend the rationale of using FAST protocol in selected patients.
3. To know the advantages and limitations of ultrasound imaging in emergency setting.

A-780 14:31

B. CT: is it always whole body?
F.H. Berger; *Toronto, ON/CA (fhberger@gmail.com)*

In the Western world, polytrauma is the major cause of mortality in people under 45 years of age. Furthermore, it is a major contributor to loss of quality of life and ability to work. The setting of polytrauma is almost always chaotic, not a favourable environment to come to timely diagnosis and treatment. To decrease morbidity and mortality, time is everything. It is our job as radiologists to contribute to the trauma team and help facilitate timely diagnosis - and in many cases, also timely treatment by interventional radiology. To reach the best treatment strategy for the patient as quickly and accurately as safely possible is the goal. In this update on imaging of polytrauma patients, I will focus on the role of CT to achieve this goal. With the progress in CT scanner development, different protocol options arise. Which CT protocols are being used and what factors do they depend upon? In addition, there has been a widespread increase in the use of whole-body CT internationally: is this a good thing or should we be more selective? What is the current evidence to select patients for targeted CT examinations in polytrauma? A lot of these questions have not been definitively resolved. This lecture aims to provide an update of the current insights into the use of CT for trauma care, with the goal of choosing wisely on how to investigate the polytrauma patient in a timely and meaningful fashion.
Learning Objectives:
1. To be familiar with currently worldwide accepted protocols in polytrauma CT imaging.
2. To know clinical conditions requiring whole-body CT.
3. To comprehend the selection of trauma patients for targeted CT examinations.

A-781 14:57

C. Where is the proper place for MRI?
K. Katulska; *Poznan/PL (katarzyna_katulska@op.pl)*

A multimodality of imaging should be involved in the diagnosis and management of severely injured multi-trauma patients. The current role of magnetic resonance imaging (MRI) of the spinal cord and brain injuries is confident. MRI examination is the imaging method of choice in the assessment of lesion morphology, extent and severity of trauma. In case of neurological symptom not completely explained in CT findings, an MRI must be performed. Among all post-traumatic intracranial pathologies, the diagnosis of diffuse axial injury remains more complex. In fact, about 30% of negative CTs are already positive on MRI. MRI is a powerful diagnostic tool that can detect signs of injury such as minute bleeding (microhaemorrhage), small areas of bruising (contusion) or scarring (gliosis), which are invisible to the CT scan. Newer, specialized types of MRI can assess brain structure at an even finer level or measure brain function to detect alterations in brain structure and function due to traumatic spinal cord and brain injury (SCI, TBI). The protocol for routine MRI of patients with TBI and SCI, which consists of SE and GRE sequences, is proposed. MRI techniques such as SWI, DWI and DTI are discussed, as a new standard protocol. In the acute setting, MRI can determine the presence and extent of injury and guide surgical planning and minimally invasive interventions. Neuroimaging also can be important in the chronic therapy of injury, identifying chronic sequel, determining prognosis, and guiding rehabilitation.
Learning Objectives:
1. To learn which patients are the best candidates for post-traumatic MRI.
2. To be familiar with standard and short MRI examination protocols.
3. To understand the impact of MR findings on further management of polytrauma patients.

15:23
Panel discussion: Summarising comprehensive guidelines, how to qualify post-traumatic patients for the proper imaging modality

14:00 - 15:30 **Room G**

Physics in Medical Imaging

RC 1513

Dose reduction and image quality implications of iterative image reconstruction in CT

A-782 14:00

Chairperson's introduction
K.N. Bolstad; *Bergen/NO (kirsten.bolstad@helse-bergen.no)*

Ever since the development of the first CT, the quest has been to get as much information as possible in as short amount of time as possible. In the early days of CT, the reconstruction time per image was limited by computer power and effective reconstruction algorithms. The filtered back projection algorithms (FBP) were a compromise between reconstruction speed and image noise. Iterative reconstruction algorithms (IR) takes into account a mathematical assumption of the CT system, which results in less image noise but with a longer reconstruction time compared to FBP. Today, with more powerful and faster computers, IR has become a part of the daily routine. The noise reduction can either be used to improve image quality at the same dose or maintain similar image quality at a lower dose, typically 25-40% dose reduction compared to FBP. Recently, more advanced model-based iterative reconstruction algorithms have become commercially available with a reconstruction time suitable for the clinical routine. These algorithms take into account a mathematical model of the entire system, from the focal spot size and x-ray spectrum to the detector system, resulting in a nearly “noise-free” image. The dose-saving potential for these newer algorithms is up to 80-90% compared to FBP. However, the application of IR does not come without a cost. Even though the image noise is reduced, the appearance of the image may change. Each vendor's IR has a different appearance and a different dose-saving potential. Radiologists need time to get used to the new appearance.
Session Objectives:
1. To learn about the origins of dose reduction using iterative image reconstruction in CT.
2. To understand dose reduction using iterative image reconstruction in CT.
3. To learn about solutions and workarounds.

A-783 14:05

A. Basics of iterative image reconstruction in CT
M. Kortesniemi; *Helsinki/FI (mika.kortesniemi@hus.fi)*

Computed tomography image reconstruction is a mathematical process where the raw data projections (sinogram data) acquired during rotational CT scan exposure are transformed into volumetric (3D) image data. As such, reconstruction is an inverse problem, with no direct analytical solution. Traditional algorithms (filtered back-projection) approximate the true acquisition method and are prone to artefacts and noise. Iterative reconstruction methods approach the final solution gradually in steps and may take quantum statistics, physical properties and limitations of image acquisition more faithfully into account. Thus, a more accurate and correct outcome may be achieved. However, more detailed modelling of the actual CT acquisition system, physics, optics and object also increases the calculation time and related CPU requirements. Especially, the forward projection phase (calculation of simulated raw data) on each iteration step is computationally intensive. More optimised reconstruction techniques with clinically acceptable reconstruction times are under active research. As the main diagnostic benefit, higher image quality in terms of lower noise and artefacts can be achieved by using iterative methods, and/or a lower radiation dose. However, users should be aware that current iterative reconstructions potentially alter the image texture in different clinically relevant contrast and detail levels. Therefore, sufficient clinical image quality should be verified when applying iterative techniques on new exam indications and protocol optimization.
Learning Objectives:
1. To learn about the basic aspects of iterative reconstruction.
2. To learn about potential dose reduction via iterative reconstruction.
3. To compare iterative reconstruction with other techniques.

A-784 14:28

B. Iterative image reconstruction in clinical practice (dos and don'ts)

H. Alkadhi; *Zurich/CH (hatem.alkadhi@usz.ch)*

The broad use of computed tomography (CT) is paralleled by concerns regarding its potential risks. In the past years, these concerns have led to the development of a set of strategies for optimising and lowering the radiation dose of CT. Of these techniques, iterative reconstruction algorithms represent a powerful tool, because they allow lowering the dose at a constant noise level and image quality. However, caution must be taken when iterative reconstruction algorithms are being used, and radiation dose can be lowered only to a level where information in the CT images are not lost. This presentation reviews the clinical challenges of using iterative reconstruction techniques in CT imaging, with a focus on low radiation dose examinations. The different iterative reconstruction techniques are discussed, along with their benefits and potential pitfalls.

Learning Objectives:

1. To understand the radiologist's requirements for image reconstruction.
2. To learn about current best practice in image reconstruction for clinical CT.
3. To learn about the potential benefits and pitfalls of using iterative reconstruction in clinical CT.

A-785 14:51

C. Image quality assessment of iterative reconstruction: pitfalls and future directions

E. Samei; *Durham, NC/US (samei@duke.edu)*

Enabled by increased computational power of recent years and motivated by a desire to reduce CT radiation dose, iterative reconstruction methods have become a staple component of modern CT technology. While these methods offer a renewed opportunity to optimise dose and image quality, they also necessitate a renewed approach towards image quality in CT. Many metrics that have traditionally been deployed to characterise and optimise CT performance, no longer directly apply to CT images that are iteratively reconstructed. The first-order metrics of contrast, resolution, and noise need to be extended to second- and third-order metrology of task transfer function (TTF), noise power spectrum (NPS), detectability and estimability indices, and noise heterogeneity. New methods have been developed to measure these new metrics and integrate them in the optimisation process. This presentation offers a description of the traditional and new CT image quality metrology, outlines the new methods of their assessment, and highlights their utility for improved patient care.

Learning Objectives:

1. To learn about basic image quality metrics employed in CT.
2. To understand why image quality assessment is difficult with iterative reconstruction.
3. To learn about up-and-coming methods for image quality assessment.

EFRS Workshop

EFRS WS

Making the most of social media

A-786 14:00

Chairperson's introduction: Social media in healthcare

J. McNulty; *Dublin/IE (jonathan.mcnulty@ucd.ie)*

This is an essential session for any ECR attendees who are active on social media. Each year, the European Federation of Radiographer Societies (EFRS) delivers a workshop session as part of the main ECR programme with this year's session focusing on the pervasive topic of social media. Facebook, Twitter and LinkedIn, which will all be referenced in this session, have a combined total of two billion active users worldwide. Social media offer all health professionals with new opportunities and new challenges. If used appropriately, social media can: enhance peer to peer communication and communication with patients and the public; provide educational and continuous professional development (CPD) opportunities; allow professional societies to more effectively engage with their membership; enhance the reach and engagement at international congresses; and facilitate better patient engagement with imaging services. For any health professionals using social media, they must be aware of the boundaries between personal use and professional use, consider confidentiality and data protection, and respect best practice guidelines on the appropriate use of social media. For professional societies and professional regulators, there is a growing need to implement clear policies on appropriate and professional use of social media.

Session Objectives:

1. To consider the wide range of use of social media in healthcare, healthcare education, and research.
2. To highlight the importance of all health professionals being aware of best practice in professional social media use.

A-787 14:05

Enhancing communication and collaboration through social media

M.J. Díaz Candamio; *Ferrol/ES (mjdcandamio@gmail.com)*

Social media (SoMe) that changed our way of getting information and communicating is also an incredibly powerful professional networking tool. Nevertheless, health-care professionals are using SoMe to a lesser extent than specialists from other sectors, probably because it is a highly regulated field, in which data privacy is crucial, with many perceived risks and potential threats. Radiology is among the health-care fields with lesser presence in SoMe. This situation correlates with the fact that radiology professionals perform our work "in the dark", with little recognition on the part of patients. SoMe can end with this unawareness of our work. The SoMe-mediated social interactions allow many kinds of professional collaboration, including not only sharing information and experiences but also discussion on procedures or diagnosis. Personal branding of doctors, practices or institutions as well as academic publishing promotion are other well-known uses of SoMe publishing. We can utilize SoMe in radiology to disseminate knowledge, which is crucial at a time when patient-centred medicine is practised, in which patients participate in diagnostic and imaging-guided procedure decision-making. This collaborative networking is global, with fewer language barriers. Nevertheless, the use of English makes universal sharing of content easier. SoMe networks have also potential risks, including not only false information but even false identities. If you still do not use SoMe for professional purposes in radiology, you should be aware of the risks, but exploit their advantages as soon as possible. Keep in mind about being authentic and professional as well as respecting patient's data confidentiality.

Learning Objectives:

1. To explore how social media allows us to enhance communication and collaboration between colleagues and patients.
2. To consider the importance of establishing clear guidance on the use of social media for radiologists and radiographers.
3. To gain some top tips on the dos and don'ts of professional social media use.

A-788 14:20

#MedRadJClub: a Twitter journal club

N.H. Woznitza; *London/UK (nicholas.woznitza@nhs.net)*

Social media are increasingly being used by health-care professionals, including radiographers. #MedRadJclub, a Twitter-based monthly radiographer journal club was first held in March 2016. Use of the digital space removes barriers to traditional journal club participation, such as geographical boundaries, and connects radiographers across the globe. An hour-long chat, centred on a key paper chosen from the literature, acts as a forum for radiographers to discuss research, share best practice and access continuing professional development (CPD). Over 1,000 radiographers have participated in the chats, with the website accessed from 101 countries. The impact of #MedRadJclub includes accessible CPD, research collaborations and a bi-annual conference on advanced radiographer practice.

Learning Objectives:

1. To understand how Twitter can be used as an alternative to face to face journal clubs.
2. To learn how #MedRadJClub works, what it offers over conventional journals clubs, and why radiographers should participate.
3. To appreciate the impact of #MedRadJClub.

A-789 14:35

The value of social media to professional societies

E. Alfayate Sáez[1], M.A. de la Cámara Egea[2], N.I. Vega de Andrea[3]; [1]*Madrid/ES*, [2]*Jaen/ES*, [3]*Girona/ES (ealfayate@fundacioncien.es)*

The aim of this paper is to understand the importance of a digital society and the type of knowledge that can be transferred within a digital environment. Online presence that lacks activity is not synonym of success. Activity is what drives information so that it can be conveyed and create a bigger impact in

digital communities. Use requirements: integrating information related to the entity and other new content or links, and to moderate the interaction of followers in their comments. Digital marketing (content marketing): variables of engagement (encouraging conversation and commitment to the community). Effective use of popular digital channels: Facebook, LinkedIn, YouTube and Twitter. In the recruitment of key users in a WhatsApp group, the conversation has been standardised to: a) improve digital competencies, b) pinpoint interest in digital content, and c) create useful conversations for the profession. Identifying focus in each channel: the informative content (news from the corporate Web or other resources) has been adapted to each type of social network. Twitter: corporate information (digital framework), diverse subjects. Facebook: corporate information, resources for professionals. LinkedIn: corporate information, resources for professionals. YouTube: video reports of events that are useful to focus more attention on the congressional activity of the entity. External relationship: SEGRA joins health conversations that are not related to radiology. Twitter: identifying hashtags related to health. Facebook: share content and foster conversations. Value for followers and following groups: news about technology, information related to events, moderating conversations throughout the social networks, proposals of innovative topics, and to find out what the communities' needs are.

A-790/A-791 14:50

Social media at ECR

S. Lee, K. Friedrich; *Vienna/AT, (simon.lee@myesr.org), (konrad.friedrich@myesr.org)*

Social media such as Facebook, Twitter and Instagram are frequently a part of participants' experiences at medical meetings, with users' activity ranging from casual photos of their breakfast, to in-depth discussion of scientific content. For meeting organisers, engaging with social media users and encouraging interaction can be of benefit to both the event and its participants. By maintaining an active presence on social media, the organiser gives meeting attendees an easy point of contact and a reliable source of information, while also being able to monitor and contribute to conversations surrounding the event. The European Society of Radiology (ESR) has used social media to connect with attendees of its annual meeting, the European Congress of Radiology (ECR), for a number of years and has explored ways to stimulate the use of those platforms. Many ECR attendees use Facebook and Instagram to share their experience of the congress (and the ESR is active on both platforms), but it is Twitter that has been the most interesting platform for the ESR with regard to the ECR in recent years, especially in terms of feedback and discussion of programme content. A steady rise in participation on Twitter reached another new high at ECR 2017, with an increase in ECR hashtag usage, both in terms of the number of users and the volume of activity. This presentation will look at how and why the ESR uses social media in relation to its annual meeting and why Twitter is currently our primary focus.

Learning Objectives:

1. To learn how social media can be used effectively to enhance engagement in a congress.
2. To explore the scale and impact of social media at ECR 2017.
3. To consider what more social media can add to ECR.

A-792 15:05

Improving patient engagement through social media

L. Robinson; *Salford/UK (l.robinson@salford.ac.uk)*

The presentation will take a case study approach by presenting one particular example of social media in imaging: the Word of Mouth Mammogram e-Network (WoMMeN) developed for UK breast screening clients. Following a description of WoMMeN, evaluative data from the WoMMeN project will be presented to determine whether social media can lead to improved patient engagement. The definition of 'engagement' here takes on a broad perspective. It will consider not only engagement in the screening programme (i.e. attending for the examination), but also engagement in service quality improvements. Finally, the lens will be focused more narrowly to explore the impact on individual women. This will take the form of illustrative examples, online interactions taken directly from our WoMMeN social media hub and associated Facebook page.

Learning Objectives:

1. To explore how social media can be used to improve patient engagement with imaging services.
2. To learn about social media use in the Word of Mouth Mammogram e-Network (WoMMeN).
3. To appreciate the impact of online interactions with patients.

15:20

Panel discussion: Making better use of social media: what should we consider?

E³ - ECR Academies: Tips and Tricks in Pancreatic and GI Tract Imaging

E³ 1522

The anal canal: does MRI make it easy?

A-793 14:00

Chairperson's introduction

S. Halligan; *London/UK*

As chair of this session, I will introduce the topic of anal MRI, its clinical relevance, and how this will be addressed by the speakers. An interactive case presentation illustrating the topic will also be presented.

A-794 14:05

A. MRI of the anal canal: from normal anatomy to local tumour staging

C. Hoeffel; *Reims/FR*

Although a rare disease, anal cancer is increasingly being diagnosed in patients with risk factors, mainly anal infection with the human papilloma virus. Magnetic resonance imaging (MRI) with external phased-array coils is recommended as the imaging modality of choice to grade anal cancers and to evaluate the response assessment after chemoradiotherapy, with a high contrast and good anatomic resolution on the anal canal. MRI provides a performance evaluation of size, extent and signal characteristics of the anal tumour before and after treatment, as well as lymph node involvement and extensions to the adjacent organs. MRI is also particularly helpful in the assessment of complications after treatment and in diagnosis of disease recurrence. We will propose an MRI protocol for imaging of the anal canal, explain the MR anatomy of the anal canal and review possibilities of MRI in the evaluation of tumour in both the pre- and posttreatment context.

Learning Objectives:

1. To learn the relevant sequences for MRI of the anal canal.
2. To understand the anatomy as demonstrated by MRI.
3. To become familiar with the staging of primary tumour, before and after treatment.

A-795 14:33

B. Fistulae-in-ano: detect, stage, classify

D.J.M. Tolan; *Leeds/UK (djmtolan@doctors.org.uk)*

MRI is a critical tool for the evaluation of fistulae-in-ano and in particular for the surgical management of complex or recurrent cryptoglandular perianal sepsis and in patients with fistula from Crohn's disease who can be treated medically or surgically. The MRI sequence selection can target water/oedema (STIR or fat saturated T2) or contrast enhancement (post contrast fat saturated T1). Correct orientation of MR scan planes to the axis of the anal canal is critical to allow correct assessment of fistula anatomy for surgical planning, and Park's Classification is the most commonly accepted by surgeons and should be used by radiologists. Reports should follow a uniform structure including the Park's classification type of the fistula, the location of internal opening, course of the fistula, position of the external opening and number and position of extensions/secondary tracks.

Learning Objectives:

1. To learn about the relevant MRI sequences in patients suspected of fistulae-in-ano.
2. To understand the most common classification of fistulae.
3. To become familiar with the questions asked by the clinician before treatment.

A-796 15:01

C. My tough cases

F. Maccioni; *Rome/IT (francesca.maccioni@uniroma1.it)*

Perianal disease (PD) has a low prevalence in the overall population, approximately of 0,01%. It develops more frequently in Crohn's disease (CD) and in haematological malignancies (HM). Usually, perianal CD develops in association with lesions of the small and large bowel, in 23% to 38% of CD patients, including children. In CD, the fistulous tracts are much more complex than that in the fistulas of cryptoglandular origin, and are usually associated with ramifications and abscess. They are considered as some of the most disabling complications of Crohn's disease (CD), especially in children and young adults. Perianal disease is, in fact, frequently associated with aggressive intestinal or colorectal disease. The association of anal fistulas with rectal

disease represents a negative prognostic factor due to the higher risk of radical proctectomy and definitive ileostomy. Early diagnosis and prompt clinical management are fundamental for a positive outcome. High-resolution MRI is the gold standard for the first diagnosis and staging of perianal fistulas. MRI results are crucial in the therapeutic planning, addressing the patients towards pharmacological or surgical treatment. MRI also plays a primary role in the assessment of fistula healing after medical or surgical treatment. Perianal fistulas, unfortunately, tend to recur in more than 30% of cases, despite pharmacological and surgical treatments.

Learning Objectives:

1. To learn from clinical experience the unusual presentation of diseases of the anal canal.
2. To understand how to report on MRI after treatment.

A-797 14:00

A. Diagnostic and therapeutic injections in the athlete: pearls and pitfalls
P. Peetrons; *Brussels/BE (ppeetrons@his-izz.be)*

Before any treatment of tendons and ligaments with any ultrasound-guided technique, a correct diagnosis must be achieved. One of the main pitfalls is to treat incorrectly diagnosed lesions. This is unfortunately too often the case. Patients sometimes come for therapy with a wrong diagnosis or a non-imaged documented diagnosis. Some examples are the so-called pes anserine bursitis, the so-called trochanteric bursitis, an underestimated rotator cuff tear which appears to be a full-thickness instead of a partial thickness tear, and a Haglund deformity considered as an Achilles tendinopathy. The examples are numerous. A second pitfall is the use of a treatment which is non-adapted to the pathology. Using steroids to cure the degenerative changes within a tendon may lead to a short-time improvement, but not to a longtime healing of the lesion. Depending on the scheduled and importance of sports activity, the choice of the treatment can be different. Tendon needling and PRP injections are the major actual treatments for long-term regeneration of collagen fibres within tendons and ligaments. But they need time and rest. A good post-therapy rehabilitation must be followed by the sportsman.The quality and quantity of the plasma and the platelets are also of very big importance. In tendons, in athletes, the plasma must be as poorly cellular as possible, and the centrifugation of the blood must give 1.5 to 2.5 the native account of platelets. It has been shown that a too heavy concentration may have adverse effects on regeneration.

Learning Objectives:

1. To become familiar with the most common requests and indications for sports-related injections.
2. To learn about technical considerations for performing MSK injections.
3. To understand reasons to delay injections or avoid certain injectables.

Author Disclosure:
P. Peetrons: Investigator; GE for evaluation of an Ultrasound Unit.

A-798 14:30

B. Injectables, percutaneous tendon fenestration and tenotomy: clinical outcomes and current evidence
J. Jacobson; *Ann Arbor, MI/US (jjacobsn@umich.edu)*

For joint abnormalities and tendinopathy, there exists many percutaneous treatment options. Anaesthetic agents are used, often combined with corticosteroids, to inject joints and bursae for diagnostic and therapeutic purposes. With regard to anaesthetic agents, all are cytotoxic to chondrocytes and synovial cells to some degree. Corticosteroids may be used to decrease inflammation within a synovial space. The use of corticosteroid to treat tendinopathy is counterintuitive, as inflammation is not present, injection into tendon causes tenocyte death, and the analgesic effect of corticosteroids is short lived, and therefore the underlying tendon pathology is not treated. A number of ultrasound-guided tendon treatments can be used for tendinopathy. One treatment is percutaneous tendon fenestration or tenotomy. With this procedure, a needle is passed through the abnormal tendon segment repeatedly to break up the degenerative process, induce bleeding and inflammation, and initiate the healing of the abnormal tendon. Other procedures include the injection of autologous whole blood during the fenestration process, as well as the injection of platelet-rich plasma during fenestration. With this latter technique, the autologous whole blood is centrifuged to concentrate the platelets for injection. All three of these percutaneous tendon treatments have been shown to be effective, although it is controversial which technique is best. The cost of each procedure should also be considered. There exists newer and more controversial percutaneous tendon treatment, such as injection of mesenchymal stem cells, human amniotic membrane, and deer antler velvet. These procedures are largely considered experimental until research studies demonstrate their safety and efficacy.

Learning Objectives:

1. To be aware of the indications and benefits of available injectables used to treat sports-related injuries.
2. To learn about technical considerations for performing tendon fenestration and tenotomy.
3. To become familiar with the current evidence on results of MSK procedures in the literature.

Author Disclosure:
J. Jacobson: Advisory Board; GE, Philips. Author; Elsevier. Consultant; Bioclinica.

A-799 15:00

C. Interactive case discussion (part 1)
P. Peetrons; *Brussels/BE (ppeetrons@his-izz.be)*

Interactive discussions on cases will be performed with the audience. The indication of percutaneous treatment of tendons and muscles will be emphazised, compared with indications of steroid injections. The importance of a correct diagnosis, prior to any interventional technique, will be stressed out.

Learning Objectives:

1. To learn the targeted approach to injecting joints, ligaments, tendons and tendon sheaths.
2. To appreciate pitfalls to avoid in MSK procedures for treatment of sports-related injuries.
3. To understand evidence-based data on various MSK procedures in order to give patients realistic expectations after treatment.

Author Disclosure:

A-800 15:15

C. Interactive case discussion (part 2)
J. Jacobson; *Ann Arbor, MI/US (jjacobsn@umich.edu)*

The purpose of the interactive case discussions is to emphasize the teaching points made in the prior lecture reviewing injectables, percutaneous fenestration, and tenotomy. One topic to be addressed will be the imaging findings and potential treatment algorithm for greater trochanteric pain syndrome. In this clinical scenario, a true distended and inflamed bursa is not common and the primary pathology relates to gluteal tendinopathy. Before pursuing an interventional procedure, conservative management such as proper eccentric physical therapy should be exhausted. The next consideration could be injection of corticosteroid in the subgluteus maximus (or trochanteric bursa) for the primary purpose of providing temporary pain relief so that the patient can tolerate eccentric physical therapy. The corticosteroid injection is not used as an anti-inflammatory agent as true inflammation is not present, and the pain relief is typically short lived. If the patient again fails eccentric physical therapy, then the patient may be offered percutaneous fenestration, autologous whole blood injection, or platelet-rich plasma injection. While all three have been shown to be effective, it is still unclear which treatment is best. The dramatic differences in cost should be a consideration when selecting the tendon treatment.

Learning Objectives:

1. To learn the targeted approach to injecting joints, ligaments, tendons and tendon sheaths.
2. To appreciate pitfalls to avoid in MSK procedures for treatment of sports-related injuries.
3. To understand evidence-based data on various MSK procedures in order to give patients realistic expectations after treatment.

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1621
Errare humanum est

A-805 16:00
A. Errors in chest radiograph
J. Cáceres; *Barcelona/ES (josecac@gmail.com)*

Errors in diagnostic imaging are not uncommon and the radiologist is responsible for most of them. In this presentation, I intend to analyse the most common causes of errors in chest imaging and how to avoid them. Perceptual errors are the most common ones, accounting for up to 50% of errors committed by radiologists. For a variety of reasons, in this type of error the radiologist does not see the abnormality, which may be obvious or subtle. Some search findings are missed because we do not search for additional abnormalities after the first one is found. Perceptual errors can be avoided if we get into the habit of using checklists.

Learning Objectives:
1. To learn to recognise ambiguous signs in plain films.
2. To learn to avoid the most common pitfalls in reading plain chest films.

A-806 16:45
B. Errors in CT of the chest
J. Vilar; *Valencia/ES (vilarsamper@gmail.com)*

Observer errors in Chest radiographs and chest CT: The aetiology of error in radiology is multi-factorial. In this presentation, I will concentrate on errors attributed to the radiologist. Not seeing a lesion (perceptual error) and not recognizing a pathology (interpretative error) are by far the most common causes. In a study of 500 cases, perceptual errors accounted for 80% and 20% were interpretative errors. Perceptual errors occur in CT, as in chest radiographs, despite the fact that CT is a tomographic technique. These errors may be related to technical factors such as noise, resolution, and use of adequate technical protocols including the use and timing of contrast media. Vigilance errors are those due to an insufficient time (reading too fast), satisfaction of search (interrupting vigilance), or inadequate clinical information (ignoring suspicion of pathology). Erroneous interpretation of the findings may be related to ignorance and inadequate information. The radiologist could avoid these errors by applying simple rules such as using checklists, taking enough time to read the studies, comparing with previous examinations, and using the clinical data. In this interactive presentation of cases, I will analyze some common causes of errors in chest CT and offer simple clues to avoid them.

Learning Objectives:
1. To learn to interpret ambiguous chest CT signs.
2. To learn to avoid the most common pitfalls in reading chest CT images.

16:00 - 17:30 **Room B**

Abdominal Viscera

RC 1601
Tumour response assessment in abdominal imaging

Moderator:
S.M. Erturk; Istanbul/TR

A-807 16:00
A. Colorectal liver metastases
S.K. Venkatesh; *Rochester, MN/US (venkatesh.sudhakar@mayo.edu)*

Metastatic liver disease occurs in 30-50% of colorectal cancer patients. Neo-adjuvant chemotherapy (NAC) is the treatment of choice for colorectal liver metastases (CRLM). Local control with percutaneous ablation methods and surgical resection in those who show response to NAC have evolved as treatment options in patients with CRLM only. Accurate definition of number, distribution, site and response of CRLM is critical information defining anatomic resectability. It is therefore important to assess the response of CRLM to chemotherapy and ablation methods for assistance in guidance to further management. Standard methods (RECIST) use size criteria to assess decrease in size as response; however, there are pitfalls to these methods. Viability of CRLM can also be assessed with dynamic contrast-enhanced MRI (DCE_MRI), diffusion weighted imaging (DWI), and positron emission tomography (PET) after NAC. The chemotherapy also causes liver toxicity including sinusoidal obstruction syndrome and fatty change that affect the assessment of response of CRLM and define resectability. This presentation will review the response of CRLM to treatment, methods of response assessment, and limitations and advantages of these methods in the management.

Learning Objectives:
1. To learn about different methods to assess the tumour response in the colorectal metastases.
2. To understand usefulness and limitation of techniques and the role of different contrast media.
3. To appreciate variable response pattern of colorectal liver metastases.

A-808 16:30
B. Rectal carcinoma
M.J. Lahaye; *Amsterdam/NL (MJ.Lahaye@gmail.com)*

MRI is the modality of choice for rectal cancer (re)staging. The high soft-tissue contrast of MRI can accurately assess the extramural tumour spread and relation to surrounding structures after chemoradiation. This lecture will have practical approach in determining the role of MRI in the restaging of rectal cancer. The relevant anatomy, MRI techniques, rationale for neoadjuvant treatment, and post-chemoradiation therapy imaging (including detection of patients with a complete response) will be discussed with special attention to how to apply recent advances in knowledge to daily clinical practice.

Learning Objectives:
1. To learn about the rationale for neoadjuvant treatment in rectal cancer and the impact on subsequent surgery.
2. To understand why imaging is needed to assess response to neoadjuvant therapy, what to look for when judging response, and where the challenges lie.
3. To appreciate when surgery can be deferred or avoided and how best to follow-up these patients.

A-809 17:00
C. Pancreatic adenocarcinoma
M. Zins; *Paris/FR (mzins@hpsj.fr)*

Patients with pancreatic ductal adenocarcinoma (PDA) must be selected for first-line surgery based on the likelihood of achieving complete curative resection with negative margins (R0). In doubtful cases and when the risk of incomplete resection (R1 or R2) is high, neoadjuvant chemoradiotherapy should be given. Neoadjuvant therapy can convert tumours classified as locally advanced by initial imaging studies to resectable tumours. However, the imaging study evaluation of the response to neoadjuvant therapy is extremely complex. Thus, the diagnostic performance of imaging studies is not sufficient to ensure the accurate selection of patients in whom negative-margin resection is likely to be achieved. More specifically, standard criteria for predicting vascular invasion, based on the amount of tumour-vessel contact, are not valid after neoadjuvant therapy. The high risk of underestimating the histological response warrants surgery in all patients without indisputable evidence of disease progression after chemo(radio)therapy. Patients with even partial decreases in tumour size and/or tumour-vessel contact are particularly good candidates for surgery. The role for functional imaging techniques can be expected to increase in the next few years.

Learning Objectives:
1. To understand the rationale for neoadjuvant treatment in pancreatic adenocarcinoma.
2. To learn the limitations of CT in assessing treatment response.
3. To learn how to accurately select patients for curative-intent surgery after neoadjuvant therapy.

16:00 - 17:30 **Room N**

Cardiac

RC 1603

Coronary CT angiography: how to start practice, perform and evaluate the exam?

Moderator:
M. Hrabak Paar; Zagreb/HR

A-810 16:00

A. Beautiful cases from clinical practice: coronary arteries
S. Feger; *Berlin/DE (sarah.feger@charite.de)*

Coronary computed tomography angiography (CTA) is a non-invasive diagnostic test with high diagnostic accuracy in detecting coronary artery disease (CAD). Due to its very high negative predictive value, it is especially suitable for ruling out CAD in patients with low to intermediate pretest probability. For stable chest pain patients in this pretest probability range, the current European guidelines already recommend the use of CTA. Additionally, in patients with unstable chest pain and a low CAD probability, CTA can be considered to detect relevant differential diagnoses. An important advantage of CTA compared with invasive coronary angiography is the possibility to perform a differentiated plaque analysis including the detection of high-risk plaque features besides the stenosis quantification. Different acquisition techniques are applied in clinical practice. Initially, retrospective ECG-gated CTA was routinely used. While this approach is very robust, especially for high or irregular heart rates, radiation exposure is relatively high. Prospective axial scanning reduces radiation exposure, since data acquisition is only performed in predefined ranges within the RR interval with the tube current entirely being turned off outside the acquisition window. Further approaches to reduce radiation exposure are the adjustment of scanning parameters, ECG-gated tube current modulation (adjusted to the heart rate and variability), automatic tube potential selection and, recently, the introduction of iterative reconstructions.

Learning Objectives:
1. To learn about cardiac CT acquisition techniques, pitfalls, and dose-reduction strategies.
2. To summarise current indications and clinical applications of CT coronary angiography.
3. To review the diagnostic performance of CT for the diagnosis of coronary artery disease.
4. To learn how to make a structured report of the coronary CT angiography.

A-811 16:35

B. Staff training and technical requirements
S. Harden; *Southampton/UK (stephen.harden@uhs.nhs.uk)*

Imaging the coronary arteries with CT is an increasingly frequent CT examination being performed in radiology departments in Europe and across the world. It is unusual as a diagnostic CT technique in that it is a procedure, involving careful pre-scan drug administration and fine attention to detail such that good image quality is obtained at a reasonable radiation dose to the patient. As such, this requires a team approach, with every member of the team performing a crucial function to ensure the safety of the patient and a successful procedure. Staff training is important and this is required for new staff, but also for experienced staff where practice review and optimisation meetings allow ongoing service improvement. Given that the drugs administered change cardiac physiology, staff must be trained in basic life support techniques and there must be a process for calling for urgent clinical backup even though these situations are rare. As this technique becomes more widely used and available, we are seeing an increasing role for CTCA in acute chest pain imaging and the team approach to patient care is as important if not more important in the acute or emergency setting.

Learning Objectives:
1. To become familiar with technical prerequisites and post-processing tools for coronary CT angiography.
2. To discuss a necessary team setup and training modules for radiologists and technical staff.
3. To evaluate the role of coronary CT angiography and requirements for the radiological team in routine imaging and in emergencies.

A-812 16:55

C. Beautiful cases from clinical practice: stents and bypasses
G. Bastarrika; *Pamplona/ES (bastarrika@unav.es)*

Advances in cardiac CT and development of new multidetector computed tomography (MDCT) scanners have allowed accurate and robust non-invasive assessment of coronary artery revascularization procedures. This requires development of detailed CT acquisition protocols with specific reconstruction parameters and the appropriate use of different post-processing techniques. From the clinical perspective, radiologists need to become familiar with diverse types of grafts as well as with typical CT findings after coronary artery bypass grafts (CABG) surgery and stent placement. In this lecture, the value of coronary CT angiography after coronary intervention will be underlined by defining MDCT acquisition protocols designed to evaluate coronary artery revascularization procedures. Further, the surgical aspects of CABG, postoperative graft anatomy, and interpretation of pitfalls when evaluating CABG and stent patency will be discussed.

Learning Objectives:
1. To emphasise the value of coronary CT angiography after coronary interventions.
2. To outline CT acquisition protocols and contrast administration strategies to evaluate coronary stents and coronary artery bypass grafts (CABG) in individuals undergoing coronary revascularisation.
3. To describe usefulness and limitations of different post-processing techniques in assessing stent and CABG patency.

16:00 - 17:30 **Studio 2018**

Special Focus Session

SF 16

Placental imaging: how, when and why?

A-813 16:00

Chairperson's introduction
M. Weston; *Leeds/UK (michael.weston2@nhs.net)*

The high rates of caesarean delivery and the later ages that women are choosing to have their children are leading to an increase in the incidence of placental problems. Both placenta praevia and abnormal placental attachment disorders are commoner the greater the number of prior uterine surgical interventions and the older an expectant mother is. Radiologists are finding new roles in helping their obstetric colleagues manage these complications. Magnetic resonance imaging and interventional procedures are developing apace. These three presentations will give us an up-to-date insight into their application.

Session Objectives:
1. To understand the new imaging modalities available to assess the placenta.
2. To recognise the signs of abnormal placentation.
3. To learn about new interventional techniques in the management of postpartum haemorrhage.

A-814 16:05

Modern MRI of the placenta
N. Siauve; *Colombes/FR (nathalie.siauve@aphp.fr)*

Recent developments in magnetic resonance imaging (MRI) offer new perspectives for placental imaging, using fMRI tools to explore vascularisation, oxygenation and metabolism. Diffusion weighting imaging (DWI) and intra-voxel incoherent motion (IVIM) MRI study the movement of water molecules within tissues and provide information about vascularisation and tissular structure. Quantitative parameters are available: the apparent diffusion coefficient (ADC), the perfusion fraction (f), the pseudo-diffusion coefficient (D*) and the diffusion coefficient (D). Blood oxygen level-dependent (BOLD) MRI uses the hemoglobin (Hb) as an endogenous contrast agent. The oxygen saturation of Hb modifies its magnetic properties, and modifications of T2* can be depicted when two different statuses of oxygenation are compared. Arterial spin labelling (ASL) MRI relies on magnetically labelled water to quantify the blood flow (F). Dynamic contrast-enhanced MRI (DCE-MRI) is best able to quantify perfusion and permeability. The enhancement of the organ of interest after intravenous injection of a gadolinium-based contrast agent is compared to the enhancement of the arterial input function, using compartmental model. However, the use of gadolinium-based contrast agents during pregnancy is still limited to situations when the benefits outweigh the potential risks. Modern imaging of the placenta will integrate fMRI techniques in the follow-up of pregnancy as numerous biomarkers will become available. The objectives of such modern imaging will be to improve the detection of placental insufficiency

and the management of high-risk foetuses. A platform dedicated to human foeto-placental research (LUMIERE) will be created soon and will allow further research in this area.

Learning Objectives:

1. To describe how the vascularisation and the oxygenation of the placenta can be explored, using functional MRI.
2. To list and explain the different parameters of each functional MRI technique that is available.
3. To give an overview of the potential applications in normal and pathologic pregnancies.

A-815 16:30

Placental abnormalities, timing of imaging, methods and diagnosis

G. Masselli; *Rome/IT (gabrielemasselli@libero.it)*

Placental abnormalities have a profound impact on morbidity and mortality of both mother and foetus, underlining the importance of an early diagnosis. The placenta may show pathologies in terms of size, adherence, cord insertion, cord location and bleeding, and in few cases may also develop trophoblastic and non-trophoblastic tumours. Placental adhesive disorders (PADs) are characterized by different levels of uterine myometrial invasion that relate to different levels of severity and risk of blood loss upon delivery. PADs seem to parallel the increase in C-section rate and maternal age, and can be easily diagnosed by ultrasound (US); magnetic resonance imaging (MRI) is likewise performed either for delivery planning or equivocal cases. Another cause of third trimester bleeding is placenta abruption, defined as premature separation of the placenta that complicates 1% of pregnancies; US has a sensitivity as low as 25% and, when negative, MRI is usually diagnostic. Systematic assessment of the placenta by US is the standard imaging examination during pregnancy. MRI is used for equivocal cases or when further placental characterization is required in view of its multiplanarity, its improved tissue contrast and lack of radiation. We will discuss which imaging modalities are used to study the placenta, which sequences and planes better delineate this organ, and which are the circumstances that require their use, particularly with regard to PADs. The advantages of MRI in the diagnosis and management of patients affected by these pathologies will be thoroughly discussed along with the most common pitfalls.

Learning Objectives:

1. To learn about the likelihood and causes of abnormal placental attachment.
2. To understand the role of US and MR in making the diagnosis.
3. To appreciate the imaging signs and pitfalls.

A-816 16:55

Abnormally invasive placenta: vascular anatomy and interventional radiology approaches to management

C. Hammond; *Leeds/UK (christopherhammond@nhs.net)*

Abnormal placentation is increasing in incidence. It now occurs in about 1 in 500 deliveries in the West. It encompasses a range of pathological entities from superficial adherence of placental villi to the myometrium (accreta) to penetration through the uterine wall and invasion into surrounding organs (percreta). It is associated with massive haemorrhage at delivery in some women, though the risks of this are difficult to prospectively determine with any certainty, even in women with typical imaging features of abnormal placentation. The classical approach to management of abnormal placentation has been caesarian hysterectomy, though a number of uterus-conserving surgical techniques have been developed. The interventional radiological [IR] techniques of balloon occlusion (of various arteries) and embolisation (with various agents, and in various vascular territories) have been undertaken to either augment or replace open surgery. Evaluation of these techniques is complicated by a heterogeneity of approaches between studies and the difficulty of accurately assessing haemorrhage risk beforehand. This talk will discuss the vascular anatomy of the gravid uterus and its relevance to both IR and surgical approaches to the management of actual or potential massive obstetric haemorrhage in the presence of abnormal placentation. The evidence in support of these techniques will be examined including evidence of safety and outcome. The logistical and infrastructural requirements for a truly multidisciplinary approach to the management of abnormal placentation will be reviewed and then finally the pre-procedural imaging information needed by the surgeon or IR will be highlighted.

Learning Objectives:

1. To discuss the arterial supply to the uterus and its importance in haemorrhage control in abnormal placentation
2. To discuss the options for haemorrhage control and evidence to support each approach
3. To examine the logistics and infrastructure required to provide an obstetric haemorrhage service

Author Disclosure:

C. Hammond: Advisory Board; NICE GDC AAA. Author; Papers on haemorrhage control in massive obstetric haemorrhage.

Big data: implications for medical imaging and the need for data protection and cyber security

A-817/A-818 16:00

Chairpersons' introduction

N. Bedlington[1], L.E. Derchi[2]; *[1]Vienna/AT, [2]Genoa/IT (derchi@unige.it)[2]*

This session will see different presenters discuss about "big data" in radiology, each from his/her perspective. This is a difficult but important topic which will have great impact on our discipline (and on the whole healthcare sector). The session will specifically address the need for data protection. It is in fact quite important to understand the topic of protection of "sensible" data and of cyber security. Then, hopefully, it will provide a platform to share opinions and decisions on a topic which is getting more and more important in the whole healthcare sector and, specifically, in the imaging field.

Session Objectives:

1. To understand the importance of big data in medical imaging and related implications for patients, radiologists, and radiographers.
2. To understand the need for data protection and cyber security to combat the vulnerability of healthcare.
3. To learn practical examples.

A-819 16:10

Implications of protection of medical imaging data: a European perspective

C.D. Becker; *Geneva/CH*

The new general data protection regulation of the European Union will be effective in May 2018. Processing and communication of health data including images will require explicit consent by the data subject and all patients must have access to their personal data. Key elements of the new regulation also include the right to obtain rectification of his/her personal data; the right of the data subject to transfer personal data to another service provider ("data portability"); or the right of the data subject to be informed when his/her data have been hacked. The new GDPR implies that all organisations processing personal data must be able to prove that they comply with the rules. It also proposes a European Data Protection Board and requires institutions which process certain types or volumes of data to have a designated data protection officer (DPO) who is in contact with the national data protection authorities.There is an obvious need to find a reasonable balance between protection of individual health data and data use in the interest of public health and research projects by means of " big data" analysis. Anonymisation and pseudonymisation of digital data are undispensable tools in this context. Codes of conduct may be created by specific groups of users to define exceptions such as big data analysis or biobanks for scientific purposes. Specific rules may also be defined by national law.

Learning Objectives:

1. To understand the impact of the new data protection regulation for processing and sharing of imaging data.
2. To understand the need to find a balance between protection of individual health data and data use in the interest of public health and research projects including “big data".
3. To discuss safeguards for data processing in the context of research and public health projects, including "big data”.

A-820 16:25

Cyber security in radiology

J. Sosna; *Jerusalem/IL (jacobs@hadassah.org.il)*

The increase in the number of imaging studies worldwide and especially in Europe necessitates the need to secure the integrity of the data. Although many organizations have cyber security programmes, many others have not

yet acknowledged the seriousness of the threat. Security breaches occur when hackers enter the Internet Protocol (IP) address of medical equipment and data centres that appears to be at risk. Hackers can use the device as an entry point to access the rest of the facility's network. The hacker could cause the imaging equipment to malfunction or block access to PACS and RIS. This can be potentially life threatening, such as in a case of increasing radiation in a CT scanner for instance or limiting access to patient studies when necessary. Radiologists need to be familiar with such treats and help integrate cyber security into the workplace culture. The threats and possible solutions will be presented and discussed.

Learning Objectives:

1. To understand what cyber security is and its implications for radiology.
2. To learn a practical example from Israel and lessons learnt.

Author Disclosure:

J. Sosna: Advisory Board; Persimio. Consultant; Xact.

A-821 16:40

Importance of data protection from a patient's view

E. Briers; *Hasselt/BE (erikbriers@telenet.be)*

Not all patients are equal, and not all diseases are equal. Some patients have illnesses that can be interpreted as benign, such as a common cold. For others, the disease is serious and even life threatening. Very often patients with serous diseases face long disease journeys with multiple visits to doctors, hospitals and even treatments. During this journey, data are generated in every step, simple and complex data, but all pertaining to the patient. This information, these data, describes the fate of the patient: what has happened, is happening and what will happen to this patient. Patients do not like this to be read or seen by everybody. If this information is made available to an insurer, the patient, after having been pronounced cured, may not be eligible for insurance coverage. If the patient looks for a new employment, the information on his or her misfortune with the disease may make him unappealing to an employer. But, during the journey and even after the journey, the medical records contain important data that may speed up future diagnosis, make new symptoms understood quickly and help implement correct treatments faster. All those from the multi-professional team then need access to the complete data. They need to be bound by their professional ethics not to abuse this information. In clinical trials, sharing data is from the patient's perspective included in the concept and for patients sharing real-world data that could improve future applications of treatment is so far an unfulfilled dream.

Learning Objectives:

1. To understand the importance of data sharing and protection of patient data.
2. To learn implications of misuse of patient data.
3. To understand the necessity of data sharing to improve the patient journey through her/his disease.

A-822 16:55

Experiences from the US

J.A. Brink; *Boston, MA/US*

Data security in health care is governed in the United States by the Health Insurance Portability and Accountability Act (HIPAA) of 1996. The HIPAA privacy rule established standards to secure the personal/protected health information (PHI) and medical records of US citizens. It applies to all health-care providers who interact with individual patient's health records and includes all relevant electronic communications and transactions. Moreover, it applies to all relevant health-care institutions, insurance companies, and affiliated institutions that have access to protected health information. PHI refers generally to information that may identify individuals and the care they receive through medical history details, imaging and laboratory results, insurance information and other demographic information.

Learning Objectives:

1. To discuss the status of data protection and cyber security in the US.
2. To learn a practical example of data misuse, implications and lessons learnt.

17:10

Panel discussion: What is the future direction of data protection and cyber security in medical imaging?

WG 1

Ultrasound-guided interventional procedures: new techniques and applications

Moderators:

P.L. Pereira; Heilbronn/DE

D.A. Clevert; Munich/DE

A-823 16:00

Liver

E. Leen; *London/UK (edward.leen@imperial.ac.uk)*

The real-time nature of US combined with its low cost and higher availability remains the modality of first choice for needle guidance for biopsy, drainage and ablation in the liver. Needle guiding device is recommended for deeply located lesions, especially for less experienced users. The biopsy technique used is dependent on the examiner's skills and the accessibility of the target. Image fusion with CT or MR and navigation systems may be helpful for ultrasound guidance in lesions difficult to visualize on ultrasound with or without contrast agents (CEUS). Local ablative procedures play a key role in the management of patients with malignancies such as hepatocellular carcinoma (HCC) or metastases. US and CEUS play an important role before, during and after ablation procedures. CEUS enables (a) the assessment of the lesions to be treated by ablation (number, size, degree and homogeneity of lesion enhancement, presence of feeding vessels, to define the eligibility for treatment and the best ablation strategy), (b) the depiction of previously undetectable lesions with the support of fusion imaging, enabling needle/probe guidance to occult lesions and (c) the detection of viable tumour persistence following locoregional treatment.

Learning Objectives:

1. To learn about new results and application of ultrasound in guided interventional procedures: liver malignancy biopsy, primary liver malignancy ablation, secondary liver malignancy ablation.
2. To understand consolidated and new indications to ultrasound-guided interventional procedures: PEI, RFA, MWA, IRE.
3. To appreciate accuracy of ultrasound-guided interventional procedures from consolidated to new applications: analysis of data from personal experiences and literature series comparison and discussion.
4. To become familiar with the new techniques of ultrasound guidance and with the new diagnostic and therapeutic indications for ultrasound-guided interventional procedures: CEUS imaging, fusion imaging, elastosonographic imaging for liver malignancy biopsy and treatment, MWA, IRE, combination treatment.

A-824 16:20

Pancreas

M. D'Onofrio; *Verona/IT (mirko.donofrio@univr.it)*

Percutaneous interventional diagnostic and therapeutic procedures under ultrasound guidance are largely employed in pancreatic diseases. Diagnostic procedures include cytologic and/or histologic sampling with fine needles or coarse needles to sample pathologic tissue or fluids/collections for biochemical, cytologic and microbiologic examinations. Therapeutic procedures include the drainage of fluid collections by needle or catheter and nowadays the ablation procedures. The advantage of ultrasound guidance is strictly linked to the real-time aspect of the examination. Nowadays to amplify the view of the image, a method employing CT or MR fusion imaging can be used. New results and applications of ultrasound-guided interventional procedures such as pancreatic malignancy biopsy or primary pancreatic malignancy ablation have been increasingly reported, moving from consolidated to new indications to ultrasound-guided interventional procedures. The accuracy of ultrasound using new techniques such as CEUS and fusion for guiding interventional procedures has improved as reported in literature.

Learning Objectives:

1. To learn about new results and application of ultrasound-guided interventional procedures: pancreatic malignancy FNA and biopsy, primary pancreatic malignancy ablation.
2. To understand consolidated and new indications to ultrasound-guided interventional procedures: FNA and biopsy, RFA.
3. To appreciate accuracy of ultrasound-guided interventional procedures from consolidated to new applications: analysis of data from personal experiences and literature series comparison and discussion.
4. To become familiar with the new techniques of ultrasound guidance and with

the new diagnostic and therapeutic indications for ultrasound-guided interventional procedures: CEUS imaging, fusion imaging, elastosonographic imaging for panceratic malignancy biopsy and treatment, RFA, MWA, IRE, combination treatment.

A-825 16:40

Kidney
J.-M. Correas; *Paris/FR (jean-michel.correas@aphp.fr)*

Ultrasound-guided interventional procedures are playing an increasing role for both diagnosis of diffuse and focal diseases and therapeutic applications. When the target lesion can be identified using US imaging, it is the modality of choice due to the ability to visualize real-time needles, catheter and electrodes. New techniques such as contrast-enhanced ultrasound, shear-wave elastography and fusion imaging are further improving the capabilities of US-guided procedures. However, adequate training remains mandatory, particularly in the case of difficult procedures.
Learning Objectives:
1. To learn about new results and application of ultrasound-guided interventional procedures: renal malignancy FNA and biopsy, primary renal malignancy ablation.
2. To understand consolidated and new indications to ultrasound-guided interventional procedures: FNA and biopsy, RFA.
3. To appreciate accuracy of ultrasound-guided interventional procedures from consolidated to new applications: analysis of data from personal experiences and literature series comparison and discussion.
4. To become familiar with the new techniques of ultrasound guidance and with the new diagnostic and therapeutic indications for ultrasound-guided interventional procedures: CEUS imaging, fusion imaging, elastosonographic imaging for renal malignancy biopsy and treatment, RFA, crioablation, MWA, combination treatment.

A-826 17:00

Thyroid
G. Mauri; *Milan/IT (vanni.mauri@gmail.com)*

Ultrasound-guided interventional procedures in thyroid disease have shown great expansion and are more and more widely applied in the clinical practice in a larger spectrum of applications. On the one hand, ultrasound-guided fine needle aspiration has become the standard practice for diagnosing the nature of thyroid nodules, which are increasingly detected in the population. On the other hand, the development of dedicated technique such as laser ablation or radiofrequency ablation with specific devices has expanded the role of interventional ultrasound in the treatment of both benign and malignant thyroid disease. Ultrasound-guided ablation has achieved a more important role in the everyday treatment of benign nodules (even hyperfunctioning ones), representing a minimally invasive, safe and effective treatment strategy. Moreover, the application of thermal ablations to malignant disease, both primary and recurrent, seems to represent a promising strategy in order to reduce the invasiveness of surgical treatment in such difficult anatomical region. In this presentation, consolidated and new applications of interventional procedures in the thyroid will be presented and discussed, with particular focus on new application of thermal ablations in the setting of both benign and malignant disease.
Learning Objectives:
1. To learn about new results and application of ultrasound-guided interventional procedures: thyroid malignancy FNA, thyroid nodule ablation.
2. To understand consolidated and new indications to ultrasound-guided interventional procedures: FNA, RFA.
3. To appreciate accuracy of ultrasound-guided interventional procedures from consolidated to new applications: analysis of data from personal experiences and literature series comparison and discussion.
4. To become familiar with the new techniques of ultrasound guidance and with the new diagnostic and therapeutic indications for ultrasound-guided interventional procedures: CEUS imaging, fusion imaging, elastosonographic imaging for thyroid malignancy FNA.

Multidisciplinary Session

MS 16

Psychoradiology: a blend of molecular, functional and structural imaging with a taste of psychology

A-827 16:00

Chairperson's introduction
B. Ertl-Wagner; *Munich/DE (Birgit.Ertl-Wagner@med.uni-muenchen.de)*

Psychoradiology is a field of radiology that investigates the brain and mind both in health and disease. It usually applies various methods including structural and volumetric magnetic resonance (MR) imaging, functional MR imaging, MR spectroscopy and diffusion tensor imaging (DTI). A combination of methods increases the soundness of the results. Psychoradiology can help to both unravel the physiological processes of the mind and to understand pathological alterations that lead to disease. In recent years brain stimulation techniques have been gaining increasing attention for the treatment of various psychiatric disorders. Psychoradiology may become an important tool to guide the target of the intervention and to understand the changes in the brain´s networks associated with this treatment.
Session Objectives:
1. To become familiar with the interdisciplinary aspects of psychoradiology.
2. To learn about the methodological principles of structural, functional and molecular imaging of the brain.
3. To understand the pathophysiological concepts underlying psychiatric disorders.

A-828 16:05

A psychiatrist's view on neuroimaging
F. Padberg; *Munich/DE (frank.padberg@med.lmu.de)*

During the last three decades, psychiatrists have developed a comprehensive view on brain functions, which underly symptoms and syndroms of psychiatric disorders. Different avenues from genetic and molecular research, neurophysiology, and multimodal neuroimaging have contributed to this development. More recently, parallel to the introduction of the Diagnostic Manual DSM-5, the National Institute of Mental Health (NIMH) has challenged the diagnostic categories by introducing Research Domain Criteria (RDoC) as a new matrix for cognitive and behavioral domains forming human experience and behavior. These domains can be addressed from cellular to system Levels. Neuroimaging represents a key technology for the investigation of these domains and will play a pivotal role in psychiatric research (Bhugra et al. 2017). This lecture will outline these issues and give examples of the diagnostic value of neuroimaging, research on pathophysiology and mechanisms of therapeutic action (example: brain stimulation; Padberg et al. 2017), and finally prediction of individual outcome as well as monitoring progress of disease. References: Bhugra D, Tasman A, Pathare S, et al. The WPA-Lancet Psychiatry Commission on the Future of Psychiatry. *Lancet Psychiatry. 2017; 4:775-818.* Padberg F, Brem AK, Palm U, et al. Discovering the individual brain: brain stimulation in psychiatry: Editorial I to the supplement from the 2nd European conference on brain stimulation in psychiatry. *Eur Arch Psychiatry Clin Neurosci. 2017; Nov 20. doi: 10.1007/s00406-017-0853-3.*
Learning Objectives:
1. To understand the important role of imaging in the diagnostic evaluation of psychiatric patients.
2. To become familiar with important imaging patterns that may be encountered in patients with psychiatric disorders.
3. To understand future trends in neuroimaging of patients with psychiatric disorders.

A-829 16:23

Advanced imaging techniques: their role in neuropsychiatric disorders
S. Stöcklein; *Munich/DE (sophia.stoecklein@med.lmu.de)*

Structural MR imaging in neuropsychiatric disorders includes volumetric techniques, such as whole-brain voxel-based morphometry and automated segmentation of brain structures, as well as assessment of tissue

characteristics such as myelin content. With the advent of advanced data mining and machine learning techniques, the results of these approaches can be combined to detect disease-specific patterns, as singular volumetric measures might lack specificity. For example, hippocampal volume is not only reduced in Alzheimer's disease, but also in depression and schizophrenia. Ultrahigh field MRI will further facilitate the detection of disease-specific changes, e.g. in the hippocampal subfields in schizophrenia. Functional MRI in neuropsychiatric disorders largely relies on resting-state paradigms, as they are easily implementable and less dependent on patient cooperation and command of language than task-based paradigms. Many fMRI studies have investigated differences between patient and control groups and have provided valuable insight into alterations of functional brain connections and networks in neuropsychiatric diseases. However, applications in the individual patient are still sparse. Technical advances such as individualized functional networks, reliability correction, and also optimized scan length and the collection of large healthy reference populations are currently paving the way towards applications of fMRI as an individualized imaging marker for neuropsychiatric disorders. Molecular imaging techniques such as PET/SPECT and MR spectroscopy have provided insight into alterations in neurotransmission and metabolism in neuropsychiatric disorders. Recently, molecular imaging of neuroinflammatory markers such as microglia activation has increasingly attracted interest, due to increasing evidence suggesting a role for inflammation in the pathogenesis of neuropsychiatric disorders.

Learning Objectives:

1. To become familiar with the principles and practice of using structural and volumetric methods in patients with neuropsychiatric disorders.
2. To understand methods and applications of task-based and resting-state functional MR imaging techniques in neuropsychiatric patients.
3. To learn about the role of spectroscopy and molecular imaging in patients with neuropsychiatric disorders.

A-830 16:41

Can images predict psychiatric diagnosis and treatment response?

N. Koutsouleris; *Munich/DE*

"no abstract submitted"

Learning Objectives:

1. To become familiar with the principles of imaging-based prediction methods.
2. To understand the role of neuroimaging in predicting neuropsychiatric diagnoses.
3. To learn about imaging-based methods to predict treatment response in psychiatry.

A-831 16:59

Neuroimaging and neuromodulation: where are we heading

D. Keeser; *Munich/DE (daniel.keeser@med.lmu.de)*

Non-invasive transcranial brain stimulation (NIBS) methods (e.g. transcranial direct current stimulation - tDCS, repetitive transcranial magnetic stimulation - rTMS and others) provide a unique in vivo intervention for probing the functional role of regions and hubs in human neural systems that play a role in the pathophysiology of psychiatric disorders. Recent research has shown that the individual human brain functional MRI connectivity (fcMRI) shows distinct patterns of within- and between-subject variability. Anatomically targeted analyses of NIBS in neuropsychiatric patients and healthy subjects have generated promising results. Even combining several neuroimaging methods (resting state fcMRI, task-based fMRI, magnetic resonance spectroscopy (MRS)) may be useful to detect classifiers that can reliably predict NIBS effects. These neuroimaging methods allow individual brain properties as well as the evaluation of state dependency. By combining neuroimaging and NIBS (term: imaging stimulation), new functional models are expected to be developed and compared in different states of health and pathology, e.g. during the course of psychiatric disorders from preclinical stages to relapsing-remitting or chronic disorders.

Learning Objectives:

1. To understand the principles of neuromodulation.
2. To become familiar with methods of imaging-based neuromodulation.
3. To become familiar with future prospects of neuroimaging and neuromodulation.

Urogenital

A-832 16:00

Chairperson's introduction

R.H. Oyen; *Leuven/BE (Raymond.Oyen@uzleuven.be)*

We aim to become familiar with the imaging presentation of common neoplastic and infectious disorders of the kidneys, describe the typical imaging features of calculus and neoplastic disorders of the ureter and bladder and understand the imaging presentation of benign and malignant disorders of the prostate. Cross-sectional imaging (ultrasound, CT, MRI) has become the key modality for the evaluation of the adrenals, kidneys, upper urinary tract and bladder in symptomatic patients. In addition, because of the increased use of imaging, abnormalities and disease processes of the urogenital tract are seen more frequently in patients not referred for symptoms related to the urogenital tract. Such findings can be relevant or not relevant and include anatomical variants and inflammatory processes; both may erroneously be interpreted as neoplastic lesions (pseudotumours) and benign and malignant tumours. It is important to become familiar with some typical imaging features of common neoplastic disorders of the kidney and urinary tract, of urolithiasis and of inflammatory processes to enable accurate reporting, provide a diagnosis or at least a list of suitable differential diagnoses, and suggest appropriate further studies (imaging, biopsy,) to eventually refine the diagnosis. The aim is to select patients in whom therapy is indicated from those where therapy has to be avoided. MRI now is the key modality for the detection of prostate cancer and the staging of known prostatic cancer. However other prostatic disease processes, including inflammation, benign hyperplasia and cancer may occur simultaneously to a variable extent, thus complicating the reading and interpretation of MRI. In this respect, structured reporting MRI studies based on the PI-RADS system contributes to standardized reporting and communication with referring physicians.

Session Objectives:

1. To become familiar with the imaging presentation of common neoplastic and infectious disorders of the kidneys.
2. To describe the typical imaging features of calculous and neoplastic disorders of the ureter and bladder.
3. To understand the imaging presentation of benign and malignant disorders of the prostate.

A-833 16:06

A. Renal and adrenal imaging

N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Kidneys and adrenals are retroperitoneal organs contained within a perirenal space. Variants of adrenals involve essentially their shape, whereas many variants involve kidneys including ectopia, fusion, dystopia and duplication. Renal masses are frequent. Most are simple cysts. Cystic masses must be classified according to Bosniak classification to guide management. Conversely, most of the solid masses are malignant, but diagnosis of benign angiomyolipoma can be confirmed by imaging only. Adrenal masses are usually solid, and most of them are benign with typical imaging features based on evaluation of their lipid content and perfusion level. The role of imaging in parenchymal disease remains limited, except for infections, acute or chronic.

Learning Objectives:

1. To describe the normal imaging anatomy and variants of the kidney and adrenal.
2. To understand the imaging features of benign and malignant tumours of the kidneys.
3. To describe imaging features of benign and malignant tumours of the adrenal glands.
4. To explain the imaging features of infectious disorders of the kidneys.

Author Disclosure:

N. Grenier: Advisory Board; Supersonic Imagine, Aix-en-Provence, France.

A-834 16:34

B. Imaging of the ureter and bladder

M.N. Özmen; *Ankara/TR (mozmen@hacettepe.edu.tr)*

Imaging has a very important role in evaluating the urinary tract. Over the past years, computed tomographic urography (CTU) has become the main imaging modality for this purpose in various clinical settings. Dose reduction techniques have also enabled us to obtain CTUs with very low radiation doses. Several

anomalies of the ureter may be seen, including duplication, muscular dysfunction or abnormal termination. An intraluminal disease process in the ureter might cause obstruction. Ureteral stone is by far the most frequent with high attenuation values on unenhanced CT. Dual-energy CT may contribute to the prediction of the chemical composition of the stone. A filling defect seen on CTU usually raises the suspicion of urothelial neoplasm. Other entities such as clot, metastasis, and tuberculosis might also obstruct the ureter and must be considered in the differential diagnosis of selected patients. The prevalence of urothelial neoplasms is high in elderly patients with a history of smoking, analgesic use or occupational exposure to chemical carcinogens. Urothelial cancer has to be considered as a 'systemic' disease, with often multiple, synchronous or metachronous lesions. CTU not only depicts the neoplastic lesion, but also enables the examination of the entire urothelium during staging or follow-up. Several treatment options are available and imaging plays an important role for tailoring this treatment. In case of haematuria, where CTU is the main diagnostic tool for upper urinary tract evaluation, cystoscopy is the primary diagnostic tool for screening for bladder neoplasms. CTU is indicated for the evaluation of upper urinary tract and staging purposes.

Learning Objectives:

1. To explain the imaging anatomy and variants of the ureter and bladder.
2. To understand the diagnostic evaluation and imaging features of calculi of the ureter and bladder.
3. To describe the imaging features of benign and malignant tumours of the ureter and bladder.

A-835 17:02

C. Prostate imaging

H.C. Thoeny; *Berne/CH (harriet.thoeny@insel.ch)*

Prostate imaging is increasingly performed using multiparametric MRI (mpMRI) to detect and stage significant prostate cancer as well as for active surveillance in patients with a known cancer. The requirements to perform correct mpMRI including high-resolution T2w, diffusion-weighted MRI (DW-MRI) and dynamic contrast-enhanced MRI (DCE-MRI) are specified in PIRADS vs 2 (Prostate Imaging and Reporting Data System). The aim of prostate imaging is to detect a significant cancer defined as a tumour with a volume $\geq$ 0.5 cc or a Gleason score of $\geq$ 7 and/or extraprostatic extension. PIRADS version 2 uses a 5-point scale based on the likelihood that a combination of mpMRI findings on T2w, DW-MRI and DCE-MRI correlates with the presence or absence of clinically significant prostate cancer for each lesion in the prostate gland. PIRADS 1 or 2 means that clinically significant cancer is unlikely to be present, PIRADS 3 is intermediate/equivocal and PIRADS 4 and 5 indicate a high likelihood of significant prostate cancer (PIRADS 4: size< 1.5cm, PIRADS 5: size< 1.5 cm). Most of the prostate cancers are located in the peripheral zone, where DW-MRI is the dominant sequence to make the correct diagnosis. In the transition zone, T2w is the dominant sequence. In this presentation, typical findings will be discussed and also benign diseases such as prostatitis and benign prostatic hyperplasia will be demonstrated as potential differential diagnoses.

Learning Objectives:

1. To explain the PIRADS system in prostate imaging.
2. To describe the imaging features of benign prostatic hypertrophy.
3. To understand the imaging features of prostate cancer.
4. To describe the imaging features of inflammatory changes of the prostate.

Emergency Imaging

RC 1617

Why do I miss fractures in emergency?

A-836 16:00

Chairperson's introduction

S. Wirth; *Munich/DE (stefan.wirth@med.uni-muenchen.de)*

Sometimes, things may become more difficult and easier at the same time. On one hand, advances in imaging allow for very precise and also fast diagnoses in a continuously increasing number of cases. On the other hand, radiologists have to be more and more aware of clinical entities, pathological patterns, and interdisciplinary networks to quickly and precisely provide our clinical partners with the information they need. Although these changes are apparent, overlooked fractures remain a big and also common challenge. Aiming to reduce the typical potential problems like arthrosis and pain, this should also take into account social dimensions like medical costs and patient's ability to work. Which way we should go: More and better education and training? More clinical integration? More lowest-dose CT instead of radiographs? More quality assurance and management? The three lectures will develop answers to theses questions and will also provide high educational value with a focus on differences between children and adults, as well as on likelihood and complexity of related other injuries.

Session Objectives:

1. To learn the typical constellations and findings of missed fractures.
2. To understand the potential complications resulting from missing fractures.
3. To appreciate direct and indirect fracture signs with different imaging modalities.

A-837 16:05

A. Missed fractures in children

A.C. Offiah; *Sheffield/UK (amaka.offiah@nhs.net)*

Fractures in children may be missed in the Emergency Department for several reasons. Firstly, a normal variant may be misdiagnosed as a fracture (or vice versa). Secondly, normal physiological absence of ossification of the epiphyseal centres makes assessment of alignment difficult. Finally, some fractures are themselves subtle. This lecture will predominantly focus on radiographs, but use cross-sectional imaging to highlight specific points. Particular fractures to be covered are accidental (as opposed to inflicted) and include skull, vertebral, clavicular, elbow, scaphoid, pelvic (including avulsion injuries and slipped capital femoral epiphysis) and tibial fractures.

Learning Objectives:

1. To become familiar with the common fractures in childhood.
2. To understand the choice of the best-suited imaging modality.
3. To learn about atypical imaging findings in different clinical scenarios.

Author Disclosure:

A.C. Offiah: Advisory Board; Alexion, BioMarin. Consultant; Alexion, BioMarin. Grant Recipient; Alexion. Research/Grant Support; Alexion. Speaker; Alexion, BioMarin, InfoMed.

A-838 16:30

B. Missed fractures in adults

A. Pinto; *Naples/IT (antopin1968@libero.it)*

Falls are the most common cause of injuries among adult patients: advanced age substantially increases the likelihood of hospitalization after a fall. The most commonly fractured bones in adults are: (1) the hip, femur, pelvis, and vertebrae; (2) the humerus, forearm, and hand; (3) the leg and ankle bones. Radiography remains the initial modality to detect or exclude the presence of a fracture. The main cause of diagnostic error in the Emergency Department is the failure to correctly interpret radiographs: the majority of the diagnoses missed on radiography are fractures. Some of the fractures are subtle; however, the majority are obvious, which suggests inadequate training and/or poor technique in radiological interpretation. In other situations, the fractures are observed but misinterpreted as normal variants or old injuries. Misinterpretation of fractures may determine a delayed treatment and poor outcome for patients treated in the Emergency Department. It is also one of the most frequent factors leading to medical legal claims. With a high clinical index of suspicion, further evaluation with additional imaging is typically required, particularly if the results of this imaging will affect clinical management. Radiologists should more completely understand the limitations of radiography in the diagnosis of subtle fractures and can best indicate the need for more advanced imaging, such as CT, for a correct diagnosis in an appropriate time frame. Key elements to reduce errors in the diagnosis of fractures on plain radiographs are knowledge, experience, and correct application of the imaging protocols.

Learning Objectives:

1. To become familiar with the most common fractures in adult patients.
2. To understand which additional data will influence the choice of the correct imaging modality.
3. To learn about atypical imaging findings in adult patients after trauma.

A-839 16:55

C. Missed musculoskeletal injuries in whole-body MDCT examinations

T. Ruder; *Whangarei/NZ (Thomas.Ruder@northlanddhb.org.nz)*

Whole-body CT has become the first-line modality in the imaging workup of patients with multiple injury trauma in many hospitals across the world. Accurate and rapid reporting of whole-body CT in trauma patients is critical for patient management. However, reading huge stacks of images under time pressure while being frequently interrupted presents great challenges to radiologists and carries the risk of missed injuries. The aim of this presentation is to provide an overview of common musculoskeletal injuries in multiple injury trauma patients, provide insight into the causes of missed injuries, highlight the effect of missed injuries on patient care, offer strategies to reduce sources of errors, and suggest a systematic approach to reading trauma CT. The first part

of the lecture covers frequently encountered musculoskeletal injuries and their relationship to distinct trauma mechanisms. The second part addresses the reasons for blindness and bias in diagnostic radiology. The third part focuses on a step-by-step approach for reporting whole-body CT in multiple injury trauma patients.

Learning Objectives:

1. To become familiar with the most common musculoskeletal injuries in patients after polytrauma.
2. To understand the clinical impact of missed subtle injuries on clinical outcome of the trauma victims.
3. To be familiar with less typical imaging findings in musculoskeletal injuries.

17:20

Panel discussion: How to reduce the rate of missed fractures most effectively and efficiently

Musculoskeletal

RC 1610

The radiological investigation of musculoskeletal tumours

A-840 16:00

Chairperson's introduction

F.M.H.M. Vanhoenacker; *Antwerp/BE (filip.vanhoenacker@telenet.be)*

Plain films are the initial imaging modality in the detection and characterization of bone tumours, as they accurately depict matrix, cortical permeation or disruption and periosteal reaction. However, the sensitivity of this technique for the detection of small lesions is limited. CT can be used for characterization in anatomically complex areas, such as the spine, pelvis and skull. The CT appearance is similar to radiography. Due to radiation restraints, CT is not recommended in children or for evaluation of the appendicular skeleton in adults. Conventional MRI may be of additional help in narrowing the differential diagnosis of bone tumours. Soft tissue tumours based on imaging remains even more limited and histology is usually required for a definitive diagnosis. Ultrasound is mostly nonspecific, but may be used for superficially located cystic STT. On MRI, analysis of multiple parameters (shape, presence of signal voids, fluid-fluid levels, SI, intratumoural necrosis, multiplicity, pattern/degree of enhancement) yields the best results. The highest confidence is reached in benign lesions such as lipomas, vascular lesions, benign neural tumours, periarticular cysts, haematomas, PVNS, GCTTS, and abscesses. The major role of MRI consists of local tumour staging and therapy monitoring. The European Society of MusculoSkeletal Radiology (ESSR) has published guidelines for the detection, characterization, and referral pathway of musculoskeletal tumours based on conventional imaging. The specific aim of this session is to discuss the role of recent advances in ultrasound technology, advanced CT and MR techniques, and hybrid imaging in imaging evaluation of musculoskeletal tumours.

Session Objectives:

1. To learn how to differentiate tumours from other non-tumoural pathologies.
2. To understand the value of imaging modalities in this field.
3. To appreciate how to determine resectability and extension of the tumour.

A-841 16:05

A. Radiographs and ultrasound

L.M. Sconfienza; *Milan/IT (io@lucasconfienza.it)*

Besides advanced techniques, such as computed tomography and magnetic resonance imaging which are important in the workup of musculoskeletal tumours, plain films and ultrasound still play a crucial role. Plain films still represent the cornerstone in the evaluation of bone tumours, as they allow detecting the presence of a bone lesion and giving important information about characterization of the lesion such as the presence and type of periosteal reaction, the pattern of bone destruction, the lytic or sclerotic appearance of the lesion, the presence of soft tissue involvement or of associated findings such as pathological fractures. However, plain films have limitations in particularly complex anatomical locations (e.g. spine and pelvis) and in the evaluation of soft tissue tumours not involving the bone. Ultrasound has limitations in the evaluation of bone tumours, as the ultrasound beam can only minimally cross the bony cortex. However, ultrasound may detect the presence of a periosteal reaction in early stages and may be used to assess the involvement of surrounding soft tissues and neurovascular bundles by bone tumours. On the other hand, ultrasound is accurate in the detection and evaluation of soft tissue tumours, being able to correctly evaluate the size and the relationship of the mass with the surrounding structures. The use of supplementary tools, such as power Doppler, contrast-enhanced ultrasound, and elastography has been proved to be useful in increasing the diagnostic performance of ultrasound in certain conditions. However, ultrasound may be limited by low contrast resolution, small field of view, and deep lesions.

Learning Objectives:

1. To learn about the value of radiography and US in the diagnostic work-up of MSK tumours.
2. To be familiar with the most recent advances and trends in the development of US technology, including contrast-enhanced US and elastography.

Author Disclosure:

L.M. Sconfienza: Other; Travel grants from Bracco Imaging Srl, Esaote, and Abiogen.

A-842 16:28

B. MRI and whole-body MRI

S.L.J. James; *Birmingham/UK (stevenjames@nhs.net)*

MR imaging is the modality of choice for local staging of musculoskeletal tumours. When dealing with primary bone tumours, MRI enables both the intra- and extraosseous extent of the lesion to be delineated so that limb salvage surgery can be considered. Soft tissue tumours can be assessed relative to the compartmental anatomy and involvement of adjacent neurovascular structures. Once again, this facilitates potential curative excision to be planned. A routine MR protocol will be presented for primary bone and soft tissue musculoskeletal tumours. Additional advanced sequences will be discussed including chemical shift imaging, diffusion-weighted imaging, MR spectroscopy and post-contrast imaging. Current evidence for the use of these advanced imaging sequences will be reviewed. The role of whole-body MRI in staging of musculoskeletal tumours will be discussed including current evidence for its use in primary musculoskeletal tumours. This talk will not, however, discuss the use of MRI or whole-body MRI in the assessment, staging or follow-up of multiple myelomas or metastatic disease.

Learning Objectives:

1. To learn how to perform an advanced clinical MR protocol for MSK tumours.
2. To explore the potential of new MR techniques.
3. To learn the impact of MR imaging and whole-body techniques in MSK tumour imaging.

A-843 16:51

C. CT and hybrid imaging

T. Bäuerle; *Erlangen/DE (tobias.baeuerle@uk-erlangen.de)*

For imaging of musculoskeletal tumours, CT as well as the hybrid techniques PET/CT and PET/MRI offer a broad spectrum of methods for diagnosis, staging and follow-up. On the morphologic level, bone destruction ranging from osteolytic to blastic lesions and adjacent soft tissue tumours, e.g. in Ewing sarcoma or lytic bone metastases, are captured by CT. Beyond morphology, PET radiopharmaceuticals including [18]F-fluorodeoxyglucose ([18]F-FDG) or [18]F-sodium fluoride ([18]F-NaF) report on tumour and bone metabolism, respectively. Whereas the soft tissue tumours of rhabdomyosarcoma or bone marrow involvement in multiple myelomas is assessed by [18]F-FDG, osteoblastic activity is captured using [18]F-NaF, for example in sclerotic metastases. Due to the excellent sensitivity of PET, information on the molecular level is available when administering tumour-specific radiotracers such as the [68]Ga- or [18]F-labelled prostate-specific membrane antigen (PSMA) ligands for prostate cancer bone metastases. In conclusion, this lecture will summarize the use of CT and hybrid imaging techniques PET/CT and PET/MRI in primary and secondary musculoskeletal tumours. Current state-of-the-art techniques on the morphologic, metabolic and molecular level will be given as well as an outlook on future developments, particularly in hybrid imaging.

Learning Objectives:

1. To learn about the role of CT and hybrid imaging in the evaluation of MSK tumours.
2. To understand how hybrid imaging allows the intrinsic combination of functional and anatomical image information.
3. To be aware of the future developments of novel PET tracers and integrated PET/CT and MRI/PET in MSK tumours.

Demystifying MRI: things you always wanted to know

Moderator:
I. Seimenis; Alexandropolis/GR

A-844 16:00

A. Basic MR: the building blocks of pulse sequences
D.G. Norris; *Nijmegen/NL (david.norris@fcdonders.ru.nl)*

To understand how NMR signals are produced, it is important to realise that the hydrogen nucleus has a magnetic moment which causes it to precess when placed in a static magnetic field. I shall explain how the presence of multiple nuclei gives rise to a bulk magnetisation, and how the orientation of the magnetisation vector can be manipulated by the application of radiofrequency pulses. Using the example of a bicycle dynamo, I will show how rotating transverse magnetisation gives rise to a measurable signal. Following excitation, the longitudinal magnetisation recovers (spin-lattice, or T1 relaxation) and the transverse magnetisation loses phase coherence (spin-spin, or T2 relaxation). I shall explain the physical basis for these processes and the use of inversion-recovery sequences to obtain T1 contrast, and spin-echo sequences to obtain T2 contrast. Finally, I shall show some modern examples of quantitative measurements of T1 and T2.

Learning Objectives:
1. To learn about how NMR signals are produced.
2. To understand the basic concepts of relaxation.
3. To learn about the operation of inversion-recovery and spin-echo pulse sequences.

Author Disclosure:
D.G. Norris: Advisory Board; fMRIB, Oxford.

A-845 16:30

B. MR imaging basic concepts: how to turn signals into images
D.J. Lurie; *Aberdeen/UK (d.lurie@abdn.ac.uk)*

To generate images in MRI, NMR signals must be “labelled” with their location. Three techniques of spatial encoding are employed, all of which use the magnetic field gradient. By sending electrical current (hundreds of amperes) through a gradient coil, a magnetic field is produced, whose strength varies linearly with position inside the scanner bore. In frequency encoding, the NMR signal is recorded while a field gradient is applied. Since the magnetic field varies with position along the gradient direction (e.g. X), the NMR resonant frequency (Larmor frequency) is a function of position, so the detected signal contains a range of frequencies; analysing the frequency content generates a one-dimensional projection of the water distribution within the patient. A method called phase encoding is employed in the second in-plane dimension (e.g. Y); here, the gradient is pulsed on and off prior to measurement of the signal, affecting the phase of the NMR signal as a function of position. Finally, the slice itself is defined using selective excitation, in which the radiofrequency pulse used for NMR excitation is specially shaped and applied in the presence of a field gradient perpendicular to the slice plane (e.g. along Z). To generate data for an image of NxN pixels, the pulse sequence is usually applied N times, varying the phase-encode gradient amplitude with each repetition. A two-dimensional Fourier transform of the raw data matrix yields the MR image, which can be encoded with NMR parameter (T1, T2, diffusion, etc.) information to assist in diagnosis.

Learning Objectives:
1. To learn how magnetic field gradients encode spatial information.
2. To understand the main ways in which field gradients are used.
3. To appreciate the basic concepts of data collection and image reconstruction in MRI.

Author Disclosure:
D.J. Lurie: Research/Grant Support; GE Healthcare.

A-846 17:00

C. Practical MRI: a toolkit of standard MR pulse sequences
G. Hagberg; *Tübingen/DE (gisela.hagberg@tuebingen.mpg.de)*

The MR sequence is the essential tool to measure MR properties in tissues, increase contrast between these and quantify relevant data. Besides furnishing the desired tissue-derived MR signal, the sequence must allow spatial encoding to take place as efficiently as possible to enable patient compliance, and high-quality MRI at the same time. Starting with a brief introduction regarding MR tissue properties and spatial encoding in k-space, I will describe the fundamental MR toolkit, based on single echo spin-echo (SE) and gradient-echo (GE) and show how these are extended to different multiple-echo regimes. I will describe the basic image contrast and how imaging parameters, repetition time, TR; echo time, TE; flip angle, FA; inversion delay, diffusion gradients, etc., influence contrast. The possibility to further enhanced imaging by adequate spin-preparation, inversion or magnetization transfer pulses, etc., will also be discussed. Imaging speed can be achieved while remaining in the single echo regime by faster RF pulsing giving valuable information linked with magnetic susceptibility as in the GE-based FLASH method, based on spoiling of unwanted echoes. Another possibility is to use subsequent (spin) echoes to read out different k-space lines, without the cost of greater saturation that comes with shorter TRs, as in the SE-based method RARE. An alternative possibility that further extends available image contrast is to retain the full magnetization in GE-based sequences and acquire images in the different steady-state free-precession regimes. The latter techniques have gained momentum through the advent of magnetic fingerprinting and are a fundamental part of the standard MRI toolkit.

Learning Objectives:
1. To learn about common types of MR pulse sequence.
2. To understand the difference between gradient-echo and spin-echo.
3. To appreciate the factors influencing choice of pulse sequence.

16:00 - 17:30 **Room K**

Radiographers

RC 1614

Optimising computed tomography

A-847 16:00

Chairpersons' introduction (part 1)
U. Nikupaavo; *Helsinki/FI*

Computed tomography (CT) is an essential diagnostic tool in many indications. New indications for CT imaging and technical development of the CT systems have increased the number of elective and emergency CT examinations. This has led to an increase in the collective radiation dose. The base of radiation safety in CT is a good referral practice. Justified CT examination includes adequate information of the patient, so that proper indication-based protocol can be used for the best diagnostic result and patient care. The goal of CT optimization is to minimize radiation exposure while maintaining diagnostic image quality. Technical methods for this purpose include the use of automatic exposure control (AEC) (i.e. automatic tube current modulation), bowtie filters, lower tube voltage (kVp) settings, adaptive section collimation, partial scanning, and iterative reconstruction methods. Correct preparation and positioning of the patient and optimized contrast agent protocols have great impact on the resulting radiation dose and image quality. Multiprofessional team work is essential to achieve justified and optimized CT examinations. Traditionally, the radiologist is in charge of adequate image quality level and the physicist coordinates the dose management and quality control. The radiographer has responsibilities in the following areas: daily workflow, preparation of patient, operation of scanner, use of contrast agent, and CT optimization, in general.

Session Objectives:
1. To review the importance of availability and appropriate CT techniques for the diagnosis and treatment of stroke patients.
2. To appreciate practical measures to optimise both, radiation dose and image quality in CT.
3. To understand how intravenous contrast agent delivery can best be optimised in CT to maximise diagnostic capability.

A-848 16:03

Chairpersons' introduction (part 2)
I. Lupescu; *Bucharest/RO (ilupescu@gmail.com)*

Worldwide, stroke is the second most common cause of mortality and the third most common cause of disability. In most centres, in the hyperacute phase, multimodal computed tomography (CT) evaluation is preferred, because of its availability and rapid scan times, containing three techniques: a noncontrast CT for detecting intracranial haemorrhage, a CT perfusion and a CT angiography, allowing the assessment of the site of vascular occlusion, infarct core, salvageable brain tissue and degree of collateral circulation. CT is widely used to obtain high-quality diagnostic images, with an increase of patient’s irradiation. The effective dose for CT examinations can significantly increase, in situations when more CT phases are required. Due to the high CT radiation doses, it is necessary to track patient dose data and CT protocol scanning parameters, and also to apply the system's optimisation and dose reduction

techniques. The dose from the CT examinations can be reduced by controlling certain scanning parameters and optimizing the scanning protocols, delivering the minimum dose required to ensure the proper diagnosis. Current CTs offer reducing dose technologies, such as iterative reconstruction or automatic exposure control. With multidetector CT, intravenous contrast material administration and CT protocols have become challenging and complex. The clinical utility of contrast medium administration and CT scan timing is to achieve diagnostically adequate contrast enhancement in a specific organ using the lowest radiation exposure and the lowest dose of a non-ionic iodinated contrast media injected at the lowest rate in correlation with the renal and cardiovascular function of each patient.

Session Objectives:

1. To review the importance of availability and appropriate CT techniques for the diagnosis and treatment of stroke patients.
2. To appreciate practical measures to optimise both, radiation dose and image quality in CT.
3. To understand how intravenous contrast agent delivery can best be optimised in CT to maximise diagnostic capability.

A-849 16:05

A. Optimising access to CT in stroke

G. Ioannidis; *Larissa/GR (i.giorgio@yahoo.gr)*

Purpose: Computed tomography is the method of choice for the diagnosis of ischaemic stroke. Early diagnosis is of great importance for early treatment. The purpose of this speech is to review the “Golden Hour” of stroke diagnosis and therapy. How useful the cooperation of all the specialities involved will be noted, so that the patient with suspected stroke will arrive on time at the computed tomography department. It is also necessary to indicate the usefulness of CT in relation to the corresponding methods in magnetic tomography (DWI). Finally, the importance of the image of CT in the achievement of thrombolysis is noted. Material and Methods: Protocols that are applied for ischaemic stroke imaging as well as methods for the patient’s protection against radiation are mentioned. Modification of all these in the last few years, comparison of the protocols between CT and MRI, estimation of time from the first symptoms up to the initiation of thrombolysis and the usefulness of image analysis are reviewed. Conclusion: The optimizing access to CT is very important for the immediate treatment of ischaemic stroke. The radiographer has a leading role in this process. Therefore, he should be perfectly aware of the subject to provide the maximum care for the immediate indication of the problem so as to achieve early treatment.

Learning Objectives:

1. To review the golden hour of stroke diagnosis and therapy.
2. To understand strategies for providing timely access to CT for patients with suspected stroke.
3. To appreciate challenges involved in providing timely access to CT and the need for multidisciplinary collaboration.
4. To become familiar with optimal CT protocols for diagnosis and therapy of stroke.

A-850 16:28

B. Optimising radiation dose and image quality

R. Booij; *Rotterdam/NL (r.booij@erasmusmc.nl)*

The number of computed tomography (CT) scans performed worldwide is increasing, which makes radiation dose optimisation of the utmost importance. Thereby, continuous technical improvements have been impressive; accordingly increasing the number of adjustable scan acquisition and reconstruction parameters. Overall, these developments led to improved image quality while reducing radiation dose. However, many parameters are interrelated and part of automated algorithms, making them less easy to adjust individually and more difficult to understand. Consequently, optimisation can be a challenge, e.g. patient positioning may seem to be a minor action; however, it is not. Patient positioning affects the patient’s shape on a localiser radiograph, directly affecting dose modulation settings, as well as the efficacy of a bowtie filter. Therefore, a consolidate knowledge of CT scan parameters and their effects on radiation dose and image quality is needed to optimise CT exams.

Learning Objectives:

1. To enhance our understanding of the challenge of balancing image quality and dose reduction.
2. To review the options available to users for image quality and dose optimisation.
3. To consolidate knowledge to effectively use scan parameters and innovative technologies to optimise CT protocols.
4. To learn how to improve patient positioning and its effect on radiation dose.

A-851 16:51

C. Optimising contrast delivery with MDCT

A. Svensson; *Stockholm/SE (anders.svensson@karolinska.se)*

The administration of intravenous contrast media (CM) is essential for detecting lesions at most computed tomography (CT) examinations. There are several physiological factors that affect the CM-enhancement, where body size (defined by body weight and body height) and cardiac output are the most important factors. Also, technical factors have great influence on CM-enhancement, e.g. x-ray tube potential (kVp), injection rate and iodine dose. Traditionally, the same amount of CM has been given to all patients. However, the volume of distribution, i.e. plasma and extravascular interstitial space into which the CM is diluted is related to the body size and, therefore, a more individualised dosage of CM is nowadays regarded to be ¨state-of-the-art¨. The goal is to achieve a more uniform CM-enhancement independent of body size. This will also reduce the amount of CM given to smaller patients, i.e. reducing the risk of side effects associated with overdosing of CM. When reducing kVp at CT, CM will attenuate a greater number of x-ray photons. Approximately, 50% higher image contrast can thereby be achieved from the same amount of CM when reducing the x-ray tube potential from 120 kVp to 80 or 70 kVp. Vice versa, CM dose can be halved if the tube potential is lowered to down to 70 kVp from 120 kVp.

Learning Objectives:

1. To review injection and patient related factors that affect intravenous contrast medium (IV CM) enhancement during computer tomography (CT).
2. To understand the effect of different tube potential settings and its impact on IV CM enhancement during CT.
3. To gain knowledge about different aspects of individualised IV CM dosage.
4. To appreciate practical "tips and tricks" for successful CT angiography examinations.

17:14

Panel discussion: How to create an optimisation team in CT?

16:00 - 17:30 **Room M 1**

ESR Audit and Standards Session

Audit across Europe: directive and perspective

A-852/A-853 16:00

Chairpersons' introduction

A. Brady[1], D.C. Howlett[2]; *[1]Cork/IE, [2]Eastbourne/UK (adrianbrady@me.com)[1], (david.howlett@nhs.net)[2]*

Under the EU 2013/59 Directive, Clinical Audit will be a required activity for all radiology departments within the EU from February 2018. Many departments already engage in this activity, but for some this will be a new venture. The ESR Audit & Standards Subcommittee has developed a package of suggested audits, with guidance for their completion, to assist with this new requirement. This package (The Esperanto Audit Project) was piloted among Eurosafe Imaging Star departments in late 2017 and will be made available widely following this pilot. During this session, the principles of Clinical Audit will be explained. The distinction between audit and external inspection will be explored and the complementarity of the two will be discussed. The Esperanto Audit Project pilot will be outlined and the initial results presented. Finally, an industry perspective on audit and quality improvement from a commercial perspective will be presented, with reference to change management.

Session Objectives:

1. To understand the principles of Clinical Audit (CA).
2. To appreciate the distinction between CA and external inspection.

A-854 16:05

The Esperanto Audit Project: results from the pilot project and roll out

B.E. Kelly; *Belfast/UK*

In 2018, Euratom Directive 2013/59 will come into effect. This will mandate the regular use of Clinical Audit as a tool for measuring, among other parameters, patient safety and radiation protection. In 2017, the Audit subcommittee produced a booklet (Esperanto) designed to guide the user through the principles of clinical audit. A pilot study, performed during the summer of 2017, tested the efficacy of the templates within the booklet. The results of this indicated that respondents found the algorithm straightforward, the templates navigable and the subjects audited relevant.

Learning Objectives:
1. To learn about the nature of the pilot project.
2. To understand the pilot's significance with regard to the EU 2013/59 Directive.
3. To appreciate the necessity of Clinical Audit.

A-855 16:25

Engaging in the Pilot: The Eurosafe Imaging Star Perspective

G. Paulo; *Coimbra/PT (graciano@estescoimbra.pt)*

EuroSafe Imaging focuses on promoting appropriateness in medical imaging, maintaining doses within diagnostic reference levels, and emphasising the importance of using up-to-date equipment to develop a patient safety culture in medical imaging. The EuroSafe Imaging Call for Action number 2 focuses on developing and promoting a clinical audit tool for imaging to increase the quality of patient care and improve justification. Clinical audit is a systematic examination or review of medical radiological procedures. It seeks to improve the quality and the outcome of patient care through structured review whereby radiological practices, procedures, and results are examined against agreed standards for good medical radiological procedures. Clinical Audit is required under the Euratom Basic Safety Standards Directive and therefore mandatory in the EU. The ESR Audit Tool aids departments in carrying out audit in a more comprehensive manner and thereby complying with the directive by assuring the protection of their patients. Participating in the pilot project gave us the opportunity to engage better with the clinical audit process concept, mainly by focusing on the specificity of radiology departments, using a comprehensive library of templates. A very positive aspect of taking part in this ESR pilot was the fact that for the first time, a multidisciplinary team has been created, involving radiologists, radiographers, medical physicists, students and academic staff. This strategy revealed important aspects, namely, that integrating audit concepts into the clinical placements of radiography students will contribute to an easy adaptation and understanding to the audit philosophy.

Learning Objectives:
1. To learn about participation in the pilot project.
2. To understand the audit template.
3. To appreciate the advantage of performing Clinical Audit.

A-856 16:45

Quality improvement and change management: Audit in industry

S. Lee; *Amsterdam/NL (steven.lee_1@philips.com)*

Clinical-audit might be likened to the process of ‘continuous improvement’ of quality in industry. The latter focuses on improving performance for competitiveness by raising the quality (as perceived by the customer) and reducing the cost of products and services, while the former focuses on improving the quality of patient care by ensuring that clinical practice is delivered in line with defined standards. Both face the challenges of engaging people, developing supportive cultures and using systematic methods for sustaining the improvement process. While industry has deployed quality improvement practices extensively over many decades, the practice of clinical audit in many health-care organisations is by comparison relatively immature. The talk considers the evolution of different industrial management practices and paradigms concerned with quality improvement from the middle of the last century. During that time, the growing emphasis on the people dimension of improvement and change is highlighted, as is the significance of using an agreed, common and structured process (e.g. PDSA, DMAIC) for effecting quality improvement. The central importance of quality improvement for achieving competitiveness in an industrial setting is described, as are the major ‘trends’ deployed in realising such improvement. Potential areas of symbiosis between clinical-audit and management paradigms (Lean, Six Sigma, etc.) are proposed, particularly Lean principles, people change management and alignment of structured quality improvement processes. Working to align the intrinsic motivation of people with the practice of audit and quality improvement, by highlighting the benefits offered to customers (patients), is emphasised as key to securing staff engagement.

Learning Objectives:
1. To learn about the genesis of audit.
2. To understand the importance of audit in industry.
3. To appreciate the symbiosis between audit and management paradigms.

Author Disclosure:
S. Lee: Employee; Employee of Philips.

A-857 17:05

HERCA and Audit: Inspection vs Clinical Audit. What's the difference?

S. Ebdon-Jackson; *Didcot/UK (steve.ebdon-jackson@phe.gov.uk)*

EC Directive 2013/59/Euratom is intended to provide basic safety standards for protection against the dangers arising from exposure to ionising radiation. Member States are expected to transpose the Directive into national law. The Directive includes provisions for inspections to be carried out by the competent authority. In addition, within Chapter VII on Medical Exposures, there is a requirement that Member States ensure that clinical audits are carried out in accordance with national procedures, recognising that clinical audit extends beyond the scope of radiation protection and is normally carried out under professional initiatives and not under regulatory frameworks. While there may be some overlap between the information gathered as part of these separate approaches, the aims and conduct of regulatory inspections and clinical audit are different. These differences and the potential for these proceses to be complementary are discussed.

Learning Objectives:
1. To learn about the duality of the process.
2. To understand the role of the inspector.
3. To appreciate the differences between Inspection and Clinical Audit.

17:25
Panel discussion: Does Audit make the patient journey safer?

16:00 - 17:30 **Room M 2**

E³ - ECR Master Class (Interventional Radiology)

E³ 1626a

Interventional radiology in the venous system: vessel and eye opening

Moderator:
C. Binkert; Winterthur/CH

A-858 16:00

A. Varicose vein

L. Oguzkurt; *Istanbul/TR (loguzkurt@yahoo.com)*

Varicose vein of the leg is a very common disease. Saphenous vein insufficiency is the cause in almost 95% of cases. Varicosities are not a sole cosmetic problem, as it may induce symptoms such as pain, fatigue, heaviness and night cramps which may influence the quality of life of people. Saphenous vein insufficiency is also part of chronic venous insufficiency causing leg swelling, skin changes and rarely venous ulcers. Surgery with saphenous vein stripping and high ligation was the primary treatment for years, but endovenous ablation methods are now the first-line treatment. There are several options for endovenous treatment of the saphenous vein insufficiency, such as laser, radiofrequency and steam (thermal) ablations or mechanicochemical, foam or glue (nonthermal) ablations. All these methods proved to be very effective and safe to treat truncal vein ablation. Ultrasound-guided foam sclerotherapy is not very effective for truncal vein ablation as recurrence rates are high. However, it is very effective for ablation of secondary or residual varicosities. Ambulartory phlebectomy or sclerotherapy for the secondary varicosities can be performed concomitantly or as a staged procedure and the former is preferred in most centres. Complications of truncal vein ablation include pain, bruising, tenderness, and phlebitis over the treated vein which are usually mild and self-limited. Deep vein thrombosis, pulmonary embolisms are extremely rare, but reported as case reports. Technical and short-/long-term clinical outcomes of endovenous ablation of the saphenous veins are very good with improvement of both cosmetic problems and clinical complaints.

Learning Objectives:
1. To learn about clinical and imaging assessment.
2. To understand the role of thermal and non-thermal devices.
3. To review the role of foam sclerotherapy and mini-phlebectomy for ancillary therapies.

A-859 16:30

B. Lower limb acute deep vein thrombosis

J. Kettenbach; *St. Pölten/AT (joachim.kettenbach@stpoelten.lknoe.at)*

Deep vein thrombosis (DVT) is common and, if left untreated, can lead to life-threatening conditions. Drug anticoagulation as a standard therapy primarily prevents progression of thrombosis and life-threatening pulmonary embolism. Long-term consequences with high morbidity, such as the post-thrombotic syndrome, cannot be prevented by anticoagulation. Systemic thrombolysis is

no longer indicated because of the high rate of major bleeding complications, whereas surgical thrombectomy is increasingly being replaced by endovascular procedures. Open surgical thrombectomy may be suitable only in selected patients who are candidates for anticoagulation, but in whom thrombolytic therapy is contraindicated (2C). In patients with iliofemoral DVT, catheter-assisted procedures, in addition to anticoagulation, are very well suited to rapidly revascularize extensive thrombosis. Combining local thrombolysis and thrombectomy as a pharmaco-mechanical thrombectomy (PMT) may be considered over catheter-directed pharmacologic thrombolysis (CDT) alone if expertise and resources are available. There is increasing evidence that this preserves venous valve function, reduces longer-term venous hypertension, and lowers the incidence of postthrombotic syndrome (PTS). Pharmaco-mechanical thrombectomy also reduces the required thrombolytic dose and allows single-session intervention. Residual stenoses or venous obstructions are treated by balloon dilatation and stent implantation. In the long term, the severity of a after iliofemoral thrombosis can be significantly reduced. Solitary minor deep calf vein thrombosis can be safely treated with compression stockings and anticoagulation without the need for urgent intervention such as CDT or mechanical thrombectomy, given the associated low morbidity and mortality.

Learning Objectives:

1. To understand the evidence supporting endovascular therapy.
2. To learn about clinical and imaging assessment.
3. To review what is new in terms of techniques and devices.

A-860 17:00

C. Lower limb chronic deep vein occlusion

R. de Graaf; *Maastricht/NL (r.de.graaf@mumc.nl)*

Chronic deep venous obstruction is a relatively prevalent condition caused by either or a combination of two factors: post-thrombotic vein damage or extraluminal venous compression. Post-thrombotic syndrome (PTS) develops in up to 50% of patients in the months or years following a deep venous thrombosis (DVT). Non-thrombotic iliac vein lesions (NIVL) are usually caused by an overriding artery (e.g. May-Thurner), alternatively by any two pelvic structures wedging the iliac vein. Both conditions impede venous outflow of the lower extremity and are linked to symptoms associated with chronic venous disease. Endovascular treatment has been shown to achieve high technical and clinical success. Overall, stents to treat NIVL show higher patency rates than those implanted for post-thrombotic lesions. The variation in patency rates might be dependent on multiple aspects, e.g. diagnostic sensitivity, anticoagulation regimens, stents characteristics and venous inflow impairment. Stent design might pose a very important variable in long-term patency. With increasing awareness and knowledge of deep venous interventions, new devices will be introduced which may improve technical success and support clinical outcome. The nearest challenge will be to identify a common approach in deep venous treatment by appraisal of the current data, moving towards international guidelines.

Learning Objectives:

1. To understand the evidence supporting endovascular therapy.
2. To learn about clinical and imaging assessment.
3. To review what is new in terms of techniques and devices.

E³ 1626b

Quantitative imaging in oncology

A-861 16:00

Chairperson's introduction

J. O'Connor; *Manchester/UK (james.o'connor@manchester.ac.uk)*

Tumours are biologically heterogeneous and this is considered to have prognostic significance and may also influence response to therapy. For many decades, diagnostic imaging has been used to provide 3D morphological assessments of the spatial variation in tumours and quantify overall tumour complexity. More recently, there has also been considerable interest in using functional imaging techniques derived from CT, MRI, ultrasound and nuclear medicine techniques to quantify the spatial variation in tumour pathophysiology. In this ECR Masterclass, we will discuss the image analysis methods currently used to quantify spatial heterogeneity within tumours. We will consider how and when analysis of intratumour heterogeneity can provide benefit over more simple biomarkers such as tumour size and average function. We will consider how imaging biomarkers of heterogeneity are best integrated with genomic and pathology biomarkers into multi-scalar assessments of heterogeneity. The Masterclass will also identify the challenges for imaging tumour heterogeneity that must be addressed before such biomarkers become integrated into guiding patient care.

Session Objectives:

1. To understand the impact of tumour heterogeneity on diagnosis and treatment.
2. To learn the basics of quantitative imaging of heterogeneity.
3. To approach the future impact of quantitative imaging of heterogeneity.

A-862 16:05

A. Intra- and interindividual tumour heterogeneity and the impact for cancer diagnostics

M. Eisenblätter; *Münster/DE* (*eisenblaetter@uni-muenster.de*)

Malignant tumours are biologically complex systems with spacially variable gene expression patterns, consecutively variable biochemistry, histopathology and macroscopically variable structure. In the tumour microenvironment, genetic variability of tumour cells meets external stressors and the host immune system. The result is a regional heterogeneity of stromal architecture, biological activity and expression of e.g. chemokines and growth factors. Consecutively, the development of tumour vasculature, nutrient supply, cell growth and death etc. exhibit significant, regional variation. This variation occurs within a single tumour lesion, between primary tumour and metastasis and of course and pronounced between tumour lesions - even of the same tumour type - in different individuals. Generally, a high degree of heterogeneity is associated with poor prognosis and is at the same time increasingly relevant for therapy selection and monitoring, due to ever more specific therapy approaches. Various imaging approaches basically allow for visualisation of spatial heterogeneity in tumours. However, recorded and documented information is often limited to lesion size and macroscopic heterogeneity. In this context, relevant information, silently acquired even during clinical standard examinations, is ignored and dismissed unused. A rigorous analysis of all radiologic imaging data can help discovering this hidden information and provide additive information on tumour biology, relevant for tumour therapy. This talk is intended as an overview of the different levels of tumour heterogeneity, experimental and established imaging approaches to assess tumour heterogeneity and the possibility to provide adequate biomarkers for state of the art tumour therapy by integrated image data analysis.

Learning Objectives:

1. To learn about tumour heterogeneity.
2. To review current strategies to explore biological heterogeneity.
3. To understand how this heterogeneity impacts diagnosis and treatment.

A-863 16:23

B. Quantitative image biomarkers for targeted tumour therapies

R. García Figueiras; *Santiago de Compostela/ES (roberto.garcia.figueiras@sergas.es)*

Clinical imaging systems are a significant source of non-invasive imaging biomarkers (IBMs) that may reflect important biological properties of cancers. IBMs can provide quantitative information on tumour hallmarks and can be used to evaluate tumour heterogeneity. They may also help us to understand the mechanism of action of therapies and their effects on the tumour microenvironment, offering objective measures of change in response to a therapy. This presentation will explain the biologic basis for a number of commonly available IBMs obtainable clinically. Besides this, we will illustrate how quantification of IBMs is undertaken and provide the validation of such measurements. Finally, the role of IBMs for the assessment of therapy response will be reviewed.

Learning Objectives:

1. To learn how heterogeneity can be quantified from images.
2. To understand how the main types of heterogeneity features.
3. To review limits and pitfalls of features extraction.

A-864 16:41

C. Requirements for quantitative data extraction and analysis

H.K. Hahn; *Bremen/DE*

We will focus on the question how to extract valuable quantitative information from in-vivo imaging data, ultimately leading to clinically relevant imaging biomarkers and phenotypes. We enter the topic by discussing the influence of image quality and resolution on the accuracy and precision of the derived measurements. In addition to signal-to-noise and partial volume effects, which always affect image based quantification, image non-uniformity plays a role in particular for MRI. A review of the concept of Radiomics will highlight the potentials of integrated diagnostics. Radiomics relates imaging based quantitative phenotyping to genomics, laboratory medicine, and risk scores

etc., and ultimately to therapy outcomes and further clinically relevant parameters. Recently, tremendous advances in machine intelligence were demonstrated and successfully applied to medical imaging problems. Deep learning and convolutional neural networks will play an important role in next generations of automated imaging biomarker extraction and big data analysis systems. We will provide a few examples of what is already feasible today and also describe additional technological components required for successful clinical implementation, such as precise anatomical coregistration of multimodal and longitudinal medical images. For instance, the localised assessment of disease progress over time will be greatly facilitated by a combination of prior-to-current image registration and pattern quantification. Not least, we will discuss the requirements regarding infrastructure for the validation and interactive exploration of evolving imaging biomarkers.

Learning Objectives:

1. To learn how to optimise acquisition of images for quantitative imaging.
2. To understand image processing which may impact quantification.
3. To become familiar with the concepts behind quantification.

A-865 16:59

D. Imaging heterogeneity and genomic variability in ovarian cancer

E. Sala; *Cambridge/UK (evis.sala@gmail.com)*

Cancer is caused by genetic (DNA) and epigenetic alterations and frequently arises as a clonal growth from a founder cell. The subclonal heterogeneity provides the basis for inter-metastatic heterogeneity which is of utmost clinical importance. New tumour sampling techniques and circulating tumour DNA methods may allow for more comprehensive evaluation of clonal composition. As both primary tumours and metastatic lesions are spatially and temporally heterogeneous, they would require multiple biopsies to extract and analyse small portions of tumour tissue, which still does not allow for a complete characterisation of the tumour genomic landscape. Therefore, imaging has great potential for a comprehensive evaluation of the entire tumour burden in ovarian cancer, as it is noninvasive and is already often repeated during treatment in routine practice, in contrast to genomics or proteomics, which are still challenging to implement into clinical routine. While initial retrospective studies linking phenotype with genotype in ovarian cancer have shown high prognostic power, they do not provide any spatial information as quantitative imaging features are generated and averaged over the entire tumour, assuming that tumours are heterogeneous but well mixed. This approach ignores spatial heterogeneity readily apparent on imaging. Indeed, recent genomics work has highlighted the presence of intratumour variation in gene mutation and expression. However, little effort if any has been put into integrating imaging, histopathology and genomics and thus there is a clear need for well-designed prospective studies focused on meaningful integration of phenotype and genotype rather than genomics in isolation.

Learning Objectives:

1. To learn about an application of imaging tumour heterogeneity.
2. To understand how imaging heterogeneity may relate to biological heterogeneity.
3. To become familiar with new imaging concepts such as imaging phenotypes and signatures.

17:17

Panel discussion: What can we quantify and why is it essential?

16:00 - 17:30 **Room M 4**

E³ - ECR Academies: Tips and Tricks in Pancreatic and GI Tract Imaging

E³ 1622

Peritoneum and mesentery

A-866 16:00

Chairperson's introduction

A. Ba-Ssalamah; *Vienna/AT (ahmed.ba-ssalamah@meduniwien.ac.at)*

The abdominal cavity is subdivided into the peritoneal cavity, lined by the parietal peritoneum, and the extraperitoneal space. The visceral peritoneum covers the intraperitoneal organs and part of the pelvic organs. The parietal and visceral layers of the peritoneum are in sliding contact, the potential space between them called the peritoneal cavity which is part of the embryologic abdominal cavity or primitive coelomic duct. A thorough understanding of peritoneal anatomy is fundamental in determining the cause and recognising the extent of peritoneal involvement, as well as in decision-making about the appropriate therapeutic approach, whether surgery, conservative treatment, or interventional radiology. On imaging, signs of peritoneal involvement include fluid collections or solid tumors along the ligaments, mesenteries, and/or within the potential spaces of the peritoneal cavity. The spectrum of disorders include inflammatory, infectious, and neoplastic diseases, as well as trauma. Radiologist, by taking into account the patient's age, gender, symptoms and risk factors, in addition to the key features, including location, textural composition of the lesions either cystic or solid and number of lesions come up with a list of differential diagnoses. Reports should include measurements, pertinent negatives and any other relevant findings that influence patient management.

A-867 16:05

A. Understanding primary tumours

C. Dromain; *Lausanne/CH (Clarisse.Dromain@chuv.ch)*

Primary tumours arising in the peritoneum and the mesentery are rare. Most imaging findings of primary peritoneal and mesenteric tumours are nonspecific and very similar to those of peritoneal metastases associating soft-tissue masses and ascites. However, several key findings can be helpful for the diagnosis and proper management of these patients. Key points to consider are the clinical context (sex, age, risk factor such as asbestosis exposition, absence of history of cancer, FAP ···), the location of the peritoneal implant (mesentery vs peritoneum cavity meso and fold), tissular composition of the lesions (cystic vs solid, vascularisation), and number of lesions (isolated vs multiples). The most common primary mesenteric tumours are cystic tumours, such as lymphangiomas and mesothelial cysts, and tissular lesions including desmoid tumours (often associated with FAP), GIST, NET (with high fibrous content and retraction), primary mesenteric lymphomas, Castleman tumours (highly vascularized) and mesenchymal benign and malignant tumours. The most common primary peritoneal tumours are mesotheliomas, desmoplastic round cell tumours (young male), primary papillary serous carcinomas (PPSC; mimicking metastases from ovarian cancer), peritoneal lymphomatosis, and leiomyomatosis. Imaging features of mesothelioma depend on the histological type. Multicystic mesothelioma has a very typical multiloculated cystic appearance with thin septations easily diagnosed on MRI. Benign papillary mesothelioma and malignant epitheliod mesothelioma (linked to asbestosis exposition) have very similar pattern mimicking peritoneal metastases. Sarcomatoid and biphasic mesotheliomas are predominantly solid and localized with large masses and no ascites. Differential diagnoses include peritoneal metastases, pseudomyxoma peritonei (PMP), splenosis, tuberculosis, actinomycosis, and peritoneal endometriosis.

Learning Objectives:

1. To become familiar with the spectrum of tumours of the mesentery and peritoneum.
2. To understand how imaging helps in narrowing the differential of mesenteric and peritoneal masses.
3. To learn the role of percutaneous or surgical biopsy.

A-868 16:33

B. Peritoneal carcinomatosis

P.K. Prassopoulos; *Alexandroupolis/GR (pprasopo@med.duth.gr)*

Intraperitoneal dissemination of primary GI and gynaecological primary tumours - the so-called peritoneal carcinomatosis - is a common process in the evolution of these malignancies and has a significant impact on therapeutic decisions. The location of implants in peritoneal carcinomatosis is governed mostly by peritoneal fluid circulation and by anatomic pathways formed by peritoneal reflections, namely ligaments, mesenteries and omenta. The most common sites where the peritoneal fluid may be temporarily arrested - facilitating implantation of cancer cells - include cul-de-sac, distal small bowel mesentery, right paracolic gutter, posterior sub-hepatic space, greater omentum and subphrenic spaces. The role of imaging is to disclose the presence and extent of the disease - that is fundamental in candidates for cytoreductive surgery - to monitor response to treatment and to reveal recurrences. MDCT with thin collimation and i.v. contrast material supplemented by multiplanar reconstructions remains the primary imaging modality for the investigation of peritoneal carcinomatosis, assessment of disease distribution and routine post-treatment evaluation. Ascites, contrast-enhanced smooth, nodular, or plaque-like peritoneal thickening, peritoneal nodules, plaques or masses, rounded, ill-defined soft-tissue or cystic mesenteric masses, mesenteric fixation with increased attenuation values and thickening, irregular soft-tissue permeation of omental fat or confluent solid omental masses are the most frequent MDCT findings of peritoneal carcinomatosis. MRI-DWI can alternatively be used. Post-gadolinium-enhanced 3d FLASH sequence with fat saturation is advantageous in cases of diffused layered type of peritoneal/mesenteric involvement. PET/CT and DW-MRI have specific indications in post-treatment imaging evaluation.

Learning Objectives:
1. To become familiar with the usual origin and spread of peritoneal carcinomatosis.
2. To learn about the role of CT, MRI and PET for the detection and staging of peritoneal carcinomatosis.
3. To understand how imaging helps the clinician for the evaluation of response to treatment.

A-869 17:01

C. From misty mesentery to mesenteritis

G.A. Krombach; *Giessen/DE (gabriele.krombach@uniklinikum-giessen.de)*

The mesentery can be affected by a variety of entities ranging from spread of diseases occurring in adjacent organs, such as necrosis in pancreatitis or oedema following thrombosis of the portal or superior mesenteric vein to benign or malignant diseases directly arising within the mesentery. Sclerosing mesenteritis is an autoimmune disease initiated by an allergic reaction to long-term expose of allergens regularly contained in food or constantly present in the proximity of the patient. IgG4-antigenes are formed against such antigens and mesenteritis is a sequel of cross reaction of the IgG4-antigenes to proteins contained in the connective tissue of the mesentery. Mesenteritis usually is biphasic with a first active phase, marked by cellular infiltration with plasma cells and lymphocytes and oedema, and a chronic phase with the hallmark of almost acellular storiform fibrosis triggered by the cytokines TNF-α and IL-2 and -4 released by granulocytes. In imaging, in all modalities the mesentery appears “misty”, while the tissue immediately surrounding the mesenteric vessels is spared from the change, called fat-ring sign. The area of the increased density (or altered signal intensity in MRI) in almost all cases and phases is sharply surrounded by a pseudocapsule. Contrast enhancement and T2 signal intensity vary with the disease phase. The mesenteric lymph nodes are often enlarged, which can render differentiation from lymphoma challenging in some patients. Symptoms may range from not present to abdominal pain, fever, weight loss to severe complications, including stenosis of the mesenteric vessels and ischaemia of the bowel, ileus or perforation.

Learning Objectives:
1. To become familiar with the differential between incidental mesenteric abnormalities, tumour infiltration and true mesenteritis.
2. To understand how mesenteritis can be associated with other organs lesions in case of systemic disease.
3. To learn which imaging (CT, MRI, PET) is relevant for the detection and follow-up of inflammatory diseases.

A.J. Grainger; Leeds/UK

A-870 16:00

A. Postoperative shoulder MRI after instability surgery

L.W. Bancroft; *Orlando, FL/US (laura.bancroft.md@flhosp.org)*

Purpose: To become familiar with the expected and abnormal MR imaging findings after labral repair, capsular shift/capsulorrhaphy, remplissage and Latarjet/Bristow procedures. Methods and Materials: MR imaging will be used to demonstrate the various normal and abnormal imaging appearances after shoulder instability surgery. Results/Conclusion: Labral re-tear will be evident as contrast or joint fluid extension into linear or complex tear cleft, absent/truncated/fragmented labrum, or labral displacement from anatomic location. Capsular shift results in smaller capacity joint and sometimes irregular capsular nodularity. Complications of capsulorrhaphy include capsular tears and subluxation of humeral head. Postoperative MR imaging can evaluate healing after combined remplissage and Bankart repair for moderate size, ngaging Hill-Sachs lesions. Laterjet and Bristow procedures may be performed in patients with recurrent dislocations and glenoid deficiency. Incorporated bone will yield non-anatomic glenoid configuration, and complications include non-union, fatty degeneration of subscapularis muscle, and osteoarthrosis.

Learning Objectives:
1. To become familiar with the expected and abnormal MR imaging findings after labral repair.
2. To learn about the postoperative imaging features after capsular shift/capsulorrhaphy.
3. To appreciate normal imaging and complications after remplissage and Laterjet/Bristow procedures.

Author Disclosure:
L.W. Bancroft: Author; Lippincott - Book Royalties.

A-871 16:30

B. ACL reconstruction and cartilage repair

C. Weidekamm; *Vienna/AT (weidekamm@icloud.com)*

The aim of ACL reconstruction is to stabilize the knee and prevent chondral and meniscal injuries, which are the sequelae of anteroposterior translation and are associated with early osteoarthritis. The idea of the double-bundle ACL graft was to restore normal joint kinematics by anatomic reconstruction of the anteromedial and the posterolateral bundle of the original ACL. This was expected to improve clinical outcomes and restore anterior and rotational knee stability. The single-bundle technique, however, causes less osseous defects and is still a popular technique. Complications, such as ACL graft failure, impingement, cyclops lesion, arthrofibrosis, and patellar inferior syndrome, are discussed. The second part of this presentation will illustrate cartilage repair techniques and imaging findings. The radiologist must be familiar with the different cartilage repair procedures and characteristics in cartilage imaging to evaluate long-term progression or failure. Abnormal postoperative findings include hypertrophic filling, incomplete integration of the transplant into the surrounding cartilage, or subchondral defects, osteophytes, cysts, and persistent bone marrow oedema and joint effusion.

Learning Objectives:
1. To review the common and uncommon ACL reconstruction techniques.
2. To appreciate the expected and abnormal MR imaging findings after ACL reconstruction.
3. To understand common cartilage repair techniques, and corresponding normal and abnormal postoperative MRIs.

A-872 17:00

C. Interactive case discussion (part 1)

L.W. Bancroft; *Orlando, FL/US*

To engage in interactive case discussions with the expected and abnormal MR imaging findings after labral repair, capsular shift/capsulorrhaphy, remplissage and Laterjet/Bristow procedures. An interactive case discussion will be used to demonstrate the various normal and abnormal imaging appearances after shoulder instability surgery. Labral re-tear will be evident as contrast or joint fluid extension into linear or complex tear cleft, absent/truncated/fragmented labrum, or labral displacement from anatomic location. Capsular shift results in smaller capacity joint and sometimes irregular capsular nodularity. Complications of capsulorrhaphy include capsular tears and subluxation of humeral head. Postoperative MR imaging can evaluate healing after combined remplissage and Bankart repair for moderate size, ngaging Hill-Sachs lesions. Laterjet and Bristow procedures may be performed in patients with recurrent dislocations and glenoid deficiency. Incorporated bone will yield non-anatomic glenoid configuration, and complications include non-union, fatty degeneration of subscapularis muscle, and osteoarthrosis.

Learning Objectives:
1. To learn how to differentiate normal and failed labral repairs with MRI.
2. To become familiar with the diagnostic features of failed ACL reconstructions.
3. To understand the imaging features of intact and failed cartilage repair.

Author Disclosure:
L.W. Bancroft: Other; Lippincott - Book Royalties.

A-873 17:15

C. Interactive case discussion (part 2)

C. Weidekamm; *Vienna/AT*

Postoperative imaging after ACL or cartilage repair is indicated in patients with ongoing pain/instability or repetitive injury. Radiography remains the initial imaging modality; however, further assessment with CT or MRI is recommended. With a clear emphasis on MRI, we will review normal postoperative findings and complications after ACL reconstructions and cartilage repair. The case discussion will cover the most significant pathologies and pitfalls, and normal postoperative findings will be illustrated.

Learning Objectives:
1. To learn how to differentiate normal and failed labral repairs with MRI.
2. To become familiar with the diagnostic features of failed ACL reconstructions.
3. To understand the imaging features of intact and failed cartilage repair.

Sunday, March 4

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1721
Cardiac imaging

A-874 08:30
A. Grown-ups with congenital heart disease
A.M. Taylor; *London/UK*

This session will describe how MRI and CT can be used to image adults with congenital heart disease. The common conditions that occur in childhood will be described (acyanotic and cyanotic heart disease) and what operations they undergo that will be important for imaging them when they become adults. Finally, those CHDs that may be diagnosed in adulthood will be described.
Learning Objectives:
1. To be familiar with the clinical and radiologic presentations of these patients.
2. To learn about imaging findings and management options.

A-875 09:15
B. Imaging cardiac valves
R. Salgado; *Antwerp/BE (rodrigo.salgado@uza.be)*

Valvular heart disease forms an important part of the workload in every cardiology practice. While echocardiography remains a cornerstone in the assessment and follow-up of valvular heart disease, an important role is reserved for MR and CT imaging, although in different contexts. MR, with its ability to investigate the valvular morphology as well as the haemodynamic consequences on the cardiac chambers, forms an important complementary tool to the echocardiographic findings. It provides a reproducible quantification of transvalvular flow and has in recent years gained further importance in tissue characterisation with the introduction of T1/T2 mapping techniques for the detection and distribution of fibrosis. CT has recently gained a prominent place in the non-invasive investigation of the aortic root before transcatheter aortic valve replacement and is also becoming a primary imaging modality in emerging mitral valve interventions. Furthermore, its role in the evaluation of prosthetic heart valves is currently the subject of intense investigation, providing valuable additional information not easily acquired through other imaging methods. During this lecture, the different advantages and limitations of valvular imaging with CT and MR will be discussed, and practical recommendations for clinical practice will be given.
Learning Objectives:
1. To understand the impact of imaging.
2. To know the limitations and potential pitfalls of CT and MR techniques.
3. To learn about the imaging technique.

08:30 - 10:00 **Room B**

Abdominal Viscera

RC 1701
Abdominal MRI: from standard to advanced protocols

A-876 08:30
Chairperson's introduction
F. Caseiro Alves; *Coimbra/PT (caseiroalves@gmail.com)*

Abdominal MR imaging is a continuously evolving technique where researchers, vendors and clinical users get together to push it to the next level of medical practice. Recent advances in the MR field include the development of dedicated DWI sequences, increased spatial resolution and functional imaging capabilities, to name a few. Therefore, there is a clear-cut need to use and take advantage of the most recent and best suited protocols. In this session, we will deal with three important common clinical situations: a) suspected pancreatic cancer where MR appears not only as a problem-solving tool, but also as a competitive diagnostic modality compared with MDCT, ranging from DWI to high-resolution MRCP and time-resolved dynamic imaging; b) inflammatory bowel disease, which, as a chronic relapsing disease, is one of the cases where MR may contribute to drive patient management, exquisitely monitoring the inflammatory activity of the disease; and c) MRI of pelvic floor disorders that consists in the use of high-resolution morphological data together with functional information under straining conditions. Its diagnostic power and contribution to patient management is well acknowledged today, but protocol optimisation and proper quantification assume vital importance. To enhance the educational value of this session, an illustrative clinical case for each clinical problem will be presented exploring the benefits and/or MR limits.
Session Objectives:
1. To learn the importance of MR protocolling for different abdominal conditions.
2. To become familiar with both dedicated and advanced MR imaging.
3. To learn through a case-based approach its impact on report quality.

A-877 08:35
A. Suspected pancreatic tumour
R. Manfredi; *Rome/IT (riccardo.manfredi@unicatt.it)*

Pancreatic cancer is the fourth leading cause of cancer-related death. Surgical resection is the sole curative treatment option; however, only 15%-20% are resectable at the time of diagnosis. Furthermore, the prognoses for patients with pancreatic cancer remain poor. Although the 5-year survival rate is up to 20% after complete resection, it is further improved to more than 75% in patients with a diagnosis of stage 1 disease. Computed tomography (CT) remains the initial imaging modality of choice for pancreatic solid neoplasms, because recent improvements in multidetector CT technology, including improved temporal and spatial resolution, have facilitated more precise timing of multiphasic imaging and increased the accuracy of CT for the detection and staging of pancreatic adenocarcinoma. Recently, magnetic resonance (MR) imaging has acquired a role in the early diagnosis of adenocarcinoma, because of diffusion-weighted (DW) MR imaging. By means of DW imaging, MRI is able to depict changes in water mobility caused by interactions with cell membranes, macromolecules, and alterations to the tissue environment, and thus provides a tissue contrast that is different from that on conventional T1- and T2-weighted images. DW imaging plays a role in oncology for tumour detection, in general. DW imaging allows detection of pancreatic adenocarcinomas with high sensitivity and specificity, because it appears hyperintense compared with the rest of the gland. DW-MR imaging is also useful in finding small functioning neuroendocrine neoplasms, responsible for a clinical syndrome, but difficult to diagnose because of their small size.
Learning Objectives:
1. To learn about the role of MRI in the assessment of a patient with suspected pancreatic tumour.
2. To become familiar with the optimal MRI protocols including the role of DWI and secretin in this group of patients.
3. To appreciate the advantages and limitations of MRI in comparison with other imaging techniques.

A-878 08:58
B. Inflammatory bowel disease
S.A. Taylor; *London/UK (csytaylor@yahoo.co.uk)*

Magnetic resonance enterography (MRE) is increasingly used, particularly for Crohn's disease assessment. It has an evolving role not only in grading inflammation and detecting complications, but also for monitoring the course of the disease. The diagnostic accuracy of MRE is heavily influenced by the technical quality of the examination. Patient preparation, bowel distension, sequence selection and scan technique must all be optimised to produce high-quality examinations. This presentation will review the recommendations of the recent ESGAR consensus statement on MRI small bowel imaging and will address commonly encountered problems that can arise before and during scan acquisition. The utility of novel sequences such as DWI and motility will also be discussed.
Learning Objectives:
1. To learn about the role of MRI in patients with IBD.
2. To become familiar with the optimal MRI protocols including bowel distension in this group of patients.
3. To appreciate the role of functional imaging techniques for assessment of IBD.
Author Disclosure:
S.A. Taylor: Consultant; Robarts.

A-879 09:21
C. Pelvic floor disorder
D. Weishaupt; *Zurich/CH (dominik.weishaupt@triemli.zuerich.ch)*

Imaging of the female pelvic floor is of rising interest due to an ageing population, harbouring an increasing incidence of pelvic floor disorders (PFD), and the rising need for comprehensive diagnosis and treatment. Magnetic resonance imaging (MRI) of the female pelvic floor combines high-resolution imaging with an excellent soft tissue contrast and provides the possibility to

assess noninvasively and objectively a spectrum of possible disorders affecting the pelvic floor in one examination. There is general agreement that MRI of the pelvic floor should include static and dynamic MR images, whereas dynamic means imaging under maximum stress to the pelvic floor and MR defecography. Static MR images visualize pelvic floor anatomy and defects of the supporting structures, while dynamic MR images visualize pelvic organ mobility, pelvic floor weakness, pelvic organ prolapse (POP) and associated compartment defects. In this lecture, a standardized approach regarding indications, patient preparation, sequence acquisition, interpretation and reporting of MRI for diagnosis and grading of PFD is presented. Due to the different views of the clinical specialists involved in the treatment of PFD, adapting the MRI reporting scheme according to the speciality of the referring physician is discussed. Finally, the limitations of the technique are addressed.

Learning Objectives:

1. To learn about the clinical relevance of MRI in the management of patients with pelvic floor disorders.
2. To become familiar with the optimal patient preparation and MRI protocols in this group of patients.
3. To appreciate the advantages of MRI relative to other imaging modalities including conventional defecography.

Chest

RC 1704

Thoracic manifestations of systemic disease

Moderator:
A. Chodorowska; Wroclaw/PL

A-880 08:30

A. Systemic sclerosis
N. Sverzellati; *Parma/IT (nicolasve@tiscali.it)*

Systemic sclerosis (SSc) is variably associated with pulmonary involvement, which is a paramount prognostic factor. Interstitial fibrosis and pulmonary vessel abnormalities are the two elementary lung wounds in SSc and can occur independently of each other. Chest radiograph has low sensitivity in the assessment of early interstitial lung disease (ILD) associated with SSc. Oesophageal dilation can be the only apparent finding. High-resolution computed tomography (HRCT) is pivotal in baseline staging. HRCT findings of SSc-ILD include confluent ground-glass opacities, traction bronchiectasis/bronchiolectasis, fine reticulation, and honeycombing. The HRCT pattern of non-specific interstitial pneumonia (NSIP) is common, actually reflecting more than 75% frequency of histologic NSIP. The combination of HRCT and pulmonary function tests (PFTs) has been proposed for prognostication of SSc. ILD extent <10% has lower risk compared to >30%, with minor influence from PFTs. On the other hand, PFTs can further stratify prognosis among subjects with ILD extent 10-30%. Quantitative CT methods are being developed to measure the ILD extent. SSc patients are at increased risk of lung cancer. Its surgical treatment is mostly prevented by extensive ILD. Pulmonary hypertension (PH) can occur independently of ILD, reflected by isolated reduction of DLCO at PFTs. In particular, PH is more common in limited cutaneous systemic sclerosis, also known under the acronym CREST syndrome.

Learning Objectives:

1. To learn about the typical radiological appearances.
2. To be aware of the clinical relevance of scoring.
3. To know how vascular complications affect patient prognosis.

A-881 09:00

B. Granulomatosis and polyangiitis
S. Bayraktaroglu; *Izmir/TR (selenb2000@gmail.com)*

Granulomatosis with polyangiitis (GPA), formerly known as Wegener's granulomatosis, is a chronic granulomatous necrotising vasculitis of small- and medium-sized vessels. The classical clinical triad of the disease consists of upper and lower airway involvement and glomerulonephritis. The upper respiratory tract is affected in almost all patients. The majority of patients with GPA will also have pulmonary (90%) and renal (80%) involvement. The most common radiologic findings in thoracic involvement are nodules, mass lesions and areas of consolidation. Cavitation within these lesions may be seen due to the necrotic nature of the disesse. Airway involvement is characterised by circumferential tracheal wall thickening. Areas of consolidation, cavitary nodules and mass lesions represent active inflammatory disease, whereas areas of bronchiectasis and septal-nonseptal lines more often represent chronic fibrotic changes. The radiologist must be familiar with the common thoracic radiologic manifestations of the disease.

Learning Objectives:

1. To learn about the radiological appearances of small-vessels vasculitis.
2. To learn how clinical and radiological features help in differential diagnosis.
3. To appreciate the actual role of imaging in assessing disease activity.

A-882 09:30

C. Early manifestations in children and young adults
M.P. García-Peña; *Barcelona/ES (plgarciapena@gmail.com)*

Lung disease is common in children with systemic diseases, and the radiographic appearance of early-stage pulmonary changes is often subtle. Computed tomography (CT) has higher sensitivity and specificity than radiography. High-resolution computed tomography (HRCT) is the imaging technique of choice for assessing lung involvement in these patients. Even with reduction in the peak voltage and tube charge to minimize the exposure of paediatric patient to radiation, CT performed with a meticulous acquisition technique can provide detailed information. The uses of CT in evaluating systemic disease are to detect lung abnormalities, characterize the findings, assess the extent of disease, and help establish the differential diagnosis. CT also is used for follow-up evaluations, monitor the effects of treatment, and for guidance of lung biopsy when that is required. High-resolution CT may depict lung lesions in children with no clinical respiratory symptoms and normal findings at lung function testing, facilitating early identification of lesions and allowing early treatment that can benefit the course of the disease. This lecture reviews the findings on high-resolution CT of the chest in children with suspected systemic diseases, with emphasis on connective tissue diseases (juvenile rheumatoid arthritis, dermatomyositis, systemic sclerosis, systemic lupus erythematosus, and mixed connective tissue disease), vasculitis, primary and acquired immunodeficiencies, immotile cilia syndrome, cystic fibrosis, and Langerhans cell histiocytosis.

Learning Objectives:

1. To learn about the radiological manifestations in children.
2. To review the most adapted scanning protocols.
3. To appreciate the role of imaging to monitor the effects of treatment.

08:30 - 10:00 **Room X**

Joint Session of the ESR and ESTRO

New imaging approaches for radiotherapy

A-883/A-884 08:30

Chairpersons' introduction
V. Valentini[1], M.H. Fuchsjäger[2]; [1]*Rome/IT,* [2]*Graz/AT (michael.fuchsjaeger@medunigraz.at)*[2]

This session focuses on the importance of imaging for radiation oncology. Specific emphasis will be laid not only on current cooperation but also on potential future opportunities for radiology and radiation oncology collaboration. Furthermore, the latest imaging as a well as radiotherapy technologies will be discussed. The understanding of these technologies, ultrasound, dual-energy CT, MR-LINAC and MR-PET only forms the basis for clinical applications and successful therapy. A panel discussion on how radiation oncology and radiology as technological innovation leaders will be able to take advantage of each other in the near and distant future will complete this session.

Session Objectives:

1. To understand the increasing importance of imaging in radiation oncology techniques.
2. To learn about the cooperation opportunities between radiologists and radiation oncologists.
3. To become familiar with the most modern radiotherapy technologies.

A-885 08:35

Dual-energy CT: what are the benefits for radiotherapy?
P. Wohlfahrt[1], C. Richter[1], C. Möhler[2], S. Greilich[2]; [1]*Dresden/DE,* [2]*Heidelberg/DE (patrick.wohlfahrt@oncoray.de)*

For about a decade, dual-energy CT (DECT) has been clinically available, mainly for radiology applications. In contrast, in the field of radiotherapy DECT has gained relevant interest over the last few years and here clinical use is still far away from being standard. In this lecture benefits of DECT for radiotherapy applications will be discussed. The focus will be on application for treatment

planning in proton therapy, namely the individual prediction of tissue stopping power relative to water (SPR) as an alternative to the standard approach using a generic look-up table (HLUT). The manifold information gathered by two CT scans with different X-ray spectra allow for a patient-specific and direct calculation of relative electron density and SPR. This enables the consideration of intra- and inter-patient variabilities in CT-based SPR prediction and ultimately a more accurate range prediction. The talk will cover the validation of the SPR prediction accuracy in realistic ground-truth scenarios, the investigation of clinically relevant differences between the DECT-based and the standard HLUT-based SPR prediction in clinical patient data as well as the status of its clinical implementation. Furthermore, additional applications in radiotherapy, e.g. for photon treatment planning, delineating and material differentiating will be briefly discussed.

Learning Objectives:

1. To learn about technical aspects of dual-energy CT acquisition.
2. To understand the strengths and limitations of the dual-energy CT applications in oncology.
3. To appreciate the benefits relative to the use of dual-energy CT in the radiotherapy workflow.

A-886 08:55

Ultrasound imaging in radiotherapy: "old" technology with new applications in RT?

E. Harris; *Sutton/UK (Emma.Harris@icr.ac.uk)*

Medical ultrasound was first introduced in the 1940's and has become a powerful diagnostic tool throughout the world. Its real-time, soft-tissue imaging capability and non-ionizing nature have contributed to its ubiquitous use in disease diagnosis and image guidance in interventional and surgical procedures. Ultrasound guidance of radiotherapy is a relatively new field with the first commercial systems becoming available in the late 1990's. Despite possessing clear benefits for imaging a variety of tumour sites, challenges associated with implementing ultrasound in the radiotherapy clinic initially impeded its widespread adoption. The influence of effective training on interobserver variation and operator performance was an early barrier. Contemporary ultrasound image guidance techniques have done much to overcome these problems and modern systems are used clinically for interfraction motion estimation in prostate and breast and for intrafraction prostate motion monitoring. Other promising clinical applications under investigation include intrafraction motion estimation in liver, pancreas and kidney, and augmentation of cone beam CT data for the purpose of adaptive radiotherapy of the prostate and gynecological cancer. This talk will give an overview of the clinical use of ultrasound in radiotherapy, discuss the advantages and limitations of ultrasound and present future perspectives for ultrasound guided radiotherapy technology and practice. Finally, some exciting new applications of ultrasound functional imaging for monitoring of tumour response to radiotherapy will be introduced.

Learning Objectives:

1. To learn about ultrasounds applications in radiotherapy.
2. To understand the clinical advantage of using ultrasounds based techniques.
3. To appreciate the modern perspectives of this technique.

A-887 09:15

MR-LINAC technological advances and potential usability in clinical setting

O. Jäkel; *Heidelberg/DE (o.jaekel@dkfz-heidelberg.de)*

Radiotherapy has reached a point, where dose highly precise dose delivery is achieved with various techniques. The next big gain can only be made, when dose adaption is achieved not only in 3 dimensions as for static targets, but can also be maintained in 4 dimensions, i.e. including temporal changes in the patient. Image guided radiotherapy, based mainly on X-ray cone beam CT imaging, up to now has mostly been used to improve daily setup accuracy and to a lesser extent enabled modest adaption for inter-fractional changes. MRI, however, being non-invasive and yielding excellent soft tissue contrast, is an optimal tool for continuous monitoring of tumor motion during delivery and for allowing intra-fractional adaption of treatment plans. The idea to integrate a linear accelerator into an MRI was put forward by the Utrecht group already in 2000. Due to the technical complexity, it took until 2017 to realize a clinical prototype. First patients were treated in 2017 and a commercial product by Elekta is expected to be released in 2018. Also in 2017, first patients were treated with another commercial system by Viewray, using a 0.35T split bore Magnet and a 4MV linac. The latter was modified from the MR-Cobalt unit, which is available since 2014. The availability of commercial hybrid systems will now enable investigations of the clinical potential of these hybrid systems in different tumor sites. In parallel the systems will be continuously developed further, in order to exploit their full clinical potential.

Learning Objectives:

1. To learn about the technological advances of MRI-LINAC technology.
2. To understand the physical principles of hybrid treatment units.
3. To appreciate the clinical advantages of the use of this technology.

A-888 09:35

Multiparametric MR-PET for differentiation of residual disease vs treatment-induced inflammatory changes

M. Becker; *Geneva/CH (minerva.becker@hcuge.ch)*

The purpose of this lecture is to provide a simplified, systematic approach on how to detect tumour recurrence on MR-PET examinations of patients treated for head and neck squamous cell carcinoma. First, the relevant imaging findings of post-therapeutic expected tissue alterations with a special focus on their temporal relationship are discussed. Then a brief discussion of common complications affecting the soft tissues, vasculature and bony structures will follow. A systematic review will include key MRI, diffusion-weighted imaging (DWI) and PET features of osteoradionecrosis, soft tissue necrosis, neck fibrosis and scar tissue mimicking tumour recurrence. Typical radiologic findings of tumour recurrence will be discussed with an emphasis on the early detection of lesions, their appearance on MR-PET with DWI and the added value and complementarity of multiparametric information extracted from hybrid imaging techniques. The potential pitfalls of post-therapeutic image interpretation and how to avoid them taking into consideration multiparametric data will be addressed. Results of combined MR-PET evaluations for the correct staging of recurrent tumours will be presented. Major emphasis will be put recently published research results and on quantitative information that can be easily extracted in clinical routine. Pitfalls of image interpretation will be addressed and how to avoid them.

Learning Objectives:

1. To learn about hybrid imaging based tissue characterisation techniques.
2. To understand the challenges of hybrid imaging use after oncologic treatments.
3. To appreciate the performance of hybrid MR-PET techniques in differential diagnosis.

A-889 08:30

A. Imaging of the premature brain

S.M. Aukland; *Bergen/NO (stein.magnus.aukland@helse-bergen.no)*

Imaging is essential in detecting and monitoring brain injury in premature newborns. Cerebral ultrasonography (CUS) is still the modality of choice in an emergency setting, but magnetic resonance imaging (MRI) is a complementary modality. The classical findings include haemorrhage and white matter disease (WMD)/periventricular leukomalacia (PVL). The haemorrhages are usually part of the germinal matrix haemorrhage-intraventricular haemorrhage continuum (GM-IVH). Small sub-ependymal haemorrhage and small IVH usually disappear in a few weeks, but larger haemorrhages carry a high risk of causing hydrocephalus and/or periventricular venous haemorrhagic infarctions, which demands close follow-up. CUS is an excellent tool in detecting GMH-IVH and cystic WMD, but MRI is more sensitive in detecting non-cystic WMD and cerebellar pathology. MRI is also superior to CUS in detecting hypoglycaemic parenchymal injury. GMH-IVH and cystic-WMD are associated with major disabilities, and the subtle WM and cerebellar lesions seem to be associated with behavioural and attention difficulties later in life. MRI at term-equivalent age (TEA) is now a routine examination in some institutions, but the value of this screening must be evaluated by long-term follow-up studies. In short-term studies of extremely preterm, abnormalities detected on late CUS and near-term MRI are associated with the outcome and TEA may be the best time point for scanning. Several studies have compared the value of serial CUS and near-term MRI without strong conclusions. Conventional MRI at TEA probably

gives additional prognostic information, and advanced MRI is promising but its role is still unclear.
Learning Objectives:
1. To discuss the roles of US, (CT) and MRI in preterm imaging.
2. To give an overview of the different imaging findings in the preterm brain related to age.
3. To discuss the prognostic role preterm brain imaging.

A-890 09:00

B. Abusive head trauma: the role of CT and MRI
R. Van Rijn; *Amsterdam/NL (r.r.vanrijn@amc.uva.nl)*

Abusive head trauma (AHT), defined by the American Academy of Pediatrics as an inflicted injury to the head and its contents including those injuries caused by both shaking and blunt impact, is one of the most severe forms of child abuse. Imaging plays an important role in establishing the diagnosis and potential outcome of AHT. In this session, the most common neuroradiological findings, with their evidence base, in AHT are presented. In short, the differential diagnosis and the limitations of CT and MRI will be discussed, as well as the imaging strategy as proposed in the newly published guideline 'The radiological investigation of suspected physical abuse in children' of the Royal College of Radiology and the Society and College of Radiographers.
Learning Objectives:
1. To discuss the role of CT and MRI in imaging of abusive head trauma (AHT).
2. To give an overview of common CT and MRI findings in AHT.
3. To understand the strengths and limitations of CT and MRI in imaging AHT.

A-891 09:30

C. Imaging in hypoxic-ischaemic injury and hypothermia: an update
F.M. Triulzi; *Milan/IT (Fabio.triulzi@policlinico.mi.it)*

Hypoxic-ischemic encephalopathy (HIE) is the major recognized perinatal cause of neurological morbidity both in premature and full-term newborns. The incidence of HIE ranges from 1 to 8 per 1000 live births in developed countries, it accounts for approximately 15%-20% of neonatal mortality in full-term neonates. Immediately after an acute HIE episode, proton MR spectroscopy is often the most useful modality due to the increase of lactate, while diffusion-weighted imaging (DWI) may be falsely negative in this time frame. However, pseudonormalization of lactate levels, which occurs approximately 24 hours after birth, may confound interpretation of early MR imaging spectra. Cerebral blood flow increases after 24-28 hours in brain areas subsequently exhibiting injury, whether or not hypothermia is administered. Consequently, it has been suggested to combine a perfusion study using arterial spin labelling technique to increase the prognostic value in the acute phase of HIE. After approximately 24 hours of age, even DWI becomes a sensitive technique, due to the presence of cytotoxic oedema and it remains positive for approximately 1-5 days, after which it may pseudonormalize; at this point, T1- and T2-weighted MR images may be most useful to depict brain damage. Due to the reduction in the extent of brain injury on conventional T1- and T2-weighted MRI, it is mandatory to account for hypothermic treatments when evaluating MR images during the acute phase.
Learning Objectives:
1. To discuss the role of US, (CT) and MRI in hypoxic-ischaemic injury (including advanced MR techniques).
2. To give an overview of common imaging findings in hypoxic-ischaemic injury (HIE).
3. To understand the importance of timing and prognostic value of imaging in HIE.

08:30 - 10:00 **Room N**

New treatments for musculoskeletal tumours

A-892 08:30

Chairperson's introduction: What is changing?
J.L. Bloem; *Leiden/NL (j.l.bloem@lumc.nl)*

Biologic tumour behaviour and patient compliance should be primary considerations in treating patients with musculoskeletal sarcoma. Diagnostic tests in combination with systemic and focal therapy are used to reach curative or palliative goals. The progress made in diagnostic tests, treatment strategies, and understanding biologic behaviour of tumours increases options to serve our patients, but also increases therapy-related morbidity, diagnostic tests-related anxiety, and costs. The current challenge is to use our diagnostic and therapeutic means not only to increase survival chances, but also to preserve the quality of remaining life, while involving the patient's opinion in decision-making. The change of ingredients for this balancing act is explored in this introduction.
Session Objectives:
1. To understand the demand for new treatment concepts.
2. To understand how multimodality imaging can influence therapeutic balancing between tumour control and quality of life.

A-893 08:35

New treatment paradigms in orthopaedic oncology
M.A.J. van de Sande; *Leiden/NL (majvandesande@lumc.nl)*

Knowing if the sarcoma will return remains the basic patient paradigm in cancer treatment and follow-up, but going from if to when it returns seems to be the next step in follow-up optimisation and stress reduction. All prediction models for sarcoma available at present are applicable only at the time of baseline, such as the time of diagnosis or surgery. However, updated patient information during the follow-up as well as changing covariate effects over time may change the prognosis of a patient, which is not accounted for in these models. The concept of dynamic prediction allows to include updated information; on disease status, patient characteristics and imaging results during follow-up. This information can be used to provide better individualised treatment and follow-up options that depend on the dynamic assessment of a patient's prognosis. The findings of time-varying effects as well as the importance of time-dependent covariates such as LR and DM found in our multicentre analysis confirm the inadequacy of the baseline models for predictions later on in follow-up. A model designed for dynamic prediction, which updates survival probabilities, is needed and it is provided in this work. To this end, an APP (PERSARC) was developed to assist in shared decision-making in clinic. Following up on this, we analysed the timing of LR and DM during FU. We concluded that in patients with localised STS after curative surgery, the rates of LR and DM are highly non-constant over time and are strongly modified by tumour characteristics. These findings contradict a "one-size-fits-all" aftercare policy, but rather support the concept of a time- and risk-adapted strategy for personalised post-surgical follow-up.
Learning Objectives:
1. To understand the impact of treatment choices on survival chances and quality of life.
2. To learn about the influence of imaging, patient and disease characteristics on developing new treatment options.
Author Disclosure:
M.A.J. van de Sande: Grant Recipient; National Cancer Fund.

A-894 08:58

Multimodality imaging in treating and monitoring bone sarcoma
M.-A. Weber; *Rostock/DE (marc-andre.weber@med.uni-rostock.de)*

The histopathologic response to chemotherapy and radiation therapy is an important prognostic indicator of disease-free survival after the treatment of musculoskeletal sarcomas. Several studies report that therapy response assessment may rely on functional PET data. Moreover, a decrease in tracer uptake indicates early response to neoadjuvant chemotherapy. However, to plan surgical resection of the tumour, the surgeon needs reliable information on tumour size and extent of infiltration to the adjacent structures. MRI is the best additional imaging modality for local staging, as it allows for accurate assessment of the extent of the disease and the effect of the tumour on the surrounding structures including the joint, neurovascular structures, muscle compartments and skin. MRI also gives details of the extent of the compartmental involvement to help complete excision of the tumour. Additional MRI techniques such as diffusion-weighted imaging (DWI), MR spectroscopy (MRS), and dynamic contrast-enhanced (DCE) MR imaging are not routinely used for bone tumour assessment. The potential of DWI to reveal tumour cellularity, MRS to noninvasively assess metabolic aberrations, and DCE to assess treatment response in which traditional size-based assessment criteria may underestimate efficacy has been reported. The role of FDG- or NaF-PET/CT and PET/MRI in the initial diagnostic workup of bone tumours is still not established. There is an overlap in the maximum standard uptake value between benign and malignant tumours. Therefore, PET/CT does not yet have a role in the initial differentiation of benign from malignant bone tumours, but may aid in problem-solving in suspected local recurrence.
Learning Objectives:
1. To learn how to use multimodality imaging in personalised treatment planning aimed at survival and preserving quality of life.
2. To learn how to use multimodality imaging in monitoring response to neo-adjuvant therapy.

A-895 09:21

Multimodality imaging in treatment and surveillance of soft tissue sarcoma

C. Messiou; *London/UK (Christina.Messiou@rmh.nhs.uk)*

Limb-sparing surgery is potentially curative for primary non-metastatic extremity soft tissue sarcomas. The addition of radiotherapy results in higher local control rates. MRI is standard imaging before and after radiotherapy and is critical for surveillance of often complex post-treatment appearances. However, histopathologic changes that occur after radiotherapy confound dimension-based assessments of response. Except for myxoid liposarcoma, significant dimensional radiologic responses are rare. Dimension-based assessments have been shown to have no correlation with outcome or histopathologic response, and alternative assessments are needed. Current consensus from the EORTC-STBSG suggests that the addition of functional diffusion-weighted MRI to standard anatomic and postcontrast MRI greatly facilitates interpretation because the combination of reduced enhancement and increasing apparent diffusion coefficient (ADC) may increase confidence for response. After radiotherapy, new enhancement alone should be interpreted with caution, because this may be a result of vascular disruption rather than histologic response. Machine learning is likely to play a crucial role in allowing us to fully exploit the quantitative capabilities for use in routine, research and adaptive treatment regimens. Alternative methods of assessment are poorly understood; however, a small study of 18F FDG PET/CT in high-grade sarcomas has shown promise. CT is the mainstay of surveillance and response assessment for metastatic disease. However, methods of response assessment are evolving beyond dimension-based (RECIST 1.1) measurements. Furthermore, patients with the best radiological responses often have the worst outcomes, as this reflects high tumour grade. This highlights the need for appreciating the significance of imaging responses with regard to outcome.

Learning Objectives:

1. To learn how to use multimodality imaging in personalised treatment planning aimed at survival and preserving quality of life.
2. To learn how to use multimodality imaging in surveillance strategies.

09:44

Panel discussion: Increasing quality of life in sarcoma patients without decreasing survival. What is needed from an imaging perspective to allow and support this?

Imaging strategies in renal tumours

A-896 08:30

Chairperson's introduction

C. Nicolau; *Barcelona/ES (cnicolau@clinic.ub.es)*

The detection of incidental renal masses has increased due to a large number of imaging studies being performed for different clinical indications. The characterization and differentiation between benign and malignant renal lessions is essential for their management. The objectives of this session are to become familiar with the indications and optimal protocols of the current and emerging renal imaging modalities as well as to describe the evidence regarding renal mass characterization and learn about the capabilities of renal imaging to stage renal tumours.

Session Objectives:

1. To become familiar with current and emerging renal imaging modalities.
2. To learn about the capabilities of renal imaging in diagnosis and staging of renal tumours.

A-897 08:35

A. Imaging methods, CT and MRI: the best out of two

M.A. Cova; *Trieste/IT (cova@gnbts.units.it)*

CT is currently the imaging modality of choice for the evaluation of renal masses. The advantages of CT are its widespread availability, high speed of acquisition, high spatial resolution and isotropic imaging. MRI can be a powerful problem-solving tool in clinical practice for characterisation of renal masses, especially for characterisation of lesions with indeterminate enhancement at CT and of lesions in which a small amount of fat is suspected. Like CT, MRI provides excellent anatomic information on the evaluation of renal lesions. Moreover, unlike CT, advanced MRI techniques can provide information about tissue structure and function without exposure to ionising radiation and without using iodinated contrast. The disadvantage of MRI compared to CT is the longer examination time. Optimal MDCT protocol for renal masses includes a noncontrast phase followed by postcontrast acquisitions with corticomedullary, nephrographic and delayed phases of enhancement at approximately 40 seconds, 90 seconds and 7 minutes after contrast injection. The nephrographic phase is acquired for assessing the presence of a renal lesion and its enhancement, and is therefore sufficient for detection and characterisation of renal lesions. Corticomedullary and urographic phases are often performed to provide additional information for presurgical planning. Optimal MRI protocol for renal mass evaluation includes TSE T2-weighted imaging, TSE T1-weighted imaging with and without fat suppression, T1-weighted opposed-phase imaging (with in-phase and out-of-phase sequences) for the detection of microscopic fat, DWI, fat-suppressed 3D T1-weighted gradient-echo acquisition before and after administration of intravenous gadolinium contrast in corticomedullary, nephrographic and urographic phases, and subtraction imaging.

Learning Objectives:

1. To become familiar with the optimal CT and MRI protocols for renal imaging.
2. To understand the best choice of CT or MRI according to the clinical need.
3. To illustrate the advantages and disadvantages of CT and MRI.

A-898 08:58

B. Differential diagnosis of renal masses

N. Grenier; *Bordeaux/FR (nicolas.grenier@chu-bordeaux.fr)*

Imaging is the main source of detection of renal masses. Differenciation between complex cystic and solid masses is not always straightforward and may require several contrast-enhanced methods, and DCE-MRI and CEUS are more sensitive for that purpose. Considering cystic masses, Bosniak classification is required. Considering solid masses, characterization of fat-rich angiomyolipomas is based on plain CT, but fat-poor AMLs can be distinguished from carcinomas by multiparametric MRI only. Multiparametric MRI includes chemical shift gradient echo (GRE) sequences, signal intensity on T2-weighted images, DCE sequences, diffusion-weighted sequences and late contrast-enhanced images. Using different combinations of two or several parameters, now makes it possible to clearly distinguish some renal tumours such as fat-poor AMLs, papillary carcinomas and clear cell carcinomas, the latter being difficult to separate from oncocytoma when a central scar is absent. A larger validation of all these combinations is still necessary to define those having a clinical significance for routine practice. Percutaneous biopsy remains mandatory before such a validation, as soon as pathological result is supposed to have an impact on tumour management.

Learning Objectives:

1. To learn about the histologic spectrum of renal tumours.
2. To understand the capabilities of imaging for renal tumour characterisation.
3. To become familiar with functional techniques applied to characterise renal tumours.

Author Disclosure:

N. Grenier: Advisory Board; Supersonic Imagine, Aix-en-Provence, France.

A-899 09:21

C. Staging and organ-preserving strategies

P. Asbach; *Berlin/DE (patrick.asbach@charite.de)*

Accurate CT- or MRI-based staging of the two most common malignant neoplasms involving the kidneys, renal cell carcinoma (RCC) and transitional cell carcinoma (TCC) is an important prerequisite for surgical decision-making, especially in the early stages of the disease. The TNM staging system is particularly different between RCC and TCC regarding the T-stage. Tumour size and invasion of the perirenal fat are important criteria for local staging of RCC, whereas invasion of the muscular layer of the renal collecting system and invasion into the renal parenchyma are important criteria for staging TCC, the latter being more complex based on imaging as compared to RCC. Different organ-preserving strategies are evolving, especially for treatment of RCC (e.g. local excision versus partial nephrectomy). Also, important additional information such as detailed vascular anatomy is needed by the surgeon, which has impact on the respective preoperative imaging protocol.

Learning Objectives:

1. To understand the TNM-staging system for renal tumours.
2. To become familiar with optimal staging protocols and imaging findings in staging of renal tumours.
3. To learn about actual organ-preserving strategies.

09:44

Panel discussion: How to implement an optimal renal imaging protocol?

Abdominal emergencies: friends and enemies

A-900 08:30

Chairperson's introduction

I. Arkhipova; *Moscow/RU (iarkhipova77@mail.ru)*

Non-traumatic emergencies as well as traumatic ones in the abdomen require immediate medical care; however, the absence of a clear reason like trauma or a variety of clinical features may often lead to a life-threatening delay of the correct diagnosis or of a misdiagnosis. Prompt and qualified imaging with either “friendly” or “enemy” pitfalls is a fundamental and crucial part in the evaluation of different diseases and conditions, which are to be discussed in the five (5) lectures with clinical case presentations. The goal of this session is to review current imaging strategies, controversies and reports, corresponding to requests of clinicians in the evaluation of common and uncommon acute non-traumatic abdominal emergencies.

Session Objectives:

1. To learn about the main radiological features of life-threatening non-traumatic emergencies in abdomen.
2. To become familiar with the most frequent requests and expectations of surgeons.
3. To be familiar with interpretation of cases in emergency imaging.
4. To find out possible points that could be useful in daily radiological practice in emergency department.
5. To discuss and understand diagnostic strategy for high-quality and faster diagnosis at the end of the session.

A-901 08:35

Abdominal vascular emergencies: no time to lose

V.E. Sinitsyn; *Moscow/RU (vsini@mail.ru)*

Acute abdominal vascular emergencies could be traumatic or non-traumatic according to their aetiology. Risks of rapid blood loss with development of hypovolemic shock and critical organ ischaemia dictate the need for rapid and accurate diagnostic assessment. These emergencies could be a result of arterial or venous pathology. Major types of vessel injuries are ruptures accompanied by active haemorrhage, lacerations or dissections, thrombotic or mechanical occlusions with following organ ischaemia, and the formation of pseudoaneurysms and fistulae. CT is a most used diagnostic technique in such cases. It has several advantages over abdominal US. CT is quick, covers large anatomical areas, is widely available, and its results are not dependent on patient's preparation. MRI or hybrid imaging is not routinely used in such cases. The preferable technique is biphasic CT. In cases of acute vascular emergencies, CT is comparable to catheter angiography. CT can show the direct signs of vessel injury, intraluminal thrombi or extravascular blood and clots, and ischaemia of critical organs (e.g. mesenteric ischaemia). Modern systems can be used to see so-called "blush" - a sign of acute extravasation of contrast material. It helps to locate the site of continuing acute bleeding. Potential pitfalls in CTA interpretation (missed acute bleeding or thrombosis) could be related to the low rate of bleeding, stopped bleeding, dilution of blood by fluid, and missed signs of organ ischaemia. The use of abdominal MDCT in cases of vascular emergencies helps to define and plan the best treatment strategy (endoscopic intervention, angiographic embolization, surgery, or active surveillance).

Learning Objectives:

1. To learn about types and aetiology of non-traumatic abdominal vascular emergencies.
2. To be familiar with the appropriate imaging protocols.
3. To know about CT findings in various acute life-threatening abdominal vascular diseases.
4. To understand modern approach to diagnostic work-up and reporting in vascular emergencies.

A-902 08:50

When to call the interventional radiologist and when to call the surgeon?

K.K. Pyra; *Lublin/PL (k.pyra@poczta.fm)*

Vascular abdominal emergencies are not common but, when present, may be catastrophic, with significant morbidity and, frequently, mortality. The physical examination may not reveal clear abnormalities, making the diagnosis more difficult. Due to wide MDCT technology availability, the first-line assessment of vascular abdominal emergencies is CTA. The findings of various types of vessel injury include laceration, rupture with active haemorrhage, occlusion and, for arteries formation of aneurysm, pseudoaneurysm, dissection or fistula. Most of them are life-threatening emergencies, since they may cause a heavy hypovolemic shock and/or severe organ ischaemia and therefore prompt diagnosis and treatment are required. Due to the rapidly growing field of endovascular treatment, interventional radiology is increasingly used as a first-line treatment. This presentation focuses on differences in clinical and radiological presentations of vascular emergencies, usual and unusual emergencies, endovascular methods of treatment and what is most important in choosing appropriate treatment strategy: endovascular or open surgery.

Learning Objectives:

1. To learn about differences in clinical and radiological presentations of vascular emergencies.
2. To demonstrate examples of usual and unusual emergencies of the abdominal vessels.
3. To become familiar with the endovascular methods of treatment.
4. To learn how to choose appropriate treatment strategy.

A-903 09:02

Closed loop obstruction: a challenging diagnosis

M. Zins; *Paris/FR (mzins@hpsj.fr)*

Closed-loop small bowel obstruction (CL-SBO) is a form of mechanical intestinal obstruction in which a segment of bowel is occluded at two contiguous points. Adhesive bands and internal and external hernias are the main causes of CL-SBO. CL-SBO is the most common cause of strangulation with a rate of intestinal ischaemia ranging from 43 to 84 %. Computed tomography (CT) remains actually the best modality to detect ischaemia in small bowel obstructions (SBO) with reported sensitivities ranging from 73% to 100% and specificities from 61% to 100%. In patients with CL-SBO and absence of other CT signs of ischaemia, non-surgical management is successful in 25% of the cases. Increased unenhanced bowel wall attenuation is the only CT finding significantly associated with bowel necrosis in patients with adhesive bands or internal hernias CL-SBO. When present, this sign could help to differentiate reversible partial mural bowel ischaemia from irreversible transmural bowel infarction.

Learning Objectives:

1. To be able to differentiate simple mechanical small-bowel obstruction from closed loop obstruction (CLO) at CT.
2. To learn about atypical presentation of CLO at CT.
3. To become familiar with the most specific CT signs of ischaemia complication CLO.
4. To learn new insights in clinical outcome of CLO related to adhesive bands.

A-904 09:17

Expected and unexpected emergencies of abdominal viscera: radiology before surgery?

C. Stoupis; *Männedorf/CH (c.stoupis@spitalmaennedorf.ch)*

Evaluation of acute abdominal conditions is sometimes difficult. Various factors can obscure the underlying cause, delaying the correct diagnosis with subsequent adverse patient outcome. Imaging is one of the most important diagnostic tools in acute abdomen and many times radiological examinations are done prior to use of other diagnostic tools. This presentation will demonstrate the examples of usual and unusual entities of the upper abdominal organs that are seen as emergency conditions (imaging on demand, not planned) and require timely intervention to limit morbidity and mortality. Examples of life-threatening bleeding conditions of the liver and spleen, examples of immediate treatment requiring infectious diseases of the liver, cases of inflammatory processes of the pancreas and unexpected lesions of the adrenals will be shown. The relation of the organ pathology and the clinical presentation will be discussed, as a potential guide or even indication of danger, to proceed with the correct radiological diagnosis; expected vs surprising radiological findings (treat the patient, not the image). Appropriate imaging techniques will discussed, with specific emphasis on CT, as a most valued tool, demonstrating the advances of imaging in the evaluation of emergency pathologies. A short overview of interventional techniques will be discussed as well, as an alternative to surgical procedures to treat effectively patients with high morbidity, without open or laparoscopic surgery.

Learning Objectives:

1. To demonstrate examples of usual and unusual emergencies of the upper abdominal organs (liver, pancreas, spleen, adrenal).
2. To learn about differences in clinical and radiological presentations of those entities.
3. To learn about imaging strategies (time, cost, efficiency, protocols).
4. To learn about the potential of interventional radiological procedures as treatment choice.

A-905 09:32

Life teaches us case by case

M.-L. Riibak; *Tallinn/EE (mlriibak@gmail.com)*

With a speedy workflow, as is very often necessary at the department of emergency radiology, or on the night shift, it might be quite easy to overlook some important pathologies. Acquiring some useful habits such as measuring densities or comparing and paying attention to 'hints' we see during radiological studies could guide us to serious conditions not noticed initially. Good clinical and laboratory information are often necessary to come to the right conclusion.

Learning Objectives:

1. To recognise the signs of pathology in non-traumatic acute abdomen.
2. To recognise common finding "as friends" in not so common "unfriendly" situations and vice versa.
3. To become familiar with what the clinician might be interested to know besides the diagnosis.

09:44

Panel discussion: Every imaging sign could matter!

08:30 - 10:00 **Room E1**

E³ - ECR Master Class (Breast)

E³ 1726a

The high-risk patient enigma

Moderator:

F. Kilburn-Toppin; Cambridge/UK

A-906 08:30

A. Lesions with an elevated risk for breast cancer

G. Forrai; *Budapest/HU (forrai.gabor@t-online.hu)*

The histological, clinical presentation, together with the mammography and US appearance of the high-risk lesions, would be demonstrated. They have very different probability figures of developing cancer, and this would be detailed for each type of lesion. The concept and the global problem of the management of these lesions will be explained, together with the conflict of over/underdiagnosis/treatment.

Learning Objectives:

1. To learn about different types of high-risk lesions.
2. To become familiar with the risk of developing a cancer.
3. To appreciate the different imaging modalities for diagnosis.

A-907 09:00

B. Value of breast MRI. Rate of underestimation and impact on treatment decision: is breast MRI increasing the number of high-risk lesions?

R.M. Mann; *Nijmegen/NL (r.mann@rad.umcn.nl)*

The evaluation of high-risk lesions on biopsy with MRI is commonly performed. One of the major ideas is to ascertain that there is not more disease present than seen with other techniques. As many high-risk lesions are in fact accidental findings on needle biopsy, the absence of enhancement within the breast reduces the likelihood of more extensive disease. Nevertheless, the underestimation rate with MRI is dependent on the type of high-risk lesion initially found and is still substantial for lesions like atypical ductal hyperplasia and lobular neoplasia. Moreover, several high-risk lesions may in fact enhance strongly in breast MRI, but are not upgraded at subsequent pathological assessment. In this lecture, MRI features of common and less common high-risk lesions will be discussed. In general, MRI cannot preclude the need for extensive tissue sampling, but it may be used for guiding of the biopsy and may obviate complete surgical excision.

Learning Objectives:

1. To learn about the evidence on MRI for evaluating high-risk lesions.
2. To become familiar with various imaging appearances of high-risk lesions.
3. To appreciate the added value for diagnosis and treatment decision.

Author Disclosure:

R.M. Mann: Advisory Board; Screenpoint Medical, Transonic imaging. Grant Recipient; Siemens Healthineers, Bayer Healthcare, Medtronic, Elswood, Identification solutions inc., Seno medical, Micrima.

A-908 09:30

C. Can surgery be avoided?

S.J. Vinnicombe; *Dundee/UK (s.vinnicombe@dundee.ac.uk)*

Within the UK National Health Service Breast Screening Programme (NHSBSP), a median of 7% of screen-detected lesions subjected to needle core biopsy are categorised as B3, of uncertain malignant potential. These lesions comprise a diverse group of pathological entities, with or without epithelial atypia, mostly manifest as mammographic microcalcification. B3 lesions tend to be heterogeneous (such that the area sampled by needle core biopsy may not be representative) and are associated with a variable rate of upgrade to malignancy, either in situ or invasive, at surgical excision biopsy, which has been the treatment of choice until recently. However, the approach to B3 lesions is changing. With increasing concerns about overdiagnosis (and subsequent overtreatment) in breast screening and the widespread availability of large-bore needle biopsy devices, minimally invasive modes of treatment are increasingly used for these lesions. Various techniques are available, including large-bore vacuum-assisted devices where the lesion is removed in a piecemeal fashion, and devices which remove the lesion in its entirety with a single pass. These approaches to management of B3 lesions are cost-effective and well tolerated, but oncological safety must be the key consideration. In this respect, the literature is challenging to synthesise, since there is wide variability in the rates of surgical excision in differing series and it seems likely that B3 lesions that are surgically excised differ from those treated non-operatively, introducing a source of bias. Nonetheless, many countries are gradually adopting minimally invasive approaches and some consensus has been achieved.

Learning Objectives:

1. To learn about the different non-invasive modalities to excise high-risk lesions.
2. To become familiar with the risk of avoiding surgery.
3. To appreciate the standard protocols in different countries.

08:30 - 10:00 **Room E2**

Diffuse low-grade gliomas: new things you should know

Moderator:

F.W. Cartes-Zumelzu; Innsbruck/AT

A-909 08:30

A. Molecular basis for classification, treatment and predicting outcome in low-grade gliomas

V.C. Keil; Bonn/DE *(Vera.Keil@ukbonn.de)*

Low-grade gliomas (LGG) are glial tumours with a high degree of diversity on a histological and genetic level. The status of 1p/19q and IDH1/2 genes among others has indeed become the tumour type defining criterion in the 2016 WHO classification of CNS tumours and has impact on therapy choice. Genetic status and protein expression, such as of the oncometabolite 2-HG, are also the key to understand why some LGG de-differentiate to high-grade lesions or show growth, while other lesions remain stable over decades. Quantitative MRI, MRS and PET techniques form the rapidly expanding field of “molecular imaging”. Molecular imaging promises to provide the neuroradiologist with non-invasive tools to predict the genetic and histological status of gliomas. Potential applications range from pre-operative assessment of intra-tumoural heterogeneity for biopsy targeting to follow-up and therapy monitoring. However, the greatest challenge lies in the shortage of direct molecular imaging techniques (currently 2-HG MRS is the only one) and the establishment of reliable radiological substitute biomarkers with the ability to predict patient prognosis. Molecular imaging is not yet at a point where unequivocal scientific results rendered watertight imaging biomarkers to rely on in LGG assessment. There are conflicts about the additive value of multiple imaging techniques, the reproducibility of results and also feasibility in clinical practice. In this session we will try to get an overview of the most widely used techniques molecular imaging and their current benefits and limitations for a non-invasive LGG assessment in contrast to standard, non-quantitative MRI.

Learning Objectives:

1. To learn about the role of imaging in the context of histopathology regarding the prediction of outcome.
2. To understand the role of conventional and quantitative beyond diagnosis.
3. To appreciate the translational approach of diagnosis and monitoring of glial tumour based on the histopathological background.

A-910 09:00

B. Imaging patterns suggestive of different (molecular) subtypes of low-grade gliomas

M. Smits; *Rotterdam/NL (marion.smits@erasmusmc.nl)*

Primary brain tumours are histopathologically subtyped into World Health Organisation (WHO) grades I to IV, according to - increasing - degrees of malignancy. These grades provide prognostic information and guidance on management, such as radiotherapy and chemotherapy after surgery. Despite the confirmed value of the WHO grading system, a multitude of studies and prospective interventional trials indicate that tumours with identical morphological criteria, i.e. of the same WHO grade, can have highly different outcomes. To personalise brain tumour management, we need additional diagnostic markers that can differentiate tumours beyond the current morphological WHO grading system. Molecular markers can distinguish subtypes of tumours within the same morphological type and WHO grade, and are therefore of great interest for personalised medicine. Recent genomic-wide studies have resulted in a far more comprehensive understanding of the genomic alterations in gliomas, and the suggestions of a new molecularly based classification. MR imaging phenotypes can serve as non-invasive surrogates for tumour genotypes and as such provide important information on diagnosis, prognosis, and, eventually, personalised treatment. The newly emerged field of RadioGenomics links specific MR imaging phenotypes with gene expression profiles. In this presentation, I will discuss the three best known tumoural genotypes with prognostic and - potential - therapeutic consequences: 1. isocitrate dehydrogenase (IDH) mutation, 2. 1p19q deletion, and 3. methyl guanine methyltransferase (MGMT) promotor methylation. I will give an overview of the known and potential MR imaging features of these genotypes and their value and validity in a clinical context.

Learning Objectives:

1. To learn about whether there is a change of pattern recognition based on conventional and quantitative imaging approaches.
2. To understand the heterogeneity of low-grade gliomas based on histopathology and imaging.
3. To appreciate the perspectives and challenges of diagnostic imaging in phenotyping low-grade gliomas.

Author Disclosure:

M. Smits: Consultant; independent reviewer for Parexel Ltd.

A-911 09:30

C. Advanced imaging in low-grade gliomas

N. Bulakbasi; *Mersin/TR (nail.bulakbasi@kyrenia.edu.tr)*

Due to the 2016 update of WHO classification, low-grade gliomas (LGGs) are typically IDH mutant, diffusely infiltrating, and slow growing having moderately increased cellularity, generally without mitosis, necrosis and microvascular proliferation. Some Class II and a significant number of Class III series support the addition of diffusion and perfusion-weighted MR imaging and MR spectroscopy (MRS) in the assessment of suspected LGGs. LGGs have lower cellularity (ADC), angiogenesis (rCBV), capillary permeability (Ktrans), and mitotic activity (Cho/Cr ratio) than those of high-grade gliomas (HGGs). IDH mutation can be indirectly assessed by the identification of 2-hydroxyglutarate in MRS with spectral editing. A gradual decrease in minimum ADC values, increase in Cho/Cr ratio and maximum rCBV values, and the emergence of lactate and free lipid at MRS over time are consistent with tumour progression. Quantitative assessment of peritumoural area, indicating the infiltrative nature of the tumour, also helps in the differential diagnosis of LGGs from solitary metastases and CNS lymphomas. Functional MRI combined with MR tractography is widely used for presurgical planning to demonstrate the spatial relationship between eloquent brain regions and the tumour. Small tumour diameters, artefacts due to bone or air interfaces, vascular structures, haemorrhagic, cystic/necrotic and calcific changes in tumoural area can cause critical distortions in quantifying parameters. So, the selection of a proper ROI avoiding these kinds of areas is critical to obtain proper quantified results. The quantitative multiparametric MR imaging of LGGs can either improve the diagnostic accuracy of their differential diagnosis or assess their prognosis.

Learning Objectives:

1. To learn about the spectrum and diagnostic value of the available advanced imaging techniques in neuro-oncology.
2. To understand the added value and possible pitfalls using quantitative MRI techniques in addition to conventional MRI.
3. To appreciate the importance of standardisation of advanced MR image acquisition in the clinical practice of neuro-oncology.

Interventional treatment of stroke: a game changer

A-912 08:30

Chairperson's introduction

P. Vilela; *Almada/PT (ferrovilela@sapo.pt)*

During the last years acute ischemic stroke (AIS) treatment has been revolutionised with the introduction of endovascular treatment - thrombectomy (ET). Several randomised controlled trials have clearly shown the clinical benefits of this treatment and, recent studies have broadening the inclusion criteria, specially concerning the therapeutic time window. Imaging has a central role in the acute ischemic stroke management. Diagnostic neuroradiology is essential to make the correct diagnosis of AIS and to select the appropriate candidates for ET. Imaging provides all the information needed for patient selection, excluding stroke mimics, depicting the vessel occlusion and defining the potential salvage brain tissue: evaluating the collateral arterial circulation status, the extent of irreversible lesion (core) and/or the extension of potentially reversible ischemia (penumbra). Interventional neuroradiology has achieved tremendous clinical results with the fast and high recanalization rates, but further improvements are expected. There are still some technical aspects to be improved, such as the tandem lesions, distal occlusions and anaesthesiology protocol, which will be discussed in this session. In parallel, several organisational processes, from local department/hospital to regional/national organisation, must be optimised, in order to fasten the patient access to the correct stroke center and increase the number of patients treated. The radiology/neuroradiology departments' organisation and professionals are critical for the implementation of AIS national health strategies.

Session Objectives:

1. To review the current imaging techniques and the individualised patient imaging assessment for acute ischaemic stroke.
2. To overview the current endovascular indications and techniques for acute ischaemic stroke.
3. To discuss the current endovascular treatment challenges, such as tandem lesions, distal occlusions and treatment beyond the six-hour time window.

A-913 08:35

Stroke, endovascular treatment: current approaches

T. van der Zijden; *Antwerp/BE (thijsvanderzijden@hotmail.com)*

Endovascular thrombectomy has clearly demonstrated its benefit for primary treatment of patients with acute ischaemic stroke from large vessel occlusion. During the past years, mechanical thrombectomy was mostly done by the use of stent retrievers. But, due to ongoing technical developments and experiences on the job, other techniques, such as thrombus aspiration and mixed techniques, has emerged as effective treatment tools as well. Although today very fast procedure times with impressive recanalization rates can be achieved using these techniques, it is still of utmost importance to select the correct patients for endovascular treatment to avoid futile recanalization and to prevent additional harm to ischaemic stroke patients. Besides the proper indication setting, optimal clinical circumstances during and after the procedure should be pursued as well. In this lecture, current insights into the indication setting, different endovascular techniques, choices in supportive care during an endovascular procedure and post-thrombectomy medical care will be discussed and illustrated.

Learning Objectives:

1. To review the current indications for endovascular treatment in acute ischaemic stroke.
2. To overview the endovascular treatment techniques for acute ischaemic stroke: stent retriever and aspiration.
3. To discuss the different options of anaesthesia type, blood pressure control, and post-thrombectomy medical treatment.

A-914 08:58

Stroke, endovascular treatment: tandem lesions and acute phase stenting

W. van Zwam; *Maastricht/NL (w.van.zwam@mumc.nl)*

In 20 - 30% of patients with acute ischemic stroke due to a large vessel occlusion of the anterior circulation, who are eligible for endovascular treatment, a concomitant ipsilateral cervical internal carotid artery stenosis or (pseud)occlusion is present. These so-called tandem lesions are known to be relatively refractory to intravenous rtPA administration and clinical outcome is therefore poor if not treated endovascularly. Recent studies have shown a large treatment benefit of endovascular treatment in these patients, comparable with the treatment effect in patients who have an intracranial occlusion without cervical carotid pathology. In current guidelines thrombectomy of the intracranial occlusion is therefore recommended for patients with these tandem lesions. However, no clear guidelines for the management of the extracranial carotid pathology exist, because no evidence for the optimal management is yet present. Several options like carotid stenting in the acute phase, before or after thrombectomy, PTA only followed by delayed stenting or delayed carotid endarteriectomy are available. Furthermore, different carotid pathologies like dissections and atherosclerotic lesions obviate a uniform treatment recommendation. Various extracranial carotid artery pathologies, different treatment options and available evidence from published studies will be presented and discussed in this presentation.

Learning Objectives:

1. To review the literature data regarding the incidence, natural history and treatment of tandem lesions.
2. To overview the endovascular treatment techniques for the treatment of acute ischaemic stroke: stent retriever vs aspiration, and current indications for endovascular treatment in acute ischaemic stroke.
3. To discuss the potential indications for stenting in the setting of acute ischaemic stroke and tandem lesions.

Author Disclosure:

W. van Zwam: Grant Recipient; Brain Council, the Netherlands. Speaker; Cerenovus, Stryker.

A-915 09:21

Stroke, endovascular treatment: beyond proximal occlusion and six-hour time window

J. Macho; *Barcelona/ES (jmmacho@clinic.ub.es)*

Most of the guidelines recommend endovascular recanalization in patients with acute ischaemic stroke due to large vessel occlusions up until 6 hours after symptom onset. Metaanalysis of pooled individual patient data from 1287 patients in MRCLEAN, ESCAPE, REVASCAT, EXTEND and SWIFTPRIME trials suggests that the benefit of thrombectomy rapidly decays over time and may no longer exist beyond 7.3 hours from stroke onset. The just published DAWN Trial has evaluated late and unwitnessed stroke patients. Eligible patients, with clinical and imaging mismatch (defined by age, core, and NIHSS), who receive mechanical thrombectomy have better outcomes, compared to standard medical therapy. This treatment effect is the highest out of any stroke trials to date and suggests that the presence of clinical-core mismatch is a critical predictor of treatment effect independent of time to presentation. Metaanalysis of randomized trials favoured endovascular treatment across all sites of occlussions with better endovascular treatment effect in patients with thrombi in ICA and proximal M1 MCA segments than in those with thrombi in distal M1 MCA or M2 segments because proximal thrombi are larger in volume , less likely to recanalize with intravenous alteplase and more easily reached by endovascular thrombectomy. The question of benefit with more distally located occlusions in the M2 middle cerebral artery segment is only partially addressed, because randomized trials had very few patients with more distally located occlusions in the M2 middle cerebral artery segment and do not have enough power to fully confirm benefit or harm in these patients .

Learning Objectives:

1. To review the literature data regarding the incidence, natural history and treatment of distal arterial occlusions.
2. To review the literature data regarding the incidence, natural history and treatment of wake-up strokes and arterial ischaemic strokes beyond the six-hour time window.
3. To discuss the potential indications for endovascular treatment beyond the proximal arterial occlusion and beyond the six-hour time window.

Oncologic Imaging

RC 1716

A multidisciplinary approach to prostate cancer: can we make a difference?

A-916 08:30

Chairperson's introduction

A. Baur; *Berlin/DE (alexander.baur@charite.de)*

Technical advancements and the introduction of guidelines for magnetic resonance imaging (MRI) of the prostate as well as the numerous promising study results have laid the foundation for a widespread application of this imaging technique in patients with suspected or confirmed prostate cancer. Radiological expertise in prostate MRI and standardized image interpretation is crucial to maximize the beneficial impact of imaging. Today, radiologists often work in a multidisciplinary team with urologists and radiation oncologists. To do so proficiently, they have to be familiar with the diagnostic algorithms for prostate cancer. Radiologists should also be aware of available treatment options including surgery, radiotherapy, local ablative and hormonal treatment as well as of the option to put patients under active surveillance. Finally, it is important to be aware of what kind of information urologists and radiation oncologists require to provide optimal treatment for each patient. All of these requirements will be addressed and discussed in this multidisciplinary course with experts from the fields of radiology, urology, and radiation oncology.

Session Objectives:

1. To understand the pathophysiological properties of prostate cancer and its impact on diffusion-weighted imaging and dynamic contrast-enhanced MRI.
2. To understand the necessity of functional MRI (compared with mere morphological MRI) in the assessment of prostate cancer.
3. To learn about PiRADS classification system.
4. To learn about the role of MRI in selecting patient-tailored therapy.
5. To learn about the option of active surveillance vs immediate treatment.

Author Disclosure:

A. Baur: Research/Grant Support; Bayer Pharma. Speaker; Bayer Pharma.

A-917 08:35

A. The urologist: evidence-based clinical decision making

N. Mottet; *St. Etienne/FR (nicolas.mottet@chu-st-etienne.fr)*

Prostate cancer is the third most common cause of cancer death in men. While systematic screening is not promoted, an individual early diagnosis is the standard of care. Based on risk factors (such as family history), PSA and DRE, the pathology obtained after sonography-guided biopsies is the only diagnostic possibility. A systematic pre-biopsy mpMRI is not yet the standard of care, and ongoing RCT are urgently awaited. A quality control of this mpMRI is a major prerequisite and potential limiting factor so far. However, a systematic mpMRI is the standard of care before rebiopsying. This increases the biopsy reliability using a combination of 12 systematic, plus targeted courses. The treatment policy is based on individual life expectancy, patient's wishes and staging. The classical risk categories (known as d'Amico's classification) are more and more challenged by information from image results. Apart from biopsy results (number of positive cores, Gleason score) and DRE, the local staging (T stage) is based on MRI. Its sensitivity is mild (intraprostatic localisation, microscopic extracapsular extension), but its specificity is acceptable and it is a must in intermediate-/high-risk situtions. It is also mandatory before considering active surveillance. N staging is poorly done, even with the PET. As for M staging, PSMA represents the future, although its added value regarding improved outcome remains unclear. For M staging, bone scan should be replaced by a whole-body MRI. Howerer for mCRPC progression characterisation, bone and CT scan remain the standard, as no consensus definition of progression with MRI exists yet.

Learning Objectives:

1. To understand how a diagnosis is established by PSA evaluation and biopsy.
2. To learn about different treatment options: surgery, radiotherapy, local ablative and hormonal treatment; as well as active surveillance.
3. To learn how imaging impacts treatment selection.
4. To understand what the urologist needs to know from the radiologist.

A-918 08:58

B. The radiologist: evidence-based use of multiparametric MRI

H.-P. Schlemmer; *Heidelberg/DE (h.schlemmer@dkfz.de)*

Early detection of prostate cancer with biologic characterization and staging is of fundamental importance for individualized decision-making. Localized, early-stage prostate cancer has been more frequently detected since the introduction of PSA screening. Active surveillance and less aggressive focal therapy options are accordingly emerging to reduce the side effects that may significantly reduce the quality of life. But delayed and unprecise diagnosis as well as overtreatment is still feared, because prostate cancer is characterized by multifocality with considerable variations of cancer aggressiveness. Meanwhile, a body of evidence from clinical studies is available proving that multiparametric MR imaging (mpMR) is beneficial for the detection and localization of cancer suspicious lesions, for biopsy guidance to finally diagnose or rule out significant cancer as well as for T-staging. Different transrectal or transperineal TRUS/MR image fusion biopsy methods with targeted +/- random biopsies have been developed. During active surveillance, the combination of morphologic and functional MR parameters yields important objective and reproducible biomarkers for monitoring temporal changes of cancer size and aggressiveness. Accordingly, mpMR is of increasing importance for individualized decision-making in prostate cancer patients. However, the assurance of high-quality imaging is still challenging. The PI-RADS recommendations have proven very helpful concerning this issue. This lecture will provide detailed knowledge of the evidence-based use of "state-of-the-art" mpMRI in clinical routine. It will demonstrate how the method can be integrated in the urological context of diagnosis and treatment to improve the complex management of prostate cancer patients.

Learning Objectives:

1. To learn how to perform and interpret multiparametric MRI.
2. To become familiar with the PiRADS classification system.
3. To become familiar with the role of imaging for patient stratification and treatment planning.

A-919 09:21

C. The radiation oncologist

D. Georg; *Vienna/AT (dietmar.georg@meduniwien.ac.at)*

Various treatment techniques are successfully used for treating prostate cancer (PCa) with irradiation, with an increasing tendency of using higher doses per treatment session. In conventional radiation therapy the tumour volume is irradiated with a homogeneous dose. Widespread clinical practice relies on treatment planning based on computed tomography (CT), often combined with MRI. However, recent technology developments and achievements made during the last decade enable to focus the high dose irradiation very precisely on the tumour, while sparing of the surrounding normal tissue. Improved precision of treatment planning and delivery warrant equally precise tumour definition, moreover new treatment concepts are stimulated by the advancements in imaging to visualise and quantify biological, physiological and pathological processes. Positron emission tomography (PET), perfusion computed tomography (CT) and especially multiparametric magnetic resonance imaging (mp-MRI) are continuously explored for lesion characterisation, target definition, and response assessment during and after radiotherapy of PCa. To elucidate tumor biology and to identify subvolumes of more aggressive behavior, which are often radiotherapy resistant, mp-MRI is more frequently used in clinical studies. The concept of inhomogeneous tumour irradiation according to its biological behavior, called dose painting, is motivated by selective dose escalation based on biological tumour characteristics. This approach may lead not only to higher local control but also to better sparing of normal surrounding tissue. With the clinical implementation of dose painting, improvements in the therapeutic outcome can be expected. Due to the existing technical challenges, extensive collaboration between radiation oncologists, radiologists, medical physicists and radiation biologists is needed.

Learning Objectives:

1. To learn the rationale and scientific basis for focal therapies for prostate cancer.
2. To learn how focal therapies are performed in prostate cancer.
3. To learn through personal experience and from literature how multiparametric MRI can guide focal therapies of the prostate.

MR imaging of the knee

Moderator:

M. Tzalonikou; Athens/GR

A-920 08:30

A. Cruciate ligaments: what to know and do

A. Alcalá-Galiano; *Madrid/ES (aalcalagaliano@gmail.com)*

Cruciate ligaments play a key role in knee kinematics and stability. Cruciate-deficient knees are predisposed to early osteoarthritis due to chronic instability. ACL is the most commonly injured major ligament of the knee. PCL lesions are far less common, but more frequently associated with multiligamentous injuries. MRI is the study of choice to evaluate acutely and chronically injured cruciate ligaments, associated injuries and for postoperative imaging following ligament reconstruction. Understanding the variations of their anatomy (double bundle configuration and insertion sites) is key to performing a tailored anatomic reconstruction Accurate description and grading of cruciate tears and associated injuries is essential for preoperative planning of ligament reconstruction. The primary and secondary signs and indirect imaging findings of acute and chronic ligament injury will be reviewed. Atypical findings and imaging pitfalls will also be discussed. ACL reconstruction is one of the most common orthopaedic procedures, whilst PCL reconstruction is on the rise. Knowledge of ligament reconstruction techniques allows differentiation of normal postoperative findings from complications, which may be related to graft placement, the graft itself or to the donor site. Any standard knee MRI protocol must ensure adequate detection of both soft tissue and bony injury, including the cruciate ligaments. However, protocols may be tailored for specific needs, including oblique acquisitions, 3D or metal artefact reduction sequences to better demonstrate the anatomy and facilitate detection of small tears.

Learning Objectives:

1. To review the normal anatomy and MR imaging appearances of ACL and PCL and discuss pitfalls.
2. To learn about the imaging appearances of ACL and PCL pathology and discuss imaging sequences and protocols.

A-921 09:00

B. Meniscal tears: obvious and subtle

P. Omoumi; *Lausanne/CH (patrick.omoumi@chuv.ch)*

This lecture will review the basic aspects of MRI of meniscal pathology, including some elementary technical and anatomical considerations, as well as the description of the basic semiology of meniscal tears and their classification. The common pitfalls and errors that need to be avoided will be presented. MRI is the modality of choice for the diagnosis of meniscal pathology as well as treatment planning. A certain number of technical considerations need to be understood by the radiologist. The standard sequence to image the meniscus is intermediate-weighted fast spin-echo sequences, in 2D or 3D. Certain acquisitions may influence the diagnosis of meniscal tears, including the choice of the echo time. Meniscal tears can manifest either as morphological changes or intrameniscal signal changes, with specific diagnostic criteria that will be reviewed. An appropriate terminology, based on standard arthroscopic classification, needs to be used by the radiologist to properly communicate the description of the tear to the referring surgeon. Secondary signs of meniscal tears, including parameniscal cyst and meniscal extrusion, should be used to increase the diagnostic performance for the detection of meniscal tears. Common pitfalls include anatomical variants (i.e. intermeniscal meniscal and meniscofemoral ligaments, discoid meniscus), as well as other causes for false positive findings such as meniscal flounce, chondrocalcinosis and meniscal ossicles. Knowledge of common mistakes and patterns of injury helps avoid unnecessary mistakes and improve diagnostic accuracy.

Learning Objectives:

1. To review the anatomy of the menisci and the classification of meniscal tear.
2. To familiarise with unusual imaging appearances of meniscal tears and discuss potential pitfalls.

A-922 09:30

C. Looking around the corners: posteromedial and posterolateral

U. Aydingoz; *Ankara/TR (uaydingo@hacettepe.edu.tr)*

Despite their contribution to the stability of the knee and their association with multiple ligamentous injuries of this largest joint in the human body, posterolateral and posteromedial corners of the knee are hidden from plain sight in the daily practice of reporting magnetic resonance imaging (MRI). Posterolateral corner (PLC) injuries of the knee are rare, but important conditions because of their association with the much more common anterior cruciate ligament (ACL) and other ligamentous or meniscal injury. If PLC injury is not identified and appropriately addressed, knee instability may persist, ACL reconstruction surgery may fail, and osteoarthritis may ensue. Although the anatomy of PLC is complex, its three main stabilizers that are targets for surgical reconstruction or repair in the presence of high-grade injury are identifiable: the lateral collateral ligament, the popliteus tendon, and the popliteofibular ligament. Avulsion fractures of the fibular head, where some components of the PLC attach, have a characteristic appearance on radiographs (the so-called “arcuate sign”) and must alert the radiologist to inspect the entire PLC on MRI for injury. Injuries to the posteromedial corner (PMC) of the knee are also associated with ACL, as well as the posterior cruciate ligament (PCL), tears. Major components of the PMC are the semimembranosus tendon (and its expansions), the oblique popliteal ligament, the posterior oblique ligament, the posteromedial joint capsule, and posterior horn of the medial meniscus. Unrecognized injury to PMC may result in the failure of the ACL or PCL reconstruction surgery with sustained anteromedial rotational instability.

Learning Objectives:

1. To review the relevant anatomical structures of both posteromedial and posterolateral corners.
2. To discuss imaging signs of pathology affecting the aforementioned areas.

08:30 - 10:00 **Room G**

Physics in Medical Imaging

RC 1713

Patient-specific dosimetry

A-923 08:30

Chairperson's introduction

E. Samara; *Sion/CH (elina.samara@hopitalvs.ch)*

The use of ionizing radiation in medical imaging offers substantial benefits for the diagnosis and treatment of numerous medical conditions in children and adults. However, exposure to ionizing radiation may be associated with harmful risks. Justification and optimization as principles of radiation protection make radiation dosimetry fundamental. Physicians need to know the levels of exposure and hence the risks from imaging examinations that they have to justify, and operators of x-ray equipment need to determine whether their techniques are optimized. Special cases such as examinations of children and pregnant patients or screening examinations require specific organ dose estimations. Moreover, to prevent tissue reactions, patient skin dose needs to be estimated during radiological interventional procedures. Patient characteristics, such as age, sex and size, should be taken into consideration for specific patient dose assessments. Each modality (radiography, fluoroscopy, mammography, computed tomography, etc.) has its own specificities and demands different methods to calculate the dose. Modern imaging modalities usually display conventional dosimetry metrics, such as dose-area product, incident air-kerma or computed tomography dose index that do not represent individual patient dose. Thus, numerous sophisticated concepts and methods have been proposed to estimate patient radiation dose that include either physical measurements with dosimeters and anthropomorphic phantoms or computational measurements using Monte Carlo simulations. All these methods progressively allow more accurate estimations of individual patient doses.

Session Objectives:

1. To understand the needs for personalised dosimetry.
2. To learn about existing and new methodologies used for patient dosimetry.
3. To understand the challenges for the implementation of patient-specific dosimetry.

A-924 08:35

A. Breast imaging dosimetry

I. Sechopoulos; *Nijmegen/NL (ioannis.sechopoulos@radboudumc.nl)*

Mammographic dosimetry is a subject of intense interest due to the use of this imaging modality for population-based screening. Although this topic has been studied for the last four decades, advances in the mammography systems, introduction of new imaging modalities such as breast tomosynthesis, and new insights into breast anatomy have resulted in the need for continued development of breast dosimetry methods and models. During this talk, the current method and model for breast dosimetry in mammography and tomosynthesis will be reviewed and its capabilities and limitations discussed. The concept of patient-specific breast dosimetry and its potential applications will be introduced. Finally, the upcoming new developments in the field of breast dosimetry will be presented.

Learning Objectives:

1. To understand the current method to estimate organ dose in mammography and its limitations.
2. To understand breast dosimetry in emerging modalities.
3. To learn about upcoming approaches in breast dosimetry.

Author Disclosure:

I. Sechopoulos: Advisory Board; Fischer Medical Imaging. Research/Grant Support; Siemens Healthcare, Toshiba Medical Systems. Speaker; Siemens Healthcare.

A-925 08:58

B. Patient dosimetry in CT and CBCT

S. Edyvean; *London/UK (sue.edyvean@phe.gov.uk)*

Conventional CT is a complex imaging device which can utilise narrow or wide beams, helical scanning, varying tube current, varying kV, and operating with various and dynamic collimations - all of which can affect patient dose. Different technology is used in cone beam CT, or flat panel CT, and this term usually refers to cross-sectional imaging with digital x-ray systems used in dental, digital radiography or radiotherapy. Many of the challenges are similar for both conventional CT and cone beam CT; however, there is generally more information available for the former. When considering patient-specific dosimetry, the technology, scan settings and the patient all need to be considered. As with other modalities, the scope to directly measure doses using physical dosimeters is limited. Therefore, doses need to be estimated using regular-shaped, or anthropomorphic, phantoms, or calculated using mathematical modelling techniques. The appropriate application, and the limitations, of standard dose indices (such as the computed tomography dose index, the size-specific dose index), together with their associated methodologies and phantoms, will be addressed. Monte Carlo calculations from modelled scanner and patient characteristics give more precise organ dose information, and there are a number of applied software packages developed to utilise these data. The advantages and limitations of these will be discussed.

Learning Objectives:

1. To understand what is estimated.
2. To learn how to measure it.

Author Disclosure:

S. Edyvean: Speaker; Refresher course.

A-926 09:21

C. Patient dose in fluoroscopy and interventional

A. Trianni; *Udine/IT (annalisa.trianni@asuiud.sanita.fvg.it)*

Interventional radiology contributes to significant proportion of the collective dose of the population from medical exposures. Moreover, when complex procedures are performed or procedures are repeated for the same patient, high-radiation dose levels can occur because procedures often require long fluoroscopy times and require high-quality images. For all of these reasons, dosimetric evaluations in interventional radiology are demanding. During this talk, patient dosimetry methods currently used in interventional radiology for different purposes (risk evaluation, optimisation and quality assurance) will be reviewed, together with relevant published dosimetric data. In particular, since radiation-induced skin damage might be a complication of interventional procedures, the talk will review available real-time patient skin dosimetry methods and their possible use.

Learning Objectives:

1. To review the fundamental patient dosimetry quantities.
2. To learn about calculation of patient dose for interventional procedures.
3. To learn about real time patient dose monitoring strategies.

09:44

Panel discussion: The future of patient-specific dosimetry

E³ - Rising Stars Programme: EFRS Radiographers' Basic Sessions

BR 3
Planning your career

A-927 08:30
Chairperson's introduction: What employers are looking for from new graduates
S. Huber; *Munich/DE (susanne.huber@med.uni-muenchen.de)*

What employers are looking for from new graduates? It is obvious that new graduates are expected to have passed the exam with at least good success. They should be interested, motivated and open-minded for their new working life. Additionally the graduate should show a character, which can be trusted to take care for patients and to be responsible for the own work, especially with regard to radiation protection. If the graduate should be from abroad, the language skills must be sufficient to fulfill the work requirements. Unfortunately many European countries are suffering from a shortage of radiographers. While trying to solve this problem, often radiographers are hired from abroad, which in consequence may lead to an even higher shortage in those countries. Fortunately and thanks to the mostly very good educational curricula there are still applicants with the above mentioned qualities available, but in total not enough applicants in comparison to the job vacancies. This session is about to show graduates ways to meet the expectations of their future employers. E.g. how they can prepare their personal presentation in designing their CV and to avoid mistakes while doing so. To make them aware of the importance of CPD (Continuous professional development), which eventually will lead to more competence and future carrier. The graduates will also have the opportunity to learn about the experiences of working as a radiographer in another country.
Session Objectives:
1. To understand how best to prepare your professional profile using various platforms.
2. To appreciate the potential for radiographers to work in various jurisdictions.
3. To consider the utility of professional development planning in achieving your professional goals.
Author Disclosure:
S. Huber: Author; Susanne Huber. Speaker; Susanne Huber.

A-928 08:35
The dos and don'ts of preparing your curriculum vitae
E. Kelly; *Galway/IE (eileenma.kelly@hse.ie)*

A curriculum vitae (CV) is the first impression made by a potential employee to an employer. The presentation of one's CV can influence the employer to read it or not. Therefore, a well-presented, succinct CV that is tailored to the job is essential. Many graduates consider themselves at a disadvantage when applying for positions as they lack experience, and consequently make attempts to compensate for the lack of experience by unnecessary information when constructing their CV. Many employers will research the background and experience of potential employees through social media sites such as LinkedIn, ResearchGate and EFRS RRN. Such sites can be a valuable promotional and networking tool for professionals and can lead to unexpected career opportunities. This presentation will consider how to design a CV that will grab the immediate attention of an employer. Common mistakes in design and content of a CV and how to avoid them will also be discussed.
Learning Objectives:
1. To understand qualities of a well-designed curriculum vitae.
2. To become familiar with common mistakes to avoid when preparing your CV.
3. To be aware of the potential of social media platforms such as LinkedIn, ResearchGate, EFRS RRN for your professional profile.

A-929 08:58
Radiography: your passport to travel
R. Caroço; *London/UK (caroco.rita@gmail.com)*

At the present moment, there are several countries that have radiographer shortages and therefore, welcome overseas professionals. These are mostly European countries, that can benefit from the freedom of movement under the EU law. The recognition of professional qualifications, particularly within Europe makes it highly encouraging to work abroad. Countries like Portugal have been affected by the economic and financial crisis, which combined with irresponsible coordination between education training and job opportunities, reflects very limited career prospects for radiographers. This led and continues to cause a rise in emigration for newly qualified/experienced radiographers to countries where shortages are high. The aim of this presentation is to talk about my personal experience as a radiographer trained in Portugal and working in the UK. It will list the requirements and formalities to register as a radiographer, the job seeking process, the barriers and benefits I encounter(ed). It will also give an overview of the differences in radiography career and opportunities, between these two countries.
Learning Objectives:
1. To be aware of the potential to use your radiography qualification in various jurisdictions.
2. To consider barriers to practicing as a radiographer abroad.
3. To appreciate the potential for charitable/voluntary work in developing countries.

A-930 09:21
Planning your professional development
A. Wareing; *Aberdeen/UK (a.wareing@rgu.ac.uk)*

This session will support radiographers and students in planning their professional development. There is a critical need for health-care professionals to remain professionally updated regarding continuous changes to the evidence base and technological advancements, particularly in radiography, to facilitate closure of any gaps between 'actual practice' and 'best practice'. Health services across Europe are under increasing stress and a principal factor going forwards will be managing increasing demands on health-care staff whilst supporting enhancement of the knowledge, skills and competency base. A recent body of work completed with individuals in the EFRS network has concluded that the primary feature of CPD activity should be the resulting impact - to patients, the service, the profession and the individual; with all stakeholders working in partnership. CPD activity must be flexible/multi-modal to support the changing growth/dynamic workforce. All stakeholders should utilise available communication and technology resources and make efforts to improve collaboration between the management, regulators and educators. Acknowledgement of barriers is required and actions must be taken to reduce these over time; financial burden remains a concern, whilst increasing literature has identified work pressure and lack of time as the main challenges for radiographers. An applied approach to these findings will be discussed in this session with an emphasis on realistic practices that delegates can realise and share in their own clinical environments.
Learning Objectives:
1. To understand the importance of professional development planning for radiographers in maintaining, developing and improving radiographer competencies.
2. To be aware of the essential role of CPD and further education for radiographers.
3. To appreciate how best to prepare for promotion opportunities.

ESR Publications Committee Session

How to write a scientific paper and how to get it published
Moderators:
R.G.H. Beets-Tan; Amsterdam/NL
F. Sardanelli; San Donato Milanese/IT

A-931 08:30
The study design and the structure of an original article
F. Sardanelli; *San Donato Milanese/IT (f.sardanelli@grupposandonato.it)*

"Original articles" (ORs), also named "original researches", are the most important category of articles published in medical scientific journals (MSJs): they provide new results. Apart from methodologic papers (which explain methods to be applied in ORs), all the remaining categories of articles refer to ORs as a basis. Particular types of ORs are the "technical notes" (presenting new techniques mostly applied to few cases) and "systematic reviews with/without meta-analysis", evaluating all the previous literature on a topic and providing, when possible, new "secondary" evidence by pooling data from published ORs. In short, ORs are the "core" of MSJs. The typical structure an original article (also reflected in the abstract) is composed of four sections: 1. Background/Introduction (WHY the authors made that work and study aim[s]); 2. Methods (HOW the work was done: study design and other related issues such as study population and sample size, imaging/interventional methods, readings, reference standard, statistics, etc.); 3. Results (WHAT the authors

found); 4. Discussion (interpretation of results, comparison with previous works, study limitations, conclusions). Failures in internal/external validity of an OR are determined by biases (systematic distortions) that can affect the study. The validity of a study is in its Methods. However, the most important part of Methods is the study design, sometimes poorly described in radiological papers: prospective/retrospective; transversal (cross-sectional) or longitudinal (cohort); randomized/non-randomized; patients selection; reading blindness; quality and application of the reference standard. Notably, errors in study design cannot be solved after study termination. Study design is more important than statistics.

Learning Objectives:

1. To understand that the core of an original article is the study design.
2. To understand the structure of an original article and the logics of the blocks of the abstract and of the body text.
3. To learn how systematic reviews and meta-analyses are a particular case of original articles.
4. To learn how to avoid the typical errors that candidate a manuscript for rejection.

A-932 08:50

The review process in radiology

Y. Menu; *Paris/FR (yves.menu@sat.aphp.fr)*

In single-blind peer reviews, the reviewer is aware of the author's name and institution, while authors ignore the name of the reviewer. In double-blind peer review, both reviewer and authors are anonymous. Obviously, double blind theoretically eliminates the bias of being more prompt to accept papers from renowned authors and/or institutions. Conversely, the reviewer feels safer to express criticism, avoiding potential professional conflicts. However, double blinding may fail. Commonly, manuscripts are prepared immediately after the study had been presented in a major meeting. For very focused research, the number of potential reviewers is somehow limited. However, in most cases double blind is successful in occulting authors' and reviewers' identity. Several studies have compared these two methods and the conclusions are still unclear. Some studies found that double blind ensured higher quality, while others did not find any difference. Some have even questioned the need for peer review. European Radiology has decided to go for double-blind review, as sources of manuscripts are extremely diverse, while reviewers are from a wide range of countries on all continents, therefore diminishing the risk of blinding failure.

Learning Objectives:

1. To know the variety of the review processes in radiological journals.
2. To be aware of pros and cons of the double blinded review.
3. To know how the Editor handles your manuscript.
4. To learn how to answer to reviewers' criticisms.

A-933 09:10

The review process in other clinical journals

R. Madoff; *Minneapolis, MN/US (madoff@umn.edu)*

Scientific publication is more than the road to academic advancement; it is an opportunity to contribute to your field and to share your work with others who share your interests and expertise. This session will review the principles of manuscript preparation and submission with an eye towards optimizing the chances of acceptance and publication. The practical aspects of how manuscripts are managed on the journal side, peer review, and the editorial process will be emphasized, as will various pitfalls to be avoided. In addition, the opportunities to publish in journals based on related, but non-radiologic, disciplines will be discussed. The goal of this session is to provide practical advice that will be of interest to those early in their publication career as well as to more experienced authors.

Learning Objectives:

1. To know the variety of the review processes in clinical journals.
2. To be aware of pros and cons of single-blinded or unblinded review.
3. To know how the Editor handles your manuscript.
4. To learn how to answer to reviewers' criticisms.

A-934 09:30

Important papers other than original articles

L. Martí-Bonmatí; *Valencia/ES (Luis.Marti@uv.es)*

Science is crucial for the advance of a discipline, but so is critically reviewing and commenting on hot topics. These are highly cited papers that require expertise on the topic and discipline in writing. Review papers focus either on educational aspects of imaging, with a pearls and pitfalls approach (Pictorial Reviews) or as a critical overview on emerging techniques or state-of-the-art topics with an up-to-date and innovational approach (Critical Reviews). Both Pictorial and Critical Reviews might serve the radiological community to have access to the best evidence-based knowledge and to foresee the impact of new approaches within the health-care cycle. Position papers include both imaging guidelines on patient's management aspects and consensus statements on imaging-related topics. These papers define the experts' or social representatives' opinions. Reviewing and critiquing the literature requires the ability to juggle multiple tasks. The authors have to find and critically evaluate relevant material while synthesizing the disperse information with the skills of providing new ideas from already known facts. The EQUATOR Network and the PRISMA Statement for the reporting of systematic reviews will help in some of these items. As general rules, the authors have to define the scope of the article, imposing a well-defined structure on the mess that might be the scientific literature.

Learning Objectives:

1. To know the variety of the review processes in clinical journals.
2. To be aware of pros and cons of single-blinded or unblinded review.
3. To know how the Editor handles your manuscript.
4. To learn how to answer to reviewers' criticisms.

Discussion

08:30 - 10:00 **Room M 4**

Multidisciplinary Session

MS 17
The polytrauma patient

A-935 08:30

Chairperson's introduction

M. Brink; *Nijmegen/NL (M.Brink@rad.umcn.nl)*

Severe trauma is one of the leading causes of death and disability in the world. The outcome of trauma patients improves if the trauma team collaborates closely and systematically. In this case-based and interactive session, surgeons and radiologists will discuss the multidisciplinary approach to the polytrauma patient.

Session Objectives:

1. To understand how radiologist can be an active member of the trauma team.
2. To learn how to communicate effectively in the trauma setting.
3. To learn how to optimise logistics and to tailor computed tomography (CT) imaging for an ideal setting of trauma CT acquisition.
4. To understand current controversies and recent developments in diagnosing injuries in the polytrauma patient.
5. To be updated on strengths and weaknesses of current resources and guidelines on polytrauma trauma imaging.

Author Disclosure:

M. Brink: Research/Grant Support; Toshiba Medical Systems.

A-936 08:33

Guidelines and game changers: the radiologist's perspective

M. Brink; *Nijmegen/NL (M.Brink@rad.umcn.nl)*

The outcome of trauma patients improves if the trauma team collaborates closely and systematically. As a radiologist, you therefore have to be prepared to be an active member of the trauma team. This introduction will discuss the three most important issues that radiologists should address prior to image evaluation of the polytrauma patient. Which imaging modalities are justified? Which modalities should better not be used? And how should you tailor your CT protocol?

Learning Objectives:

1. To be updated on current, most relevant guidelines on trauma imaging.
2. To discuss the most relevant CT parameters that can be tailored in the setting of polytrauma.

Author Disclosure:

M. Brink: Research/Grant Support; Toshiba Medical Systems.

A-937 08:40

The primary survey: talking ABC

J. Peters; *Nijmegen/NL (Joost.Peters@radboudumc.nl)*

The trauma surgeon's perspective: In the care of the trauma patient, time is of essence and prompt focussed action is frequently needed. The most life-threatening conditions should be diagnosed and addressed first: "Treat first, what kills first". These interventions are prioritised using the simple guidelines of the Advanced Trauma Life Support Course (ATLS), using the first letters of

the alphabet. This method provides a solid framework and common language for all involved in the care of the trauma patient. Radiologists are an essential link in the chain of trauma care. Even more, the role of the radiologist has changed in the last years with the widespread use of focussed ultrasound in trauma and low-threshold CT scanners available in the emergency department. As an active trauma team member, the radiologist needs to be aware of the phases in the trauma survey and should provide the proper input needed for decision-making. The radiological diagnostics need to be in sync with the trauma screening using "ABCDE". To obtain optimal communication and consequently good results, the fundamental guidelines of ATLS must be familiar to all involved in the primary trauma care in the emergency department; including the radiologist. A team briefing prior to patient arrival is very helpful in creating team awareness and a common-team approach.

Learning Objectives:

1. To learn how to communicate effectively within the trauma team according to ATLS principles.
2. To understand which traumatic diagnoses can be game changers during the primary survey.
3. To discuss radiology in the trauma room: how to optimise logistics in the acute setting.

A-938 08:55

The secondary survey: from head to toe

M. Holla; *Nijmegen/NL (Micha.Holla@radboudumc.nl)*

According to the ATLS, after the assessment of vital functions of a trauma patient, the secondary survey is performed. In patients with Injury Severity Scores (ISS) <16, the treating surgeon often prefers high-quality imaging of the extremities . However, in patients with severe injuries of multiple organs (ISS>16), a quick imaging procedure is needed. Fast CT scanograms and single-direction radiographs can be sufficient to perform damage control orthopaedics. High-resolution imaging of extremities must not delay the treatment of life-threatening injuries. Quick clearance of the spine can reduce the time of unnecessary spinal immobilization and its negative side effects. After the secondary survey, effective communication of a resume of all injuries highly assists in planning further treatment. A fixed order, reporting on different anatomical regions (from brain, face, neck, spine, thorax, abdomen, pelvis, right arm, left arm, right leg, left leg), can increase the speed and accuracy of this communication to all participating disciplines . This session focuses on how to effectively communicate the radiological findings to the orthopaedic surgeon and which pitfalls should be avoided.

Learning Objectives:

1. To get to know how orthopaedic surgeons approach polytrauma extremity trauma.
2. To understand how to report secondary survey findings to the surgeon.
3. To learn from diagnostic pitfalls in orthopaedic injuries and how to avoid them.

A-939 09:15

The neuroradiologist's perspective

F.J.A. Meijer; *Nijmegen/NL (Anton.Meijer@radboudumc.nl)*

Evaluation of vital functions (ABC) precedes neurological evaluation (D) in the management of trauma patients, which is also applicable to the diagnostic imaging strategy. Nevertheless, adequate and fast neurological evaluation is essential to initiate early treatment when indicated, to reduce morbidity and mortality. Every radiologist on call should therefore be skilled in the evaluation of TBI in the acute stage as part of the polytrauma patient and not consider TBI as an area reserved for specialized neuroradiologists. In this lecture, diagnostic imaging in head trauma will be discussed focused on the imaging strategy and the clinical relevance of imaging findings. Initial diagnostic imaging in the acute stage of traumatic brain injury (TBI) mainly concerns non-contrast CT. The clinical relevance for differentiating primary from secondary TBI will be emphasized. Furthermore, the role of head and neck CTA and the added value of brain MR imaging will be discussed. Finally, tips and tricks for choosing an appropriate CT angiography and MRI scanning protocol will be provided.

Learning Objectives:

1. To learn a structured approach for image interpretation of head trauma.
2. To learn about the clinical relevance of imaging findings in head trauma.
3. To give the updated on current knowledge and imaging guidelines, with emphasis on blunt cerebrovascular injuries.

09:35

Multidisciplinary case presentation and discussion

08:30 - 10:00 **Room M 5**

E³ - ECR Master Class (Emergency Imaging)

E³ 1726b

Emergencies following tumour therapy

A-940 08:30

Chairperson's introduction: The role of imaging in the early detection of complications in oncologic treated patients

D.R. Kool; *Amsterdam/NL (dignakool@gmail.com)*

Oncology patients can present with life-threatening conditions. Those conditions may be caused by local expansion and complications of the primary tumour or metastases, as for example haemorrhage, vena cava superior syndrome or spinal cord compression. Furthermore, complications can also be caused indirectly by the malignancy, as for instance thromboembolic disease or paraneoplastic metabolic or neurological symptoms. Life-threatening complications can also be the unwanted consequence of tumour therapy. Surgery, radiotherapy, interventional radiology (IR) procedures, chemotherapy and immunotherapy, each, have their own set of potential complications that can present in the emergency setting. Haematologic and metabolic complications are mainly diagnosed with clinical and laboratory findings. For other complications, diagnostic imaging is essential for making the correct diagnosis and imaging will influence treatment. Complications of surgery, radiotherapy and IR procedures will mostly be in the vicinity of the treated area. Adverse effects of systemic therapies, chemotherapy and immunotherapy can occur at remote sites. Complications of oncological treatment can be life threatening. However, when treated on time, they often are reversible. Recognizing the imaging findings of complications of tumour therapy timely and accurately is of the upmost importance. Immunotherapy is a more recent treatment and the adverse effects of immunotherapy differ from the more familiar complications of the other tumour therapies. Immunotherapy is increasingly used and the radiologist will encounter these complications more frequently. In this session, neurological complications and complications in the chest and abdomen will be discussed and their imaging findings demonstrated.

Session Objectives:

1. To learn about different approaches in tumour therapy.
2. To understand the radiological appearance of complications.
3. To appreciate the role of different imaging modalities in further management of patients.

A-941 08:35

A. Neuro

C. Calli; *Izmir/TR (cem.calli@gmail.com)*

Post-treatment neurooncological emergiencies are usually underdiagnosed by imaging methods although the clinical presentation of these conditions are obvious in many cases. The aim of this presentation is to create awareness for Radiologists who are dealing with follow-up of neurooncology patients. Neurooncology patients may suffer emergency situations secondary to either surgery, or chemotherapy, or radiotherapy. These emergency conditions mostly need the confirmation of imaging techniques to fulfill the diagnosis. Thus the radiologists should be familiar of the imaging findings of these emergency situations, which will lead the Neurooncologists to decide whether to continue the therapy or not, plus to decide further treatment options for these conditions.

Learning Objectives:

1. To be familiar with different strategies in CNS tumour therapy.
2. To understand the most common imaging findings in emergent clinical scenarios.
3. To learn how to recognise life-threatening complications.

A-942 09:00

B. Chest

H. Prosch; *Vienna/AT (helmut.prosch@meduniwien.ac.at)*

Lung cancer is the most common cause of cancer-related death in Western countries. Treatment of lung cancer is based on three pillars: surgery; radiation therapy; and systemic therapy. Imaging plays a major role in treatment decisions, response evaluation, and last, but not least, also in assessing adverse events following therapy. After surgery, acute (early) complications include pulmonary oedema (hydrostatic, permeability), atelectasis, hemothorax, acute infections, and bronchopleural fistulas. Acute complications after radiation therapy include mainly early radiation pneumonitis and infections. Following systemic therapy, in addition to infections, non-infectious

pneumonitis and sarcoid-like reactions are important complications that must be considered when investigating a patient who presents with acute symptoms.
Learning Objectives:
1. To be familiar with modern approach to malignant chest tumour therapy.
2. To learn how to differentiate clinically important complications.
3. To understand how to look for the early signs of severe and urgent conditions.
Author Disclosure:
H. Prosch: Advisory Board; Boehringer Ingelheim, Roche, MSD. Speaker; Boehringer Ingelheim, Roche, MSD, BMS.

A-943 09:25

C. Abdomen
R. Basilico; *Chieti/IT (rbasilic@unich.it)*

Despite many improvements in perioperative, post-ionising radiation therapy or pharmacological morbidity in abdominal tumour treatments, acute complications after tumour therapies in the abdomen are still common. A number of different therapies, including surgery, by means of laparoscopic approach or minimally invasive robotic surgery, radiotherapy, chemotherapy and immunotherapy, may be effectively used to treat abdominal tumours. However, these kinds of treatments are not devoid of complications and, last, abdominal emergencies may occur after therapies used for extra-abdominal tumours. Cross-sectional imaging and particularly CT play a crucial role in the diagnosis and management of the most common abdominal emergencies after tumour therapies. The main complications following abdominal, urologic or gynaecologic surgery include peritonitis, abscesses, haemorrhage, small bowel obstruction and anastomotic leaks. Specific complications following hepatobiliary surgery include bile leakage and bile duct injuries: US and MRI with magnetic resonance cholangiopancreatography (MRCP) sequencers are the preferred modalities for assessment of the postoperative biliary tract. Less common postoperative emergencies are vascular complications such as pseudoaneurysms. Small bowel obstruction caused by radiation enteritis represents one of the most frequent abdominal complications after radiotherapy of prostate and rectal cancer, whereas a less known disease such as pneumatosis cystoides intestinalis may be associated with systemic chemotherapy. Due to the increasing use of immunotherapy for different types of tumours, new inflammatory and immune-related adverse events occur also in the abdomen and need to be managed by a multidisciplinary approach.
Learning Objectives:
1. To learn about different techniques used in abdominal tumours therapy.
2. To be familiar with possible complications.
3. To understand the effectiveness of imaging modalities in evaluation of emergent complications.

09:50
Panel discussion: What is the impact of complications findings on the further management of oncologic patients?

10:30 - 12:00 **Room A**

E³ - ECR Academies: Interactive Teaching Sessions for Young (and not so Young) Radiologists

E³ 1821
Advances in musculoskeletal techniques: whole-body MR

A-944 10:30

A. Oncologic application
F.E. Lecouvet; *Brussels/BE (frederic.lecouvet@uclouvain.be)*

This interactive session will illustrate the wide range of indications of whole-body MRI in oncology, the protocols and technical requirements, the contribution of anatomic and functional diffusion sequences and their respective strengths and pitfalls. Latest technical refinements and efforts to decrease examination duration and tailor sequences to the targeted disease will be presented. Simple and more complex cases will highlight how the technique extends the exploration of the body beyond the musculoskeletal system to lymph nodes and visceral metastases screening. Specific cases will show how WB-MRI has become a modality of choice for detecting bone metastases from many cancers and bone marrow involvement by multiple myeloma or lymphoma. The comparison will be provided with bone scintigraphy, CT and PET by the time of lesion detection and for assessment of the response to treatment.
Learning Objectives:
1. To become familiar with the technical aspects of whole-body MR.
2. To learn the role of whole-body MR in the management of oncologic patients.

A-945 11:15

B. Non-oncologic applications
M. Faruch; *Toulouse/FR (mariefaruch@hotmail.com)*

Thanks to improvement in technique for shortening of examination duration, whole-body MR imaging can now be feasible for use in routine clinical practice in numerous skeletal and neuromuscular disorders as seronegative rheumatologic disease, multifocal ischaemic lesions, multifocal eosinophilic granulomas and inflammatory myopathies. Whole-body MR could be helpful for early diagnosis, evaluation of the extent and activity of the disease, and evaluation of therapeutic response. Current MRI protocols usually include anatomic sequences as T1-weighted and water-sensitive sequences as STIR, but could also provide functional DWI sequences.
Learning Objectives:
1. To become familiar with the indications for whole-body MR in non-oncologic patients.
2. To learn the role of whole-body MR in the management of non-oncologic musculoskeletal disorders.

10:30 - 12:00 **Room B**

ESR meets China

EM 3
A glance of China through images

Presiding:
B. Hamm; Berlin/DE
Z.Y. Jin; Beijing/CN

A-946 10:30

Introduction
Z.Y. Jin; *Beijing/CN (jin_zhengyu@163.com)*

The Chinese radiological system is continuously innovating. Fifteen years previously, radiologists were writing reports with pens and watching stacks of films from the light box in a dark room. Patients came to the technician with handwritten prescriptions and registration information. Now, we have jumped into a new era. The workflow is greatly facilitated by automatic machine-facilitated workflow processes. Patients receive digital imaging. Radiologists sit in front of a computer and view images from picture archiving and communication sytem (PACS). Quantitative radiology and precision radiology have become the pursuit of us in our clinical practice. Data show that CT machine possession per million population in China increased from 5.5 in 2007 to 8.6 in 2010, although still low compared to the developed countries. Health-care PACS informational process market survey in 2015 showed that about 50% general public hospitals and 33% community hospitals have PACS. To improve the radiological service in China, multiple factors should be taken care of, not only the equipment, but also the education of radiologists/technicians, the facilitation and optimization of workflow, and the appropriateness and efficiency of patient care. With more than 13.8 billion population and varied economical situation in China, we are still facing great challenges. It is our goal to improve the quality of medical service, especially in rural areas. We will also encourage private health centres, imaging centres and Web-based consulting services in addition to established public health centres. We would like to stretch our arms towards globalization and welcome international communication and collaboration.
Session Objectives:
1. To give an overview of the current situation and trend of radiology in the mainland of China.
2. To show a few examples of the diversity of clinical radiological researches in China.
3. To introduce the special focuses of Chinese radiological society.

10:39
Interlude 1: Experience of Chinese traditional music

A-947 10:42

Multiparameteric analysis in imaging liver disease

F.-H. Yan; *Shanghai/CN (ruijin665727@qq.com)*

China has a serious chronic liver disease burden, especially HBV/HCV-related cirrhosis and hepatocellular carcinoma (HCC). According to the population-based cancer registration data of Chinese National Central Cancer Registry, HCC is the third most common cancer and the second most cause of cancer-related deaths. Over 80% of HCC cases develop in cirrhotic liver by a process of multistep hepatocarcinogenesis, from regenerative nodule (RN), to dysplastic nodule (DN), and finally to overt HCC. Multiparametric imaging plays an important role for HCC surveillance, characterization with benign cirrhosis-associated nodules and noninvasively diagnostic algorithm in these extremely high-risk patients. To date, the diagnosis of HCC is mainly based on its haemodynamic hallmarks, i.e. arterial hyperenhancement followed by venous/delayed washout on multiphasic CT and MRI. It forms the foundation of current Western and Eastern HCC practice guidelines. Ancillary features, especially the presence of restricted diffusion on diffusion-weighted imaging (DWI), are preferred for early detection of HCC and to increase diagnostic confidence. MR imaging with hepatocyte-specific contrast agents has shown great promise in identifying high-grade DN and early HCC prior to neo-arterialization and progression to overt HCC. It is gradually changing the standard of diagnosis of HCC and may well be endorsed in future guidelines. Additionally, quantitative imaging techniques, including dual-energy CT, US- or MRI-based elastography, have demonstrated increasing roles for the evaluation of diffuse liver disease such as liver fibrosis, siderosis and nonalcoholic steatohepatitis.

Learning Objectives:

1. To give an introduction to the imaging features of common liver diseases in China.
2. To understand the advantages of multiparameteric analysis of liver imaging.
3. To show some interesting cases.
4. To discuss the clinical application of multiparametric analysis in abdominal pathologies.

A-948 10:57

Multimodality imaging for insulinoma detection

H.-D. Xue; *Beijing/CN (bjdanna95@163.com)*

Insulinomas are the most common hyper-functioning pancreatic endocrine tumours. Clinically, patients with insulinomas are characterized by hypoglycaemic symptoms caused by insulin overproduction. Insulinomas are generally benign and curable with surgery. Recurrence after resection is rare. Multiple lesions can be seen in patients with multiple endocrine neoplasia (MEN) syndrome. For patients with clinically suspected insulinomas, determining the location and number of tumours accurately with imaging workup allows for less invasive surgeries. Historically, detection of insulinomas by cross-sectional imaging has been difficult. Nowadays, a greater sensitivity for insulinoma detection has been reported with state-of-the-art CT and MR scanners. Routine dual-phase enhanced CT has relatively low sensitivity for insulinoma detection because of the presence of isoattenuating tumours, which account for around 25% of all tumours. Volume perfusion CT (VPCT) of the pancreas reveals increased blood flow of the tumour, as most 'isoattenuating tumours' show transient hyperenhancement, which may not be captured by traditional scanning protocols. Intra-individual comparative study shows that VPCT and mp-MR had similar high accuracy in insulinoma detection, and both were significantly more accurate than biphasic CECT. The intrinsic superior soft-tissue contrast with MRI helps to identify the tumour more easily without using contrast agents. Since insulinomas are quite small, the improved signal to noise of 3T MR compared to 1.5T and the introduction of high-resolution DWI are key factors for the improved diagnostic performance compared to the earlier reports.

Learning Objectives:

1. To give a review of "insulinoma imaging" in the past.
2. To understand the advantages of perfusion CT, multiparametric MR and PET/CT with special tracers.
3. To discuss the potential clinical workflow and decision tree for imaging patients with suspected insulinomas and other functional pancreatic endocrine tumours.

A-949 11:12

Interventional therapy for hepatocellular carcinoma: Chinese experiences

X.-G. Li; *Beijing/CN (xglee88@126.com)*

In China, due to the high prevalence of HBV infection, the incidence rate of hepatocellular carcinoma is still very high. According to the 2017 Chinese cancer statistics report, HCC ranks 3rd and 6th in the incidence of cancer of men and women in urban areas, and it ranks 3rd in the mortality rate. The features of Chinese HCC patients include background of liver cirrhosis, relatively late stage, large tumor size and high rate of portal vein thrombus. Less than 20% of patients are candidates for liver resection or transplantation, so interventional treatment plays an important role in the management of HCC. Y90 microspheres are not available in the Mainland of China, so TARE is not routinely performed except for those in Hong Kong or Taiwan. In recent several years, DEB-TACE is accepted as an alternative for cTACE in selected patients. Thermal ablation including RFA, MWA and cryoablation is usually performed in combination with TACE. For lesions located at high-risk sites, PEI or 125I seed implantation is a good option and has achieved satisfactory results. Portal vein recanalization with 125I seed loading stent or endovascular RFA is attempted in some tertiary centres.

Learning Objectives:

1. To learn the epidemiology and special features of hepatocellular carcinoma in China.
2. To review the various interventional procedures and compare their efficacies in treating patients with hepatocellular carcinoma.
3. To understand the indications and clinical applications of interventional procedures to treat hepatocellular carcinoma.

11:27

Interlude 2: Experience of Chinese tea culture

A-950 11:30

Application of artificial intelligence in prostate imaging

X.-Y. Wang; *Beijing/CN (cjr.wangxiaoying@vip.163.com)*

A prostate mpMRI-CAD system has been developed. It can be used for identification of clinically significant prostate cancer with high prediction efficacy. It was validated by a multicentre clinical trial. After integrating the CAD system into the diagnostic process as a second reader, the performance of less experienced readers can be significantly improved.

Learning Objectives:

1. To learn about the basics and feasibility of applications of artificial intelligence.
2. To understand the clinical value of applying artificial intelligence in detection, prognosis and treatment evaluation of prostate cancer.
3. To learn the technique and clinical application of artificial intelligence in abdominal pelvic imaging.

A-951 11:45

Radiomics nomogram to predict lymph node metastasis in colorectal cancer

Z. Liu; *Guangzhou/CN (zyliu@163.com)*

To develop and validate a radiomics nomogram for preoperative predicting of lymph node (LN) metastasis in colorectal cancer (CRC). The prediction model was developed in a primary cohort consisting of 326 clinicopathologically confirmed CRC patients from January 2007 to April 2010. Radiomics features were extracted from portal venous-phase computed tomography (CT) of CRC. Lasso regression model was used for data dimension reduction, feature selection and radiomics signature building. Then, multivariable logistic regression analysis was used to develop the predicting model, with radiomics signature, CT-reported LN status and independent clinicopathological risk factors incorporated, which was presented with a radiomics nomogram. The performance of the nomogram was assessed with respect to its calibration, discrimination and clinical usefulness. Internal validation was assessed. An independent validation cohort contained 200 consecutive patients from May 2010 to December 2011. The radiomics signature consisting of 24 selected features was significantly associated with LN status (p<0.0001 for both the primary and validation cohorts). The predictors contained in the individualized prediction nomogram included the radiomics signature, CT-reported LN status and carcinoembryonic antigen (CEA) level. The addition of histological grade into the nomogram failed to show incremental prognostic value. The model showed good discrimination with a C-index of 0.736 (0.759 and 0.766 through internal validation), as well as a good calibration. Application of the nomogram in the validation cohort still gave good discrimination (C index=0.778 [95%CI: 0.769-0.787]) and good calibration. Decision curve analysis demonstrated that the radiomics nomogram had clinical usefulness. This study presents a radiomics nomogram incorporating the radiomics signature, CT-reported LN status and clinical risk factors, which can be conveniently used to facilitate the preoperative individualized prediction of LN metastasis in CRC.

Learning Objectives:

1. To learn about the basics of radiomics and feasibility of clinical applications.
2. To understand the clinical value of radiomics nomogram in predicting lymph node metastasis in colorectal cancer.
3. To learn the potential applications of radiomics in various oncological studies.

10:30 - 12:00 **Room F1**

E³ - European Diploma Prep Session

E³ 1823
Paediatric

A-952 10:30
Chairperson's introduction
V. Donoghue; *Dublin/IE*

The aim of this session is to outline the imaging findings seen in congenital and acquired conditions encountered in the brain, chest and abdomen in the paediatric and adolescent population. With improvements in ultrasound and MR imaging techniques, many congenital abnormalities have now been detected antenatally. However, imaging after birth is usually requested to confirm the diagnosis and it may also provide additional information to the clinician. Acquired disorders such as small bowel volvulus and intussusception are true clinical emergencies requiring urgent treatment. Therefore, detailed knowledge of the imaging features in these conditions is mandatory. In children with respiratory distress, the chest radiograph is often invaluable in suggesting a diagnosis. CT, however, is frequently required and knowledge of good technique using the appropriate CT dose is required to get the most information possible. In children with tumours, recognition of detailed imaging findings is important in aiding the correct tumour grading and therefore in guiding appropriate therapy.
Session Objectives:
1. To understand the imaging features of the most common congenital and neoplastic disorders of the brain in children and adolescents.
2. To describe the imaging presentations of the most common disorders of the lung and mediastinum in the paediatric age group.
3. To become familiar with the imaging features of important acute disorders of the abdomen in children and adolescents.

A-953 10:36
A. Paediatric neuro imaging
M.I. Argyropoulou; *Ioannina/GR (margyrop@cc.uoi.gr)*

Age-related changes depending on neuronal migration, gyration and myelination have been described in the paediatric brain. These changes are responsible for the different imaging patterns as the paediatric brain matures. Conventional MR sequences along with diffusion tensor imaging (DTI) and functional MRI (f-MRI) offer important information regarding the structural and functional maturation of the brain. Congenital malformations of the brain can be assessed with conventional sequences, but DTI using ADC, FA maps and tractography and f-MRI offer valuable structural and functional information and help in the detection of additional malformations. The incidence and localization of different brain tumours depend on the age. Conventional MRI offers useful information, but further evaluation with DTI, susceptibility contrast-enhanced perfusion imaging, spectroscopy and f-MRI is very important in the diagnostic workup and before the application of any therapeutic scheme. A number of brain tumours may metastasize through CSF and additional imaging of the spinal canal to look for seeding metastases is necessary. MRI is the modality of choice for imaging the paediatric brain; nevertheless, in neonates and infants, brain ultrasound with colour Doppler should be the first imaging approach. Brain ultrasound offers valuable information provided that a state-of-the-art technique is applied.
Learning Objectives:
1. To describe the normal development of the brain.
2. To explain the most common congenital disorders of the brain.
3. To understand the most common brain tumours in children and adolescents.

A-954 11:04
B. Paediatric chest imaging
C. Owens; *London/UK (owensc@gosh.nhs.uk)*

Normal pulmonary and cardiovascular development will be reviewed leading on to a comprehensive overview of congenital disorders of the lung and mediastinum and their imaging features. This will include bronchopulmonary sequestration, congenital pulmonary adenomatoid malformations and thoracic duplication cysts along with an overview of congenital cardiac disorders. The role of imaging in neonatal respiratory distress syndrome will be reviewed along with a discussion of when and how to use CT in particular cases. Lastly, paediatric thoracic neoplastic disease will be comprehensively reviewed.
Learning Objectives:
1. To describe the normal development of the lung and mediastinum.
2. To explain imaging features of congenital disorders of the lung and mediastinum.
3. To understand the imaging manifestations of respiratory distress and bronchopulmonary dysplasia in infants.
4. To describe the most common tumours of the chest in children.

A-955 11:32
C. Paediatric abdominal imaging
S.G.F. Robben; *Maastricht/NL (s.robben@mumc.nl)*

Paediatric abdominal diseases are highly age dependent. Newborn infants may have congenital diseases as Hirschsprung's disease or meconium ileus or may develop necrotising enterocolitis, incarcerated inguinal herniation and midgut volvulus. Infants and preschool children have intussusceptions, urinary tract infections and (rare) haemolytic uraemic syndrome. Children and adolescents have appendicitis, genito-urinary infections, ovarian torsion and Henoch Schonlein purpura. Abdominal neoplasms can occur at any age, even at birth. Considering radiation dose in children and the excess value of ultrasonography (US) in small individuals, US plays an important role as initial diagnostic modality in paediatric abdominal emergencies. Sensitivity and specificity for US in diagnosing intussusception, midgut volvulus, urinary tract abnormalities and appendicitis is over 90%. Conventional abdominal radiographs or fluoroscopy are valuable in Hirschsprung's disease, meconium ileus, malrotation and necrotising enterocolitis. I consider CT as an additional technique when the initial techniques (US and conventional radiography) are inconclusive. MRI is seldom indicated in paediatric patients with abdominal emergencies because of motion artefacts in anxious children and sometimes limited MR capacity. However, in children with abdominal neoplasms it is the modality of choice.
Learning Objectives:
1. To understand the imaging features of congenital disorders of the abdomen.
2. To describe the diagnostic evaluation and imaging presentation of appendicitis in children.
3. To describe the diagnostic evaluation and imaging presentation of volvulus and intussusception in children.
4. To understand the imaging presentation of the most common oncologic

MR in ischaemic cardiomyopathies
F. Cademartiri; *Monastier di Treviso/IT (filippocademartiri@gmail.com)*

Ischaemic cardiomyopathy is the leading cause of morbidity and mortality in the western world. Over the years, several improvements in terms of knowledge, diagnostic capabilities and treatment options have been developed in such a way that today we are in a constant update of our technologies and treatments. Cardiovascular Magnetic Resonance (CMR) is by far the most flexible and complete imaging modality that can be applied to the evaluation of ischaemic cardiomyopathies. It can provide anatomy, function, flow, ischemia and tissue characterisation. CMR is considered the reference standard for the assessment of inducible ischemia and myocardial viability. Modern MR equipment can deliver a huge amount of information that require wide technical and clinical knowledge to be handled correctly. Especially the newer approaches with quantitative tissue mapping that are being introduced in the clinical field. With the advancement of technology also 3T CMR have become mainstream and able to add some value in certain specific fields. With the rapid growth of Cardiac Computed Tomography as the elective non invasive anatomical tool for the assessment of the coronary arteries CMR becomes the bets tool to complete a Cardiovascular Imaging Section (or viceversa).

Learning Objectives:
1. To learn about the MR derived imaging biomarkers in ischaemic cardiomyopathy.
2. To understand the value of cardiac MR to indicate and guide revascularisation in ischaemic cardiomyopathy.
3. To appreciate the potential of cardiac MR to predict the outcome of revascularisation.

A-960 13:00

MR in non-ischaemic cardiomyopathies

C. Peebles; *Southampton/UK (Charles.Peebles@suht.swest.nhs.uk)*

Non-ischaemic cardiomyopathies are a heterogenous group of inherited and acquired diseases affecting myocardial function. Cardiac MR is unsurpassed in its ability to quantify myocardial function, identify the pattern and extent of myocardial scar, and access myocardial oedema and diffuse fibrosis. Established techniques such as late gadolinium enhancement are critical to establishing a diagnosis, particularly in differentiation from ischaemic cardiomyopathy. Newer techniques such as tissue mapping are still finding their role in clinical practice, but seem to be promising tools for both diagnosis and prognosis of cardiomyopathies. This lecture will use predominantly case-based discussion to understand the established and evolving imaging biomarkers for non-ischaemic cardiomyopathy and how these are applied in clinical practice. The focus will be on establishing an accurate diagnosis in the major non-ischaemic cardiomyopathies, whilst highlighting areas of diagnostic challenge and uncertainty. The potential of CMR to provide prognostic information and the associated evidence base will also be explored.

Learning Objectives:
1. To learn about the MR derived imaging biomarkers in non-ischaemic cardiomyopathies.
2. To understand the role of cardiac MR in primary and secondary cardiomyopathies.
3. To appreciate the discriminatory power of cardiac MR in cardiomyopathies.

Infective/inflammatory disorders

F.M.H.M. Vanhoenacker; *Antwerp/BE (filip.vanhoenacker@telenet.be)*

Osteomyelitis is divided into acute, subacute and chronic osteomyelitis. Pathophysiological factors that determines imaging are patient's age, route of contamination, virulence of the causative micro-organism and the immune status of the patient. In haematogenous spread, the site and extent of the infection depends primarily on the vascularisation. The metaphysis is the common site for haematogenous osteomyelitis in children over 18 months, due to stasis of slow-flowing blood. In infants and adults, the presence of transphyseal vessels may cause spread of the infection to the epiphysis. Imaging plays a pivotal role in confirming the diagnosis of musculoskeletal infection, determining the disease extent and guiding early treatment. Plain radiography is not very sensitive for early diagnosis. Ultrasound is a reliable tool to detect subperiosteal spread in children, but its use in adults is restricted to evaluation of soft tissue infection and for aspiration of infected joints. In adults, MRI is the preferred modality, although CT may detect sequestrum formation in chronic osteomyelitis. SpA consists of a spectrum of chronic inflammatory disorders that are distinct from RA. Ultrasound is useful for grading of synovitis and early detection of erosions of peripheral joints in RA. SpA has a predilection for the axial skeleton. MRI is the preferred technique for early diagnosis and detection of active inflammatory lesions by demonstrating bone marrow oedema at the sacro-iliac joints. Two or more areas of BME or one focus of BME on at least two consecutive 3-mm slices is needed to reliably diagnose axial SpA.

Learning Objectives:
1. To learn about the pathomechanisms involved in inflammatory and infections disorders.
2. To understand the imaging appearances and their differential diagnosis in the acute, sub-acute and chronic phases of infection.
3. To become familiar with the spectrum of imaging features of inflammatory disorders in the axial and peripheral skeleton.

A. Liver tumours

T. Denecke; *Berlin/DE (timm.denecke@charite.de)*

Besides the top three malignant (HCC, CCC, metastases) and the top three benign liver tumours (haemangioma, FNH, adenoma), there is a large variety of rare entities and subtypes, which can be demanding regarding their imaging diagnostics. In this session, a number of cases will be presented to illustrate the typical and also some challenging findings of focal liver lesions, which the radiologist should know, always keeping in view the potentially severe consequences of the radiologist's judgement for patient management.

Learning Objectives:
1. To become familiar with the differential diagnosis.
2. To identify the key imaging findings.

Author Disclosure:
T. Denecke: Grant Recipient; Siemens. Speaker; Siemens, Bayer, Toshiba.

Chairperson's introduction

T. Struffert; *Erlangen/DE*

"no abstract submitted"

Session Objectives:
1. To understand the principles and techniques of angiography and image-guided interventions.
2. To become familiar with the different methods of hepatobiliary interventions.
3. To describe the most common vascular interventions.

A-971 14:06

A. Basic principles of angiography and image-guided interventions

T.K. Helmberger; *Munich/DE (Thomas.Helmberger@klinikum-muenchen.de)*

Basic knowledge of the indications and contraindications, patient preparation, typical interventional techniques, outcome and complications in vascular and non-vascular interventions is essential for every radiologist. Knowledge of the typical arterial and venous anatomy and potential variants is of ample importance both from a diagnostic perspective and with respect to planning optimal access routes, puncture site/technique, and pathways for transvascular and percutaneous procedures. These procedures include (1) a broad spectrum of transvascular interventional techniques such as vascular recanalization (e.g. balloon and stent angioplasty), occlusion (e.g. bleeding, vascular malformations), and perfusion (e.g. trans-arterial oncological interventions) in a wide variety of diseases; and also (2) basic percutaneous diagnostic (i.e. biopsy, fluid evacuation) and therapeutic procedures (i.e. drainage of e.g. abscess, haemorrhage). The understanding of the comprehensive options and benefits of these interventional techniques, together with the proper use of

image guidance makes the radiologist a valuable companion to almost all clinical specialities in solving diagnostic and therapeutic tasks.

Learning Objectives:

1. To describe the normal anatomy and normal variants of the arterial and venous vascular system.
2. To understand diagnostic and interventional angiographic techniques.
3. To explain basic percutaneous image-guided techniques including abscess drainage and biopsy taking.

Author Disclosure:

T.K. Helmberger: Consultant; Boston Scientific.

A-972 14:34

B. Image-guided interventions in oncology

J.I. Bilbao; *Pamplona/ES (jibilbao@unav.es)*

Interventional oncology (IO) is an established pillar in the management of oncologic patients. Endovascular access allows (almost) any kind of therapies. By using devices it is possible to permeabilize, occlude, obtain material, infuse chemotherapy, administer brachytherapy, implant devices or genes, among others. IO within the multidisciplinary management could offer curative procedures such as percutaneous or endovascular ablations using physical or pharmacological methods; thus, radiologists are in the front line of patients´ care which carries clinical responsabilities. IO is crucial in the downstaging/bridging towards a curative treatment such as surgery; these adjunctive procedures, are fundamental in allowing patients to be cured and should be actively promoted by radiologists. IO procedures can participate in the palliation of symptoms, offering to bring them within the established treatment protocols; as happens with any bleeding related directly with the tumour or indirectly with its treatment. IO offer other procedures essential to cancer care, but not considered primarily therapeutic such as venous access. Liver´s almost exclusive characteristic of having a dual vascularisation offers performing aggressive treatments targeting the tumour while preserving the healthy parenchyma. Particularly in the case of hepatocellular carcinoma, chemoembolization (particles with chemotherapy) and radioembolization (particles with a radioisotope) are included in the therapeutic protocol for this devastating disease. Non-vascular procedures, such as percutaneous ablation, have proved their efficacy, with improvement in overall survival in a certain group of liver tumours and are basic in the management of a wide range of lung and renal tumours.

Learning Objectives:

1. To describe the basic technical and methodological principles of imaging-guided interventions in oncological disorders.
2. To understand the principles of and indications for vascular interventions in cancer, e.g. transarterial (chemo)embolisation techniques of the liver.
3. To become familiar with the principles of and indications for percutaneous image-guided interventions in oncological disorders including thermal ablation techniques.

C. Vascular interventions

J.A. Reekers; *Amsterdam/NL (j.a.reekers@amc.uva.nl)*

In the exam preparation talk, a variety of different vascular techniques will be discussed. Endovascular treatment options of atherosclerotic diseases will be explained, and common angioplasty procedures, such as renal, iliac and femoral angioplasties, understood. The indications and techniques for arterial stenting procedures will be described, and techniques of arterial embolisation and coiling explained. All techniques will be illustrated with related patient cases.

Learning Objectives:

1. To explain endovascular treatment options of atherosclerotic diseases.
2. To understand common angioplasty procedures, such as renal, iliac and femoral angioplasties.
3. To describe indications and techniques for arterial stenting procedures.
4. To explain techniques of arterial embolisation and coiling.

Long-term follow-up magnetic resonance elastography after novel direct antiviral therapy in chronic hepatitis C virus induced liver fibrosis
S.R. Marticorena Garcia, J. Guo, H. Tzschätzsch, C.E. Althoff, M. Dürr, F. Halleck, B. Hamm, T. Fischer, I. Sack; *Berlin/DE (stephan.marticorena-garcia@charite.de)*

Purpose: Chronic hepatitis C virus (HCV) infection predisposes to liver fibrosis. The purpose of this study is to non-invasively monitor elastic properties of the liver and kidney transplants (KTX) using multifrequency magnetic resonance elastography (MRE) after direct antiviral therapy.
Methods and Materials: In this prospective and longitudinal study 13 patients with chronic HCV infection and biopsy proven liver fibrosis were treated with direct-acting antivirals (Daclatasvir/Sofosbuvir). Shear wave speed (SWS) of liver and KTX was measured by multifrequency MRE at baseline (before therapy) and during a follow-up period after therapy at 3, 6 and 15 months. The results were compared to a healthy control group (CTR, n=7). Laboratory results were obtained at each time point.
Results: Mean time point to reach undetectable viral RNA was 22±13 days and remained stable during the entire follow-up period in all responders to treatment. Compared to baseline (1.67±0.33 m/s), analysis of repeated measurements showed a significant decrease in liver SWS at 6 months (1.56±0.27 m/s; $p<0.01$), being stable at 15 months (1.55±0.26 m/s; $p<0.05$). Viral relapse occurred in one subject and liver SWS remained unchanged after treatment, despite of serological marker response. No changes of renal stiffness were observed in KTX.
Conclusion: Direct antiviral therapy is associated with an early decrease of liver stiffness and being stable until 1 year after the end of treatment. MRE could be used as biomarker for non-invasive therapy monitoring based on liver stiffness which is a potential early predictor of the treatment response.

Repeatability and reproducibility of multiparametric magnetic resonance imaging of the liver
H.R. Wilman[1,2], V. Bachitar[1], J. Jacobs[1], R. Newbould[2], M. Gyngell[1], C.J. Kelly[1], M.D. Kelly[1], R. Banerjee[1]; [1]*Oxford/UK*, [2]*London/UK (henry.wilman@perspectum-diagnostics.com)*

Purpose: LiverMultiScan™ (LMS) is a multiparametric MRI-based technology for quantitative analysis of hepatic fat, T2*, and iron corrected T1 (cT1). Here we test the robustness of LMS-derived metrics by systematically examining reproducibility of measurements across different MRI scanner manufacturers, models, software versions and field strengths.
Methods and Materials: cT1, T2* and Proton Density Fat Fraction (PDFF) maps were acquired from 61 participants on combinations of three Siemens and two Philips scanners at both 1.5T and 3T. Participants were scanned on at least two different scanner models and field strengths in pseudorandomised order with up to 1 week between scans and two acquisition repeats on each scanner. Standardisation of T1 maps across scanners were based on phantom-derived mappings from 90 acquisitions.
Results: Bland-Altman analysis of the T1 phantom measurements showed a clear reduction in bias (from -20ms to -4.7ms), tightening of the 95% Limits of Agreement (LoA: from -59.2ms - 19ms, to -25.3ms - 15.9ms) and reduction in mean coefficient of variation (CoV: 2.5% to 1.0%) after standardisation. Following T1-standardisation, cT1 in participants demonstrated high reproducibility (CoV, 3.3%, bias, 6.5 ms, 95% LoA of -76.3 ms to 89.2 ms). Both T2* and PDFF measurements also showed excellent reproducibility at both field strengths and across different scanners models.
Conclusion: We demonstrate that following T1 standardization, cT1 is reproducible across scanner manufacturer, model, software version and field strength. Combined with the excellent reproducibility of T2* and PDFF, LMS represents a robust and reliable non-invasive tool for the characterisation of liver tissue.

B-0003 10:55

Molecular features, histological parameters and enhancement measurements in NASH patients using gadoxetic acid-enhanced MR imaging
D.S. Feier[1,2], N. Bastati-Huber[2], A. Beer[2], R.M. Fragner[2], H. Einspieler[2], A. Ba-Ssalamah[2]; [1]*Cluj-Napoca/RO*, [2]*Vienna/AT (diana.feier@gmail.com)*

Purpose: To assess the relationship of organic anion transporting polypeptide (OATP1B1/3) expression with histological parameters and relative enhancement ratio in patients with nonalcoholic fatty liver disease (NAFLD), defined according to the steatosis activity and fibrosis (SAF) scoring system, which is based on the semi quantitative scoring of steatosis activity and liver fibrosis.
Methods and Materials: The local institutional review committee approved this study and waived written informed consent. This was a retrospective study of gadoxetic acid-enhanced 3-T MR imaging performed in 52 patients with NAFLD, mean age (SD) 50.46 (16.52) years. The MR images were analyzed by using the relative enhancement (RLE) (the ratio of signal intensities of the liver parenchyma before and 20 minutes after intravenous administration of gadoxetic acid). Univariate and multiple regression analyses were applied to identify variables associated with OATP1B1/3 expression.
Results: OATP1B1/3 expression correlated with RLE (r=0.49, p=0.0002), the degree of liver fibrosis (r =-0.27, p=0.04) but not with steatosis (r = -0.16, p= 0.23), ballooning (r=-0.22, p=0.1) or inflammation (r=-0.07, p=0.57). According to multivariate analysis both RLE and liver fibrosis are independent predictors of OATP1B1/3 expression (coefficient of determination R2=0.32, p=0.01).
Conclusion: The degree of OATP1B1/3 expression correlated statistically with gadoxetic acid relative enhancement and the degree of liver fibrosis in patients with NAFLD.

B-0004 11:03

Application of T1rho in evaluating liver fibrosis and correlation with liver function
Q. Yang, T. Yu, J. Huang, Y. Su, J. Li, B. Liang; *Guangzhou/CN (yangqih2@mail.sysu.edu.cn)*

Purpose: To verify the value of T1rho in evaluating liver fibrosis, find out the diagnosis threshold of T1rho and correlation coefficient between T1rho value and laboratory test results.
Methods and Materials: The study was approved by the local Institutional Review Board and informed consent was obtained from all participants. Patients suspected liver fibrosis were enrolled. Clinical data including laboratory test results were collected within 7 days before or after MRI scan for patients. All patients underwent MR scan including T1rho. Pathology results, laboratory test results were compared with T1rho and correlation test were done among them.
Results: 77 patients were enrolled and T1rho values for F0~F4 were 40.36±4.40ms, 41.99±1.63ms, 44.24±4.40ms, 47.16±2.66ms and 47.87±4.73ms. One-way ANOVA showed statistical difference among T1rho values of F0~F4 groups (P<0.001) and among T1rho values of Child A~C groups in liver cirrhosis(F4) patients. Area below ROC curve of T1rho diagnosing liver fibrosis severer than F2 was 0.87. When 42.86ms was chosen as diagnosis threshold, sensitivity was 0.91 and specificity was 0.76. Among all laboratory tests, PT, PT-INR, Bile acids, TBIL, DBIL, IBIL and APRI were positively correlated with bothT1rho and fibrosis stages,while T-CHO, ALB and A/G were negatively correlated with both T1rho and fibrosis stage.
Conclusion: T1rho could be used in early diagnosis of liver fibrosis, in differential diagnosis of mild liver fibrosis and liver cirrhosis. Correlation between laboratory test results and T1rho may be caused by liver dysfunction due to liver fibrosis.

B-0005 11:11

Quantitative evaluation of liver function using coefficient of variation value and contrast enhancement index (CEI) on gadoxetic acid-enhanced MR imaging in preoperative evaluation

S.W. Kim, H. Ryu, Y.R. Kim, Y.H. Lee, K.-H. Yoon; *Iksan/KR*

Purpose: The aim of this study was to evaluate whether coefficient of variation value and contrast enhancement index of gadoxetic acid-enhanced MR imaging can be used for preoperative evaluation of liver function and diagnosis of cirrhosis.
Methods and Materials: From July 2011 to January 2017, we included 22 patients who underwent various hepatic resections due to hepatic tumours. Gadoxetic acid-enhanced 3T MR imaging was performed before hepatic resection within 2 weeks. Heterogeneity and degree of liver parenchymal enhancement on MR imaging were analysed by measuring coefficient of variation (CV) value and contrast enhancement index (CEI). Relationship between these parameters and laboratory findings for liver function such as indocyanine green (ICG) R15 test and prothrombin time (INR) were evaluated.
Results: Among the 22 patients included in our study, 13 patients were proven presence of liver cirrhosis and 9 patients were proven absence of liver cirrhosis on histopathologic examination. CV value was linearly correlated with ICG R15 test (p=0.018) and PT INR (p=0.015). Also CV value was significantly higher in cirrhosis group than normal liver parenchyma group (3.9±0.73 vs 6.18±2.03, p=0.004). On the contrary, CEI was not correlated with laboratory findings (p=0.143, p=0.816) and was not significantly different between pathologic proven cirrhosis and normal liver parenchymal group (1.68±0.24 vs 1.74±0.29, p=0.616).
Conclusion: CV value on gadoxetic acid-enhanced MR Imaging showed well correlated with laboratory tests for liver function and presence of cirrhosis. So, quantitative evaluation of liver function using CV value on MR imaging can be used in preoperative evaluation for hepatic surgery.

B-0006 11:19

Liver volumetry: a useful tool to predict functional improvement after antiviral treatment in cirrhotic chronic hepatitis C patients

T. Di Maira, A. Torregrosa Andres, V. Navarro Aguilar, D. Sánchez Mateos, V. Fornes, M. Berenguer Haym; *Valencia/ES (asunsuso@gmail.com)*

Purpose: To asses if liver volume measured by CT-MR is a predictor of liver function in patients with sustained viral response (SVR).
Methods and Materials: Consecutive cirrhotic HVC patients assessed for liver transplantation and treated with antivirals between September 2014-September 2015 who achieved SVR were included. Pre-treatment liver volume adjusted by Body Surface Area (BSA) were calculated from CT-MR studies acquired within 360 days of the start of treatment. The liver delineation was performed by two radiologists. Two different semiautomatic software were used for volumetric quantification (one for CT and one for MR). Liver function was assessed by Child-Turcotte-Pugh and MELD scores collected at baseline, 12, 24, 52 weeks and at the end of the follow-up period. Multivariate mixed regression model was used to identify baseline factors associated with improvement of liver function overtime. Follow-up period was up to December 2016.
Results: 42 patients were included, median age 58.6 years (Q1-Q3: 52.7-68.8); MELD 14 (11-17); Child-Turcotte-Pugh 9 (8-10); Liver volume 1400.9 mL (1183.2-1601.4); BSA 1.8 m2 (1.7-2).
MELD scores at baseline and at last control were 14 (11-17) and 10 (8-12), respectively (p<0,001); Child-Turcotte-Pugh scores were 9 (8-10) and 6 (5-7), respectively (p<0,001).
In the multivariate mixed regression model, higher liver volume adjusted by BSA was associated with an improvement of MELD and Child-Turcotte-Pugh over time 95% CI (-12.14, -0.97), p=0.028 and 95% CI (-4.67, -0.65), p=0.014, respectively.
Conclusion: Liver volume adjusted by BSA is a non-invasive radiological tool that can predict functional improvement in cirrhotic patients undergoing antiviral treatment.

B-0007 11:27

GD-EOB-DTPA-enhanced MRI T1 relaxometry as an imaging-based liver function test compared with ^{13}C-methacetin LiMAx test

D. Theilig[1], P. Raabe[1], L. Lüdemann[2], J. Pratschke[1], B. Hamm[1], T. Denecke[1], D. Geisel[1]; [1]*Berlin/DE*, [2]*Essen/DE (dorothea.theilig@charite.de)*

Purpose: To compare gadolinium ethoxybenzyl diethylenetriaminepentaacetic acid (Gd-EOB-DTPA)-enhanced magnetic resonance imaging (MRI) as an imaging-based liver function test with the ^{13}C-methacetin LiMAx (maximum liver function capacity) test.
Methods and Materials: Fifty-three patients who underwent both Gd-EOB-DTPA-enhanced MRI T1 relaxometry before and 20 min after intravenous (IV) Gd-EOB-DTPA administration at our institution as well as a ^{13}C-methacetin LiMAx test within 30 days of the MRI examination were retrospectively analysed. In these patients, T1 relaxation times of liver parenchyma, total liver volume and hepatic tumour volume were determined. Patients' laboratory parameters including bilirubin were retrieved from routine laboratory tests. Pearson correlations, multiple linear regression analysis, and receiver-operating characteristic (ROC) curve analysis were performed with indices derived from T1 relaxometry, liver volumetry, and laboratory parameters to identify the best predictor of global liver function as determined by the LiMAx test.
Results: Relaxometry-derived indices, i.e. T1 reduction rate (T1 RR), T1 RR x total liver volume (TLV), T1 RR x functional liver volume (FLV), and T1 relaxation time 20 minutes after IV Gd-EOB administration (T1 post) showed a statistically significant correlation with LiMAx and a statistically significant discriminatory capacity between patients with LiMAx of > and < 315 µg/kg/h. Of the indices investigated, T1 RR showed the best discriminatory capacity and proved to be the only statistically significant parameter in multiple linear regression analysis.
Conclusion: The T1 reduction rate (T1 RR) of the liver on Gd-EOB-DTPA-enhanced MRI allows prediction of liver function as determined by the LiMAx test.

Comparison of two liver specific contrast agents in patients with different degrees of liver cirrhosis

C. Khouri Chalouhi[1], F. Vernuccio[2], B. Tuscano[1], P. Duca[1], G. Brancatelli[2], A. Vanzulli[1]; [1]*Milan/IT*, [2]*Palermo/IT*

Purpose: Compare the performance of gadobenate dimeglumine (Gd-BOPTA) and gadoxetic acid (Gd-EOB-DTPA) in giving an useful hepatobiliary phase (HBP) in cirrhotic patients with different degrees of liver dysfunction expressed by Model-of-End-Stage-Liver-Disease (MELD) score.
Methods and Materials: We reviewed a total of 258 liver MRI of 258 cirrhotic patients: 131 Gd-BOPTA-enhanced MRI (BOPTA-group) and 127 Gd-EOB-DTPA-enhanced MRI (EOB-group). For each MRI we calculated the contrast enhancement index (CEI) of liver parenchyma. We correlated the MELD score and the CEI in both the groups (multiple linear regression analysis). We made a qualitative analysis of HBP as adequate/inadequate for both the groups and we investigated the difference between the two contrast agents adjusting for MELD score (logistic regression analysis).
Results: In both the groups there was significant reverse correlation between MELD score and the CEI (r=-0.013). At the same MELD score value the CEI in EOB-group is increased by 0.23 (p<0.001) more than the BOPTA-group. Regarding the qualitative analysis at the same value of MELD score the mean odds ratio to have an adequate HBP was 3.64 (p<0.001) in the EOB-group compared to BOPTA-group, the adequacy of HBP is increasing in favour of Gd-EOB-DTPA at the increase of MELD score (exp(b)interaction= 1.233;p=0.011).
Conclusion: The HBP is negatively affected by the severity of cirrhosis for both the contrast agents. At the same MELD score value parenchymal enhancement in HBP is higher for Gd-EOB-DTPA. In cirrhotic patients the use of Gd-EOB-DTPA is preferable to have an adequate HBP, especially in patients with advanced disease.

Correlation between Gd-EOB-DTPA-enhanced MRI and T1rho in patients with and without liver cirrhosis

J.D. Stief[1], L. Lüdemann[2], T. Denecke[1], B. Hamm[1], D. Geisel[1]; [1]*Berlin/DE*, [2]*Essen/DE (jonas.stief@gmail.com)*

Purpose: The aim of this study is to find out whether there is a correlation between the functional parameter of the relative enhancement (RE) using Gd-EOB-DTPA-enhanced MRI and the fibrosis parameter using T1rho-mapping. In addition, it will be investigated which of the parameters is better able to distinguish between liver cirrhosis and the healthy liver.
Methods and Materials: A retrospective analysis was performed in patients (n=124) who received both Gd-EOB-DTPA-enhanced MRI and the T1rho-sequence. MRI was performed at 1.5 Tesla. RE was calculated for the entire liver. A T1rho-sequence with acquisition of 6 spin lock times (TSLs: 0, 10, 30, 40, 60 msec) and spin-lock frequency of 500 Hz was applied. T1rho-maps were created. T1rho value was calculated on two different levels with 3 ROIs each.

Results: There was a significant correlation between RE and T1rho time (p=0.013). The correlation coefficient according to pearson was R = -0.22. In the ROC analysis for differentiation between liver cirrhosis and normal liver, an AUC for RE of 0.755 and an AUC for T1rho of 0.717 were found. The cut-off value for RE is 0.645 and for T1rho 50.29 (sensitivity 74.0% and specificity 74.3%, respectively, 74.0% and 67.6%).
Conclusion: The MRI liver fibrosis parameter T1rho and the MRI liver function parameter RE of Gd-EOB-DTPA show a weak but significant correlation. Both parameters are able to distinguish between cirrhosis and normal liver parenchyma.

Perfusion quantification and hepatic function with Gd-EOB-DTPA: hepatic fibrosis and hepatocellular transport
S. Schmidt Kobbe[1], J.-L. Daire[2], A. Sciarra[1], B. Leporq[3], B. Van Beers[2], C. Sempoux[1], C. Pastor[4]; [1]*Lausanne/CH*, [2]*Clichy/FR*, [3]*Villeurbanne/FR*, [4]*Geneva/CH (sabine.schmidt@chuv.ch)*

Purpose: To evaluate the hepatocellular expression of the biliary transporters responsible for the uptake of hepatospecific contrast medium Gd-EOB-DTPA in patients with different stages of liver fibrosis undergoing dynamic gadoxetate-enhanced MRI.
Methods and Materials: We prospectively included 50 patients with suspected chronic liver disease that underwent dynamic gadoxetate-enhanced MRI and liver biopsy. After pharmacokinetic modelling we extracted the following MR-parameters: arterial and portal perfusion, Gd-EOB-DTPA hepatocytic uptake rate, biliary efflux, sinusoidal back flux (ml/min/100g for all), and the extracellular volume (%). Histologically, two pathologists classified fibrosis according to METAVIR and assessed the collagen proportionate area (CPA) with automated imaging analysis. The expression of the biliary transporters OATP2/8, MRP2 and MRP3 was investigated by immunohistochemistry and semiquantitatively scored according to the distribution within the lobule.
Results: The final cohort included 42 patients (32 men) with different stages of fibrosis (F0=5/F1=8/F2=11/F3=10/F4=8). Pharmacokinetic modelling was able to distinguish the different stages of fibrosis and correlated with CPA ($p<0.01$). At MRI, increasing fibrosis was associated with a progressive change from portal to arterial perfusion, a decrease in hepatocytic Gd-EOB-DTAP uptake rate, biliary efflux, sinusoidal back flux, and increased extracellular volume ($p<0.05$). At immunohistochemistry, increasing fibrosis was associated with more diffuse expression of OATP2/8 and MRP3 to the whole lobule and progressively irregular MRP2 expression ($p<0.05$).
Conclusion: At advanced stages of liver fibrosis, the decrease in Gd-EOP-DTPA hepatocytic uptake could reflect either lower interstitial bioavailability of the contrast agent or altered transporter functions. The modified immunohistochemical expression of the transporters could mean adaptive response to progressive intracellular cholestasis.

Optimisation of MRI screening in hereditary pancreatic adenocarcinoma
B. Boekestijn, M. Wasser; *Leiden/NL (B.Boekestijn@lumc.nl)*

Purpose: In CDKN2A/p16-mutation carriers with a 15-20% lifetime risk of developing pancreatic ductal adenocarcinoma (PDAC), annual surveillance using MRI has shown to successfully detect PDAC in an early stage, resulting in increased resectability and survival. In a retrospective study we assessed the value of different MRI-techniques in early detection of PDAC.
Methods and Materials: The MRI protocol consisted of axial and coronal T2 TSE, T1 dynamic contrast enhanced GRE with fat suppression and combined 2D/3D MRCP. In 2012 T1-weighted turbo field echo (TFE) was added to the protocol, followed by DWI in 2015. Three readers independently analysed the different MRI sequences of subjects with a proven PDAC for presence and location of the tumours.
Results: Since 2000, 18 pancreatic cancers were found in 205 screened subjects (9%). In 4 cases a tumour was detected at the first MRI. In 14 patients previous examinations were available for comparison. In 9 of these patients pancreatic abnormalities were retrospectively visible on previous examinations. T1 TFE was positive in 12 out of 13 cases when the sequence was available, DWI was positive in 6 of 8, T1 DCE in 18 of 22 and T2 in 15 of 22. In two patients a lesion was detected only on T1 TFE by all readers and not on other sequences.
Conclusion: Annual MRI surveillance in asymptomatic individuals at high risk of developing PDAC results in detection of tumours in a potentially resectable stage. T1 TFE especially seems to be a promising sequence for detection of pancreatic lesions.

B-0012 10:47

CT volumetry of the pancreas: gland size in a normal population and its relation to age, gender and body composition
J. Frøkjær, J. Kipp, E. Mark, A. Drewes, S. Olesen; *Aalborg/DK (jebf@rn.dk)*

Purpose: The pancreas volume is affected by different diseases, such as chronic pancreatitis, and is also known to be related to age and gender. To distinguish between normal and pathological pancreas volume, the aims were to establish a normal reference material of pancreatic size based on CT, and to explore the influence of age, gender and body composition.
Methods and Materials: 240 trauma patients, 20 in each gender and decade (20-80 years) group, were evaluated. 221 CT scans without pancreatic pathology were analysed: semiautomatic Hounsfield unit based segmentation of pancreas volume, 7 different two-point pancreatic measurements, and a calculated volume (formula with 6 two-point measurements). Body composition with cross-sectional area (CSA) of visceral and subcutaneous fat at L4 level, and body size as L1 vertebral dimensions (height, width, depth) were measured.
Results: Segmented pancreas volume was higher for men ($84.1\pm22.6 cm^3$) than for women ($72.4\pm19.7 cm^3$, $P<0.001$), with correlation to both the calculated volume ($r=0.73$, $P<0.001$) and all the two-point measurements (two best: transverse-head: $r=0.50$, $P<0.001$; AP-head: $r=0.48$, $P<0.001$). In a multivariate regression model only age, L1 width and CSA of visceral fat (all $P<0.001$) were explaining the volume, whereas gender was without influence ($P=0.42$).
Conclusion: A gender- and age-specific normal reference material of pancreas volume was established. Several two-point measurement-based parameters are well correlated to pancreas volume. Pancreas volume decrease with age, but body size and visceral fat, which could be the true explanation behind the gender difference, should be taken into consideration when evaluating pancreas volume.

B-0013 10:55

Quantitative MRI of the pancreas: a feasibility study

N. Vietti Violi[1], T. Hilbert[1], J. Bastiaansen[1], J.-B. Ledoux[1], A. Stemmer[2], A. Stemmer[2], R. Meuli[1], T. Kober[1], S. Schmidt Kobbe[1]; [1]*Lausanne/CH*, [2]*Erlangen/DE (sabine.schmidt@chuv.ch)*

Purpose: To show the feasibility of quantitative T2 assessment in the pancreas.

Methods and Materials: T2 mapping of the pancreas was performed using an accelerated multi-echo-spin-echo prototype sequence with respiratory trigger on 10 healthy volunteers. The experiment was repeated with repositioning to study intra-subject variability. Quantitative maps were reconstructed by employing a combination of generalised auto-calibrating partially parallel acquisition (GRAPPA) and model-based accelerated relaxometry by iterative non-linear inversion (MARTINI), dubbed "GRAPPATINI". Two radiologists independently delineated 3 regions of interest inside the head, body and tail of pancreas in each acquisition to measure mean T2 and standard deviation (SD). Inter- and intra-subject comparisons were conducted to estimate the range of normal pancreatic T2 values. Robustness of the method was assessed by evaluating the variation between scan and rescan measurements. In addition, T2 values of each liver lobe were measured to compare the obtained T2 value to existing literature.

Results: The respiratory-triggered accelerated T2-mapping GRAPPATINI sequence was successfully performed on all subjects with a mean acquisition time of 2:48±0:43min. T2 values were similar across all subjects (inter-subject) with low SD (head: 52.8±2.8ms, body: 52.8±4.9ms, tail: 55±3.3ms). An intra-subject comparison showed low variability between the different acquisitions (SD<3.7ms). The measured hepatic T2 values (right lobe: 50.6±4.1ms, left lobe: 50.4±4.1ms) showed good agreement with reported in the literature (51±5.4ms).

Conclusion: The feasibility of free-breathing quantitative T2 measurements with GRAPPATINI at 3T in moving abdominal organs was demonstrated in the example of the pancreas. Furthermore, the obtained T2 values of healthy volunteers exhibited good reproducibility and showed low SD between healthy subjects.

Is MRCP necessary to diagnose pancreas divisum?

N. Bogveradze[1,2], P. Mayer[2], M. Klauss[2], K. Lashkhi[1], H.-U. Kauczor[2], T.F. Weber[2]; [1]*Tbilisi/GE*, [2]*Heidelberg/DE (bogveradze.nino@gmail.com)*

Purpose: To compare the performance of magnetic resonance cholangiopancreaticography (MRCP) with non-MRCP T2-weighted magnetic resonance imaging (MRI) sequences for diagnosis of pancreas divisum (PD).

Methods and Materials: Retrospective study of 342 consecutive patients with abdominal MRI including MRCP. MRCP was a coronal respiration navigated T2-weighted sequence with 1.6mm slice thickness. Non-MRCP T2-weighted sequences were (1) a coronal inversion recovery sequence (TIRM) with 6mm slice thickness and (2) a transverse single shot turbo spin echo sequence (HASTE) with 4mm slice thickness. For MRCP, TIRM, and HASTE, presence of PD and assessment of image evaluability were determined in a randomized fashion. A consensus read by two radiologists using MRCP, non-MRCP T2-weighted sequences, and other available imaging served as reference standard for diagnosis of PD. Statistical analysis included performance analysis of MRCP, TIRM, and HASTE and testing for non-inferiority of non-MRCP T2-weighted sequences compared with MRCP.

Results: 33 of 342 patients (9.7%) were diagnosed with PD in the reference standard read. Sensitivity/specificity of MRCP for detecting PD was 81.2%/69.7% (p<0.001). Sensitivity/specificity of TIRM and HASTE was 92.5%/93.9% and 98.1%/97.0%, respectively (p<0.001 each). Grouped sensitivity/specificity of non-MRCP T2-weighted sequences was 99.8%/91.0%. Non-MRCP T2-weighted sequences were non-inferior to MRCP alone for diagnosis of PD. 20,2%, 7,3%, and 2,3% of MRCP, TIRM, and HASTE, respectively, were not evaluable due to motion artifacts or insufficient duct depiction.

Conclusion: Non-MRCP T2-weighted MRI sequences have high performance for diagnosis of PD and are non-inferior to MRCP alone. MRCP may not be necessary for diagnosis of PD.

Predicting the relapse of acute pancreatitis based on radiomics signature of contrast-enhanced computed tomography

Y. Chen, X. Zhang; *Nanchong/CN (shaoer.cy@gmail.com)*

Purpose: To predict the relapse of acute pancreatitis (AP) by analysing first-time AP based on radiomics signature of contrast-enhanced computed tomography (CECT).

Methods and Materials: The radiomics signature was modeled by a primary cohort consisting of 271 first-time AP patients from January 2010 to June 2015, among whom 124 patients endured recurrent attacks afterwards. Clinical data were gathered from medical records of three tertiary referral centers. The performance of radiomics signature was assessed by an independent cohort containing 118 first-time AP patients including 57 recurrent patients. We adopted resampling as the preprocessing method before 740 radiomic features were extracted from CECT. Repeatability of the radiomic features was evaluated by test-retest reliability. The radiomics signature was performed by logistic regression after dimensionality reduction and feature selection by lasso regression. Decision curve was used to evaluate the performance of radiomics signature, clinical risk factors and the combination of the both.

Results: There were 23 radiomic features remaining after test-retest reliability and lasso regression. The accuracy of radiomics signature to predict the relapse of AP was 83.0%. The AUC of radiomics signature of the validation group was remarkably higher than clinical risk factors (0.909 vs. 0.688, p < 0.001). Decision curve showed the performance of radiomics signature was better than clinical risk factors, and was similar to the combination of both.

Conclusion: Radiomics signature based on CECT performed well to predict the relapse of AP. As a quantitative method, radiomics shows a promising future for recurrent patients to potential precaution.

B-0016 11:19

Use of CT texture analysis as a predictive biomarker of response to neoadjuvant FOLFIRINOX chemotherapy and chemoRT in pancreatic ductal adenocarcinoma

K.S. Burk, M. Patino, R. Canellas, M.J. Patel, D.V. Sahani; *Boston, MA/US (ksburk@partners.org)*

Purpose: To investigate the role of CT texture analysis (CTTA) in assessing histologic response of pancreatic ductal adenocarcinoma (PDAC) to neoadjuvant FOLFIRINOX (folinic acid, 5-FU, irinotecan, oxaliplatin) chemotherapy +/- radiation.

Methods and Materials: In this IRB-approved retrospective study, 39 patients with PDAC treated with neoadjuvant FOLFIRINOX chemotherapy +/- radiation (neoadj) were identified. Post-neoadj CT exams were analysed using the CTTA TexRAD Ltd software. Unfiltered and filtered images were evaluated and heterogeneity was quantified using histogram-based texture parameters: mean, standard deviation (SD), mean positive pixels (MPP), skewness, kurtosis, and entropy. Histologic response was collected from surgical resection pathology reports: response = CAP grade 0-1, no response = CAP grade 2-3. Logistic regression analysis was used to assess for correlation between CTTA features and histologic response.

Results: 17 patients (average age 61.9 yrs) achieved histologic response after neoadjuvant treatment, while 22 (average age 59.4 yrs) did not. Analysis of unfiltered images showed that mean (1.05, p=0.035) and MPP (1.052, p=0.039) correlated with histologic response to treatment. Analysis using five spatial scale filters (SSF) showed a significant correlation between entropy and histologic response, which persisted across all filters: SSF2 7.84, p=0.042; SSF3 8.19, p=0.035; SSF4 8.82, p=0.037; SSF5 9.40, p=0.035; SSF6 8.45, p=0.034. There was no correlation between histologic response and mean, SD, MPP, skewness, or kurtosis using any of the filters.

Conclusion: CTTA, particularly entropy, can be used as a predictive biomarker in PDAC to differentiate patients who achieved histologic response to neoadjuvant FOLFIRINOX chemo +/- radiation from those who did not.

B-0017 11:27

Intravoxel incoherent motion diffusion-weighted MR imaging of solid pancreatic masses: reproducibility and usefulness for characterisation

R. De Robertis[1], N. Cardobi[1], P. Martini Tinazzi[1], R. Grimm[2], A. Stemmer[2], M. Zanirato[3], G. Tortora[4], M. D'Onofrio[4]; [1]*Peschiera del Garda/IT*, [2]*Erlangen/DE*, [3]*Milan/IT*, [4]*Verona/IT (riccardo.derobertis@hotmail.it)*

Purpose: To evaluate measurement reproducibility and diagnostic potential of apparent diffusion coefficient (ADC) and intravoxel incoherent motion (IVIM)-derived parameters of solid pancreatic masses including ductal adenocarcinoma (PDAC), neuroendocrine neoplasm (panNEN), mass-forming pancreatitis (MFP), and normal pancreas.

Methods and Materials: 48 patients with pathologically confirmed pancreatic tumours (31 PDACs, 17 panNENs), 4 patients with mass-forming pancreatitis (MFP), and 30 subjects with a normal pancreas were included in this study. All patients underwent 1.5-T MR imaging, including IVIM diffusion-weighted imaging with 11 b values (from 0 to 800 sec/mm2). ADC, true diffusion (D), pseudodiffusion (D*), and perfusion fraction (f) were calculated by placing regions of interest (ROIs) within each lesion and normal pancreas. Intraobserver reliability of the measurements was assessed using the intraclass correlation coefficient (ICC). Kruskal-Wallis H test with pairwise comparisons using Dunn's procedure with a Bonferroni adjustment was used for comparison. The diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis.

Results: Intraobserver agreement was excellent (ICC= .996, .991, .995, .993, and .981 for ROI size, ADC, f, D and D*, respectively). D* and f values of PADCs were significantly lower than those of normal pancreas and panNENs (P< .05). For differentiation of PDACs from panNENs, perfusion-related parameters (f and D*) had the highest AUC (.981 and .829) in ROC analysis. No significant differences were found between ADC- and IVIM-derived parameters of MFP and PDACs.
Conclusion: The measurement of ADC- and IVIM-related parameters has excellent reproducibility. Perfusion-related parameters could be helpful in distinguishing PDACs from panNENs.

B-0018 11:35

MRI follow-up of IPMN: can we limit the use of gadolinium administration?
L. Bertuzzo, G. Zamboni, R. Pozzi Mucelli; *Verona/IT*

Purpose: To assess the feasibility of using a non-Gadolinium enhanced MRI protocol to follow-up patients with intraductal papillary mucinous neoplasia (IPMN).
Methods and Materials: In this retrospective study, we evaluated 138 patients (48M, 90F, average age 64.5 years) with an initial diagnosis of IPMN without malignant features (128 branch-duct IPMN, 10 combined IPMN) who underwent at least two consecutive MRI/MRCP with Gadolinium in our centre (average follow-up 12.04 months). For each patient one reader evaluated, in separate sessions, in the non-contrast and post-contrast scans: cyst size, walls/septa thickening, mural nodules, dilation of the main pancreatic duct (MPD) and contrast enhancement.
Results: We detected 376 cysts with a mean size of 10.9mm (5-29mm). Patients had a median of 2 cysts each (range 1-20; mean 2.7). The MPD was dilated in 22 patients, with a mean caliber of 4.9mm (4-9mm). At the first examination available, in the non-contrast scans 356 (94.7%) lesions did not show suspicious signs. We detected walls/septa thickening in 4 cysts and endoluminal defects in 16: 15 were classified as debris in relation to their dependent position, 1 as mural nodule. After contrast administration, none of these showed enhancement. At the next follow-up MRI, in the non-contrast scans 360 (95.7%) lesions did not show any changes, 11 (3%) showed a slight increase in size and 5 (1.3%) showed signs of progression. This was confirmed in the post-contrast scans.
Conclusion: At follow-up, non-contrast MRI would have been enough to exclude signs of malignancy in 96.4% patients (98.7% cysts).

B-0019 11:43

Multiparametric PET/MR imaging biomarkers are associated with overall survival in patients with pancreatic cancer
B.-B. Chen, T.T. Shih, Y.-W. Tien, M.-C. Chang, M.-F. Cheng; *Taipei/TW*
(bangbin@gmail.com)

Purpose: To correlate the overall survival (OS) with the imaging biomarkers of dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI), diffusion-weighted imaging (DWI), magnetic resonance spectroscopy, and glucose metabolic activity derived from integrated positron emission tomography (PET)/MRI in patients with pancreatic cancer.
Methods and Materials: This prospective study was approved by the institutional review board and informed consent was obtained from all participants. Sixty-three consecutive patients (mean age, 62.7±12 y; men/women, 40/23) with pancreatic cancer underwent PET/MRI before treatment. The imaging biomarkers were comprised of DCE-MRI parameters (peak, $IAUC_{60}$, K^{trans}, k_{ep}, v_e), the minimal apparent diffusion coefficient (ADC_{min}), choline level, standard uptake values, metabolic tumour volume, and total lesion glycolysis (TLG) of the tumours. The relationships between these imaging biomarkers with OS were evaluated with the Kaplan-Meier and Cox proportional hazard models.
Results: Seventeen (27%) patients received curative surgery, with the median follow-up duration being 638 days. Univariate analysis showed that patients at a low TNM stage (≦3, P=0.041), high peak (P=0.006), high ADC_{min} (P=0.002) and low TLG (P=0.01) had better OS. Moreover, high TLG/peak ratio was associated with poor OS (P=0.016). Multivariate analysis indicated that ADC_{min} (P=0.011) and TLG/peak ratio (P=0.006) were independent predictors of OS after adjustment for age, gender, tumour size, and TNM stage. The TLG/peak ratio was an independent predictor of OS in a subgroup of patient who did not receive curative surgery (P=0.013).
Conclusion: The flow-metabolism mismatch reflected by the TLG/peak ratio may better predict OS than other imaging biomarkers from PET/MRI in pancreatic cancer patients.

B-0020 11:51

Tumour heterogeneity of pancreas head cancer assessed by CT texture analysis: association with survival outcomes after curative resection
G. Yun[1], Y. Kim[2], Y. Lee[1]; [1]*Seongnam-si/KR*, [2]*Gyeonggi-do/KR*
(gabinyun@gmail.com)

Purpose: To evaluate the association of texture features of CT images with survival outcomes in patients with pancreas head cancer.
Methods and Materials: From January 2006 to December 2014, 88 patients with pancreas head cancer who underwent preoperative CT and curative resection were included. CT texture features (average, standard deviation, kurtosis, skewness, angular second moment, contrast, correlation and entropy) were obtained without filtration and with various filter values (fine, medium and coarse). After dichotomizing patients into recurred and non-recurred groups, clinical, pathological and texture features were compared. Based on the optimal cutoff values from ROC analysis, univariate Kaplan-Meier method and multivariate Cox regression analysis were used for the prediction of disease-free survival (DFS).
Results: The presence of nodal metastasis, texture features of average, contrast, correlation, and standard deviation without filtration and with fine and medium filter values, and average, contrast with coarse filter value showed the significant difference between recurred (n=70, 79.5%) and non-recurred group (n=18, 20.5%). In Kaplan Meier analysis, average in all filter values, contrast, correlation, and standard deviation without filtration and with fine and medium filter values showed poorer DFS. In Cox regression analysis, lower average values with homogeneous texture features (lower standard deviation and contrast, and higher correlation) were associated with poorer DFS.
Conclusion: In conclusion, CT texture features of lower average and standard deviation values are associated with poorer outcome after curative resection in pancreas head cancer. Texture features from pre-operative CT may serve as an independent prognostic marker in such patients.

Contrast volume reduction for aortic CT angiography using a volume calculator and a spiral flow device: a prospective randomised study
D. Raymakers, W. Coudyzer, S.A. Cornelissen, G. Maleux; *Leuven/BE*
(dominic.raymakers@uzleuven.be)

Purpose: To assess a method for reducing iodised contrast volume in aortic computed tomography angiography (CTA) using a contrast volume calculator and a spiral flow device.
Methods and Materials: Sixty patients undergoing aortic CTA were randomly assigned to four groups. Group 1 received a patient-specific calculated contrast volume based on weight, length and heart rate; group 2 a 20% dilution; and groups 3 and 4 a 50% dilution of the calculated volumes. A spiral flow device was used to mix contrast agent and saline. The first three groups were scanned on a Siemens Somatom Flash and group 4 on a Somatom Force with improved tube voltage modulation. Aortic contrast density was measured and image quality was evaluated using visual grading analysis (VGA).
Results: Mean contrast volumes for groups 1 to 4 were, respectively, 93, 78, 52 and 44 ml. The mean tube voltage was 27% lower in group 4 compared to the other groups (P < 0,0001). Contrast densities between groups 1, 2 and 4 were not significantly different (P > 0.05). The mean density in group 3 was 42% lower than that in group 1 (P < 0.001) and 31% lower than in group 2 (P < 0.01). The mean density in group 4 was 52% higher than that in group 3 (P < 0.001). The VGA score for group 3 was significantly lower than that for the other groups.
Conclusion: Low patient tailored contrast volumes can yield good image quality in aortic CTA using scan protocols combining contrast dilution up to 50%, a spiral flow device and reduced tube voltage.

B-0022 10:38

Non-contrast MR angiography for aortic monitoring in Marfan patients after aortic root surgery

S. Veldhoen[1], C. Behzadi[2], A. Lenz[2], F. Henes[2], M. Rybczinsky[2], Y. von Kodolitsch[2], T.A. Bley[1], G. Adam[2], P. Bannas[2]; [1]*Würzburg/DE*, [2]*Hamburg/DE (veldhoen_s@ukw.de)*

Purpose: Contrast-enhanced magnetic resonance angiography (CE-MRA) is the established imaging modality for patients with Marfan syndrome (MFS) requiring annual imaging before and after aortic root replacement. Contrast-free MRA techniques have not been evaluated in the postoperative setup. Purpose of the study was to assess the feasibility of non-contrast steady-state free precession (SSFP) MR imaging for aortic monitoring of postoperative MFS patients.
Methods and Materials: Sixty-four adult patients after aortic root replacement were included. Fourteen patients (22%) had a residual aortic dissection after surgical treatment of type A dissection. SSFP imaging and CE-MRA were performed at 1.5 Tesla. Two radiologists evaluated the images regarding image quality, artefacts and aortic pathologies. Readers measured aortic diameters at defined levels. Statistics included observer agreement for image scoring and diameter measurements and ROC analyses for comparison of diagnostic performance of SSFP and CE-MRA.
Results: Both readers observed no significant differences in image quality for both techniques (all p>.05). No significant differences were found regarding the frequency of image artefacts (all p>.05). Sensitivity and specificity for detection of aortic dissections was 100% for both readers and techniques. Compared to SSFP imaging, CE-MRA resulted in higher diameters (mean bias, 0.9 mm; p<.05). The inter-observer biases of diameter measurements were not significantly different (all p>.05), except for the distal graft anastomosis (p=.001). Using both techniques, the readers correctly identified a graft suture dehiscence with aneurysm requiring surgery.
Conclusion: Unenhanced SSFP MR imaging allows for riskless aortic monitoring with high diagnostic accuracy in MFS patients after aortic root surgery.

B-0023 10:46

Two novel methods for an objective quantification of iliac artery tortuosity derived from CT-angiography datasets in patients prior to transcatheter aortic valve implantation (TAVI)

F. Braun, T. Hadlich, H. Ruhnke, B. Jehs, C. Thilo, C. Scheurig-Muenkler, T.J. Kroencke, F. Schwarz; *Augsburg/DE (franziska.braun@klinikum-augsburg.de)*

Purpose: To develop parameters for an objective quantification of iliac-artery-tortuosity on the basis of CT-angiography datasets.
Methods and Materials: 150 patients who had undergone wide-range CT-angiography prior to TAVI were included. In a joint reading-session, a cardiologist and interventional radiologist used Volume-Rendering-Technique-Reconstructions to assign a semiquantitative grade for iliac-artery-tortuosity on a 4-point Likert-scale for each side.
As a precise measure for tortuosity('Tortuosity-Ratio'=TR), the length of the iliac arteries was measured on Curved-Planar-Reformations for each side and related to the straight distance between the start- and end-point of CPR-segmentations.
A second parameter('Simplified-Tortuosity-Ratio'=STR) was derived from axial reconstructions only by calculating the ratio between the average distance of the aortic bifurcation and femoral artery from a plane tangential to the iliac spine and the shortest distance of the iliac artery from this plane for each side.
ANOVA statistics were applied to test for differences in TR and STR in the four tortuosity-grade subgroups.
Results: The four semiquantitative tortuosity grades were assigned in 42, 174, 48 and 36 vessels(n=300). Differences in TR and STR between the four subgroups were highly significant with TR's of 1.08±0.02, 1.17±0.06, 1.34±0.09 and 1.49±0.16 and STR's of 1.27±0.08, 1.33±0.09, 1.46±0.1 and 1.54±0.13, respectively, for grade 1-4, all p's< 0.01. However, TR had significantly higher predictive value for tortuosity grade than STR.
Conclusion: We describe two novel parameters for an objective quantification of iliac-artery-tortuosity which can easily be derived from CT-angiography datasets. We demonstrate high validity of these parameters in comparison with a semiquantitative evaluation by experienced interventionalists.

B-0024 10:54

Image quality and radiation dose sparing of CT angiography for TAVI planning with low-kV, low contrast medium volume and model-based iterative reconstruction compared to standard CTA

L. Riva[1], D. Ippolito[1], C. Talei Franzesi[1], A. de Vito[1], C. Maino[1], C. Cangiotti[1], A. Santalco[1], S. Sironi[2]; [1]*Monza/IT*, [2]*Bergamo/IT (lr-doc@hotmail.com)*

Purpose: To evaluate image quality and radiation dose exposure of low-kV setting and low contrast medium volume(CM) CTA protocol in patients candidates for TAVI, in comparison with standard CTA protocol.
Methods and Materials: Eighty-nine patients, candidates for TAVI, were prospectively enrolled and examined with 256-MDCT (iCT elite,Philips): 46 patients (study-group) were evaluated using 80kV retrospective ECG-gated protocol, with tube-current modulation and 60mL of CM volume (350mgI/mL); while 43patients (control-group) underwent a standard CTA retrospective ECG-gated protocol (120kV;automated tube-current modulation;100mL of CM). Subjective image quality was evaluated using a 4-point-scale (4-excellent,1-low). Vascular enhancement(HU), SNR and CNR were assessed in each patient with multiple regions of interest (ROIs) in lumen of aorta and iliac-femoral axis at different levels (using the infra-scapular and psoas muscles for CNR). The radiation dose exposure of both groups, in terms of CTDIvol and DLP, was calculated and all data were compared and statistically analysed.
Results: In low-kV protocol significantly higher(p<0.01) mean intravascular attenuation values were achieved in all the measurements compared to the standard protocol(aortic root 367.4HU vs 314HU; external-iliac arteries 390.2HU vs 289HU). Mean DLP of study-group was significantly lower (524.5±243.8mGy*cm) than in control-group (2044±130mGy*cm), with an overall radiation dose reduction of about 74.3%, while no significant differences were observed in the image quality evaluation in both groups.
Conclusion: Low-kV with low-CM volume and IMR reconstruction CTA protocol allows to correctly perform TAVI-planning study offering high quality images and significant radiation dose exposure reduction(49%), as compared to standard CTA protocol.

B-0025 11:02

Variability of MRI-derived aortic diameters in Marfan patients: comparison of inner vs outer vessel wall measurements

J.M. Weinrich, M. Avanesov, F. Henes, A. Lenz, G. Adam, P. Bannas; *Hamburg/DE (m.avanesov@uke.de)*

Purpose: To compare the reliability and validity of inner-inner and outer-outer-edge measurements derived from non-contrast steady-state free precession (SSFP) MRI in Marfan patients.
Methods and Materials: ECG-gated 2D-SSFP at 1.5 T were retrospectively evaluated in 40 patients with Marfan syndrome. Two readers rated the delineation of both inner and outer vessel walls on a three-point Likert scale (excellent-poor) at the sinuses of Valsalva, sinotubular junction, ascending aorta, aortic arch and descending aorta. Both readers independently measured aortic diameters by assessing both inner-inner and outer-outer edge measurements at all levels. Aortic root diameters acquired by echocardiography served as reference. Results were compared using Wilcoxon test, f test, t test, and Bland-Altman analysis.
Results: Image quality and vessel wall delineation was significantly better at all levels for inner vessels walls than for outer vessels walls (all p<0.001). Inter- and intraobserver variances of aortic measurements were significantly smaller for inner-inner measurements at the sinuses of Valsalva, sinotubular junction and ascending aorta (all p<0.03). Echocardiographic measurements at the level of sinus of Valsalva were not significantly different from MRI-derived inner-inner measurements (median and interquartile range: 37 [34-40 vs. 36(32-38) mm; p=0.14], but significantly smaller when compared to MRI-derived outer-outer measurements [43(40-46) vs. 36(32-38) mm; p<0.001].
Conclusion: Non-contrast SSFP results in sharper delineation of inner vessel walls compared to outer vessel walls. Inner vessels wall measurements of the aortic root are more reliable and valid than outer vessel wall measurements. Therefore, we propose to monitor aortic root dimensions in Marfan patients using of inner-inner edge measurements in ECG-gated non-contrast MRI.

B-0026 11:10

Aortomitral calcification is an independent predictor of mortality in TAVR patients

M.J. Willemink, E. Maret, K.J. Moneghetti, J.B. Kim, F. Haddad, Y. Kobayashi, K. Higashigaito, W. Fearon, D. Fleischmann; *Stanford, CA/US (m.j.willemink@gmail.com)*

Purpose: Aortic valve calcification predicts mortality in patients with aortic stenosis; however, it is just one manifestation of left-sided valvular and annular calcification, which has been associated with systemic atherosclerosis, inflammation and cardiovascular events. We sought to evaluate whether the volume of aortomitral calcifications (AMC) as quantified by CT is an

independent predictor of mortality in patients undergoing transcatheter aortic valve replacement (TAVR).
Methods and Materials: 317 consecutive patients undergoing TAVR between October 2013 and March 2016 were included. All patients underwent pre-procedural CT angiography. AMC-volume was quantified on non-contrast thin-section CT images using commercially available software. Patients were followed for all-cause mortality. Baseline characteristics were evaluated with Mann-Whitney U and Chi-square tests. A multivariable prediction model was derived using Cox proportional hazards regression analysis.
Results: Median follow-up time of 317 patients was 367 (interquartiles 178-678) days. In total 63/317 (19.9%) patients died. AMC volume (P<0.001) and the clinically used STS score (P=0.001) were significantly different between survivors (N=254) and non-survivors (N=63). Age and gender showed no significant predictive value in the Cox analyses (P=0.159 and 0.163, respectively), whereas AMC volume (HR 1.06 (1.01-1.10) per cm^3, P=0.019) and STS score>8 (HR 1.89 (1.06-3.37), P=0.032) were independently associated with mortality after 18 months. Area under the curve 18 months after TAVR was similar (P=0.910) for AMC volume (AUC=0.638 [95%CI 0.575-0.684]) compared to STS score (AUC=0.631 [95%CI 0.582-0.691]).
Conclusion: AMC volume measured by CT is independently associated with mortality in TAVR patients and may, therefore, improve risk stratification after TAVR.

Magnetic resonance assessment of thrombus remodeling after endovascularaortic sealing of abdominal aortic aneurysms using the Nellix endosystem

N. Galea, M. Francone, S. Coco, G. Mancuso, O. Martinelli, C. Belli, I. Carbone, B. Gossetti, C. Catalano; *Rome/IT (nicogale2000@yahoo.it)*

Purpose: Novel endovascular aortic sealing(EVAS) technique with the Nellix endosystem is a valid option for the treatment of infrarenal abdominal aortic aneurysms(AAAs).The positive pressure exerted by the endobags in aneurismal sac reduces endoleak rate and compacts the thrombus,however the impact on sac remodeling is still unclear. Our aim was to elucidate the changes in aneurismal sac in patients treated by EVAS for AAAs in terms of morphology and thrombus characteristics using MRI.
Methods and Materials: We consecutively enrolled 10 patients EVAS candidates for AAA. All patients underwent MRI before,1-week and 1-year after treatment.Specific morphological features of AAA(diameter,proximal neck lenght,AAA sectional areas,sac volume,endoleak presence and lumen volume) and thrombus characteristics(thrombus volume and maximal thickness,T1 and T2 signal) were determined and compared preprocedural and at follow-up.
Results: No early or late endoleaks were observed in all patients after EVAS.A significant reduction of sac and thrombus volume was observed(mean value:44.5mL Vs 40.9mL and 7.5mL Vs 3.5mL,respectively,p:0.01-0.23),as well as AAA diameter and thrombus thickness did not change significantly at 1-year follow-up after EVAS(48.5mm vs 47.3mm, 12.4 vs 11.3mm, respectively, p >.05 for both).Analysis of thrombus MR signal showed a reduction of T1 and T2 values(mean difference:-45% and -30%,respectively,p:0.01-0.03) at the 1year follow-up,likely reflecting tissue organizing and fibrous replacement phenomena.
Conclusion: Filling the endobags inside the aneurysmal sac leads to the progressive reduction of thrombus volume and lowering of T1/T2 values,probably due to thrombus organization and squeezing of fluid content into collateral vessels.EVAS could be associated to an acceleration of thrombus remodeling after AAAs treatment

B-0028 11:26

4D flow analysis of abnormal haemodynamics within saccular aneurysm in contrast to fusiform aneurysm in abdominal aorta

M. Sugiyama[1], Y. Takehara[2], M. Alley[3], N. Unno[1], K. Katahashi[1], T. Wakayama[4], A. Nozaki[4], S. Naganawa[2], H. Sakahara[1]; [1]*Hamamatsu/JP*, [2]*Nagoya/JP*, [3]*Stanford, CA/US*, [4]*Hino/JP (m-sugi@hama-med.ac.jp)*

Purpose: Most vascular surgeons believe that saccular aortic aneurysms have more ominous natural history than fusiform aneurysm. Majorities of physiological evidences indicate that the decline of wall shear stress (WSS) produces an expression of pro-atherogenic genes. The purpose of our study is to characterise the abnormal flow dynamics within the saccular aneurysm of the abdominal aorta as compared to the fusiform aneurysm.
Methods and Materials: Ten patients with saccular, thirteen patients with fusiform abdominal aneurysm underwent 3D cine PC MR imaging (4DFlow) covering whole abdominal aorta. The MR imagings were conducted on a 1.5T or a 3.0T MR scanner with torso-array coil. Time resolved contrast-enhanced 3D MR angiography was performed for determination of aortic boundary. The acquired data was post-processed with flow analysis software (flova II, R'Tech, Japan). Streamlines of the abdominal aorta were depicted for streamline analysis. The peak systolic and diastolic WSS within saccular and fusiform aneurysm was calculated and compared using Mann-Whitney's U-test.
Results: The peak systolic WSS of saccular aneurysm was significantly lower than that of fusiform aneurysm (p=0.013). The streamline showed vortex flow within the saccular aneurysm which is isolated from the mainstream of the aorta. This trend was not observed within the fusiform aneurysm. The separated turbulent flow within the saccular aneurysm may be the reason for even lower WSS.
Conclusion: The separated vortex flow within the saccular aneurysm and consequent low WSS of its wall may be reflecting the continuing risk of atherogenic changes of the saccular aortic aneurysm compared to fusiform aneurysm.

Fully automated segmentation of ascending aorta on phase-contrast cardiac MR images: application in healthy and aneurysmatic patients

M. Codari[1], M. Scarabello[2], F. Secchi[1], C. Sforza[2], G. Baselli[2], F. Sardanelli[1]; [1]*San Donato Milanese/IT*, [2]*Milan/IT (marina.codari@grupposandonato.it)*

Purpose: To develop a fully automated method for segmenting the ascending aorta lumen on 2D+t phase-contrast magnetic resonance (MR) images.
Methods and Materials: We randomly selected, out of a large population dataset, 25 subjects with negative cardiac MR and 9 subjects with diagnosed ascending aorta aneurysm. All exams were performed from September 2008 to October 2013. The local Ethics Committee approved this retrospective study. The ascending aorta was automatically identified on all cardiac cycle phases using a priori knowledge on aortic geometry. The frame maximising the area, eccentricity, and solidity parameters was chosen for unsupervised initialisation. Aortic segmentation was then performed on each frame using active contouring without edges techniques. For each frame the aortic lumen was segmented using the previously segmented frame as initialisation mask. The manual segmentation performed by a highly experienced operator was used as a reference standard. Dice similarity coefficient (DSC), Bland-Altman analysis and Pearson's correlation coefficient were used as performance metrics.
Results: Bland-Altman analysis on healthy subjects showed a bias of -6.68 mm^2, a coefficient of repeatability of 91.22 mm^2, an average measurement of 581.40 mm^2, and a corresponding reproducibility of 85%; on aneurysmatic patients, -3.09 mm^2, 159.64 mm^2, 1741.42 mm^2 , and 91%, respectively. High correlation coefficients as well as DSC values (mean±standard deviation) were recorded in both healthy (R=0.98; 94.6±2.1%) and aneurysmatic (R=0.99; 96.4±1.9%) dataset.
Conclusion: A fully automated and robust method for ascending aorta segmentation on both healthy and pathological phase-contrast MR images was developed. Further studies on larger samples are warranted.

B-0030 11:42

MR angiography in small animals using hyperpolarised water

S. Fischer[1], R. Maeder[1], V. Denysenkov[1], M. Terekhov[2], S. Zangos[1], T. Prisner[1], T.J. Vogl[1]; [1]*Frankfurt a. Main/DE*, [2]*Würzburg/DE (sebastian.fischer@kgu.de)*

Purpose: Gadolinium based contrast agents are associated with the risk of allergic reactions, systemic nephrogenic fibrosis and potential remnants in the brain. Purpose is to examine dynamic nuclear polarisation (DNP) as an alternative method for MR angiography.
Methods and Materials: Liquid-state Overhauser DNP achieves hyperpolarisation by microwave irradiation of electron spins in TEMPOL radicals, which are coupled with the nuclear spins of water molecules. Our setup comprises a 42GHz microwave source and an 1.5T in-bore polariser, equipped with a multimode resonator. Continuously hyperpolarised water was administered with 1.2ml/min into the aorta of five C57BL/6 mice via catheterisation (0.15mm ID) of iliac vessels. The aorta and its branches were visualised with GRE-sequences (TR 110s, TE 3.8s, FoV 78x58x2mm, Matrix 256x192px) and intravascular DNP signal intensities, SNR and CNR values were measured and compared to its native values.
Results: Hyperpolarised water features high T1 signal enhancements in MR imaging and a short relaxation time. Maximum intravascular signal intensities were increased 4.3-fold from 231±47 to 994±194. Thus better SNR and CNR values were measured for hyperpolarised vessels with an SNR increased 5.3-fold from 24±2 to 126±62 and CNR increased 26.3-fold from 3±2 to 79±49.
Conclusion: The strong enhancement and its high CNR made a visualisation of the aorta and its branches possible in mice - even using a standard clinical 1.5T scanner. Thus hyperpolarised water might be a promising future alternative to Gadolinium based contrast agents in MR angiographies without risking the potential adverse effects or intracorporal remnants of Gadolinium based contrast agents.

Low-dose CT angiography for thoracicaorta: optimal combination between 80kV and last generation iterative reconstruction algorithm levels

A.D. Annoni, A. Formenti, D. Andreini, M. Guglielmo, G. Muscogiuri, G. Pontone, E. Consiglio, E. Conte, M. Pepi; *Milan/IT (andrea.annoni@ccfm.it)*

Purpose: To evaluate feasibility and optimization of a low dose CT protocol for thoracic aorta by investigating the best combination of last generation iterative algorithm level and use of 80 kV in comparison with 50% level suggested for standard 100 kV protocols.
Methods and Materials: We enrolled 60 pts scheduled for thoracic aorta CT angiography (48 men) with BMI up to 37 kg/m^2 (mean 26.3±4.9 kg/m^2). All CT examinations were performed with axial ECG-gated acquisition with new generation wide array CT scanner using 80kV, mA modulated on patient's BMI and 50 ml of contrast agent. Aortic values, noise, signal to noise and contrast noise - ratios were evaluated at different aortic locations for FBP images and for images reconstructed at different percentages of adaptive statistical iterative reconstruction algorithm - V (ASIR V) (20%, 40%, 50%, 60%, 80%, 100%). All exams were evaluated for subjective image quality by two independent readers.
Results: No exams were classified as not diagnostic. Overall mean aortic attenuation for all aortic segments was over 600 HU. The best balance between image quality (subjective and objective) and ASIR-V level was found at 60% in the overall population and at 80% in a subgroup of patients with BMI≥30 kg/m^2 . The K coefficient for interobserver agreement was 0.87. Mean effective dose was 0.98±0.26 mSv.
Conclusion: Scanning protocol for CTA of the thoracic aorta using wide detector coverage, 80 kV and ASIR-V allow good balance between dose reduction and image quality also in patients with high BMI.

Percutaneous treatment of postoperative benign hepaticojejunostomy strictures: temporary placement of covered metallic stents versus balloon dilation

G. Yun, C. Yoon, N. Seong, J. Byeon, H. Lee, Y. Kim; *Seongnam/KR (gabinyun@gmail.com)*

Purpose: To compare percutaneous temporary placement of covered metallic stent with balloon dilatation for the treatment of postoperative benign hepaticojejunostomy strictures.
Methods and Materials: From November 2004 to August 2017, 56 patients with postoperative benign hepaticojejunostomy strictures underwent percutaneous transhepatic treatments. A covered stent designed for spontaneous migration after temporary indwelling was placed in 23 patients (stent group). Balloon dilation was performed in multiple sessions to achieve <30% residual stricture in 33 patients (balloon group). The technical success, complications, the indwelling duration of percutaneous transhepatic biliary drainage (PTBD), and patency rates were compared between the two groups.
Results: The technical success was achieved in all patients of stent group and 96.8% (32/33) of balloon group after 1-6 sessions of dilation. There was no major complication in both groups. All covered stents spontaneously migrated into jejunum and passed out through the anus 2-12 months after placement (median 5 months). The indwelling duration of PTBD was shorter in stent group (median 9 vs 33 days; p=.001). Recurrent strictures requiring re-intervention occurred more frequently in balloon group (51.5% vs 8.7%; p=.001). The 1- and 2-year primary patency rates were 95.0% and 89.1% in stent group and 74.2% and 49.8% in balloon group, respectively (p=0.032).
Conclusion: In patients with postoperative benign hepaticojejunostomy stricture, percutaneous temporary placement of a covered stent provides longer patency and shorter PTBD indwelling compared with balloon dilatation. A covered stent designed for temporary placement seems to be a feasible strategy to prevent stent-related complications in postoperative benign biliary strictures.

B-0033 10:38

Preliminary experience of TIPS creation using the new controlled expansion e-PTFE covered stent

R. Miraglia, L. Maruzzelli, I. Petridis, G. Marrone, A. Luca; *Palermo/IT (gmarrone@ismett.edu)*

Purpose: To prospectively evaluate short-term outcome of TIPS creation using the new controlled-expansion e-PTFE covered stent (CES), in adult patients with portal hypertension complications.
Methods and Materials: Between 7/2016 and 9/2017, 45 consecutive patients received TIPS using CES. 38 /45 patients have a follow up longer than 3 months and represent our study group. Clinical data were obtained at baseline, 4 and 12 weeks after the TIPS.
Results: TIPS indications were: refractory ascites (n=29), variceal bleeding (n=5), other (n=4). Mean age 60.5 yrs (±10.38), mean follow-up 4.0 months (±3.18). 16 patients had partial/subtotal portal vein thrombosis. In 37 patients TIPS was dilated to 8 mm of diameter with a significant reduction of the porto-caval pressure gradient (PPG) (≤ 10 mmHg). In 1 patient, not reaching the haemodynamic target, the stent was dilated to 10 mm of diameter during the same session. Mean PPG pre-TIPS was 16.05 mmHg (±4.82), post-TIPS was 6.61 mmHg (±2.79). Grade I-II encephalopathy was registered in 10 patients (26%). Portal vein thrombosis partially/completely resolved in 13/16 patients . No recurrence of bleeding episodes were registered. Disappearance of ascites was observed in 22 cases (75.86%). In 2 patients with ascites persistence the stent was dilated to 10 mm in a further procedure. 4 patients died because of septic episodes (not related to TIPS, 2 to 7 months after TIPS).
Conclusion: CES for TIPS creation can be safely used in patients with severe portal hypertension and seems to be associated with a good short-term outcome.

B-0034 10:46

Outcomes of transjugular intrahepatic portosystemic shunt using 12-mm-diameter stent for portal hypertension with refractory ascites

A.M.K. Abdel Aal[1,2], K. Mahmoud[1], S. Kim[1], B. Heeke[1], S. Moawad[1], M. Massoud[1], S. Saddekni[1], N. A. Abouelddahab[1], A. Gunn[1]; [1]*Birmingham, AL/US*, [2]*Cairo/EG (akamel@uabmc.edu)*

Purpose: The objective of this study is to evaluate the efficacy, complications and survival outcomes of transjugular intrahepatic portosystemic shunt (TIPS) creation performed using a 12-mm-diameter stents (Viatorr, Gore) in patients with refractory ascites.
Methods and Materials: We retrospectively reviewed the medical records of 187 patients who underwent TIPS from January 2004 to January 2017, using 12-mm Viatorr stents for refractory ascites. Patients' demographics, comorbidities, need for paracentesis, model for end-stage liver disease (MELD) score, and incidence or worsening of hepatic encephalopathy (HE). Survival outcomes were also calculated.
Results: The study included 115 (61.5%) males with a mean age of 57.1 years (SD=9.2 years). The mean Charlson comorbidity index was 3.9 (SD= 1.1). The mean portosystemic gradient significantly decreased from 15.79 to 4.98 after TIPS (p<0.0001). Ascites was resolved at 3, 6 and 12 months after TIPS in 59.5%, 69.8% and 81.7% of the patients, respectively. Freedom from paracentesis was seen in 93.3% of the patients at 12 months after TIPS. Mean MELD score increased significantly after TIPS from 13.2 to 16.9 (p<0.0001). HE was seen in 6.5% and 38.2% before and 3 months after TIPS, respectively, with 17.5% of the patients medically uncontrolled. The overall survival at 3, 6, 12 and 60 months was 79.2%, 73.5%, 66.3% and 46.5%, respectively.
Conclusion: The 12-mm-diameter Viatorr stent used for TIPS in patients with refractory ascites appears more efficacious and without increased complication rate compared to published literature on the 8- and 10-mm-diameter similar stents.

B-0035 10:54

Non-invasive pressure monitoring after transjugular intrahepatic portosystemic shunt implantation with integrated sensors

C. Spink[1], B. John[1], D. Schröder[1], W. Krautschneider[1], R. Fischbach[2], M. Braunschweig[2], J.-H. Buhk[1], G. Adam[1], A. Koops[1]; [1]*Hamburg/DE*, [2]*Dresden/DE (c.spink@uke.de)*

Purpose: In vitro and ex vivo testing of a novel stent-graft with integrated pressure sensors capable of wireless digital data transmission for non-invasive pressure monitoring after TIPS.
Methods and Materials: Ten stent-grafts for TIPS-implantation (100x10 mm) were designed including integrated pressure sensors at both ends within layers of polytetrafluorethylen (PTFE). Digital data conversion was performed by integrated microcontrollers within the PTFE-membrane providing energy and data transfer by inductive coupling. The stent-grafts were placed in a silicone

liver phantom and in four explanted porcine livers via 16F applicators for intraluminal air pressure measurement.
Results: First in vitro and ex vivo testing demonstrated a capable TIPS stent-graft design with integrated sensors in a stable PTFE-covering after crimping and application into a liver phantom and the explanted porcine livers. In both setups measurements were simultaneously taken from both sensors with an accuracy of ±1.2 mmHg up to a distance of 10.2±0.9 cm in a liver phantom and a distance of 8.3±0.5 cm in the porcine livers. The minimum power input for successful data transfer had to be increased from 10±1 W in the liver phantom and to 18±2 W in the porcine livers. There was no significant difference in intraluminal air pressure measured at both setups (p=0.46).
Conclusion: First in vitro and ex vivo results demonstrate a successful approach for non-invasive pressure monitoring after TIPS implantation using integrated sensors. Further in vivo tests are scheduled before the potential implementation into a product.

B-0036 11:02

Risk factors of survival after TIPS using ePTFE covered stentgrafts in refractory ascites

M. Pitton, M. Moddemann, T. Zimmermann, S. Schotten, P. Galle, C. Düber;
Mainz/DE (michael.pitton@unimedizin-mainz.de)

Purpose: To analyse the risk factors of overall survival TIPS with ePTFE-stentgrafts in patients with liver cirrhosis and refractory ascites.
Methods and Materials: 213 patients with liver cirrhosis and refractory ascites (129 male, 84 female) were treated with ePTFE covered TIPS. Patients with portal vein thrombosis, acute and subacute bleeding with need for treatment, and Budd-Chiari-syndrome were excluded from analysis. Overall survival was analysed depending on 1. the baseline clinical characteristics before TIPS (age, sex, etiology of cirrhosis, additional diagnoses, former history of variceal bleeding, former endoscopic ligation (EBL), Child-Pugh-stage, number of paracentesis needed, history of SBP or hepatic encephalopathy (HE), hemodialysis, INR, Bilirubin, Albumin, Creatinin), 2. procedural complications during TIPS, and 3. hemodynamic outcome (portosystemic pressure gradient, PSG) after TIPS, and hemodialysis within 4 weeks after TIPS.
Results: Overall survival was 49.4 +/- 4.7 months. Technical success was 100%, with 97.2% primary sucsess rate. 3d-mortality was 0.9%, 30d-mortality 8.0%. The reintervention rate was 26.8% (25.8% dilatation/recanalisation, 8.9% TIPS reduction during follow-up). Significant risk factors for survival were age>70y, male gender, etiology (hepatits vs. alcoholic), additional diagnosis (cardiac diseases and others), creatinin, bilirubin >2mg/dl, Child-C-stage, and need for hemodialyis within 4 weeks after TIPS. Prior history of bleeding, EBL, SBP, HE, and hemodialysis before TIPS were not significant. Procedural complications, and PSG after TIPS, was also not statistically significant.
Conclusion: Survival after TIPS depends on clinical baseline characteristics. Beside clinical measures of liver function and etiology of liver disease, independent co-factors like additional diagnoses and personal characteristics should be realised.

B-0037 11:10

VesOpen procedure: the new percutaneous image-guided treatment option of HCC-induced portal vein thrombosis

M. Mizandari[1,1], T. Azrumelashvili[1], N. Habib[2]; [1]*Tbilisi/GE*, [2]*London/UK*
(mgmizandari@gmail.com)

Purpose: The novel technique of PV malignant thrombus recanalisation is presented.
Methods and Materials: 18 patients underwent percutaneous endoportal RF treatment attempt. PV tributary is accessed under US guidance; manipulation by 5 Fr diameter guiding catheter is used to conduct the guidewire across the blocked segment and portography is performed. 15 Watts power was applied for 2 minutes using bipolar endoluminal RF device (Habib™ EndoHPB, EMcision Ltd., London, UK), placed in PV-blocked segment according the guidewire. The number of RF application sessions depends on tumour thrombus extent as shown on portography. After RF application, self-expanding 14-mm-diameter vascular stent is positioned and PV patency restoration is documented by final portography. Procedure is completed by procedure track RF ablation and/or coil embolisation.
Results: The procedure was completed in 13 (72.2%) cases; in 3 (16.7%) cases we could not conduct the wire across the thrombus; in 2 (1.1%) cases we failed to conduct the RF device and procedure was completed by stenting. Portal vein obstructed segment showed the restored blood flow in all completed cases as documented by postprocedure portography, follow-up Doppler and CT studies; this resulted in liver function improvement in 8 (61.5%) of procedure technical success cases. Recanalised PV patency varied from 3 weeks to 22 months; in 4 cases patients underwent successful TACE procedure after PV recanalisation.
Conclusion: PV thrombus percutaneous recanalisation by endoportal RFA with subsequent stenting is an effective technique and should be suggested as a possible treatment option for HCC patients with PVT.

Percutaneous treatment of biliary lithiasis: personal experience

S. Zanardi, A. Cappelli, C. Mosconi, M. Renzulli, F. Modestino, R. Golfieri;
Bologna/IT (sara.zanardi10@gmail.com)

Purpose: to determine the efficacy of percutaneous procedures to remove intrahepatic bile duct stones and to treat underlying biliary strictures (BSs).
Methods and Materials: we retrospectively analysed the outcome of 91 patients with intrahepatic lithiasis percutaneously treated. Patients were divided into two groups: Group A (n= 50) and Group B (n= 41), without or with intrahepatic stenosis respectively. We also divided patients according to the ethiology of the lithiasis. Stones removal was facilitated with an occlusion balloon after sphincteroplasty and mechanical fragmentation.
Results: 1-year-primary patency was 76% and 51.2% [Group A and B respectively (p= 0.014)]; 2-year-primary patency was 72% and 39.1 [Group A and B respectively (p= 0.001)]. Secondary patency was 84% (Group A) and 63.4% (Group B) (p= 0.025). We found a statistically significant difference in the outcome of patients with or without intrahepatic stenosis and a significantly lower success rate in patients with chronic diseases [Caroli's disease and primary sclerosing cholangitis (PSC)]. Patients with post-operative anastomotic strictures tend to recur in the 21.9% at 1 year and 28.1% at 2 years.
Conclusion: percutaneous anterograde biliary stones removal and stenosis treatment resulted effective procedures with an high success rate and low complications. The procedure is a technically feasible approach when endoscopic stones removal failed. The presence of stenosis or underlying chronic diseases affect the clinical and the radiological outcome.

B-0039 11:26

Parenchymal blood volume (PBV) measurement using C-arm-Dyna-CT as a prognostic marker for the response of HCC after repetitive transarterial chemoembolisation (TACE)

T.J. Vogl, K. Graef, L. Alizadeh, R. Hammerstingl, N.-E. Nour Eldin;
Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)

Purpose: To evaluate the prognostic value of intraprocedural parenchymal blood volume (PBV) parameters using C-arm-CT for the response in hepatocellular carcinoma (HCC) after transarterial chemoembolization (TACE).
Methods and Materials: 80 patients with HCC underwent at least 2 sessions of TACE. On average the patients had four PBV measurements in 4-6-week intervals. C-arm-CT scan was created with a rotation speed of 2cm. The images were post-processed and reconstructed at a workstation to build a PBV map. Then they were overlapped with MRI to measure tumour diameter and PBV.
Results: Results demonstrate significant correlations between PBV alteration and downsizing of HCC nodules. Initial blood volume of patients was x=111.39ml/1000ml (SD=66.88) with an average size of HCC lesions of 54.24mm. After first TACE, blood volume decreased on average to 69.84ml/1000ml (SD=47.29) and lesions were reduced to 49.14 mm in diameter. After repeated TACE average blood volume decreased to 73.03ml/1000ml (SD=47.82) showing a significant reduction of the lesion to 48.85cm in diameter documented in MRI. In the course of the study a considerable reduction in volume (-34.44%) and diameter (-9.94%) was documented. In patients with initial PBV>100ml/1000ml lesions decreased 10.27% in size and 52.78% in blood volume, in patients with a PBV of 50-100ml/1000ml lesions decreased 6.88% in size and increased 5.70% in blood volume, in patients with <50ml/1000ml lesions decreased 8.48% in size and increased 57.54% in blood volume.
Conclusion: PBV measurements can determine TACE effectiveness as patients with high initial PBV respond better to TACE regarding diameter and volume reduction.

B-0040 11:34

Image-guided percutaneous drainage of pancreatic duct: what for and how

M. Mizandari[1,1], T. Azrumelashvili[1], N. Habib[2]; [1]*Tbilisi/GE*, [2]*London/UK*
(mgmizandari@gmail.com)

Purpose: To present the percutaneous image-guided pancreatic duct (PD) drainage.
Methods and Materials: 45 patients underwent PD percutaneous image-guided drainage. In 44 of them, the indication was PD obstruction-related clinical symptoms (pancreatic irritation, recently revealed diabetes); in one case of pancreatic fistula non-dilated PD was drained. PD drainage was performed under combined image guidance - US and fluoroscopy (23) or CT and fluoroscopy (22 cases). After US or CT-guided PD puncture using 22 to 18G needles, drainage catheter was placed under the real-time fluoroscopy guidance over the wire.
Results: Drainage was successful in all cases including the case of non-dilated PD in post-biopsy pancreatic fistula. Clinical improvement was documented, pancreatic fluid discharge varied between 300 and 900 ml/day.

Five patients with recent onset of diabetes showed a dramatic improvement in glycaemic control.
Conclusion: The percutaneous PD drainage appears to be a safe and effective procedure and should be considered in patients with obstructed PD, especially in cases of failed endoscopic retrograde cannulation or where impracticable.

B-0041 11:42

Fluoroscopy-guided percutaneous interventions via pancreatic duct percutaneous drainage track for diagnosis and treatment: feasibility and technique

M. Mizandari[1,1], T. Azrumelashvili[1], N. Habib[2]; [1]*Tbilisi/GE*, [2]*London/UK (mgmizandari@gmail.com)*

Purpose: To present the percutaneous procedures, which might be performed after pancreatic duct (PD) percutaneous drainage.
Methods and Materials: 21 patients underwent percutaneous image-guided procedures using PD drainage track; among them - endoluminal RFA with subsequent stenting - 9, balloon-assisted percutaneous descending litholapaxy (BAPDL) - 6, endoluminal biopsy - 3, balloon dilatation - 2, stenting -1. The obligatory first step of all procedures was the wire conduction into the duodenum performed using 5 Fr diameter advantage catheter. RFA was performed by 5 Fr diameter novel bipolar RF device (15 watts of energy applied for 2 minutes), positioned in the strictured segment over the wire; BAPDL was performed applying the pushing-down efforts by partially inflated balloon after papilla dilatation. Endoluminal biopsy was performed by endobiliary forceps biopsy set. Balloon dilatation and stenting was performed using conventional technique.
Results: In 18 (85.7%) of 21 cases the procedures were completed, achieving either PD patency restoration or adequate tissue sample obtaining; in 3 (14.3%) cases (all pancreatic head cancers) the procedure completion was impossible due to failure of guidewire conduction across the strictured segment of PD. All patients tolerated the procedure well, there was no 30-day or hospital mortality; no technique-specific complications were observed.
Conclusion: Percutaneous fluoroscopy-guided percutaneous diagnostic and treatment procedures via pancreatic duct percutaneous drainage track are safe and effective; this procedures should be routinely suggested as treatment options for selected patients.

B-0042 11:50

Interstitial transpedal MR lymphangiography in pre-interventional work-up for lymphatic interventions in patients with chylous effusions

C.C. Pieper, H. Schild; *Bonn/DE (Claus.Christian.Pieper@ukb.uni-bonn.de)*

Purpose: To evaluate the clinical usefulness of transpedal MR lymphangiography (tMRL) for pre-interventional work-up for lymphatic interventions in patients with chylous effusions.
Methods and Materials: tMRL was performed in 25 patients (m/f: 13/12, mean age 54 years) with chylous effusions scheduled for lymphatic intervention. Indications were: traumatic/iatrogenic chylothorax n=6, non-traumatic chylothorax n=8, traumatic/iatrogenic chyle ascites n=3, non-traumatic chyle ascites n=3, combined chylothorax/chyle ascites n=5. Patients underwent tMRL at 1.5T with T1-weighted imaging after pedal/interdigital injection of gadolinium contrast-medium under local anaesthesia. Contrast-enhanced images were evaluated regarding depiction of leakage, a possible access site for lymph-vessel-embolisation and anatomical variations.
Results: Contrast injection was well tolerated in all patients without complications. Sedation was necessary in one case. In 20/25 patients enhancing central lymphatics were detectable (cause of failure: restlessness despite sedation n=1, lymphoma with lymphoedema n=1, technical reasons n=3). Leakage was identified in 13/20 patients. In 5 patients with chyle ascites, contrast medium leaked intraabdominally and did not reach the cisterna chyli. In the remaining 15 patients (thoracic/cervical pathologies) a possible access site for thoracic-duct embolisation was identified in 14/15 patients (cisterna chyli in 12/15, thoracic-duct (TD) in 14/15). 8/14 patients had a single TD and 6/14 a duplicated TD. In one patient, the TD terminated in the right venous angle. Overall 20/25 tMRL exams provided useful information to guide interventions.
Conclusion: Transpedal MR lymphangiography is a new and valuable diagnostic tool in patients with chylous effusions scheduled for lymphatic interventions, providing information on the anatomy of central lymphatics. The leakage site, however, cannot be identified in all cases.

Inspiratory/expiratory xenon-enhanced area-detector CT (ADCT): capability for pulmonary functional loss and clinical stage evaluations in smokers

Y. Ohno[1], Y. Fujisawa[2], Y. Kishida[1], S. Seki[1], N. Sugihara[2], T. Yoshikawa[1]; [1]*Kobe/JP*, [2]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To evaluate the capability of inspiratory/expiratory xenon (Xe)-enhanced area-detector CT (ADCT) for pulmonary functional loss and clinical stage evaluations in smokers.
Methods and Materials: Forty consecutive smokers prospectively underwent inspiratory/expiratory xenon-enhanced ADCT as well as pulmonary function tests. Then, all smokers were classified by GOLD classification-based pulmonary function test results. Each CT data were transferred to our proprietary software to generate Xe wash-in (WI), wash-in/wash-out (=WI/WO) ratio and ventilation (=[WI-WO]/WI) ratio maps between inspiratory/expiratory CT scans. According to the previous study, each pixel within the lung was divided into three lesion groups as follows: normal lung, functional small airway disease (fSAD) and emphysema. To determine regional ventilation differences, each Xe ventilation index was compared between three groups by Tukey's HSD test. To evaluate the capability for pulmonary function loss assessment, step-wise regression analyses were performed among all Xe ventilation indexes and pulmonary function test results such as $\%FEV_1$ and $FEV_1/FVC\%$. Finally, discrimination analysis was performed to determine the concordance capability for GOLD stage classification was also determined.
Results: WI and ventilation ratio had significant difference among three lesion groups ($p<0.05$) and WI/WO ratio of emphysema had significant difference with that of others ($p<0.05$). $\%FEV_1$ ($r^2=0.71$, $p<0.05$) and $FEV_1/FVC\%$ ($r^2=0.71$, $p<0.05$) were significantly affected by ventilation ratio as 1st step and WI as 2nd step. With all Xe ventilation indexes, the concordance capability for GOLD classification was determined as 85.0 (32/40)%.
Conclusion: Inspiratory/expiratory xenon-enhanced ADCT was useful for pulmonary functional loss and clinical stage evaluations in smokers.

A meta-analysis of a UIP pattern on CT: is surgical lung biopsy necessary in patients with a possible UIP pattern?

H. Kim, S.H. Yoon, H. Hong, S. Hahn, J.M. Goo; *Seoul/KR (heekyung0363@gmail.com)*

Purpose: With the recent introduction of anti-fibrotic agents for idiopathic pulmonary fibrosis (IPF) treatment, accurate diagnosis of IPF has become more important. According to the ATS/ERS/JRS/ALAT statement in 2011, surgical lung biopsy is required to make a diagnosis of IPF for patients with a possible usual interstitial pneumonia (UIP) pattern on HRCT, while not required for those with UIP pattern. We performed a meta-analysis of whether the surgical lung biopsy is essential for IPF diagnosis with the possible UIP pattern.
Methods and Materials: We performed literature searches of the MEDLINE and EMBASE databases and included studies which conducted a radiologic-pathologic evaluation of IPF according to the 2011 guidelines. Outcomes were pooled using a random-effects model.
Results: Twelve studies were included. Pooled proportions of IPF were 99% (95%CI, 93% to 100%; $I^2=51.7\%$) for a UIP pattern and 94% (95%CI, 87% to 99%; $I^2=82.9\%$) for a possible UIP pattern. The proportion of IPF for an inconsistent UIP pattern was substantially heterogeneous ranging from 0% to 100% (median, 49%). Pooled percentage difference in proportions of IPF between UIP and possible UIP patterns was -1% (95%CI, -4% to 1 %; $I^2=0.0\%$). Proportions of IPF in possible and inconsistent UIP patterns were correlated with the prevalence of IPF (Spearman correlation coefficient, 0.605[95%CI, 0.055-0.860] for possible UIP; 0.769 [95%CI, 0.319-0.928] for inconsistent UIP).

Conclusion: Proportions of IPF diagnosis when biopsied were comparable between UIP and possible UIP pattern, indicating that IPF diagnosis can be made with a possible UIP pattern without biopsy as a UIP pattern.

B-0045 10:46

Follow-up of idiopathic pulmonary fibrosis: computed tomography vs functional metrics

G. Milanese[1], M. Silva[1], V. Seletti[1], C. Galeone[2], B. Bartholmai[3], S. Palmucci[4], S. Piciucchi[5], R. Karwoski[3], N. Sverzellati[1]; [1]*Parma/IT*, [2]*Milan/IT*, [3]*Rochester, MN/US*, [4]*Catania/IT*, [5]*Forli/IT (gianluca.milanese@studenti.unipr.it)*

Purpose: To test the prognostic value of HRCT with either visual or quantitative analysis in both short-term and long-term follow-up of idiopathic pulmonary fibrosis (IPF), and to compare it with pulmonary function test (PFT).
Methods and Materials: Consecutive patients with a multidisciplinary diagnosis of IPF were retrospectively selected from two referral hospitals. Selection criteria included: availability of baseline, 8-12 months, and 18-30 months volumetric HRCT (hereafter HRCT0, HRCT1, HRCT2, respectively); absence of exacerbation within the defined follow-up period. Visual score was performed by two radiologists for the total extent of interstitial lung disease (ILD) and its individual patterns; nominal category of longitudinal disease behavior was defined as follows: improvement, stability, or progression. Quantitative analysis included global histogram descriptors of lung density (mean density, skewness, kurtosis) and textural analysis (CALIPER). Prognostic value of both visual and quantitative measures and their deltas were evaluated by adjusted stepwise multivariate analysis, at HRCT0, HRCT1, and HRCT2. The reference standard for pulmonary function trend was defined by decline in forced vital capacity (FVC), as per official guidelines.
Results: Fifty-eight consecutive patients were followed for 43.8 months. At HRCT1, either a relative increase in ILD extent greater than 20% with CALIPER or visual categorical assessment of disease behavior improved the prognostic value of FVC decline >10% (HR 38.8; 95%CI:6.82-232.2). Likewise, combining either PVRV changes or visual categorical assessment of disease behavior at HRCT2 increased the prognostic value of the HRCT0-HRCT2 FVC trend (HR 10.96; 95%CI:2.31-51.99).
Conclusion: HRCT changes by visual or textural analysis can be added with benefit to the current spirometric reference standard to improve prediction of mortality in IPF. Annual combined HRCT-functional changes showed the greatest prognostic value.

Chest HRCT findings in adult patients with different subtypes of humoral primary immunodeficiencies and correlation with lung function test results

L. Cereser, F. Greco, E. Zanelli, P. D'Angelo, M. De Carli, C. Zuiani, R. Girometti; *Udine/IT (elisazanelli@hotmail.it)*

Purpose: To assess HRCT findings in different subtypes of patients with humoral primary immunodeficiencies (h-PIDs), and whether they predict pulmonary function test (PFT) results.
Methods and Materials: We retrospectively identified fifty-two consecutive adult patients with h-PIDs who performed HRCT (64-raw multidetector equipment) and PFT at the time of diagnosis. On a per-patient basis, one experienced radiologist recorded airway (bronchiectasis, airway wall thickening, mucus plugging, tree-in-bud and air-trapping) and parenchymal-interstitial abnormalities (consolidations, ground-glass opacities, septal thickening/linear opacities, parenchymal nodules and bullae/cysts) on HRCT. We used the chi-square test to compare the prevalence of each of the above abnormalities between different subtypes of h-PIDs included in the study. On the overall population, we also performed logistic regression analysis to assess whether HRCT findings predicted either obstructive or restrictive PFT results (absent-to-mild vs moderate-to-severe).
Results: Patients showed common variable immunodeficiency (CVID) in 38/52 cases, and CVID-like condition in 14/52 cases (11 IgG subclass deficiencies + 3 selective IgA deficiencies), respectively. We observed no significant difference in the prevalence of airway or parenchymal-interstitial HRCT abnormalities between CVID and CVID-like patients ($p>0.05$), with bronchial wall thickening being the most frequent finding in both groups (71%). On multivariate analysis, tree-in-bud and septal thickening-linear opacities were found as independent predictors ($p<0.05$) of significant obstructive defect (OR, 18.75%) and restrictive defect (OR, 13.95%), respectively.
Conclusion: There was no significant difference in HRCT findings between h-PIDs subtypes. Tree-in-bud and septal thickening-linear opacities were found to be predictors of higher risk of ventilatory obstructive and restrictive defects on PFT, respectively.

B-0047 11:02

Effect of different radiation doses and reconstruction kernels of HRCT on texture analysis-based artificial neural network classification of patients with systemic sclerosis

G. Milanese[1,2], M. Mannil[2], K. Martini[2], B. Maurer[2], H. Alkadhi[2], T. Frauenfelder[2]; [1]*Parma/IT*, [2]*Zurich/CH (gianluca.milanese@studenti.unipr.it)*

Purpose: Texture analysis (TA) uses quantitative, statistical metrics to evaluate image characteristics reflecting microstructural changes. We used TA in high-resolution Computed Tomography (HRCT) with different radiation dose (RD) and reconstruction kernels (RK) to discriminate between Systemic Sclerosis (SSc) patients and non-SSc controls by use of an artificial neural network (ANN).
Methods and Materials: Eighty-five HRCT with different RD (36 low-dose, LDCT and 49 standard dose, SDCT) were retrospectively selected. Each CT was reconstructed with filtered-back projection - FBP - and iterative - SAFIRE 3 and 5 - algorithms. Sixty-one individuals were SSc patients. 304 TA metrics were extracted at six levels through manually-drawn regions of interest. Each metric was averaged between the six levels and acted as input in an ANN with backpropagation (MultilayerPerceptron) for classification of SSc and non-SSc patients. Results were compared regarding correctly/incorrectly classified instances and Receiver-Operating Characteristics - Area under the curve (ROC-AUC). Results were compared between CT with different RK, independently from RD, and between CT with different RK and RD.
Results: The highest discriminatory power for TA-based diagnosis was on FPB-CT: the ANN correctly classified patients in the 84.9% of cases (ROC-AUC=0.904). For CT with different RD, the highest discriminatory power for TA-based diagnosis was for LDCT, and among RK, for FBP-CT. With FBP-LDCT, the ANN correctly classified patients in the 93.8% of cases (ROC-AUC=0.981).
Conclusion: TA metrics extracted from six LDCT images reconstructed with FPB show the highest discriminatory power for the TA-based diagnosis of SSc patients.

B-0048 11:10

Description of interstitial findings in patients with diverse severity of telomere shortening

H. Jofré, L. Planas, P. Luburich, A. Conejero, M. Molina; *Barcelona/ES (hector.jofre.g@gmail.com)*

Purpose: It is known that telomere shortening (TS) is a poor predictor factor for pulmonary fibrosis. This disorder presents in a majority of patients with familial pulmonary fibrosis (FPF) and in 30% of patients with idiopathic pulmonary fibrosis (IPF). A description of radiological findings and the pattern of progression are performed in patients with TS.
Methods and Materials: Descriptive retrospective study including 50 patients with TS. Telomere length was calculated through quantitative polymerase chain reaction and Z-score (mean length +/- SD) for age matched healthy controls, obtained from DNA of mouth epithelial cells. Thoracic CT of included patients were analysed. The radiological findings and their pattern of progression were characterised by comparing subgroups of different severity of TS ($p<1\%$, $p<10\%$ and $p<25\%$).
Results: 90% of patients with TS had interstitial fibrosing changes in thoracic CT. 84% of patients in the subgroup $p<1\%$ were <60 years old at diagnosis CT, while in the less severe TS subgroups ($p<10\%$ and $p<25\%$), 78% of patients were >60 years old at diagnosis CT. The UIP pattern was seen in 7% of patients in the subgroup $p<1\%$, in 46% $p<10\%$ and 52% $p<25\%$. Inconsistent UIP pattern was seen in 84% of patients in the subgroup $p<1\%$, 20% in $p<10\%$ and 11% in $p<25\%$. 77% of patients showed progression, with an average of 1.3 years in the $p<1\%$ subgroup, 3.8 years in $p<10\%$ and 3.6 in $p<25\%$.
Conclusion: Patients with severe telomere shortening ($p<1\%$) presents earlier and heterogeneous changes at thoracic CT, with faster progression.

B-0049 11:18

Correlation between pulmonary function tests and HRCT indexes in idiopathic pulmonary fibrosis (IPF) patients

S. Palmucci[1], S.E. Torrisi[1], D. Falsaperla[1], A. Torcitto[1], A. Basile[1], R. Rosso[1], A. Stefano[2], G. Russo[2], C. Vancheri[1]; [1]*Catania/IT*, [2]*Cefalù/IT (spalmucci@sirm.org)*

Purpose: The aim of this study is to investigate the correlation between pulmonary function tests (FVC and DLCO) and HRCT quantification indexes in a cohort of patients with idiopathic pulmonary fibrosis (IPF).
Methods and Materials: The analysis was carried out on 39 IPF patients having at least two HRCT (baseline and follow-up) and two spirometry tests available - collected no more than 3 months from HRCT evaluation. The extent of fibrotic disease was quantified on HRCT examinations calculating Kurtosis, High attenuation area (HAA) and fibrotic area (FA) indexes. Pearson's

correlation coefficient was performed to assess the strength of association between pulmonary function tests and HRCT indexes.
Results: Considering baseline HRCT and pulmonary function tests, Pearson correlation analysis revealed moderate correlations between Kurtosis and FVC (r=0.58 with p=0.0001), Kurtosis and DLCO (r=0.52 with p=0.0005), HAA and FVC (r=-0.56 with p=0.0001), HAA and DLCO (r=-0.48 with p=0.0017), FA and FVC (r=-0.56 with p=0.0002), and FA and DLCO (r=-0.49 with p=0.0013). On follow-up, analysing HRCT and pulmonary function tests, Kurtosis and FVC shower a positive strong correlation (r=0.62 with p<0.0001), whereas Kurtosis and DLCO maintained a moderate positive correlation (r=0.55 with p=0.0002); negative correlations were found for HAA and FVC (r=-0.62 with p<0.0001), HAA and DLCO (r=-0.50 with p=0.0011), FA and FVC (r=-0.57 with p=0.0001) and FA and DLCO (r=-0.45 with p=0.0039).
Conclusion: HRCT quantification indexes showed a moderate or good strength of association with pulmonary function tests; therefore, these indexes may be useful for radiologists in the monitoring of IPF disease.

B-0050 11:26

Performance of a software prototype for ILD patterns recognition: how does it compare to chest radiologists?

J. Cohen[1], S. Kritter[1], P. Hirt[1], J. Ghelfi[2], E. Reymond[1], G.R. Ferretti[1];
[1]*Grenoble/FR*, [2]*Meylan/FR (jcohen@chu-grenoble.fr)*

Purpose: To evaluate the performance of a deep-learning software prototype in the recognition of various patterns of interstitial lung diseases (ILDs) compared to 2 chest radiologists.
Methods and Materials: This retrospective study included 20 consecutive patients diagnosed with ILDs. 2 Radiologists retrospectively reviewed each CT and defined region of interests on 5 predefined slices for each of the following patterns : honeycombing, intralobular reticulation, traction bronchectasis, ground-glass, consolidation and healthy lung. The scans were subsequently processed by a locally designed deep-learning software which analyzed each patch of 16x16 voxels in the designed slices and attributed for each a predominant pattern. We then compared the results of the 2 radiologists and radiologist 1 and 2 versus software.
Results: Among the 20 included patients, the following diagnosis were proposed after multidisciplinary concertation: IPF (n=9), NSIP (n=2), Churg Strauss ILD (n=1), lymphangitic interstitial pneumonia (n=1), antisynthethasis syndrome (n=1), amiodarone-induced ILD (n=1), undetermined (n=5). When comparing radiologist 1 versus software, values of sensitivity/specificity/PPV/NPV were 28/97/19/98%, 30/93/25/94%, 14/96/1/100%, 46/85/26/93%, 32/99/13/100%, 52/90/95/34% for honeycombing, intralobular reticulation, traction bronchectasis, ground-glass, consolidation and healthy lung, respectively. For radiologist 2 versus software, those values were of 24/97/21/98%, 18/93/22/91%, 16/96/7/99%, 39/87/46/84%, 39/99/23/99% and 59/81/84/54% for the same patterns. Comparatively, when comparing radiologists 2 versus 1, values were of 77/98/33/96%, 35/91/24/94%, 42/98/5/100%, 67/84/33/96%, 61/99/41/100%, and 75/88/96/50%.
Conclusion: At this early stage of development, although sensitivity of detection of ILD patterns by the software remained lower than chest radiologists, its specificity was high for most pathologic patterns with very high NPVs.

B-0051 11:34

Computed tomography in primary ciliary dyskinesia: typical imaging findings in the cohort of adult patients with bronchiectasis

S. Dettmer, F. Ringshausen, J. Vogel-Claussen, J. Fuge, A. Faschkami, H.-.O. Shin, T. Welte, F. Wacker, J. Rademacher; *Hannover/DE (dettmer.sabine@mh-hannover.de)*

Purpose: Aim of this study was to evaluate specific features of Primary Ciliary Dyskinesia in computed tomography in the cohort of bronchiectasis to facilitate diagnosis.
Methods and Materials: 121 CT in patients with bronchiectasis were scored for involvement, type, and lobar distribution of bronchiectasis, bronchial dilatation, and bronchial wall thickening. Further-on, associated findings like tree in bud, mucus plugging, consolidations, ground glass opacities, interlobular thickening, intralobular lines, situs inversus, emphysema, and atelectasis were registered. Patients with PCD (n=46) were compared to patients with other underlying diseases (n=75).
Results: In patients with PCD, the extent and severity of bronchiectasis were significantly lower in the upper lobes (p<0.001-p=0.011). The lobar distribution was significantly different (<0.001) with predominance in the middle and lower lobes in patients with PCD. Significantly more common in patients with PCD were mucous plugging (p=0.001), tree in bud (p <0.001), atelectasis (p=0.009), and history of resection of a middle or lower lobe (p=0.047); less common were emphysematous (p=0.003) and fibrotic (p<0.001) changes. A situs inversus (Kartagener's Syndrome) was only seen in patients with PCD (17%, p <0.001).
Conclusion: Typical imaging features in PCD are a predominance of bronchiectasis in the middle and lower lobes, severe tree in bud pattern, mucous plugging and atelectasis. These findings may help practitioners to identify patients with bronchiectasis in which further work-up for PCD is warranted.

B-0052 11:42

CT quantitative and semi-quantitative thoracic and extra-thoracic biomarkers in COPD patients: how reliably can they predict patients' outcomes?

J. Cohen, G. Ferretti, M. Benmerad, S. Bailly, C. Ozcelik, E. Reymond, A. Jankowski, S. Bayat, J.-L. Pepin; *Grenoble/FR (jcohen@chu-grenoble.fr)*

Purpose: To evaluate the performance of CT biomarkers for predicting 5-year survival, number of pulmonary infections, hospitalisations and cardiovascular events in COPD patients.
Methods and Materials: This retrospective preliminary study included 30 COPD patients from a prospective cohort, with at least one unenhanced chest CT-scan. A chest radiologist retrospectively assessed the following parameters: inspiration %LAA-950, expiration %LAA-856, pre-pectoral subcutaneous adipose tissue (PSAT), anterior mediastinal fat surface, epicardial fat surface, mean liver attenuation, mean liver/spleen attenuation ratio (LSAR), coronary calcifications using Weston score, presence of bronchiectasis and bronchial thickenings, density of vertebral bodies in T4,7,10. PSAT, anterior mediastinal and epicardial fat were subsequently normalised by the patients' body surface area. These parameters were then compared using univariate analyses with the 5-year survival, number of hospitalisations, pulmonary infections and cardiovascular events.
Results: Median follow up time for the investigated outcomes was 7 years (interquartile range (IQR)=3 years). Median patient age was 65 (IQR=11 years). Mortality was significantly higher in patients who had a higher mean liver attenuation (p=0.02) and a lower mean vertebral density in T4-7-10 (p=0.01). Patients with more lung infections had a significantly lower PSAT area (p=0.02), mean attenuation in T4-7-10 (p=0.001) and a higher LSAR (p=0.001). A higher number of hospitalisations was associated with a lower PSAT area (p=0.02), a higher LSAR ratio (p=0.01) and %LAA-950 (p=0.01).
Conclusion: Simple CT-biomarkers show the potential to predict the 5-year survival, the risk of intercurrent infections and hospitalisations and in COPD patients. Further analyses, particularly multivariable, are needed to confirm these results.

B-0053 11:50

Solid indeterminate pulmonary nodules less than 300 mm³: application of the British Thoracic Society guidelines in clinical practice

S. Pezzotti, A. Borghesi, G. Nocivelli, A. Scrimieri, R. Maroldi; *Brescia/IT (stefy.pezzotti@gmail.com)*

Purpose: To evaluate the performance of the British Thoracic Society (BTS) recommendations for the management of solid indeterminate pulmonary nodules (SIPNs) <300 mm³.
Methods and Materials: During a 7-year period we retrospectively reviewed the chest CT of 672 consecutive patients with one or more SIPNs. The study sample was selected according to the following inclusion criteria: solitary SIPN; volume <300 mm³; 2 or more CT scans performed with the same scanner and acquisition/reconstruction protocol; thin-section 1-mm images in DICOM format; histologic diagnosis or follow-up >2 years. Patients with previous oncology history were excluded. Applying such criteria a total of 29 patients with 29 SIPNs were enrolled. For each SIPN, the volume and doubling time (DT) were calculated using a semiautomatic software throughout the follow-up period. For each SIPN, we retrospectively applied the BTS guidelines and this management was compared to what was actually done.
Results: A significant volumetric increase (more than 20% with DT <600 days) has been observed in 6/29 SIPNs. In these SIPNs a histologic diagnosis of malignancy was obtained. Applying the BTS recommendations all 6 malignant nodules would have been identified. None of the SIPNs with volume <300 mm³ and DT >600 days showed a significant growth during the follow-up period. The application of the BTS guidelines would have led to a reduction in CT examinations (1.5 CT scan for patients).
Conclusion: The application of BTS guidelines has proven to be effective in the management of SIPNs <300 mm³ with a significant reduction of radiation dose.

Contrast-enhanced ultrasound in evaluation of renal masses: a preliminary experience

M. Altamash, S.B. Grover, S. Suman, A. Katyan, A. Kumar, A.K. Mandal; *New Delhi/IN (md.altamash20@gmail.com)*

Purpose: Although grey scale ultrasound (US) and colour doppler are fairly efficient in evaluation of renal masses, characterizing complex renal masses remains a limitation. CECT is associated with significant risk for patients with hyperthyroidism, impaired renal function and allergic reactions because of iodinated contrast agents. Our study was therefore, aimed to evaluate the role of contrast-enhanced ultrasound in characterization of renal masses and to correlate it with contrast-enhanced CT and histopathology.
Methods and Materials: Twenty three patients with clinically or sonographically detected renal masses were included in this IRB approved study. Renal masses were evaluated using gray sale ultrasound and contrast-enhanced ultrasound for location, morphology and enhancement pattern. The mass lesions were categorized in benign and malignant varieties. The criteria for malignant mass lesion on contrast-enhanced ultrasound were centripetal enhancement along-with early contrast wash-in and wash out. Results were compared with contrast-enhanced computed tomography scan and histopathology.
Results: Using histopathology as gold standard, the sensitivity and specificity of contrast enhanced ultrasound in characterization of benign and malignant masses were found to be 95% and 88% respectively.
Conclusion: Currently, renal lesions are characterized by contrast-enhanced computed tomography (CECT). Our study showed that contrast-enhanced ultrasound has almost similar sensitivity and specificity to that of CECT in characterization of renal masses.Thus, contrast-enhanced ultrasound can be used as noninvasive procedure for characterization of renal masses and should be further exploited for its role in characterization of renal masses.

B-0055 10:38

Value of contrast enhanced ultrasound in evaluation of cystic renal lesions compared to computed tomography and magnetic resonance Imaging

M.H. Lerchbaumer[1], J. Rübenthaler[2], F.J. Putz[3], T. Slowinski[1], D.A. Clevert[2], E.-M. Jung[3], T. Fischer[1]; [1]*Berlin/DE*, [2]*Munich/DE*, [3]*Regensburg/DE (markus.lerchbaumer@charite.de)*

Purpose: To assess the value of contrast-enhanced ultrasound (CEUS) in the evaluation of cystic renal lesions using the Bosniak classification compared with computed tomography (CT), magnetic resonance imaging (MRI) and histopathologic findings (HP).
Methods and Materials: We performed a multicentre, retrospective analysis of 340 CEUS examinations in high volume ultrasound centres in Germany. Bosniak classification of cystic renal lesions is compared to further diagnostic up imaging (CT or MRI) and HP.
Results: Median age was 64 years (IQR: 56-72) and 69 % were male patients. CEUS showed an overall moderate correlation when compared to CT and MRI (r^2=0.55; 95% CI 0.40-0.67, p<0.001). Lesions classified by CEUS were significantly higher correlated with CT than MRI with a correlation coefficient of 0.92 (95% CI 0.91-0.98, p<0.001) and 0.42 (95% CI 0.23-0.59, p<0.001), respectively. Most frequent misclassified renal lesions in CEUS compared to MRI were Bosniak IIF (n= 14/28) and Bosniak III cysts (n= 11/21). Of 252 lesions which were classified as Bosniak IV in CEUS and therefore identified as suspect for an active malignancy 84.1% (n= 212) were identified as renal cell carcinoma through histopathologic examination (Sensitivity 99%, Specificity 0%, PPV 84%, NPV 0%).
Conclusion: Renal lesions classified by CEUS using the Bosniak classification have a high correlation when compared to current gold standard CT. MRI seems to downgrade especially Bosniak IIF and III lesions compared to CEUS. CEUS showed excellent sensitivity in detection of malignancy compared to histopathological report.

B-0056 10:46

Contrast-enhanced ultrasonography (CEUS) and time/intensity curves for the active surveillance of small renal masses

E. Bertelli, S. Agostini, G. Addeo, S. Verna, F. Parretti, C. Raspanti, A. Minervini, A. Mari, V. Miele; *Florence/IT (elena.bertelli3@gmail.com)*

Purpose: To assess the prognostic efficacy of contrast-enhanced ultrasonography (CEUS) and time/intensity (T/IS) curves for the active surveillance of small renal masses (SRM).
Methods and Materials: We performed CEUS in 288 patients to evaluate 312 renal lesions. All the lesions were confirmed by Contrast-enhanced CT or Contrast-enhanced MR. 66 patients were operated (group A), 246 (group B) are nowadays at least in a 3 years follow up. We performed a quantitative evaluation of the lesions enhancement (QE) by T/IS curves. We identify 4 type of curves: I "quick wash in (WI) and wash out (WO)", II "quick WI and slow WO", III "WI and WO synchronous to the surrounding parenchyma" IV "slow WI and WO".
Results: In the group A we performed the QE in 56 cases, 3 patients were not evaluated by time/intensity curves and 7 had cystic lesions; in the group B we performed the QE in 85 cases, 139 patients have cystic lesions and 22 were not evaluated. Patients with type I curves (16) had aggressive lesions in 96% of cases, patients with type II (40) in 57%, patients with type IV (49) in 18%; no aggressive lesions showed a type III pattern. The limits of our study are the small number of cases and the duration of follow up.
Conclusion: CEUS is a safe, cost-effective procedure, suitable for patients with impaired renal function. T/IS curves are a useful tools for active surveillance because they could provide information about the aggressiveness of renal lesions.

B-0057 10:54

Contrast-enhanced ultrasound (CEUS) as a new technique to characterise suspected malignancies in renal transplants in comparison to standard imaging modalities

K. Mueller-Peltzer, J. Rübenthaler, D.A. Clevert; *Munich/DE (katharina.muellerpeltzer@med.uni-muenchen.de)*

Purpose: Renal transplant patients have a higher risk for malignancies of the renal transplant. In most cases suspected renal malignancies will be detected during the regular ultrasound follow-up and will require cross-sectional imaging to rule out a malignant aetiology. But it is well known that contrast agents for crossectional imaging are critical in patients with limited renal function.Therefore, this study aims to compare the sensitivity and specificity of contrast-enhanced ultrasound (CEUS) and gold standard imaging in characterizing suspected renal transplant malignancies in renal transplant patients.
Methods and Materials: A total of 22 renal transplant patients with a suspected renal transplant malignancy with at least one CEUS and at least one crossectional imaging study performed between 2005 and 2017 were included. Patient ages ranged from 28.2 years to 74.6 (mean age 55.7 years; SD ± 13.0 years). CEUS of 22 patients was correlated with a standard imaging modality, CT (15 out of 22) or MRI (7 out of 22), serving as gold standard.
Results: All 22 lesions of the renal transplants described in CT or MRI could be detected using CEUS. CEUS showed a sensitivity of 100%, a specificity of 94.4%, a positive predictive value (PPV) of 80%, and a negative predictive value (NPV) of 100%.
Conclusion: CEUS is an eligible method to help characterizing suspected renal malignancies in renal transplant patients compared to the well-established imaging modalities CT and MRI. As an imaging modality with no nephrotoxic effects CEUS can be used repeatedly even in patients with limited renal function.

B-0058 11:02

Percutaneous cryoablation for renal cell carcinoma using US-guided targeting and CT-guided ice-ball monitoring: procedure time, radiation dose and mid-term outcomes

D. Kim, S. Park; *Seoul/KR (kdk7118@yuhs.ac)*

Purpose: To assess procedure time, radiation dose and mid-term outcomes of percutaneous cryoablation (PCA) for renal cell carcinoma (RCC) using US-guided targeting and CT-guided ice-ball monitoring.
Methods and Materials: A consecutive series of 39 patients (mean age, 60.6±15.3 years) who underwent PCA for biopsy-proven RCC were included. The mass targeting was performed with US guidance and a radiographic ice-ball was monitored with CT. The procedure time was defined by the interval of image acquisition between the first US and last CT images. The effective radiation dose of CT examination during PCA was recorded. The follow-up was conducted with contrast-enhanced CT or MRI (mean follow-up time, 10.1±7.0 months; range, 1-23 months). The local tumour progression was defined by the presence of focal enhancing areas at the ablation zone (CT, 20 or greater

Hounsfield unit, MRI, presence of focal enhancement on subtraction contrast-enhanced image).
Results: The mean procedure time was 110.3±22.8 minutes (range, 79-183 minutes). The mean effective radiation dose in association with PCA was 13.7±5.2 mSV (range, 8.0-28.6 mSV). The local tumour progression occurred in a single patient (2.6%, 1/39). The local tumour progression-free survival rate was 95.7%.
Conclusion: PCA using US-guided targeting and CT-guided ice-ball monitoring may allow acceptable tumour control for RCC, as reducing radiation dose.

B-0059 11:10

Is multiparametric MRI useful for differentiating oncocytomas from chromophobe renal cell carcinomas

C. Galmiche; *Bordeaux/FR (chloe.g1412@gmail.com)*

Purpose: The purpose of this study was to retrospectively evaluate the diagnostic accuracy of multiparametric MRI to differentiate oncocytoma from chromophobe renal cell carcinoma.
Methods and Materials: In this retrospective study, 26 histologically confirmed oncocytomas and 16 chromophobe RCCs that underwent full MRI examination were identified in 42 patients (25 men and 17 women) over a 6-year period. Demographic data were recorded. Double-echo chemical-shift, dynamic contrast-enhanced T1-and T2-weighted images, and apparent diffusion coefficient maps were reviewed independently by two radiologists blinded to pathologic results. Signal-intensity index (SII), tumor-to-spleen signal-intensity ratio, ADC ratio, three wash-in indexes, and two washout indexes were calculated and compared using univariate and ROC analyses. Sensitivity and specificity analyses were performed to calculate diagnostic accuracy.
Results: All carcinomas and nine oncocytomas were resected; the remaining 17 oncocytomas were biopsied. Patient age (for oncocytomas: mean, 68.2 years; range, 43-84 years; for RCCs: mean, 60.8 years; range, 20-79 years) and tumor size (for oncocytomas: mean, 35.5 mm; range, 12-98 mm; for RCCs: mean, 37.2 mm; range, 9-101 mm) did not differ significantly across groups (p = 0.132 and 0.265, respectively). Good interobserver agreement was observed for all measurements but four. Oncocytomas presented significantly higher ADC (p = 0.002) and faster enhancement (p = 0.007-0.012) but lower SII (p = 0.03) than carcinomas. This combination provided sensitivity of 92.3% (24/26), specificity of 93.8% (15/16), and accuracy of 92.9% (39/42) for the detection of oncocytomas.
Conclusion: Multiparametric MRI helps to accurately differentiate oncocytomas from chromophobe RCCs with high sensitivity and specificity.

B-0060 11:18

CT texture analysis in clear cell renal cell carcinoma: a radiogenomics prospective

S. Badia[1], D. Bellini[1], C. Marigliano[2], M. Rengo[1], M. Osimani[1], S. Picchia[1], V. Petrozza[1], A. Laghi[1]; [1]*Latina/IT*, [2]*Milan/IT (stefano.badia@gmail.com)*

Purpose: The aim of this study was to investigate whether quantitative parameters obtained from CT texture analysis (CTTA) correlate with expression of miRNA in clear cell renal cell carcinoma (ccRCC).
Methods and Materials: In a retrospective single-centre study, multiphasic CT examination (with arterial, portal and urographic phases) was performed on 64 patients with ccRCC (28 women and 36 men; mean age 65 years ± 6). Measures of heterogeneity were obtained in post-processing by placing a ROI on the entire tumour and CTTA parameters such as entropy, kurtosis, skewness, mean, mean of positive pixels and SD of pixel distribution histogram were measured using multiple filter settings. Quantitative data were correlated with miRNAs obtained from histopathological analysis (miR-21-5p, miR-210-3p, miR-185-5p, miR-221-3p, miR-145-5p). Both evaluations (miRNAs and CTTA) were done on normal corticomedullar and tumour tissue for comparison. Analysis of variance with linear multiple regression model methods were obtained with SPSS statistic software. For all comparisons, statistical significance was assumed $p<0.05$.
Results: The expression of miR-21-5p, miR-210-3p and miR-221-3p resulted up-regulated in tumour samples. Among all miRNAs, normal tissue entropy was not related to miR-21-5p (R^2= 0.06), while a trend of positive correlation was found with tumour tissues (R^2=0.27). Excluding some patients with extreme over-expression of miR-21-5 (10%), excellent relation of entropy in tumour with miR21-5p was found (R^2= 0.64; $p<0.05$).
Conclusion: Entropy and miRNA 21-5p show positive correlation in ccRCC; in addition CTTA features, in particular, mean and entropy show a statistically significant increase in ccRCC as compared with normal tissue.

B-0061 11:26

Assessing venous thrombus in renal cell carcinoma: preliminary results for non-contrast enhanced magnetic-resonance 3D-SSFP

L. Adams, B. Ralla, G. Engel, G. Diederichs, J. Busch, F. Fuller, B. Hamm, M.R. Makowski; *Berlin/DE*

Purpose: To test the potential of non-contrast-enhanced cardiac- and respiratory-motion-corrected three-dimensional-steady-state-free-precession (3D-SSFP) MR imaging for the assessment of inferior vena cava (IVC) thrombus in patients with renal cell carcinoma (RCC), compared to standard contrast enhanced MRI.
Methods and Materials: 14 patients with RCC and suspected IVC thrombus, who received a contrast-enhanced abdominal MRI and 3D-SSFP at 1.5T as a standard preoperative work-up procedure between June 2015 and September 2017, could be included in this retrospective study. Contrast-to-noise-ratios (CNR), image quality and diagnostic performance of 3D-SSFP and standard MRI were compared. Additionally, in vivo- findings were validated against intraoperative results and histopathological examinations.
Results: Both 3D-SSFP and contrast-enhanced MRI correctly identified the extent and approximate volume of all IVC thrombi, confirmed by surgery and histopathology. 3D-SSFP reached a significantly higher CNR in the supra- and infrarenal IVC compared to morphologic imaging (T2-HASTE), the unenhanced, the portal venous, nephrogenic and delayed phase. 3D-SSFP showed a significantly higher CNR in the infrarenal IVC (mean CNR of 8.61±3.90 vs. 3.84±1.54 in the delayed phase, p=0.005) and a slightly higher CNR in the suprarenal IVC (mean CNR of 8.66±3.76 vs. 5.00±6.31 in the late arterial phase, p=0.055). The thrombus delineation score for 3D-SSFP (4.38±0.76) was higher compared to standard MRI (3.76±0.71, p=0.016).
Conclusion: This preliminary study indicates that cardiac- and respiratory-motion-corrected 3D-SSFP can achieve an accurate delineation of IVC thrombus in RCC patients without the need for contrast administration. 3D-SSFP may thus offer a valid alternative for patients with contraindications to gadolinium-based contrast agents.

Can we diagnose T1 stage UB (urinary bladder) cancer from T2 stage with an inchworm/stalk sign on 3T-MRI?

D. Kim, B. Kang, Y. Ko; *Seoul/KR (kangbc@ewha.ac.kr)*

Purpose: To evaluate diagnostic performance of an inchworm sign/ stalk sign on MRI for T1 stage UB cancer.
Methods and Materials: Among 261 consecutive UB cancer patients underwent radical cystectomy with neobladder. We described the tumorous high signal intensity curve on DWI as an 'inchworm sign' and the fibrovascular stalk on T2WI as a 'stalk sign'. If the inchworm sign(DWI) or stalk sign(T2WI) was shown, it was grouped as T1 staging. If not shown, it was grouped as over T2 staging. If there was hydronephrosis associated with UB tumour, even having that signs, it was grouped as over T2 staging. We compared the preoperative MR T-stage and postoperative pathological T-stage in all enrolled patients. We evaluated the diagnostic significance an inchworm sign (DWI) and a stalk sign (T2WI) statistically by χ^2 -Test and McNemar test/Fisher's exact test.
Results: For diagnosing T1 stage UB cancer, the "inchworm sign(DWI)" and the "stalk sign(T2WI)" showed high specificity (94%, 95%), high positive predictive value (81%, 77%), and high accuracy (80%, 76%). And we found their diagnostic accuracy to increase (86%, 79%) with hydronephrosis. So, even inchworm sign or stalk sign were seen, with associated hydronephrosis, we can preoperatively indicate over T1 staging urinary bladder cancer with more higher prediction.
Conclusion: We can easily diagnose T1 UB cancer from T2 by detecting an inchworm sign(DWI), or a stalk sign(T2WI) on MRI. If there is associated with hydronephrosis, suggesting UVJ muscle layer invasion by UB cancer, its diagnostic value could be increased.

B-0063 11:42

Investigation of intravoxel incoherent motion diffusion-weighted imaging for assessing bladder cancer invasiveness

F. Wang, G. Wu, W. Chen; *Shanghai/CN*

Purpose: To investigate whether intravoxel incoherent motion (IVIM) diffusion-weighted imaging (DWI) could differentiate non-muscle-invasive bladder cancer (NMIBC) from muscle-invasive bladder cancer (MIBC) and to assess whether there were correlations between IVIM parameters and the Ki-67 labelling index (LI).
Methods and Materials: Thirty-six patients diagnosed with bladder cancer confirmed by histopathological findings underwent magnetic resonance imaging including DWI with 8 b-values ranging from 0 to 1000 s/mm2 before transurethral resection (TUR). Molecular diffusion coefficient (D), perfusion-related diffusion coefficient (D*), perfusion fraction (f), and apparent diffusion coefficient (ADC) were calculated by bi-exponential and mono-exponential model fits, respectively. Comparisons were made between the MIBC and NMIBC group. Differences in these values were analysed by comparing the areas under the receiver operating characteristic curves (AUC). The correlations between these parameters and Ki-67 LI were also analysed.
Results: ADC and D values were significantly lower in patients with MIBC compared to those suffering NMIBC ($p<0.01$). The AUC of D value (0.894) was significantly ($p<0.05$) larger than those of ADC value (0.786). The sensitivities and specificities of D and ADC values were 95% and 87.5% and 80% and 68.7%, respectively. In addition, there was a negative correlation between D value and Ki-67 LI ($r=-0.785$, $p<0.01$).
Conclusion: D value obtained from IVIM could provide better performance than conventional DWI in distinguishing NMIBC from MIBC and serve as an imaging biomarker reflecting the invasive and proliferative potential of bladder cancer.

Predictionof treatment response after immunotherapy in metastatic or recurrent urothelialcarcinoma: potential imaging biomarker using CT texture analysis-a preliminary study

K. Park; *Seoul/KR (kyejin629@gmail.com)*

Purpose: To evaluate the relationship between tumour heterogeneity assessed by computed tomography (CT) texture analysis and treatment response after immunotherapy in patients with metastatic or recurrent urothelial carcinoma.
Methods and Materials: From January and April 2017, ten consecutive patients who had recurrent/metastatic urothelial carcinoma and underwent immunotherapy (Durvalumab, pembrolizumab or atezolizumab) were retrospectively evaluated. Texture analysis of all metastatic lesions (42 lesions) were performed with CT imaging for immunotherapy planning using in-house software. Histogram-based uniformity, entropy and kurtosis as well as 11 run-length matrix (RLM) and 25 gray level co-occurrence matrix (GLCM) features were obtained with manual delineation of a region of interest on metastatic lesion. Determination of responder and non-responder was done with clinicoradiologic follow-up after at least two consecutive CT reviews. The statistical analysis was done using Mann-Whitney U test.
Results: Six patients were classified as responder and four as non-responder. There was statistically significant difference of all three histogram-based features, seven RLM and ten GLCM features between responder and non-responder ($p<0.05$). Higher kurtosis (1.25 vs. 0.13, $p=0.01$) lower entropy (6.80 vs. 7.09, $p=0.006$), and higher uniformity (0.011 vs. 0.008, $p=0.010$) were observed in responder group.
Conclusion: In patients with recurrent or metastatic urothelial carcinoma, non-responders appeared to be more heterogeneous on CT texture analysis (higher entropy and lower uniformity) than responders. This preliminary result may be useful to predict treatment response after immunotherapy prospectively.

The value of readout-segmented diffusion-weighted imaging in the evaluation of parotid gland tumours

Z. Zhang, J. Cheng; *Zhengzhou/CN (yinierzhang@sina.com)*

Purpose: The purpose was to investigate the role of readout-segmented echo-planar imaging using parallel imaging and a two-dimensional navigator-based reacquisition (RESOLVE) in differentiating various types of common parotid gland tumours.
Methods and Materials: Sixty-five patients with parotid gland tumours confirmed by pathology received preoperative conventional MRI and RESOLVE DWI (b-values of 0 and 1000 s/mm^2). The apparent diffusion coefficient (ADC) values of the lesions were calculated and the receiver operating characteristic curves was drawn to obtain the cut-off value for differentiating benign and malignant parotid gland tumours.
Results: The mean ADC value of pleomorphic adenomas were significantly higher than that of all other examined subtypes. ADC values of warthin tumours were significantly lower than pleomorphic adenoma ($p=0.000$), basal cell adenoma ($p=0.000$) and malignant tumours ($p=0.001$). ADC cut-off values were 1.22×10^{-3}mm^2/s between pleomorphic adenomas and malignant tumours and 0.90×10^{-3}mm^2/s between Warthin tumours and malignant tumours; using 0.90×10^{-3}mm^2/s≤ADC values<1.22×10^{-3}mm^2/s to make a diagnosis of malignant tumour, the sensitivity, specificity, and accuracy were 93.8%, 81.4%, 84.7%, respectively.
Conclusion: RESOLVE has high accuracy in differing benign and malignant lesions of the parotid gland by producing high-resolution DWI.

B-0066 10:38

Sensorineural hearing loss in vestibular schwannoma relies on the presence of utricular hydrops, as diagnosed with heavily weighted T2 sequences

M. Eliezer[1], G. Poillon[2], A. Gillibert[2], C. Maquet[2], J. Horion[2], E. Gerardin[2], A. Trintignac[2], N. Magne[2], A. Attye[3]; [1]*Paris/FR*, [2]*Rouen/FR*, [3]*Meylan/FR (mcheliezer@gmail.com)*

Purpose: Due to the increased protein concentration in the perilymph liquid, FIESTA-C has recently been proposed to assess endolymphatic spaces without administration of contrast media in patients with vestibular schwannoma. The aim of this study was to assess whether vestibular endolymphatic space dilatation, as evaluated with 3D-FIESTA-C sequences, is related to the degree of hearing loss in patients with schwannoma.
Methods and Materials: In this retrospective study (IRB E2017-23), we performed 3D-FIESTA-C sequences in 32 patients with schwannoma, as diagnosed on the basis of typical image findings. Two radiologists independently checked the visualization and evaluated the volume of the utricle and saccule. Pearson and Spearman tests were used to explore the correlation between the volume of the tumor, the volume of the vestibular endolymphatic space and the degree of hearing loss - as evaluated with the levels of pure-tone average (PTA) and speech recognition threshold (SRT).
Results: The endolymphatic space can be evaluated in 72% (23 out of 32 patients) of patients with schwannoma on non-contrast 3D-FIESTA-C sequences. The mean saccular, utricular and tumor volume were 3.17 mm^3, 14.55 mm^3 and 1.74 cm^3 respectively. There was a significant correlation between the volume of the utricle and the degree of hearing loss as evaluated with the levels of PTA ($p=0.015$) and SRT ($p=0.004$). There was no significant correlation between the saccular and tumour volumes and the degree of hearing loss.
Conclusion: The volume of the utricle in schwannoma patients is related to the degree of hearing loss.

Imaging of facial neuritis using T2-weighted gradient-echo fast imaging employing steady-state acquisition after gadolinium injection

A. Venkatasamy, A. Al Najdi, M. Abu Eid, A. Charpiot, C. Debry, F. Veillon; *Strasbourg/FR (aina.vnkt@gmail.com)*

Purpose: MRI is the modality of choice for the imaging of facial neuritis. Previously, gadolinium-enhanced T1WI of the petrous bone was thought to be the most informative sequence in the evaluation of facial neuritis. The goal of this study is to evaluate the value of gadolinium-enhanced T2WI steady-state free precession sequences for the diagnosis of facial neuritis.
Methods and Materials: We performed an MRI of the petrous bones in 38 patients with unilateral peripheral facial palsy, using T2WI steady-state-free precession sequences and T1WI after intravenous gadolinium injection, and compared these to 60 normal patients (control group) imaged with the same MRI protocol and to 32 healthy volunteers (volunteers control group) imaged by T2WI steady-state free precession sequence without gadolinium injection.
Results: All patients presenting with a facial neuritis presented with a pathological enhancement of the facial nerve on the pathological side on T2W steady-state free-precession sequences (FIESTA-C and CISS) acquired after gadolinium injection. 94.7% of patients presented with a strong enhancement (Grade 2), which had a specificity of 100%, a sensitivity 94.7% and an accuracy of 97.9%. T1WI sequences following IV gadolinium injection were positive in 79% of the patients with facial neuritis and enhancement was also observed in the control group.
Conclusion: Enhancement of the facial nerve canal on T2WI steady-state free precession sequences (FIESTA-C) is a sensitive and specific sign of homolateral facial neuritis and is superior to T1WI images for the positive imaging diagnosis of facial neuritis.

D-prep magnetic resonance imaging for the visualisation of the facial nerve

P. Bos[1], B. Jasperse[1], A.J.M. Balm[1], L.C. ter Beek[1], F.W. van Leeuwen[2], M.W.M. van den Brekel[1], R.G.H. Beets-Tan[1], T. Buckle[2]; [1]*Amsterdam/NL*, [2]*Leiden/NL (pa.bos@nki.nl)*

Purpose: Facial nerve damage can be a serious complication of parotid surgery. Pre- or peroperative localization of the facial nerve may help the surgeon to avoid this complication. Diffusion-prepared MRI (D-prep MRI) is a novel technique designed to specifically visualize nerve structures. This study evaluates the ability and extent D-prep MRI to detect the Facial nerve.
Methods and Materials: D-prep MRI was performed in 24 patients (13 male/11 female, mean age 60 ± 11 years) that underwent a MRI for (suspected) head and neck cancer between December 2016 and August 2017. The visibility, length and thickness of the different branches of the Facial nerve were assessed by one neuro/head and neck radiologist based on the course of the nerve.
Results: Two patients were excluded because of poor MRI quality. For the remaining 22 patients the main trunk (from the mastoid foramen to the bifurcation of zygomaticofacial and oromandibular branches) was visible in 15 patients (length between 4 and 26 mm, median thickness: 1.3 mm), the posterior auricular nerve in 4 patients (6-11 mm; 0.9 mm), the zygomaticofacial branch in 6 patients (2-12 mm; 1.1 mm), the oromandibular branch in 6 patients (1-23 mm; 1.0 mm) and temporal in 1 patient (6 mm; 1.6 mm). In 7 patients the Facial nerve could not be identified.
Conclusion: The facial nerve can be identified and its course delineated with D-prep MRI in most cases. Further optimization of this sequence will hopefully result in more detailed visualization and delineation of Facial nerve branches.

B-0069 11:02

Is gadolinium really necessary for intralabyrinthine schwannomas MRI examination?

A. Venkatasamy, A. Karol, T. Huynh, A. Charpiot, C. Debry, F. Veillon; *Strasbourg/FR (aina.vnkt@gmail.com)*

Purpose: Our aim was to confirm the usefulness of T2-weighted (T2W) gradient-echo sequence for detection and topographic diagnosis of intralabyrinthine schwannomas (ILS) compared to T1W contrast-enhanced sequence as gold standard to evaluate the necessity of intravenous gadolinium injection in ILS imaging.
Methods and Materials: 30 patients with ILS were retrospectively enrolled and compared to a control group of 30 patients with no inner ear pathology. All patients underwent a T2W gradient-echo steady-state free precession (SSFP) acquisition at 3T, which was visually analysed by two radiologists and compared to contrast-enhanced T1W sequence. A quantitative analysis was also performed, with the measurement of the tumour and inner ear signal on T2W images and the measurement of the tumour length in cochlear schwannomas.
Results: T2W FIESTA-C sequence correctly diagnosed ILS with a sensitivity (Se) of 95% and a specificity (Sp) of 100%, with matching results for their topographic evaluation (Se 92%, Sp 98%) compared to the gold standard. The error rate was only 2.5%, with excellent interobserver agreement. The tumour signal on T2W images was significantly lower than the normal bright signal of the normal inner ear fluids (mean signal ratio = 0.42 vs 0.98).
Conclusion: The positive and topographic diagnostic accuracy of T2W FIESTA-C sequence was excellent compared to the T1W contrast-enhanced sequence, even though the latter remains easier and faster to analyse for an untrained radiologist. The performances of T2W gradient-echo sequence at 3T renders it sufficient for the imaging of ILS, especially for follow-up imaging.

B-0070 11:10

Is post-contrast MRI imaging necessary in the investigation of cholesteatoma recurrence when non-echo planar diffusion-weighted imaging is available? A diagnostic accuracy study

R. Kavanagh, A. Carroll, Y.M. Purcell, A.E. Smyth, S.G. Khoo, G. McNeill, D.E. Malone, R.P. Killeen; *Dublin/IE (richkavanagh@rcsi.ie)*

Purpose: The diagnosis of recurrent cholesteatoma is important in order to avoid the associated complications. This has traditionally been done through second-look surgery and more recently with contrast-enhanced MRI. Non-echo planar (EP) diffusion-weighted imaging (DWI) has been shown to be useful in the diagnosis of cholesteatoma. The aim of this study is to assess the diagnostic accuracy of a shortened imaging protocol for cholesteatoma recurrence, without the use of gadolinium, compared to our standard contrast enhanced protocol, used as the gold standard.
Methods and Materials: This is a retrospective study of 100 consecutive MRIs performed for suspected cholesteatoma recurrence in a single institution from Jan 2012 to May 2016. Our standard MRI protocol includes T2, PROPELLER DWI and pre and post-contrast T1-weighted sequences of the temporal bone. Using the standard protocol as the gold standard we assessed the sensitivity and specificity of a shortened protocol, which did not include the post-contrast sequence, for the detection of cholesteatoma recurrence.
Results: Using the standard protocol, including post-contrast imaging, as the gold-standard, the sensitivity and specificity of the shortened protocol is 100% and 95.3%, respectively. The accuracy of the shortened protocol is 98%. The calculated positive predictive value is 96.6% and the negative predictive value is 100%. Using McNemar's Test, no statistical difference was found between the two diagnostic tests (p=0.16).
Conclusion: MRI imaging in patients with suspected cholesteatoma recurrence can be performed using a shortened protocol without the need for further contrast-enhanced sequences.

B-0071 11:18

Role of magnetic resonance neurography [MRN] for the diagnosis of peripheral trigeminal nerve injuries in patients with prior molar tooth extraction

R.A.K. Dessouky[1,2], Y. Xi[2], J.R. Zuniga[2], A. Chhabra[2]; [1]*Zagazig/EG*, [2]*Dallas, TX/US (rihamdessouky@gmail.com)*

Purpose: Evaluate the role of magnetic resonance neurography [MRN] for the diagnosis of peripheral trigeminal nerve [PTN] injuries in patients with prior molar tooth extraction.
Methods and Materials: In this retrospective study, nerve caliber, T2 signal intensity ratio [T2SIR] and contrast to noise ratios [CNR] were recorded by two observers for bilateral PTN branches, the inferior alveolar [IAN] and lingual nerve [LN]. Subject demographics and correlation of the MRN findings with Sunderland classification of nerve injury and intraoperative findings of surgical patients were obtained.
Results: Among 42 subjects, mean ± SD age for cases and controls was 35.8 ± 10.2 and 43.2 ± 11.5. Male to female ratios were 1:1.4 and 1:5, respectively. Cases had significantly larger differences in nerve thickness, T2SIR and CNR than controls for IAN and LN [p values = 0.01 & 0.0001, 0.012 & 0.005 and 0.01 & 0.01, respectively]. ROC analysis showed significant association among differences in nerve thickness, T2SIR and CNR and nerve injury [AUC = 0.83-0.84 for IAN and 0.77-0.78 for LN]. Interobserver agreement was good for IAN [ICC = 0.70 - 0.79] and good to excellent for LN [ICC = 0.75 - 0.85]. MRN correlations with NST and surgical classifications were moderate to good. Kappa of 0.60 and 0.77 and Pearson's correlation coefficients of 0.68 and 0.81 were observed for differences in nerve thickness.
Conclusion: MRN can be reliably used in diagnosis of PTN injuries related to molar tooth extractions with good to excellent correlation of imaging with clinical findings and surgical results.

DKI can early differentiate radio-insensitive human nasopharyngeal carcinoma xenograft in nude mice

X. Zheng, Y.Y. Chen, Y. Xiao, D. Zheng; *Fuzhou/CN*

Purpose: To explore the feasibility of DKI sequence in early differentiating radio-insensitivity of nasopharyngeal carcinoma xenografts in nude mice.
Methods and Materials: Seventy-two nude mice were implanted with CNE-1 (low radiosensitivity) and CNE-2 (high radiosensitivity) nasopharyngeal carcinoma cells, and the xenografts were obtained. Then, the mice were underwent fraction irradiation separately. Nude mice of each cell line were randomly divided into non-irradiated group (G0), 10Gy group (G1), 20Gy group (G2), 30Gy group (G3) and 3 and 5 days after the whole dose irradiation group (G4, G5). DKI sequence was performed on each group. Volumes, parameters D and K were measured by two experienced radiologists double blindly. Student's t test and receiver operating characteristic (ROC) curve analyses were included in our study. Significant level α was chosen as 0.05.
Results: The difference of volumes' shrink rate between CNE-1 and 2 were first found in G2, with the shrink rate of 5.954% and 27.716% (p=0.032). D value decreased first (D_{G1}, p=0.001) and then increased, K value increased first (K_{G1}, p=0.001) and then decreased after irradiation in CNE-2, but not in CNE-1 xenografts (p>0.05). The AUC of D_{G1} and K_{G1} were 0.875 and 0.917, with sensitivity of 0.667 and 0.833, specificity of 1.000 and 1.000, respectively, in the cutoff values $1.27\times10^{-3}mm^2/s$ of parameter D and 0.88 of parameter K.
Conclusion: Both D and K can early (before volumes changed) distinguish radio-insensitive NPC xenografts from others. D_{G1} and K_{G1} may be the most useful parameters.

Application of dynamic contrast-enhanced MRI and diffusion-weighted imaging in differentiating nasopharyngeal carcinoma and nasopharyngeal lymphoma

C. Song, C. Jingliang; *Zhengzhou/CN (songchengru@126.com)*

Purpose: To evaluate the utility of DCE-MRI and DWI in the differentiation of nasopharyngeal carcinoma (NPC) and nasopharyngeal lymphoma (NPL).
Methods and Materials: 42 NPC patients and 27 NPL patients were recruited and underwent conventional MRI and DCE-MRI. The MR signals, time signal-intensity curves(TIC) types, time to peak(TTP), enhancement peak(EP), maximum contrast enhancement ratio(MCER), mean ADC value, and relative ADC value of all the subjects were calculated and analyzed, thereafter, inter-group comparison was performed. The threshold values of ADC and rADC for differentiating NPC from NPL were determined using a ROC analysis.
Results: For NPC group, 32 cases (76.19%) demonstrated obvious heterogeneous enhancement. The mean TTP, EP, MCER and WR were 48.29s, 1475.38, 136.89% and 16.81, respectively. For NPL group, 24 cases (88.89%) demonstrated obvious homogeneous enhancement. The mean TTP, EP, MCER and WR were 63.21s, 1161.82, 113.47% and 7.39, respectively. The ADC and rADC value were 842.34×10^{-6} mm^2/s and 0.74 in NPC, whereas 652.15×10^{-6} mm^2/s and 0.56 in NPL. The differences of above parameters between NPC and NPL were statistically significant (P<0.05). The TTP of NPC was lower than that of NPL, whereas the opposite for the remaining parameters. The best differentiate threshold value of ADC and rADC were 736.5×10^{-6} mm^2/s, 634.0×10^{-6} mm^2/s, respectively. While the AUC, sensitivity, specificity and Youden index of ADC and rADC were 0.943, 0.909, 0.852, 0.761, and 0.951, 0.955, 0.852, 0.77, respectively. rADC value was slightlly superior to ADC value in differentiation.
Conclusion: DCE-MRI and DWI are effective in differentiating NPC from NPL.

B-0075 11:42

Shape-based and quantitative MRI radiomic features in the assessment of non-metastatic nasopharyngeal carcinoma

R. Du, P.-L. Khong, H. Yuan, D.L. Kwong, V.H. Lee, V. Vardhanabhuti; *Hong Kong/HK (du94@hku.hk)*

Purpose: To investigate the association between MRI radiomic features and progression-free survival (PFS) of patients with nasopharyngeal carcinoma (NPC) after treatment.
Methods and Materials: A cohort of 100 patients with histologically confirmed NPC that underwent standard treatment was retrospectively obtained. A total of 102 radiomic features were extracted from contrast-enhanced T1-weighted (CE-T1W) scans acquired at diagnosis. Univariate and multivariate analysis was conducted to assess the association between radiomic features and PFS. Mann-Whitney U test and log-rank test of Kaplan-Meier estimate was conducted for univariate analysis. Minimum redundancy and maximum relevance feature selection was used to select the most optimum subset of features for multivariate analysis. Logistic regression and support vector machine were trained with the selected features and validated using 5x8 repeated k-fold cross validation. The performance of the models was assessed by receiver operator characteristic analysis.
Results: Both univariate and multivariate analysis has identified the shape feature tumour sphericity to be significantly associated with 3-year PFS (Mann-Whitney U test: p < 0.0001; log rank: p < 0.0001; logistic regression: AUC=0.765; SVM: AUC=0.799). No significant separation in PFS was seen with clinical staging. No increase in performance was found with multivariate models.
Conclusion: There is a significant association between MRI radiomic features and PFS of NPC patients after standard treatment. Tumour sphericity has been identified to be most correlated to 3-year PFS. Radiomic models could potentially offer a non-invasive method of predicting treatment outcomes.

Digital breast tomosynthesis vs digital mammography: early performance measures in a population-based screening programme

T. Hovda[1], Å.S. Holen[2], H. Bjørndal[1], S. Sebuødegård[2], S. Hofvind[2]; [1]*Drammen/NO*, [2]*Oslo/NO (tone.hovda@vestreviken.no)*

Purpose: Screening with digital breast tomosynthesis (DBT) in combination with digital mammography (DM) has demonstrated a higher rate of recalls and screen-detected breast cancer compared with DM alone. We aimed at comparing results of early performance measures when screening with synthetic mammography (SM) and DBT vs DM alone in BreastScreen Norway.
Methods and Materials: The study group consisted of 37,185 women screened with SM+DBT at the screening unit in Oslo, 2014-2015. Data on DM were acquired from two comparable screening units (Vestfold and Vestre Viken) in the same period (n=61,743), comprising the control group. We calculated recall rates and cancer detection rates and performed descriptive analyses comparing the two groups. Two-proportion Z-tests were used to test for statistical significance (p<0.05).
Results: The recall rate due to abnormal mammographic findings was 3.4% (1253/37,185) and 3.3% (2038/61,743), p=0.56, for SM+DBT and DM, respectively. The rate of screen-detected breast cancer was 9.4 per 1000 screened with SM+DBT and 6.1 per 1000 screened with DM (p<0.01). Both the rates of screen-detected ductal carcinoma in situ and invasive breast cancer were statistically significantly higher for SM+DBT compared with DM (p<0.01 for both).
Conclusion: The rate of screen-detected breast cancer was about 50% higher for women screened with SM+DBT compared with women screened with DM. This represents one of the largest increases in breast cancer detection between SM+DBT vs DM reported in the literature. Further studies are needed to investigate the benefits and potential harms by detecting additional cancers with DBT.

B-0077 10:47

Digital breast tomosynthesis (DBT) as a primary screening test in a population-based screening programme: interim results of the Trento DBT pilot study

D. Bernardi[1], M. Gentilini[1], M. De NIsi[1], M. Pellegrini[1], C. Fantò[1], M. Valentini[1], V. Sabatino[1], N. Houssami[2]; [1]*Trento/IT*, [2]*Sydney/AU (dnlbernardi@gmail.com)*

Purpose: To report interim results of a pilot screening study implementing DBT (instead of standard mammography, MX) for all women who prospectively attended an invitation to screening, and to compare screen-detection measures with those obtained two years earlier for a historical cohort screened with MX alone
Methods and Materials: From January to December 2015, according to a study protocol approved by local health authorities, a prospective cohort of 24.060 women presenting for screening had DBT screening. Synthetic 2D images were reconstructed and read in integration with DBT. Cancer detection rate (CDR), recall rate (RR) and positive predictive value for recall (PPV) were calculated, and compared with those measured for a historical cohort of 20.815 women screened with MX, by calculating the rate ratio (rr). Results were then analysed for prevalent and incident screens
Results: CDR per 1000 screens for DBT-screened and MX-screened cohorts were 9.68 versus 5.77, respectively (rr 1.68, 95% CI 1.35-2.09). Recall rates

were 2.76% for DBT and 3.42% for MX (rr 0.81, 95% CI 0.73-0.9). DBT implementation increased the PPV for recall from 16.71 to 35.09 (rr 2.10, 95% CI 1.68-2.62). The results have been confirmed both for prevalent and incident examinations, although the reduction of RR and the increase of PPV have been superior in the prevalent
Conclusion: Population-based implementation of DBT screening was associated with increase in cancer detection, reduction in recall with significantly increase PPV for recall. Our results indicate that DBT screening improves screening-detection metrics however further research needs to assess health benefits

B-0078 10:55

A prospective study on sensitivity and reading time of different reading strategies with DBT + synthetic 2D in breast cancer screening

F. Caumo[1], G. Romanucci[2], M. Zorzi[1], S. Brunelli[2], [1]*Padua/IT*, [2]*Verona/IT*
(francesca.caumo@iov.veneto.it)

Purpose: To compare detection rates (DR) and reading time (RT) of five reading strategies within the DBT+synthetic2D-based mammographic screening program of Verona (Italy).
Methods and Materials: From April 2015 to March 2017, 34.071 50-69-year-old asymptomatic women were screened for breast cancer with DBT+synthetic2D. We compared the sensitivity for invasive cancer (IC) and ductal carcinoma in situ (DCIS) and RT of five reading strategies: (1) double reading, (2) single reading, (3) double reading of synthetic2D plus mediolateral oblique (MLO) or (4) craniocaudal (CC) DBT view, and (5) double reading of synthetic2D plus DBT for suspicious findings (BIRADS 3). We report the relative sensitivities (RS) vs strategy (1) with 95% confidence intervals (95%CI).
Results: Strategy (1) detected 315 cancers (271 IC, 44 DCIS; DR 9.26‰); mean RT 180 seconds. Strategy (2) detected 276 cancers (238 IC, 38 DCIS; DR 8.11‰). RS 0.88 (95%CI 0.70-1.10, p=0.25); mean RT 90 seconds. Strategy (3) detected 307 cancers (264 IC, 43 DCIS; DR 9.02‰). RS 0.97 (95%CI 0.78-1.22, p=0.82); RT 102 seconds. Strategy (4) detected 309 cancers (266 IC, 43 DCIS; DR 9.03‰). RS 0.98 (95%CI 0.78-1.23, p=0.86); RT 102 seconds. Strategy (5) detected 245 cancers (213 IC, 32 DCIS; DR 7.49‰). RS 0.78 (95%CI 0.61-0.98, p=0.03); RT 66 seconds.
Conclusion: Compared with double reading synthetic2D+DBT, double reading of synthetic2D plus a single DBT view reduces RT by 43% without affecting sensitivity for cancer. DBT+synthetic2D single reading is affected by a clinically (although not statistically) significant loss in sensitivity.

B-0079 11:03

Synthetic 2D mammography can replace digital mammography as an adjunct to digital breast tomosynthesis: experience with a wide angle DBT system

P. Clauser[1], P.A.T. Baltzer[1], P. Kapetas[1], R.A. Woitek[1], M. Weber[1], F. Leone[2], M. Bernathova[1], T.H. Helbich[1]; [1]*Vienna/AT*, [2]*Milan/IT*
(paola.clauser@meduniwien.ac.at)

Purpose: To evaluate the diagnostic performance of synthetic mammography (SM) with wide-angle-digital-breast-tomosynthesis (WA-DBT) compared to digital mammography (DM) alone and with WA-DBT using one view (1v, medio-lateral oblique) and two-view (2v) protocols.
Methods and Materials: Included in this retrospective, IRB-approved, study were 205 patients with 179 lesions (89 malignant, 90 benign) who underwent bilateral 2v DM and WA-DBT at our institution. Standard of reference was histology and/or one year stability. Four blinded readers randomly evaluated images according to BIRADS using five protocols: 2vDM alone; 2vDM with 2vWA-DBT; 2vSM with 2vWA-DBT; 1vDM with 1vWA-DBT and 1vSM with 1vWA-DBT. Lesion detection, sensitivity, specificity, and accuracy were calculated and compared using multivariate analysis. Readers` confidence and image quality were evaluated.
Results: Average detection rate was 75.4% for 2vDM, 80.2% for 2vDM with WA-DBT, 78.5% for 2vSM with WA-DBT, 77.4% 1vDM with WA-DBT, and 75.0% 1vSM with WA-DBT. 2vDM with 2vWA-DBT achieved a higher detection compared to 2vDM alone (P=0.004). No significant differences in detection were found between 2vDM with WA-DBT and 2vSM with WA-DBT (P>0.110). Detection was higher when two-views were available, for both SM and DM (P<0.034). Sensitivity and accuracy were lower with DM alone compared to all other reading protocols (P<0.001). Readers' confidence and image quality were good to very good for all protocols.
Conclusion: WA-DBT combined with DM or SM increases lesion detection, sensitivity and accuracy without reducing specificity, with no differences between SM or DM. Two-view protocols allow a higher detection rate than 1-view protocols using DM or SM.

Microcalcifications in breast tomosynthesis including synthesised mammography, multiple angulated reconstructions and standard stack reconstructions

C. Neubauer, J. Neubauer, M. Windfuhr-Blum, M. Langer; *Freiburg/DE*
(claudia.neubauer@uniklinik-freiburg.de)

Purpose: Our aim was to compare ratings on depiction, diagnostic accuracy and lesion characterisation of conventional synthesized mammography (SM), multiple angulated mammography reconstructions (INSIGHT3D) and standard stack reconstructions in digital breast tomosynthesis (DBT) for microcalcifications.
Methods and Materials: In our retrospective study we included patients with microcalcifications, who had received a DBT and histology over a period of four months and the same number of normal cases without microcalcifications. Patient's data were deidentified and the images randomised and independently analysed by 3 radiologists regarding the depiction, distribution, morphology and BI-RADS score of microcalcifications in SM, INSIGHT3D and standard stack reconstructions. In addition, the reading time was measured. Friedman and post hoc Nemenyi tests, Cochrane´s Q and post hoc Wilcoxon sign tests, Fleiss´ kappa and receiver operating characteristics were used for statistical analysis.
Results: We included 41 histopathologically proven and 41 normal cases. Depiction of microcalcifications was rated best in stack reconstructions and better in INSIGHT3D than in SM (P<0.001). Reading time was lower in both SM and INSIGHT3D compared to stack reconstructions (P<0.001). Diagnostic accuracy and inter-rater correlation were comparable for all analyses.
Conclusion: Although depiction of microcalcifications was best in stack reconstructions, INSIGHT3D depicts microcalcifications better than SM while maintaining a lower reading time compared to stack reconstructions. Our preliminary assessment suggests INSIGHT3D as a potential successor to SM.

B-0082 11:19

Breast screening with synthetic 2D and digital breast tomosynthesis (DBT): is it really more expensive?

F. Caumo[1], G. Romanucci[1], M. Zorzi[2], S. Brunelli[1]; [1]*Verona/IT*, [2]*Padua/IT*
(francesca.caumo@aulss9.veneto.it)

Purpose: To compare the costs of a breast screening program with synthetic2D + DBT versus full-field digital mammography (FFDM).
Methods and Materials: costs of an organized screening program in Verona using FFDM are known. The same analysis was retrospectively carried out for two consecutive years of breast screening using FFDM (and synthetic2D + DBT only on second level assessment) from 1st April 2014 to 31 march 2015 and synthetic2D + DBT from 1st April 2015 to 31 march 2016. The cost of the entire screening process for single screened woman was calculated by adding: the cost of technology (mammograms, ecotomographs, workstations, PACS space); the cost of staff (radiographers, radiologists, nurses, secretarial staff); the cost of material for invasive assessment.
Results: the cost of the screening program with FFDM (14374 screened women with 76 cancers detected; DR 5.29 per 1,000 screens) was 53.8 euros for single screened woman. The cost of the screening program with FFDM (DBT performed only on second level assessment; 14423 screened women with 78 cancers detected; DR 5.41 per 1,000 screens) was 66.8 euros for single screened woman. The cost of the screening program with synthetic 2D + DBT (16666 screened women with 155 cancers detected; DR 9.30 per 1,000 screens) was 64.2 euros for single screened woman.
Conclusion: the implementation of an organized DBT breast screening has a minimal additional cost compared to FFDM-organized screening, especially if additional cancers are found.

B-0083 11:27

Comparing two visualisation protocols for tomosyntesis in screening: specificity and sensitivity of slabs vs planes plus slabs

V. Iotti, P. Giorgi Rossi, S. Ravaioli, A. Nitrosi, M. Bertolini, E. Bacchini, R. Vacondio, M. Pescarolo, P. Pattacini; *Reggio Emilia/IT*
(valentina.iotti@ausl.re.it)

Purpose: Tomosynthesis (DBT) showed to be more sensitive than digital mammography (DM), but it needs longer reading time, limiting its introduction as primary screening test. Simplified visualisation protocols have been designed. We compared accuracy of a simplified protocol with slab only vs. a standard protocol of slab plus planes, both integrated with synthetic 2D.
Methods and Materials: All DBTs were acquired in RETomo trial experimental arm. The first set, to estimate specificity, included 894 randomly selected DBT (including 12 cancers), and was read by two radiologists(CAM-RV). The second set included 273 screening DBTs enriched with 24 cancers, 8 of which present in the first set; it was read by one of the first radiologists and another radiologist(RV-SR); 28 cancers with 64 independent readings were used to estimate sensitivity. DBTs were read by both radiologists with both protocols

separated by 3 months wash out. The order of protocol reading was randomly assigned 1:1. Only women that were positive at the screening reading were assessed, to date follow up data for negatives are still not available.
Results: Sensitivity was 82.8% (53/64, 95% confidence interval (95%CI) 71.3-91.1) and 90.6% (95%CI 80.7-96.5) with simplified and standard protocol, respectively (p=0.19). In the random screening setting specificity was 97.9% (1727/1764, 95%CI 97.1-98.5) and 96.3% (95%CI 95.3-97.1)(p0.005). Inter-reader agreement was 0.70 and 0.57 with simplified and standard protocol, respectively. Median reading time decreased by 20%.
Conclusion: A simplified protocol without the presentation of planes, increased DBT specificity and reproducibility, but may have a negative impact on sensitivity.

Overview of early clinical implementation of digital breast tomosynthesis: a single-centre experience
S. Soo, K. Rahmat; *Kuala Lumpur/MY (suetwoonsoo@gmail.com)*

Purpose: To evaluate the impact of performance of mammographic study before and after the introduction of digital breast tomosynthesis (DBT) into the clinical practice in University of Malaya Medical Centre (UMMC).
Methods and Materials: A retrospective study was conducted on patients who underwent breast biopsy in UMMC from October 2013 to February 2015. The biopsy rate, cancer detection rate, sensitivity and positive predictive values (PPV) were calculated and compared between the groups. Analysis was done using SPSS version 22.0 and a p-value <0.05 was considered as statistical significant different.
Results: The patients were divided into two groups: Full Field Digital Mammography (FFDM) (n = 1250) and FFDM + DBT (n = 2174). Histopathological examination results were the gold standard of the study. The combination of FFDM and DBT resulted in significant reduction of biopsy rate from 57.5% to 37.0% (p = 0.03). The cancer detection rates were statistically significant different between FFDM and FFDM + DBT groups from 30.1% to 44.5% (p<0.03). The sensitivity and positive predictive value (PPV) were 90% and 36% for FFDM group; and 92% and 38% for FFDM + DBT group, respectively.
Conclusion: The combination of FFDM and DBT significantly reduced biopsy rate and increased the cancer detection rate compared to FFDM alone. The sensitivity and PPV were also increased from 90% to 92% and 36% to 38%, respectively, indicating that incorporation of DBT in mammographic examinations increased the number of true positive cases. A larger cohort study is needed to validate these findings.

B-0085 11:43

Breast screening 2D-mammography or breast tomosynthesis: comparison in terms of cancer detection and recalls
F. Fernandez Valverde, S. Romero Martin, J.L. Raya Povedano, J.E. Gordillo Arnaud; *Cordoba/ES (sararomero@hotmail.com)*

Purpose: To evaluate tomosynthesis compared with 2D-mammography in terms of cancer detection and recalls in a screening program. To assess positive predictive value (PPV) of recalls.
Methods and Materials: Prospective study included women (age 50-69) who participated in the breast screening program between January 2015 and December 2016. Three digital mammographs and one tomosynthesis were available, being women appointed for different devices randomly. Blind and independent double reading was the standard practice and five radiologists participated. The study was approved by a regional ethics committee. The comparisons between qualitative variables were performed using the Chi-squared test and p value of less than 0.05 was considered statistically significant.
Results: 39851 women participated. 2180 women were recalled (5.5%) and 214 cancers were detected (5.3/1000 screens). 23783 women were appointed for digital mammographs and 16068 women for tomosynthesis. 1471 recalls occurred with digital mammographs (6.2%) compared with 709 recalls with tomosynthesis (4.4%). It meant a significant decreased of 29% (95%IC: 7.8%-66.2%, p<0.001). 122 cancers were detected with digital mammographs (5.1/1000 screens), compared with 92 cancers with tomosynthesis (5.7/1000 screens), showing an increase in cancers detection of 10.5% (95%IC: 1.3%-51.5%, p=0.425). PPV of recalls was 8.3% with digital mammographs (122 cancers/1471 recalls) and 13.0% with tomosynthesis (92 cancers/709 recalls), which showed an increase of 36.2% (95%IC: 16.1%-62.4%, p=0.001).
Conclusion: The use of tomosynthesis in a breast screening program results in an increase in cancer detection rate and significant decreases in recall rate. Tomosynthesis has also shown a significant increase in PPV recalls.

Noncontrast ASL-perfusion in pre-surgical glioma diagnostics
A. Batalov, N. Zakharova, I. Pronin, E. Pogosbekyan; *Moscow/RU (batalov89@gmail.com)*

Purpose: To study the tumor blood flow (TBF) in the supratentorial brain gliomas by ASL-perfusion in comparison with the histolpathological characteristics of the tumors.
Methods and Materials: The study group included 126 patients with primary supratentorial gliomas of varying degrees of malignancy. Of them, 35 low-grade gliomas (I-II grade WHO) and 91 high-grade gliomas (41-III grade WHO, 50 - IV grade WHO). 64 female and 62 male aged from 12 and 75(median-44, interquartile range 30-54). Patients were examined on a 3.0 T MR-tomograph. The pseudo-continuous ASL (pcASL) technique was used to determine tumor blood flow,. Post-processing of data was carried out in the ReadyView (GE) program. Tumor blood flow was normalized regarding intact white matter of the semiovalicular center of the contralateral hemisphere was performed.All diagnoses were confirmed histopathologically.
Results: Mean tumor blood flow in the group of low-grade gliomas was 28.85 ± 14.99 ml/ 100 g/ min. Normalized TBF was 1.52±0.77. In the group of high-grade gliomas, the tumor blood flow was 152.75±92.82 ml/100 g/min. Normalized TBF was 8.09±5.24. The sensitivity and the specificity of this technique in the differential diagnosis of low-grade and high-grade gliomas was 88.6% and 91.2%, accordingly, AUC 0.958. Cutoff-51 ml/100 g/min or 2.3 (normal blood flow).
Conclusion: ASL-perfusion is a reliable quantitative technique that allows estimating blood flow in gliomas. ASL can be used in differential diagnosis of low-grade and high-grade gliomas at the pre-operative stage. This technique has a high sensitivity (88.6%) and specificity (91.2%).

B-0087 10:38

Building an apparent diffusion coefficient radiomics to yield high diagnostic performance in identifying atypical primary CNS lymphoma mimicking glioblastoma
M. Kim, J. Park, H. Kim; *Seoul/KR (manzae.kim@gmail.com)*

Purpose: To test the technical feasibility, diagnostic performance, and generalizability of a radiomics model utilizing apparent diffusion coefficient (ADC) for identifying atypical primary central nervous lymphoma (PCNSL) mimicking glioblastoma.
Methods and Materials: This retrospective study was approved by our institutional review board. We used a training set of 112 patients (70 glioblastomas, 42 PCNSLs) and extracted 1618 radiomic features (17 first order, 7 volume and shape, 162 texture, and 1432 wavelet) from their ADC maps and contrast-enhanced T1-weighted images (CE-T1WI). Different combinations of 12 feature selection and 8 classification methods were optimized using 10-fold cross-validation. The model was validated internally and externally, in a set of 42 patients (21 glioblastomas, 21 PCNSLs) and 42 patients (28 glioblastomas, 14 PCNSLs) with atypical PCNSL and compared to the histogram parameters of cerebral blood volume (90% cutoff, CBV90) and ADC (10% cutoff, ADC10) using the area under the ROC curve (AUC).
Results: The ADC radiomics model was optimized with the combination of recursive feature elimination and a random forest classifier (mean AUC= 0.983, stability 2.52%). In internal validation, the ADC model (AUC = 0.984) showed similar performance with CE-T1WI radiomics (AUC = 0.968) and was better than CBV90 (AUC= 0.905) or ADC10 (AUC= 0.787) in atypical PCNSL diagnosis. The ADC radiomics model showed robustness (AUC = 0.944) in external validation.
Conclusion: The ADC radiomics model had good generalizability and yields a better diagnostic performance than single-parameter measurements in identifying atypical PCNSL mimicking glioblastoma.

B-0088 10:46

Wavelet-based reconstructions of dynamic susceptibility MR perfusion: a new method to visualize hypervascular brain tumours

T. Huber, L. Rotkopf, W.G. Kunz, S. Bette, B. Wiestler, J. Gempt, C. Zimmer, W.H. Sommer, K. Thierfelder; *Munich/DE (h-thomas@gmx.de)*

Purpose: Wavelet-based reconstructions of dynamic perfusion datasets offer an innovative and elegant way of vascular visualization. This novel technique has shown benefits in dynamic CT-perfusion datasets, but it has not been applied to MRI yet. The aim of this study was to demonstrate if wavelet-based reconstructions can be transferred to dynamic MR-perfusion datasets (wavelet-MRP) to visualize hypervascular tumours, like glioblastoma.
Methods and Materials: Consecutive preoperative 3T dynamic susceptibility MR perfusion datasets of 46 subjects with glioblastoma (mean age: 63±13.1 years, 18f) were included in this IRB-approved feasibility study. Wavelet-MRP was calculated after initial motion correction using the wavelet transform (Paul wavelet, order 1) of each voxel time course. Five different aspects of image quality were each rated on a 5-point Likert scale and compared to cerebral blood volume (CBV) maps. Quantitative analysis included Weber-contrast and signal-to-noise ratio. Wilcoxon signed-rank test was applied.
Results: Generation of wavelet-MRP was successful in 46/46 subjects (mean time 2.45±.12 min). Wavelet-MRP achieved higher scores in all qualitative ratings: tumour depiction (4.02 vs 2.33), contrast enhancement (3.93 vs 2.23), central necrosis (3.86 vs 2.40), morphologic correlation (3.87 vs 2.24), and overall impression (4.00 vs 2.41), all p<.0001. Quantitative image analysis showed a higher Weber-contrast (8.08±5.14 vs 2.58±.843; p<.0001) and a higher signal-to-noise ratio (3.66±1.67 vs 1.80±.887; p<.0001) for wavelet-MRP.
Conclusion: Our study demonstrates the feasibility of wavelet reconstructions in MR perfusion datasets. This method allows a fast and reproducible evaluation of MR-perfusion data and generates maps with a clearer tumour depiction compared to standard CBV maps.

Differentiation of glioblastoma multiforme and single brain metastasis by the distribution pattern of intratumoral susceptibility sign derived from susceptibility-weighted imaging

H. Kang, S. Jang; *Seoul/KR (knroo@hanmail.net)*

Purpose: The aim of this study is to determine whether the distribution pattern of intratumoural susceptibility sign (ITSS) derived from susceptibility-weighted imaging (SWI) could differentiate glioblastoma multiforme (GBM) and single brain metastasis.
Methods and Materials: 58 intracranial brain neoplasm patients (55 male and 3 female, age 69.8 ± 8.2 years (mean ± SD), 42 brain metastases and 16 with GBM) were enrolled in this study. These patients underwent examinations that included SWI in addition to conventional magnetic resonance (MR) sequences on a 3T. Two radiologists investigated the distribution patterns of ITSS of the tumours and applied an ITSS grading system based on the degree of the ITSS. Then, we compared the grade of the visibility of ITSS in the central portion of tumours; the inner three-quarter area of tumour volume (CITSS) and in the tumour capsular area; the outside one-quarter area of tumour volume (PITSS) on SWI.
Results: Wilcoxon rank sum test showed that the grades of the CITSS in GBM were statistically higher than brain metastasis ($p < 0.0001$) and the PITSS in GBM was statistically lower than brain metastasis ($p < 0.0001$).
Conclusion: Our findings suggest that there were different characteristics of ITSS between GBM and brain metastasis on SWI due to the profound difference in histologic feature of capillary between the two tumour types. The CITSS within the GBM represents the complex immature neovascularity and blood leakage, and PITSS in the metastasis represents the mechanical disruption of the BBB, lack capillaries and prominent feeding or draining vessels.

B-0090 11:02

In vivo assessment of tumour heterogeneity in WHO 2016 glioma grades using diffusion kurtosis imaging

J.-M. Hempel, J. Schittenhelm, C. Brendle, M. Skardelly, B. Bender, G. Tabatabai, S. Castaneda Vega, U. Ernemann, U. Klose; *Tübingen/DE (johann-martin.hempel@uni-tuebingen.de)*

Purpose: To assess the diagnostic performance of normalized and non-normalized diffusion kurtosis imaging (DKI) metrics extracted from different tumour volume data for grading glioma according to the integrated approach of the revised 2016 WHO classification.
Methods and Materials: Sixty patients with histopathologically confirmed glioma were retrospectively assessed between 01/2013 and 08/2016 from a prospective trial approved by the local institutional review board. Mean kurtosis (MK) and mean diffusivity (MD) metrics from DKI were assessed by two blinded physicians from four different volumes of interest (VOI): whole solid tumour including ($VOI_{tu\text{-}ed}$) and excluding perifocal oedema (VOI_{tu}), infiltrative zone (VOI_{ed}), and single slice of solid tumour core (VOI_{slice}). Intra-class correlation coefficient (ICC) was calculated to assess inter-rater agreement. One-way ANOVA was used to compare MK between 2016 CNS WHO tumour grades. Friedman's test compared MK and MD of each VOI. Spearman's correlation coefficient was used to correlate MK with 2016 CNS WHO tumour grades. ROC analysis was performed on MK for significant results.
Results: The MK assessment showed excellent inter-rater agreement for each VOI (ICC, 0.906-0.955). MK was significantly lower in IDH_{mutant} astrocytoma (0.40±0.07) than in 1p/19q-confirmed oligodendroglioma (0.54±0.10, p=0.001) or $IDH_{wild\text{-}type}$ glioblastoma (0.68±0.13, p < 0.001). MK and 2016 WHO tumour grades were strongly and positively correlated ($VOI_{tu\text{-}ed}$, r=0.684; VOI_{tu}, r=0.734; VOI_{ed}, r=0.625; VOI_{slice}, r=0.698; p < 0.001).
Conclusion: Non-normalized MK values obtained from VOI_{tu} and VOI_{slice} showed the best reproducibility and highest diagnostic performance for stratifying glioma according to the integrated approach of the recent 2016 WHO classification.

Lipid mapping for grading of gliomas

P. Seow, N. Ramli, A.T. Hernowo, V. Narayanan, J.H. Wong; *Kuala Lumpur/MY (norlisahramli@gmail.com)*

Purpose: To evaluate the potential of lipid map generated from magnetic resonance imaging (MRI) chemical shift gradient echo in-and opposed-phase (IOP) sequence for characterisation lipid landscape and as a tool in grading of gliomas.
Methods and Materials: Forty histologically proven glioma patients underwent a standard MRI tumour protocol with the addition of IOP sequence. The subregions of tumour (solid enhancing, solid non-enhancing, cystic and tumour core) were delineated using snake model (ITK-snap) with reference to structural MRI images (T1, T2, FLAIR, ADC & DWI). The lipid maps were computed based on signal loss ratio (SLR) obtained from IOP imaging. The mean SLR values of the subregions were obtained from the lipid maps after post-processing of the MRI images using SPM12.
Results: The mean SLR of solid non-enhancing portion of tumour (mean SLR_{II} = 0.047, mean SLR_{III} = 0.061, mean SLR_{IV} = 0.079, & p= 0.003) and tumour core (mean SLR_{II} = 0.057, mean SLR_{III} =0.059, mean SLR_{IV} =0.073, & p=0.013) demonstrated statistically significant differences between the WHO grades (grades II, III & IV). The classification probabilities for solid non-enhancing (grade II (S_{II}=0.77), grade III (S_{III}=0.25) and grade IV (S_{IV}=0.67)) and tumour core (grade II (S_{II}=0.60), grade III (S_{III}=0.38) and grade IV (S_{IV}=0.59)) were higher than the other tumour subregions. Moderate positive correlations were seen between WHO grades with mean SLR on lipid map of solid non-enhancing (=0.579, p<0.001) and tumour core (=0.461, p=0.003).
Conclusion: Lipid quantification via lipid mapping provides useful information on lipid landscape in tumour heterogeneity characterisation of glioma.

Arterial spin labelling and diffusion tensor magnetic resonance imaging-derived metrics for differentiation of post-treatment brain tumour recurrence from tissue necrosis

M. Talaat[1], A. Abdel Razek[2], L. Elserougy[2], G. Gaballa[2]; [1]*Kafr Elsheikh/EG*, [2]*Mansoura/EG (dr_MonaTalaat@hotmail.com)*

Purpose: Differentiating post-treatment brain tumour recurrence from tissue necrosis using arterial spin labelling (ASL) perfusion and diffusion tensor imaging (DTI)-derived metrics in the enhancing and oedema regions.
Methods and Materials: The study was done on 42 treated brain tumour patients with post-treatment enhancing lesions on MRI. Conventional MRI, ASL, and DTI imaging were done. Tumour blood flow (TBF), fractional anisotropy (FA), and mean diffusivity (MD) were measured at the enhancing

and oedema regions and the values were recorded for each case. Lesions were categorised as recurrence or necrosis by histopathology.
Results: Comparing recurrence to necrosis, there was high significant differences in TBF measured in the enhancing and oedema regions (both P < 0.001), accuracy (92.5%, 90%), sensitivity (93.8%, 81.2%), and specificity (91.7%, 95.8%), respectively. FA values revealed significant differences (P< 0.001, P<0.04), accuracy (80%, 67.6%), sensitivity (81.2%, 68.8%), and specificity (79.2%, 66.7%), respectively. MD values revealed significant difference (both p< 0.001), accuracy (92.5%, 80%), sensitivity (93.8%, 81.2%), and specificity (91.7%, 79.2%), respectively. Combined ASL and DTI metrics of the enhanced lesion revealed AUC of 0.98, accuracy of 95%, sensitivity of 93.8%, and specificity of 95.8%. Combined ASL and DTI metrics values in the peri-lesion oedema revealed AUC of 0.97, accuracy of 92.5%, sensitivity of 93.8%, and specificity of 91.7%.
Conclusion: ASL and DTI metrics in enhancing and oedema regions are valuable non-invasive tools in differentiating post-treatment recurrent brain tumour from tissue necrosis using individual and combined metrics.

Histogram analysis of diffusion kurtosis imaging estimates for in vivo assessment of 2016 WHO glioma grades

J.-M. Hempel, J. Schittenhelm, C. Brendle, B. Bender, M. Skardelly, G. Tabatabai, S. Castaneda Vega, U. Ernemann, U. Klose; *Tübingen/DE (johann-martin.hempel@uni-tuebingen.de)*

Purpose: To assess the diagnostic performance of histogram analysis of diffusion kurtosis imaging (DKI) maps for in vivo assessment of the 2016 World Health Organization Classification of Tumours of the Central Nervous System (2016 CNS WHO) integrated glioma grades.
Methods and Materials: Seventy-seven patients with histopathologically confirmed glioma who provided written informed consent were retrospectively assessed between 01/2014 and 03/2017 from a prospective trial approved by the local institutional review board. Ten histogram parameters of mean kurtosis (MK) and mean diffusivity (MD) metrics from DKI were independently assessed by two blinded physicians from a volume of interest around the entire solid tumour. One-way ANOVA was used to compare MK and MD histogram parameter values between 2016 CNS WHO-based tumour grades. Receiver operating characteristic analysis was performed on MK and MD histogram parameters for significant results.
Results: The 25th, 50th, 75th, and 90th percentiles of MK and average MK showed significant differences between IDH1/2$_{wild\text{-}type}$ gliomas, IDH1/2$_{mutated}$ gliomas, and oligodendrogliomas with chromosome 1p/19q loss of heterozygosity and IDH1/2$_{mutation}$ (p < 0.001). The 50th, 75th, and 90th percentiles showed a slightly higher diagnostic performance (area under the curve (AUC) range; 0.868-0.991) than average MK (AUC range; 0.855-0.988) in classifying glioma according to the integrated approach of 2016 CNS WHO.
Conclusion: Histogram analysis of DKI can stratify gliomas according to the integrated approach of 2016 CNS WHO. The 50th (median), 75th, and the 90th percentiles showed the highest diagnostic performance. However, the average MK is also robust and feasible in routine clinical practice.

B-0094 11:34

Differentiating primary CNS lymphomas from glioblastomas and inflammatory demyelinating pseudotumour using relative minimum apparent diffusion coefficients

J. Wen; *Shanghai/CN (wen123jianbo@163.com)*

Purpose: Our purpose was to evaluate the diagnostic performance of diffusion-weighted imaging (DWI), the relative ADCmin (rADCmin) in differentiating primary central nervous system lymphomas (PCNSL) from glioblastomas (GBM) and inflammatory demyelinating pseudotumours (IDP).
Methods and Materials: MRI images were reviewed retrospectively in 82 patients including 39 PCNSLs, 35 GBMs, and 8 IDPs. Regions of interest (ROI) were drawn around the tumour on contrast-enhanced images, these images were transferred onto coregistered ADC maps to obtain the minimum ADC (ADCmin) and the normalized ADCmin ratios (rADCmin) were calculated using the formula rADCmin = ADCmin of the lesion/ADCmin of the normal white matter. The rADCmin values were compared between PCNSLs, GBMs and IDPs using the ANOVA test. ROC curves were constructed to evaluate the diagnostic performance of rADCmin values and to determine the optimum thresholds. Simple logistic regression was analysed to evaluate the relationship between ADCs and tumour cellularity.
Results: The rADCmin value was significantly lower in PCNSLs (0.675±0.113) than GBMs (0.765±0.059) and IDPs (0.834±0.067) (PCNSL vs GBM, p<0.001; PCNSL vs IDP, p<0.001). rADCmin was a significant assessor for differentiating PCNSLs from non-PCNCLs (p<0.001). The optimal cut-off value was 0.722 (sensitivity: 74.5%; specificity: 74.1%; AUC: 0.803) on ROC analysis. A stronger negative correlation (r = -0.755, p = 0.000) was obtained between the cytoplasm and rADCmin.
Conclusion: rADCmin value is helpful in differentiating PCNSL from GBM and IDP. Thus, ADC values may provide a useful supplement to the information obtained from conventional contrast-enhanced MR imaging, and assist in future treatment planning.

B-0095 11:42

Percentage signal recovery (PSR) calculated from dynamic susceptibility contrast perfusion MRI: accuracy in differentiating various enhancing intracranial mass lesions

J.P. Sharma, T. Singh, K. Singh, I. Mohapatra, M. Singh; *Gurgaon/IN (doc.sharmajai24@gmail.com)*

Purpose: To determine whether percentage signal recovery (PSR) derived from dynamic susceptibility-weighted contrast (DSC)-enhanced perfusion MR imaging is accurate in differentiating various enhancing intracranial mass lesions like GBM, metastasis, lymphoma and tuberculoma.
Methods and Materials: This prospective study included 65 patients who underwent DSC perfusion MRI. T2* mean signal intensity recovery curves were drawn to calculate minimum, maximum, mean and relative PSR (rPSR). Accuracy of these parameters was assessed using ROC curves, one-way ANOVA, Student's t test and Chi-square test.
Results: Minimum, maximum, mean, rPSR were much higher in lymphoma (149.6, 216.6, 198.2, 2.16 ± SD) as compared to GBM (65.0, 86.7, 78.2, 0.91), tuberculoma (85.5, 122.3, 131.5, 1.54) and metastasis (52.9, 74.3, 63.9, 0.75). Mean curve in all cases of lymphoma crossed above the baseline. ROC curves of minimum, maximum, mean, rPSR for differentiating lymphoma from others (GBM, tuberculoma, metastasis) yield high AUC values of 0.987, 0.988, 0.963 and 0.961, respectively (p <0.0001) and sensitivity of 100%, specificity of 93.0%, 96.5%, 94.7% and 94.7% with optimum cut-off of 108, 147.5, 136.0 and 1.55, respectively. ROC curves of minimum, maximum, mean, rPSR for differentiating metastasis from others (GBM, lymphoma, tuberculoma) yield AUC values of 0.800, 0.803, 0.804, 0.839, respectively, with p<0.001. Similar ROC curves for differentiating tuberculoma from GBM, lymphoma and metastasis yield AUC values of 0.627, 0.722, 0.748 and 0.744 with p<0.05 for mean PSR and rPSR.
Conclusion: PSR is a practical and simplified perfusion MRI parameter which is effective in differentiating lymphoma and metastasis from other enhancing lesions with high sensitivity and specificity.

B-0096 11:50

qMRI using relaxometry detects non-visible peritumoural contrast enhancement in malignant gliomas

I. Blystad[1,1], J.B. Warntjes[1,1], Ö. Smedby[2,1], P. Lundberg[1,1], E.-M.B. Larsson[3,1], A. Tisell[1,1]; [1]*Linköping/SE*, [2]*Huddinge/SE*, [3]*Uppsala/SE (ida.blystad@regionostergotland.se)*

Purpose: Malignant gliomas are diffusely growing, infiltrative tumours. This study was performed to investigate if there is non-visible contrast enhancement in the peritumoural area of malignant gliomas using relaxometry with synthetic magnetic resonance imaging (syMRI).
Methods and Materials: 25 patients with a radiological appearance of malignant glioma were included. The quantitative MR-sequence (MAGIC), measuring longitudinal relaxation (R_1), transverse relaxation (R_2) and proton density (PD), was added to the standard MRI protocol before surgery. Diagnosis was confirmed by histopathology. Five patients were excluded, three due to another diagnosis and two due to motion during MR examination. In 20 patients, synthetic MR images were created from the quantitative scan. Manual regions of interest (ROIs) outlined the visibly contrast-enhancing border of the tumours and the peritumoural area in conventional and synthetic images. Contrast enhancement was quantified by subtraction of native images from post-Gd-images, creating T1- and R_1-difference maps, where the ROIs were used to analyse the tissue of interest. Peritumoural T1- and R_1-differences were normalized to the normal appearing white matter in the contralateral hemisphere. A one-sided T test was performed on the peritumoural- and the NAWM-ROIs.
Results: The malignant gliomas have heterogeneous relaxometry values. After normalization to normal appearing white matter, the quantitative R_1-difference maps showed significant, non-visible contrast enhancement in the peritumoural area (p<0.001), whereas conventional spin echo images did not.
Conclusion: Relaxometry detects non-visible contrast enhancement in the peritumoural area of malignant gliomas. This could represent infiltrative tumour growth.

Vascular calcification on mammography and coronary artery disease identified by computed tomography

S.L. McLenachan, M. Williams, F. Camilleri, D.E. Newby; *Edinburgh/UK (suzannemclenachan@gmail.com)*

Purpose: This sub-study of the SCOT-HEART randomised controlled trial of computed tomography coronary angiography (CTCA) in patients with suspected stable angina aimed to assess the prevalence of breast arterial calcification (BAC) and associations with cardiovascular risk factors, coronary artery calcification, coronary artery disease on CTCA and subsequent outcomes.
Methods and Materials: 405 female participants underwent CTCA and subsequent mammography. Mammograms were assessed for the presence of BAC.
Results: BAC was identified in 92 (23%) patients who were slightly older (62.9±6.6 versus 58.6±8.0 years; p<0.001), had higher cardiovascular risk scores (19.0±17 versus 16.7±10.5; p=0.018) and were more likely to be non-smokers (73% versus 51%; p<0.001). Age and non-smoking status were the only independent risk factors for BAC. Coronary artery calcification was present in 57 (62%) patients with BAC (relative risk 1.26 (95% confidence intervals 1.04-1.53, p=0.02). In patients with BAC, non-obstructive coronary artery disease was identified in 38 (14%) and obstructive coronary artery disease in 19 (21%). Patients with BAC were more likely to have obstructive coronary artery disease (relative risk 1.66 (95% confidence intervals 1.01-2.73; p=0.046), but this had poor discrimination (AUC 0.560, p=0.149) and was not independent of age or cardiovascular risk factors. Fatal or non-fatal myocardial infarction at 3 years occurred in one patient with BAC (1.1%) and three without BAC (1.0%, p=0.649).
Conclusion: BAC occurs in one-fifth of the patients referred for assessment of suspected coronary artery disease, but is not associated with traditional cardiovascular risk factors and is a poor discriminator for obstructive coronary artery disease.

Should breast artery calcifications be graded?

Ç.M. Altay[1], E. Düsünceli Atman[2], C. Uzun[2], M.F. Arslan[2]; [1]*Karabük/TR*, [2]*Ankara/TR (cetinmurataltay@gmail.com)*

Purpose: The aim of this study was to determine the relationship between the severity of mammographically detected breast arterial calcifications (BACs) and severity of coronary artery calcium (CAC) score on ECG gating coronary artery computed tomography angiography(CA-CTA).
Methods and Materials: Between July 2011- September 2016, 112 women (age 40-72 years, mean 55,3±8,8) who underwent both mammography and ECG gating CA-CTA were reviewed to determine BACs and CAC score, retrospectively. The exclusion criteria were determined a. malignant microcalcification on mammography, b. previous breast surgery, c. chest radiotherapy, d. chemotherapy for any reason, e. coronary bypass and stenting. BACs on mammography and CAC score on CA-CTA were identified with radiological consensus. BACs were graded in three groups, grade 1: no calcification, grade 2: dot like calcifications and grade 3: linear calcifications on any artery. The computer software was utilized to calculating CAC score .
Results: The rate of patients with left BACs was 15.2% (n:17) and right BACs was %15,2 (n:17). Patients with BACs were older than patients without BACs (p<0,001). The presence of right or left BACs predicted with 47.2% sensitivity and 96.1% specificity in patients with CAC ≥1. Positive correlation was detected between BACs severity grading and CAC score (p<0,001). CAC score was higher in patients with high BACs grade.
Conclusion: BACs are an indicator of presence of CAC. The relationship between BACs and CAC was evaluated from a different point of view in the general literature. BACs grading is an indicator of severity of CAC score.

B-0099 10:46

Breast arterial calcification on screening mammography can predict significant coronary artery disease in women

B.S. Kelly, E. Heffernan, S. McNally; *Dublin/IE (brendanskelly@me.com)*

Purpose: Breast arterial calcification (BAC) on digital mammography has been associated with an increased risk of coronary artery disease (CAD). We aimed to investigate the association of BAC with findings on coronary computed tomography angiography (CCTA) within a symptomatic cohort of women from the national breast screening programme (BreastCheck).
Methods and Materials: Data of symptomatic women (chest pain) aged between 50 and 65 years who underwent a CCTA and who also had a screening mammography between 2014 and 2015 were recorded. BAC and CAD-RADS™: Coronary Artery Disease-Reporting and Data System were scored by separate blinded specialist radiologists. Cardiac risk factors were recorded. Patients' cardiac follow-up (with exercise stress test, percutaneous coronary intervention or echocardiography) and cardio-protective medications were also documented.
Results: 219 eligible women underwent a CCTA. Of these, 104 patients also underwent digital mammography. Using standard linear regression, BAC was identified as the only significant predictor of CAD-RADs ≥3 disease. Using binomial logistic regression, BAC remained independently associated with CAD-RADs ≥3 (p=0.023). A significantly higher proportion of patients with BAC >1 were on cardio-protective medications (p=0.041) and had medications initiated or changed, or had further cardiac investigation (p=0.037 and p=0.019, respectively) than those with no BAC, after a mean follow-up of 20.6 (range 15-27) months.
Conclusion: BAC diagnosed on 2 yearly screening mammography predicts CAD-RADs ≥3 disease in symptomatic patients.

B-0100 10:54

Comparing computer-aided diagnosis (CAD) system with manual method for detecting breast arterial calcification (BAC)

A.N. Kamble, M. Popli; *New Delhi/IN (akshaykumar.kamble92@gmail.com)*

Purpose: Cardiovascular disease parthenogenesis starts from vessel changes due to chronic conditions like diabetes and hypertension. Breast arterial calcification (BAC) provides the unique opportunity to screen women for these vascular changes, but unfortunately, they are often ignored in the final report.
Methods and Materials: 299 women were screened with mammography. BAC was evaluated first by manual method followed by CAD method to prevent bias from CAD results. Grading of BAC was done from grade 1 to grade 3. The manual method of detecting BAC, after being confirmed by two readers, was taken as gold standard. 299 women were screened with mammography. Manual method of detecting BAC, after being confirmed by two readers, was taken as gold standard.
Results: There was the statistically significant difference between BAC detected by CAD method and manual method (chi-squared 116.4, p<0.0001). Sensitivity of detecting BAC by CAD method was only 56.10%, though it had good specificity 97.67%. Area under curve (AUC) was 0.77, positive predictive value being only 78.83%. CAD detected grade 2 and 3 calcifications with more accuracy than grade 1 calcifications (p<0.0001).
Conclusion: CAD has still a long way to go before it could match the sensitivity of manual method of BAC detection. Even though specificity of CAD is good, it cannot replace manual method for detection of breast arterial calcifications.

B-0101 11:02

Do we diagnose it better? - new BI-RADS classification for microcalcifications

J. Vucetic, M. Ortega Millán, J. Rivera Mata, J. Palao Errando, C. Barber Hueso, R. Garcia Garcia; *Valencia/ES (vucetic_jelena@yahoo.com)*

Purpose: To analyze all microcalcification biopsies performed after the publication of new edition of BI-RADS and compare it to our previous approach.
Methods and Materials: A retrospective review was performed for all microcalcification biopsies carried on in our center between June 2013 and May 2017. The cutpoint for two groups was the implementation of the new BI-RADS classification (May 2015), where low suspicion microcalcifications previously classified as BI-RADS 3 (no biopsy), passed to BI-RADS 4a (biopsy). Histology results were reviewed. Fisher's exact test was performed and p-values less than 0.05 were considered statistically significant.
Results: There were 19,086 mammograms performed in the cited period. A total of 269 patients with diagnosed microcalcifications were biopsied. In the period previous to the cut-point there were 86 biopsies and 23 cancers were detected (26.74%). After the new BI-RADS recommendations were implemented in our screening units, we experienced over two fold increase in biopsies performed, 183 biopsies, yet only 37 cancers diagnosed (20.22%). This increase in cancer diagnosis was not significant, p=0.271. The increase in

diagnosis of carcinoma in situ (CIS) was also not significant (21 vs 34, p=0.259).
Conclusion: Change in management of microcalcifications led to increase in number of biopsies performed as well as cancers diagnosed, especially CIS, although this increase is not significant in our series. It is yet to be seen if diagnosing more CIS reduces the rate of finding infiltrative cancers in years to come.

B-0102 11:10

Incidental breast lesions on chest computed tomography: prevalence, clinical significance, and differential features for referral

Y. Choi, C.H. Park, G. Hye Mi, T.H. Kim, E. Son; *Seoul/KR*

Purpose: With increasing use of chest CT, incidental breast lesions are increasingly being encountered. It is important that clinicians be familiar with CT characteristics of breast lesions. The aims of this study were to evaluate the CT features of incidental breast lesions on chest CT and to suggest useful criteria for referral to specialist breast units.
Methods and Materials: Between May 2009 and April 2014, 12268 chest CT reports containing the keyword "breast" were reviewed retrospectively. Patients with known breast disease or who had undergone non-enhanced CT examination were excluded. Patients who were referred to specialist breast units and then underwent pathological confirmation or follow-up over a 1-year period were included. Finally, 86 patients were enrolled. Two chest radiologists evaluated lesion characteristics, including size, location, shape, margins, and enhancement ratio. The correlations between the CT features and breast pathologies were evaluated, and overall diagnostic accuracy of CT features in various combinations was assessed to diagnose breast cancer.
Results: Overall, the malignancy rate of incidental breast masses on chest CT was 16.3%. Among the CT features, irregular shape, non-circumscribed margin, and enhancement ratio > 1 were significantly different between malignant and benign lesions. The combination of non-circumscribed margin and high contrast enhancement had the highest accuracy (97.7%).
Conclusion: Reliable CT features for incidental malignant breast masses are irregular shape, non-circumscribed margin, and high contrast enhancement. The combination of non-circumscribed margin and high contrast enhancement could help distinguish incidental malignant breast lesions on chest CT and indicate referral to specialized breast units.

B-0103 11:18

Breast MRI: internal thoracic artery lymph node assessment in patients with invasive breast carcinoma

M. Nadrljanski, Z. Milosevic; *Belgrade/RS (dr.m.nadrljanski@gmail.com)*

Purpose: To assess MRI features of physiological and metastatic internal thoracic artery (ITA) lymph nodes (LNs).
Methods and Materials: Thirty-four patients with T2 category histologically confirmed invasive breast carcinoma (n1=18 physiological LNs; n2=16 metastatic LNs), were assessed with DCE-MRI (1.5T) and DWI-ADC (b 0, 1000) for the morpho-functional features of LNs: short axis, long axis, short-to-long axis ratio, DWI-ADC and positive enhancement integral (PEI) values.
Results: Difference in morphologic features (short axis, long axis) between physiologic and metastatic LNs was considered highly statistically significant (short axis: 7.68+/-0.87 mm vs. 4.50+/-0.86 mm, p<0.0001; 13.0+/-1.75 mm vs. 8.62+/-1.61 mm, p<0.0001). The same applied for DWI-ADC value (0.58+/-0.06 vs. 0.80+/-0.05, p<0.0001). However, the difference in the short-to-long axis ratio and PEI values between the two subgroups was not considered highly statistically significant (0.59+/-0.08 vs. 0.53+/-0.09 mm, p=0.002; 636.97+/-74.50 vs. 530.44+/-68.85, p=0.002). No significant correlation was detected in the subgroup of metastatic LNs between the selected morphologic and functional parameters.
Conclusion: Morphologic LN features like short and long axis, and DWI-ADC values may contribute to better discrimination between physiological and metastatic ITA LNs in patients with invasive breast carcinoma.

B-0104 11:26

Comparison of invasive lobular and invasive ductal carcinomas of the breast using 3T DCE-MRI

T. Torheim, R. Woitek, A.J. Patterson, R. Bedair, I.A. Mendichovszky, C. Caldas, F. Markowetz, F.J. Gilbert; *Cambridge/UK (Turid.Torheim@cruk.cam.ac.uk)*

Purpose: To compare the dynamic contrast-enhanced (DCE) magnetic resonance imaging (MRI) characteristics of invasive lobular carcinomas (ILC) and invasive ductal carcinomas (IDC) of the breast.
Methods and Materials: In this prospective study, 48 patients with biopsy-proven IDC (n = 30, mean age 59 years, range 32 - 83) or ILC (n = 18, mean age 58 years, range 38 - 81) underwent 3T DCE-MRI prior to surgery. Following motion correction, pharmacokinetic maps (K^{trans}, v_e, k_{ep}) were calculated using the standard Tofts model with T1 mapping and B1 inhomogeneity correction. Distribution measures of mean, median, skewness and kurtosis for each parameter within the lesions were calculated and compared between the two subtypes using Wilcoxon's signed-rank test.
Results: The k_{ep} parameter was most sensitive to differentiate between IDC and ILC, showing significant differences in all distributional measures (p values < 0.05). ILC had lower k_{ep} values, with a more skewed parameter distribution compared to IDC cases. Apart from K^{trans} being skewed towards lower values in ILC (p value 0.04), there were no significant differences between the two subtypes regarding v_e and K^{trans}.
Conclusion: Our results show that the k_{ep} parameter, which is representative of contrast agent washout, is more sensitive to the difference between ILC and IDC than the more commonly reported K^{trans} and v_e parameters. This highlights a difference in uptake curve shape between these two subtypes of breast cancer.

B-0105 11:34

Role of diffusion-weighted MRI (DWI) and intravoxel incoherent motion (IVIM) in monitoring treatment response to neoadjuvant chemotherapy in locally advanced breast cancer

M.F.A. Kamis[1], K. Rahmat[1], M.T. Ramli Hamid[2]; [1]*Kuala Lumpur/MY*, [2]*Selangor/MY (fandi_mohd@yahoo.com)*

Purpose: This study is to investigate diffusion weighted MRI (DWI) and changes in IVIM parameters [Random diffusion(D) and functional fraction(f)] of invasive breast carcinoma in patients undergoing neoadjuvant chemotherapy (NACT). We also aim to evaluate baseline MRI imaging phenotypes of breast carcinoma versus normal breast tissue (using ADC and IVIM parameters).
Methods and Materials: A prospective study involving women with invasive breast carcinoma (n= 15) between the age of 29 to 66 years (mean age=43.4) who are planned for 6 cycles of NACT. DCE MRI were performed at 3 different intervals (Pre-NACT, post-first and third cycles of NACT). DWI data of the target lesions were obtained using ROI measurements. The IVIM parameters (from multiple b-values) were calculated.
Results: Mean ADC values for malignant breast lesion is (0.74 x 10-3 mm2/s) compared to normal breast tissue (1.90 x 10-3 mm2/s). Following the three cycles of NACT, quantitative findings showed increase in mean ADC values (1.29 x 10-3 mm2/s). IVIM parameters showed increase in D-value and reduction of f-value which reflects reduce in microcapillaries density post NACT.
Conclusion: DWI is useful to characterize breast tumour cellularity. ADC values showed significant increase as early as the first cycle of NACT. IVIM parameters provides noninvasive indicator to microperfusion properties of malignant breast lesion, thus may be used as alternatives to monitor the response to NACT for patients with contraindication to gadolinium These tools are expected to enhance the role of MRI in monitoring treatment response of cancerous lesions in the breast.

B-0106 11:42

The diagnostic performance of automated breast ultrasound (ABUS) compared with handheld ultrasound (HHUS)

M. Yoshida[1], K. Enokido[2], T. Nishiyama[1]; [1]*Tokyo/JP*, [2]*Kanagawa/JP (ymiwa2000@gmail.com)*

Purpose: For women with dense breasts, the combination of mammographic and ultrasound screening was reported to detect more invasive cancers. However, handheld ultrasound (HHUS) has also some limitations, such as operator dependent and insufficient reproducibility. Automated breast ultrasound (ABUS) which acquires 3-D volume images of whole breast can potentially overcome these limitations of HHUS. The aim of this study was to evaluate the diagnostic performance of ABUS compared to HHUS in terms of the detection and characterization of breast lesions.
Methods and Materials: From January 2016 to May 2017, 390 breasts of 195 women (Median age 43) examined by both HHUS and ABUS: using Invenia ABUS (GE Healthcare Inc.) scanner. Of them, 135 women concurrently underwent mammography. The images were interpreted by more than two physicians who has sufficient experience of breast ultrasound.
Results: BI-RADS assessment categories in ABUS coincided with those in HHUS of 92% (357/390 breasts). Twenty-three lesions, which were diagnosed as cancers, were all classified as BI-RADS 4/5 both in ABUS and in HHUS. Three cancers of them were undetectable by mammography. In 7 cases where the lesions were classified as BI-RADS 4 in ABUS but as BI-RADS 1 in HHUS, those were considered as image artifacts. In most cases with disagreements between ABUS and HHUS, there were mismatches of BI-RADS 2 and BI-RADS 3.
Conclusion: The capability of ABUS for detection and characterization of breast lesions was nearly equivalent to HHUS. It can be further improved by learning more about image artifacts peculiar to ABUS.

B-0107 11:50

Primary tumour location predicts the site of local relapse after nipple-areola complex (NAC)-sparing mastectomy

L. Vassallo[1], N. Tomasi Cont[1], V. Doronzio[1], R. Panzone[1], D. Regge[2], L. Martincich[1]; [1]*Candiolo/IT*, [2]*Candiolo-Torino/IT*
(lorenzo.vassallo1987@libero.it)

Purpose: To evaluate if primary tumour location can predict the site of local relapse after nipple-areola complex (NAC)-sparing mastectomy.
Methods and Materials: 518 consecutive women submitted to NAC-sparing mastectomy in the period between 2010 and 2015 were enrolled in the study. All the patients underwent pre-surgical breast MRI (1.5T magnet) following the recommended technical requirements and intraoperative assessment of NAC status. Subsequently, subjects underwent routine clinical and imaging follow-up. For each local recurrence identified, location and imaging and biological characteristics were evaluated.
Results: Fourteen subcutaneous local relapses (2,7%) occurred over a mean follow-up of 33 months. Mean time to recurrence was 38 months. In all the cases, relapse was observed in patients with highly proliferative primary tumour. Recurrences were identified by clinical examination in eight cases, MRI in five and ultrasound in one. A comparison of clinical-pathological characteristics revealed that primary tumours and local recurrences were located in the same breast quadrant in most of the patients (12/14; 85,7%). No local relapses occurred in women who received radiotherapy. A single case of NAC recurrence developed as a Paget's disease in patient without sub-areolar and proximal nipple duct involvement at mastectomy. MRI findings of local recurrences were represented by small mass lesion with regular margin and rapid early homogeneous enhancement. All of them were located in the same breast quadrant of the primary tumour.
Conclusion: Our study shows that local recurrences after NAC-sparing mastectomy almost invariably develop in the same quadrant where the primary tumour was located.

The performances of radiographic criteria for bone malignancy when applied to computed tomography and magnetic resonance imaging

T. Onal[1], G.O. Afacan[1], G. Akansel[2], A.S. Arslan[2], Y. Anık[2], N. Inan[1], B. Muezzinoglu[2], F. Corapcioglu[2]; [1]*Istanbul/TR*, [2]*Kocaeli/TR*
(tugayonalx@gmail.com)

Purpose: The conventional radiological features to differentiate benign from malignant bone lesions were originally described using radiography (XR). When evaluating sectional imaging studies such as MRI and CT one may tend to apply these principles to identify malignant bone lesions. The aim of this study is to evaluate the performances of these radiographic features for detecting malignity when applied to CT and MRI.
Methods and Materials: Thirty-nine patients with histopathological proof of a high-grade bone malignancy and preoperative imaging data obtained at least with two different modalities were included in the study. Four radiologists reviewed the images and scored the lesions for the distinctness of margins, presence and type of periosteal reaction, matrix mineralisation, and presence of soft tissue mass. The average score for each modality was then tested for accuracy with regard to the histopathology.
Results: When lesion margins were considered, XR was the best modality to detect a high-grade malignancy. MRI, especially post-contrast T1-weighted sequence was the least helpful in this regard. There was no significant difference between CT and XR, nor between CT and MRI. When the periosteal reaction was considered, XR was the best modality to detect the malignant type periosteal reaction. In this regard, MRI and CT were misleading either by not detecting or under-grading periosteal reaction.
Conclusion: Conventional imaging criteria for bone malignancy can be misleading when applied to MRI, or CT. When cross-sectional imaging features contradict with those from XR, the latter should be the guide for clinical management.

B-0109 10:38

Can quantitative diffusion weighted imaging segregate malignant from benign bone lesions? A 3-T MRI feasibility study

A.A.A. Doweidar[1], M.R. Nouh[2], A.M. Khalil[1], K. Dashti[1]; [1]*Kuwait/KW*, [2]*Alexandria/EG (ahmeddoweidar1@yahoo.com)*

Purpose: The study aims to probe the potential of apparent diffusion coefficient (ADC) in differentiating malignant from benign bone tumours and tumour-like lesions on magnetic resonance imaging (MRI) using multiple b values.
Methods and Materials: We included 50 patients (26 males and 24 females) with 56 primary or secondary malignant bone tumours, benign bone tumours or tumour-like lesions in this study. The diagnosis of all lesions was histopathologically confirmed. The MRI studies were conducted using a 3-T scanner. MRI protocol included diffusion weighted (DW) images using multiple b values. ADC maps were derived from DW-MR imaging data and analysed by two radiologists who were blind to the histopathological results. The mean ADC values were obtained for statistical analyses.
Results: The histopathological results revealed that 39/56 (69.6%) lesions were malignant, 11/56 (19.6%) were benign tumours, 3/56 (5.4%) were tumour-like solid, and 3/56 (5.4%) were tumour-like cystic lesions. The mean ADC values were significantly different in the malignant tumours ([0.92±0.35] $\times 10^{-3}$ mm^2/s) versus benign tumours ([1.25±0.37] $\times 10^{-3}$ mm^2/s) ($p<0.009$), tumour-like solid lesions ([1.24±0.11] $\times 10^{-3}$ mm^2/s) ($p<0.026$) and all non-malignant lesions ([1.36±0.46] $\times 10^{-3}$ mm^2/s) ($p<0.001$). Applying a mean ADC cutoff value of $\leq 1.185 \times 10^{-3}$ mm^2/s for detecting malignancy resulted in a sensitivity of 87.2%, a specificity of 64.7%, and an accuracy of 81.5% (95% confidence interval [CI] 70.1%-93%). The inter-rater reliability was nearly perfect (ICC = 0.969; 95% CI = 0.947-0.982).
Conclusion: Although there was some overlap, DWI proved highly useful in differentiating malignant from benign tumours and tumour-like bony lesions.

B-0110 10:46

mDixon is superior to frequency-selective fat suppression in musculoskeletal tumour imaging

W. Huijgen[1,2], C.S. van Rijswijk[1], J.L. Bloem[1]; [1]*Leiden/NL*, [2]*Den Haag/NL*

Purpose: The modified Dixon technique (mDixon) allows reduction of acquisition times relative to conventional Dixon, while reducing sensitivity to B0-inhomogeneity and maintaining the advantages of FSE frequency selective fat saturation techniques. The purpose was to determine the value of mDixon relative to conventional FSE (FSE) in musculoskeletal tumour imaging.
Methods and Materials: In a HIPAA-compliant prospective study, 265 patients who required a musculoskeletal tumour MR scan were included. mDixon and FSE sequences with similar acquisition times were compared in fluid sensitive (T2) and non-fat Gd (Gd) images. Two radiologists, blinded to protocols, scored 9 parameters (5-point scale, paired samples t test) including fat suppression homogeneity, motion artefacts, and overall preference.
Results: Overall, reviewers preferred mDixon in 20% (T2) and 27% (Gd) of cases, preferred FSE in 17%(T2) and 10% (Gd) and had no preference in 63% (T2) and 63% (Gd). The mean score for fat suppression homogeneity in mDixon was superior to FSE by 0.56 points in T2 and 0.65 points in Gd ($p<0.01$). Highest differences in scores in favour of mDixon were found in cases with susceptibility and magnet inhomogeneity problems. In only 2 cases with motion artefacts FSE performed considerably better.
Conclusion: mDixon showed similar image quality to FSE images, without time penalty, but was superior to FSE when susceptibility artefacts were present. Thus, replacing FSE by mDixon water reconstructions in T2 and Gd-enhanced MSK tumour imaging yields superior image quality without disadvantages. The advantage of Dixon to reconstruct multiple water-fat balanced images was not evaluated.

B-0111 10:54

Feasibility study of intra-voxel incoherent motion MR imaging for the differentiation of benign and malignant soft tissue tumours

Y. Li, C. Ren, J. Cheng; *Zhengzhou/CN*

Purpose: The purpose is to investigate the application of IVIM and furtherly evaluate the ability of IVIM parameters to differentiate benign and malignant soft tissue tumours.
Methods and Materials: Thirty-five patients with tissue tumours (diagnosed according to biopsy) were included in this study. 21 for benign tumours and 14 for malignancies. All the patients were scanned by IVIM sequence based on a 3T MR scanner. The IVIM scanning was performed with 10 b-values. All the above parameters were measured by drawing ROIs within the periphery of the lesions(P_D, P_Dstar, P_f short for periphery D, periphery Dstar, periphery f) and the center of the lesions(C_D, C_Dstar, C_f short for center D, center Dstar, center f). And the all the parameters were compared by using Mann-Whitney U test with SPSS software (version 16.0). And ROC analysis was performed to assess the sensitivity and specificity of every parameter. The

parameters which showed a significant difference were selected and combined as the feature vectors for the classification by using SVM classifier.
Results: The results revealed that P_D and C_D value is significantly different (P <0.05). The ROC analysis results showed the ability of the above parameters to differentiate lesions. The AUCs (area under the curve) of P_D and C_D are 0.776 and 0.752 respectively. And the SVM classifier showed a high classification accuracy (82.73%), sensitivity (87%) and specificity (76.45%) for differentiating malignant from the benign lesions.
Conclusion: The IVIM related parameters of tissue diffusivity (D) increases diagnostic confidence of soft tissue tumours.

B-0112 11:02

An artificial intelligence approach for the automatic diagnosis of lipoma and liposarcoma: a pilot radiomics study

L. Malinauskaite, J. Hofmeister, S. Burgermeister, S. Martin, X. Montet, S. Boudabbous; *Geneva/CH (sana.boudabbous@hcuge.ch)*

Purpose: To assess the contribution of MRI-based radiomics in the automatic diagnosis of lipoma and liposarcoma using artificial intelligence (AI).
Methods and Materials: Lipoma (n=20) and lipocarcoma (n=17) were retrospectively identified on histopathological analyses of percutaneous or surgical resection specimen, and their respective pre-operative MRI images were retrieved from our institutional PACS. Two senior radiologists manually segmented these lesions on Spin Echo T1-weighted images. An open-source python library was then used to extract a large number of radiomics features (n=123063) from each lesion. Benign (i.e. lipoma) and malignant (i.e. liposarcoma) discrimination based on radiomics data was achieved through features selection, dimension reduction (using principal component analysis) and classification (using a support vector machine classifier). A *Leave-One-Out Cross-Validation* approach was used to estimate the prediction error of our model due to the medium sample-size.
Results: Our approach achieved an overall classification accuracy of 83,8% in identifying lipoma (versus liposarcoma), with a sensitivity of 100%, specificity of 64,7%, positive predicting value of 76,9% and negative predictive value of 100%.
Conclusion: Our radiomics-based method for classification of lipomatous soft tissue tumor yielded promising results, notably with very high accuracy in identifying benign lesions.

B-0113 11:10

Tumour load in patients with multiple myeloma: β_2-microglobulin levels vs low-dose whole-body CT

V. Pfahler, M. D'Anastasi, H. Duerr, J. Ricke, A. Baur-Melnyk; *Munich/DE (vanessa.pfahler@med.uni-muenchen.de)*

Purpose: Beta-2-microglobulin is a serum marker of tumour burden in multiple myeloma (MM). Our aim was to correlate serum ß2-microglobulin levels in patients with MM to tumour mass determined by low-dose whole-body CT.
Methods and Materials: 54 patients with newly diagnosed, untreated MM who underwent low-dose whole-body CT at our department between 2003 and 2014 were included retrospectively. The low-dose whole-body CT scans were assessed by two musculoskeletal radiologists in consensus for focal lesions. The Durie and Salmon PLUS staging System was used for staging patients in stage I-III. ß2-microglobulin was also subdivided into stage I-III (stage I: < 3,5 mg/L; stage II: 3,5-5,5 mg/L; stage III: > 5,5 mg/L) according to R-ISS.
Results: Using the Durie and Salmon PLUS staging system criteria for image evaluation we were able to identify stage I (low grade) MM in 19 patients, stage II (intermediate) MM in nine patients and stage III (high grade) MM in 26 patients. As expected most patients with stage I disease had normal ß2-microglobulin levels. However eight of nine patients with stage II MM and 16 of 26 patients with stage III MM had normal ß2-microglobulin levels. Thus, 24 of 35 patients (68,6%) had 5 or more focal lesions and false-negative ß2-microglobulin levels.
Conclusion: ß2-microglobulin may not indicate the full extension of bony disease in a significant subset of myeloma patients.

B-0114 11:18

MRgFUS treatment for painful bone metastases, analysis of non-responders: are there imaging features associated with poor clinical response?

S. Guerri[1], D. Mercatelli[1], C. Gasperini[1], M. Aparisi Gomez[2], E. Rimondi[1], U. Albisinni[1], A. Napoli[3], G. Battista[1], A. Bazzocchi[1]; [1]*Bologna/IT*, [2]*Valencia/ES*, [3]*Rome/IT (guerri.sara@gmail.com)*

Purpose: Magnetic resonance guided focused ultrasound (MRgFUS) proved to be effective and safe in the treatment of painful bone metastases. However, a few patients experience poor response. The purpose of this study was to evaluate the existence of imaging features at pre-operative examination predictive of poor outcome.
Methods and Materials: We retrospectively reviewed 19 non-responders (patients with no improvement in VAS score, or pain increase after treatment; group-A: 20 lesions) and compared them to 20 responders (group-B: 25 lesions), out of more than 150 treatments performed at our Institute. The following quantitative imaging features were analysed: size and type of the lesion (osteolytic/non-osteolytic), extent of anterior/posterior cortex destruction (graded 0-5 on pre-treatment-CT), soft-tissue involvement, pretreatment bone and soft-tissue oedema (graded 0-3 on T2-fat-sat sequences), post-treatment bone oedema, degree of vascularisation, minimum/maximum distance of the skin from the lesion, skin and subcutaneous tissue thickness and the presence of vessels/nerves/synovial structures in the proximity of the lesion. The Chi-Square statistic was used to test frequencies in the two groups. This work has been supported by the "Programma di ricerca Regione-Università, Regione Emilia-Romagna, bando Giovani Ricercatori "Alessandro Liberati" 2013 to AB "Magnetic Resonance guided High Intensity Focused Ultrasound treatment of bone metastases: pain palliation, and local tumor control?".
Results: 55% and 75% of lesions in the group-A showed a bone oedema and a soft tissue oedema, respectively, ≥2 (vs. 16% and 32% in the group-B); 70% of lesions in the group-A showed an extent of posterior cortical destruction ≥3 (vs. 36% in the group-B).
Conclusion: Larger pre-treatment bone and soft tissue oedema areas and greater posterior cortex destruction are associated with poor outcome in terms of VAS reduction after MRgFUS.

B-0115 11:26

Percutaneous image-guided cryoablation of musculoskeletal metastases to the chest wall: a single-centre experience

C. Lord, L. King; *Southampton/UK*

Purpose: A single-centre experience describing the efficacy and safety of percutaneous image-guided cryoablation for local tumour control in the treatment of musculoskeletal metastases to the chest wall.
Methods and Materials: A retrospective review of consecutive patients treated from October 2011 to October 2017 for the indication of oligometastatic cancer to the chest wall was performed. 9 lesions were treated in 9 patients during the time period. The mean age of the cohort was 67 years (range 56-78), 44% female (4/9) and 56% male (5/9). Serial follow-up imaging was assessed for local tumour control against RECIST 1.1 and MDA criteria.
Results: The 9 lesions (5 renal, 1 lung, 1 colon, 1 breast, 1 ocular melanoma) were followed up for a mean of 1 year 3 months (range 3-35 months). Of the patients with available follow up, local tumour control rates were 89% (8/9) at 3 months and 85% (6/7) at 6 months and 83% at (5/6) at 12 months. 3 patients who had stable disease at 6 month follow up had not yet been imaged beyond 12 months. 3 of the patients who had follow up beyond 20 months showed long term local control. Procedural complication rates were low with 1 patient sustaining a haemothorax requiring drainage without long term sequelae.
Conclusion: Percutaneous image guided cryoablation is a safe and effective treatment for oligometastatic disease to the chest wall and in certain patients can provide long-term disease control.

B-0116 11:34

Radiological changes of giant cell tumour of bone in treatment with Denosumab

S. Bonilla, J. Llauger Rossello, C. Nuñez Peralta, S. Valverde Lavirgen, J. Palmer Sancho; *Barcelona/ES (santibonilla22@gmail.com)*

Purpose: To describe the clinical and radiological progressive changes on giant cell tumour of bone (GCT) on patients in treatment with Denosumab.
Methods and Materials: Retrospective study of 20 patients with GCT confirmed histopathologically with an unresectable tumour, post surgical recurrence or disseminated tumour. The follow up was made with MRI and CT. We analysed the treatment response and the radiological changes of tumoural size, the enhancement, tumoural matrix changes, tumoural margin and the changes of signal in the different MRI sequences.
Results: None of the patients in our study demonstrated a progression of the basal disease and the 55% showed a partial response with the treatment. The radiological changes were diverse but the most important and frequent were the decrease of the tumour size, tumoural enhancement, the changes on the tumoural matrix like peripheral sclerosis and central necrosis and/or quistification. The radiological features were confirmed histopathologically. A clinical improvement observed in all the patients was most frequently the pain improvement. Only one patient showed a complication with osteonecrosis of the jaw due to the treatment.
Conclusion: The most important radiological changes were the decrease on tumoural size, tumoural enhancement and the changes on tumoural matrix in patients with partial response. None of all the patients showed a progression of the basal disease and more than a half showed a partial response. The treatment with Denosumab on GCT seems to be useful in the clinical and radiological response on a specific group of patients.

B-0117 11:42

MRI characteristics of 26 onychomatricomas

L. Lassalle[1], S. Eminian[2], A. Buisson[1], E. Pessis[3], R. Campagna[1], N.E. Regnard[1], W. Khaled[1], L. Moya[1], J.L. Drape[1]; [1]*Paris/FR*, [2]*Clarens/CH*, [3]*Saint Denis/FR (louis.lassalle@gmail.com)*

Purpose: Onychomatricomas are rare benign fibroépithélial tumours of the nail matrix. We describe the MRI characteristics of onychomatricomas, and identify subgroups with different imaging features.
Methods and Materials: MRI studies of 26 fingers or toes with histopathologically proven onychomatricomas were retrospectively reviewed by two MSK-radiologists. MRI protocol included T1w, T2w and gadolinium-enhanced T1w sequences. MRI characteristics were noted (size, T1 and T2 signal, enhancement, topography, morphology).
Results: 26 MRI were reviewed: 19 (73.1%) fingers and 7 (26.9%) toes. 18 patients (69.2%) were females, and mean patient age was 52.8yrs (range: 31-76). All tumours presented a proximal head in the matrix cul-de-sac (mean diameter 5.9mm) and distal filamentous expansions included inside the nail plate. The proximal head showed an hyposignal in T1w (69.2%) and T2w sequences (69.2%), and enhancement was present in 55.6%. Lesions had a "hairy" pattern (regular filamentous expansions) in 9 cases and a "cryptic" pattern (irregular filamentous expansions) in 17 cases. "Central" (n= 17) and "lateral" (n = 9) subgroups showed significant differences in location (p = 0.01), in T2 signal (p = 0.03) and height (p = 0.01) of the proximal component, in demarcation with the surrounding dermis (p = 0.02), in the deformity of the nail matrix ("glove finger" invagination) (p = 0.0006), and in the length of the filamentous extensions (p = 0.01).
Conclusion: MRI findings of onychomatricomas are specific and allow differentiating two subgroups according to the "central" or "lateral" location in relation to the nail matrix.

B-0118 11:50

Follow-up of incidental cartilaginous tumours in the knee of middle-aged women

S. Breda, B.A. De Vries, G. Bessems, D. Schiphof, J. Heeringa, G.P. Krestin, M.W. Vernooij, S.M. Bierma-Zeinstra, E. Oei; *Rotterdam/NL (s.breda@erasmusmc.nl)*

Purpose: Enchondromas are benign cartilaginous tumours frequently found incidentally on MRI of the knee and should be differentiated from low-grade chondrosarcoma. Information on natural course is essential to help clinical decision making regarding need to follow-up. We provide follow-up data of incidental cartilaginous tumours on knee MRI in the large population-based Rotterdam Study.
Methods and Materials: 891 females aged 45-60 (mean 55) years underwent non-contrast bilateral knee MRI (1.5T) at baseline. 700 (79%) participants were re-scanned at 5 years follow-up. We analysed growth by comparing the largest dimension (of three directions) between baseline and follow-up. Measurements were obtained independently by two trained researchers. Lesions >1 cm and/or those with endosteal scalloping or cortical disruption were referred for dynamic contrast-enhanced MRI (DCE-MRI).
Results: In 1782 MR scans, we identified 54 incidental cartilaginous tumours in 46 patients at baseline (5.2%), of which 16 were referred (32.6%). In the absence of malignant features on DCE-MRI, none of referred lesions were treated. Mean follow-up duration was 4.6 years (SD 0.6, range 4-6). Mean largest dimensions were 12.1 mm at baseline (range 4.1-40.6) and 12.5 mm (4.1-44.1) after follow-up for observer 1 and 12.1 mm (4.4-41.3) and 12.8 mm (4.1-44.1) for observer 2, with an intraclass correlation coefficient of 0.99 between both observers for all lesions.
Conclusion: In middle-aged women, incidental cartilaginous tumours are present on 5.2% of knee MRI scans, and show only minor progression after 5 years. No features of low-grade chondrosarcoma were found on additional DCE-MRI of referred lesions.

Teaching radiation safety intuitively with a head-mounted display

N. Loy Rodas[1], P. Ghimire[2], M. de Mathelin[1], A. Gangi[1], N. Padoy[1]; [1]*Strasbourg/FR*, [2]*Dijon/FR (nloyrodas@unistra.fr)*

Purpose: A considerable amount of unnecessary exposure and risk underestimation results from a lack of awareness and poor knowledge of the behavior of ionizing radiation during x-ray guided procedures. While current radiation safety training is usually based on courses, lectures and presentations of theoretical aspects, we propose to use a head-mounted display (HMD) to teach intuitively about radiation behavior.
Methods and Materials: A virtual interventional room (C-arm, table, clinicians, and patient) is displayed through an HMD (Microsoft's HoloLens). The user interacts with the scene to set the C-arm angulation and imaging parameters. Virtual color-coded radiation safety information corresponding to the current scene configuration is overlaid in the user's view. The displayed radiation-related data is accurately pre-computed with Monte Carlo simulations.
Results: Through an HMD, the trainee can visualize patient and clinicians' models colored according to their ongoing exposure levels or the 3D propagation of scattered radiation for the current scene configuration. First feedback from users has been promising since the system provides an engaging, game-like and risk-free learning environment. Additionally, it provides an immediate feedback to maximize learning about the effects that altering simultaneously interacting parameters can have on radiation exposure.
Conclusion: Reducing medical radiation exposure requires to increase staff's awareness and knowledge about radiation. We propose to make radiation safety training more intuitive and engaging with HMDs. The trainee can visualize the effect of different C-arm configurations on the patient/staff dose and on the scattered radiation diffusion. This allows to learn the best safety practices intuitively, safely and anywhere.

B-0120 10:38

National audit on the appropriateness of CT and MRI examinations in Luxembourg

A. Bouëtté[1], A. Karoussou-Schreiner[1], H. Ducou Le Pointe[2], M. Grieten[3], E. de Kerviler[2], L. Rausin[4], J.-C. Bouëtté[5], P. Majerus[1]; [1]*Luxembourg/LU*, [2]*Paris/FR*, [3]*Genk/BE*, [4]*Liège/BE*, [5]*Montreal, QC/CA (aurelien.bouette@ms.etat.lu)*

Purpose: In Luxembourg, the frequency of CT and MRI examinations per inhabitant is among the highest in Europe. A national audit was conducted to evaluate the appropriateness of CT and MRI examinations according to the national referral guidelines for medical imaging.
Methods and Materials: 388 CT and 330 MRI requests forms corresponding to already-performed examinations were provided by all radiology departments in Luxembourg. Four external radiologists analysed the clinical elements for justification present in each request. They consensually assessed the appropriateness of each requested examination with regard to the national referral guidelines and their clinical experience.
Results: The appropriateness rate was higher for MRI requests than for CT requests (79% vs 61%; p <0.001). For CT, the appropriateness rates were better when the requests concerned paediatric rather than adult patients (82% vs 68%; p<0.001), when the requests concerned head (79%) and chest (81%) areas rather than spinal (28%), extremity (51%) and abdominal-pelvic (60%) areas (p<0.001), and when the requests were referred by medical specialists rather than by general practitioners (70% vs 37%; p<0.001). The appropriateness rates also varied significantly depending on the radiology department for both CT requests ([46%-86%]; p<0.001) and MRI requests ([57%-92%]; p=0.001).
Conclusion: A high proportion of CT and MRI examinations requested were found to be inappropriate. Inappropriate requests of CT examinations could potentially lead to unnecessary patient exposures, but the results observed for paediatric imaging requests and for two radiology departments suggest prolonged efforts could improve the justification of imaging in Luxembourg.

B-0121 10:46

Combination of environment recognition sensors and conventional x-ray settings

A. Corbi Bellot[1], F. Albiol[1], A. Albiol[2]; [1]*Paterna/ES*, [2]*Valencia/ES*
(alberto.corbi@ific.uv.es)

Purpose: Combination of radiographic information (generated in ordinary x-ray settings) with the patient's volume and/or visible markers to derive 3D anatomical information and density images. These images highlight soft tissues or bony regions, separately.
Methods and Materials: We measure and track the patient's volume/location with scene recognition sensors. This allows the derivation of 3D information from pairs of radiographs generated at different patient positions. Also, using the same tracking equipment, we can derive the traversed lengths (through ray-casting) within the patient's skin isosurface. These lengths are pixel-wise associated to the original radiograph and used to derive densitometric data. To obtain all this information, both the x-ray tube and the tracking sensors have to be optically registered and the captured geometry needs to be translated to the point-of-view of the x-ray system.
Results: Resolution of anatomical lengths with millimetric precision. Besides, the obtention of density-based images that can be used to enhance soft tissues or bone structures, alongside. In the first type, the dynamic range is shrunk, improving the visibility of high gradient areas, extending contrast manipulations, and correcting underexposed X-ray images. This images also contain more information, according to modern pattern recognition algorithms and the concept of mutual information. In the bone-enhancement type, a single radiograph emphasises the skeletal structure just like a DEXA setup (impact in dose reduction).
Conclusion: The interplay of affordable contour assessment and motion detection equipment with plain x-ray settings can be used to add valuable information to plain radiographs: 3D real positions/lengths and density-based images.

Radiation dose optimisation in intraoperative computed tomography of the brain

R. Forbrig, M. Patzig, C.G. Trumm, R. Stahl, F. Dorn; *Munich/DE*
(robert.forbrig@gmx.de)

Purpose: Intraoperative computed tomography (CT) with stereotactic head frames is an integral part of navigated neurosurgery. CT scanners must offer both a maximal diagnostic accuracy with reduced metal artefacts and a reasonable radiation dose. We report on our experience.
Methods and Materials: 200 patients (84 female, mean age 63) received an intraoperative contrast-enhanced CT of the brain on a 128 slice CT scanner (SIEMENS SOMATOM Definition AS+). For metal artefact reduction, the same iterative reconstruction algorithm (ASIR) was used in each patient. Regarding dose optimization, in 100 patients the CT protocol comprised automated tube current (CARE Dose4D) and voltage (CARE kV) modulation, in 100 patients fixed parameters (300 mAs, 120 kV). Radiation doses and image quality of both groups were compared.
Results: In the automated modulation group, tube current ranged between 475 and 1065 mAs (mean, 658 mAS), and tube voltage between 100 and 140 kV (mean, 118 kV). Mean dose length product (DLP) was 1524 mGy*cm (range, 692-2140 mGy*cm), mean CTDIvol 89 mGy (range, 43-135 mGy), and mean effective dose 2.90 mSv (range, 1.31-4.01 mSv). In the group with fixed parameters, mean values of DLP, CTDIvol, and effective dose were 753 mGy*cm (range, 683-896 mGy*cm), 43 mGy (range, 42-43 mGy), and 1.43 mSv (range, 1.30-1.70 mSv). All parameters were significantly lower in the latter group ($p<0.01$, each). Image quality was sufficient in both groups.
Conclusion: In stereotactic brain CT, automated dose modulation results in an unnecessary boost of radiation dose and should therefore be replaced by a low-dose protocol.

B-0123 11:02

Overranging dose reduction by dynamic collimators: evidence from clinical practice

N. Saltybaeva, H. Alkadhi; *Zurich/CH (Natalia.Saltybaeva@usz.ch)*

Purpose: Evaluation of dynamic collimators used in spiral CT has been performed so far only on cylindrical phantoms with a limited scan length. The purpose of this study was to assess the efficacy of dynamic collimators in daily clinical routine.
Methods and Materials: The overranging dose was assessed for 1690 CT examinations performed on a third-generation dual-source CT scanner (Somatom Force, Siemens Healthineers, Germany). The data for three standard clinical protocols (abdomen, chest and heart) with pitch values of 0.6, 1.2 and 3.2, respectively, were collected by dose tracking software (tqmDose, Qaelum, Belgium). The overranging length was defined as the difference between the actual scan length and length of the reconstructed volume. The exposed range was calculated as the ratio of reported DLP to the CTDIvol. The collimator efficiency for each of the exams was defined as percentage of overranging dose in terms of DLP which was blocked by the dynamic collimator relative to the total dose of the CT scan.
Results: The number of overranging rotations was inversely proportional to the pitch factor, while the absolute overranging length increases with the increase of pitch from 30 mm for abdomen CT to 50 mm for heart examinations. We found a strong correlation between relative dose reduction and pitch factor ($p<0.005$). The average efficiency of dynamic collimators was 6%, 11% and 20% for spiral CT examinations with pitch values of 0.6, 1.2 and 3.2, respectively.
Conclusion: In spiral CT, the dynamic collimator is highly efficient for radiation dose reduction, especially in high pitch scan modes.

B-0124 11:10

Evaluating the effect of image truncation in the calculation of water equivalent diameter

A. Dedulle[1,1], P. Moussalli[1,2], J. Jacobs[1], N. Fytousi[1]; [1]*Leuven/BE*, [2]*Lodz/PL*
(an.dedulle@qaelum.com)

Purpose: To evaluate the necessity of correcting the Water Equivalent Diameter (WED) that is calculated from truncated axial images.
Methods and Materials: A set of 191 non-truncated chest CT examinations were analyzed and the WED was calculated using the dose management system DOSE by Qaelum (Leuven, Belgium). The middle axial image of each case was manually truncated symmetrically and non-symmetrically at different Truncation Percentages (TP) up to 50%. The TP (ratio of patient border touching image edges to the total patient border) and the truncated WED (WED_{trunc}) were automatically calculated. Correction factors proposed in the literature were applied on WED_{trunc} resulting in WED_{corr}. Percentage difference (D_{trunc}) between the initial WED and WED_{trun} and percentage difference (D_{corr}) between WED and WED_{corr} were evaluated.
Results: The application of correction factors worked well, especially for symmetrical truncation with TP of 30-50%, where the correction factor improved the WED calculation to a D_{corr} of -0.4% ± 3.7% while D_{trunc} was -6.7% ± 3.1%. For TP up to 20%, the error due to truncation was small (0.6% ± 0.6%), thus the gain from correction is small but nevertheless significant ($p<0.0001$). In non-symmetrical truncation, the curve fit was significantly different ($p<0.0001$) than the symmetrical one. When TP increases, the curves deviate more from each other.
Conclusion: A small symmetrical truncation underestimates the WED only by a small percentage. For truncation up to 50%, WED needs to be corrected to reduce the error in the calculation. In non-symmetrical truncation, results deviate more, especially for increased truncation percentages.

Impact of patient size and radiation dose on spectral accuracy in spectral detector CT: a phantom study

S. van Hedent, C. Tatsuoka, S. Carr, B. Eck, R. Kessner, N. Grosse Hokamp, P. Ros, D.W. Jordan; *Cleveland, OH/US (svhedent@vub.ac.be)*

Purpose: Iodine quantification (IQ) and Virtual Non-Contrast (VNC) images produced by Spectral Detector CT (SDCT) can be used for various clinical applications. We investigate the performance of SDCT in different phantom sizes and varying radiation doses, including a low-dose pediatric setting.
Methods and Materials: Three phantom sizes (simulating a 10-year old child, an average and a large sized adult) were scanned with iodine solution inserts with concentrations ranging 0-32 mg/ml, using the SDCT. Each phantom size was scanned with $CTDI_{vol}$ 2-15 mGy. The smallest phantom underwent additional scans with $CTDI_{vol}$ 0.9-1.8 mGy. All scans were repeated 5 times. We determined the accuracy and precision of VNC attenuation and IQ, by comparison to the known iodine concentrations.
Results: For scans from 2-15 mGy, mean VNC attenuation and IQ error in the iodine inserts in the small, medium and large phantom were +1.15 HU ± 3.19, -1.18 HU ± 14.92, +2.59 HU ± 23.58; and +0.12 mg/cc ± 0.41, -0.88 mg/cc ± 0.88 and -1.81 mg/cc ± 1.76 respectively. Scans with $CTDI_{vol}$ 0.9-1.8 mGy in the small phantom showed very limited, but statistically significant lower VNC attenuation precision and IQ accuracy (-0.4778 HU ± 5.265 and -0.333 mg/cc ± 0.454 respectively) compared to higher dose scans in the same phantom size.

Conclusion: Performance of iodine quantification and subtraction in SDCT is largely dose independent, with the primary factor being patient size. Low dose pediatric scan protocols do not clinically impact IQ or VNC attenuation values.

B-0126 11:26

Validation of a task based automatic dose rate control (ADRC) method for interventional cardiology and radiology x-ray systems

M. Dehairs, N. Marshall; *Leuven/BE (michiel.dehairs@uzleuven.be)*

Purpose: To propose and validate an ADRC control method for specific tasks and requested image quality levels in interventional cardiology and radiology.
Methods and Materials: The new ADRC sets exposure parameters that maximize a figure of merit (FOM) for a specified object material, object velocity and image quality level. To achieve this, three quantities must be accurately predicted: reference air kerma (K_{ref}), detector dose and SDNR. The predicted values were empirically verified on a Siemens Artis Q interventional cardiology system as a function of field size and phantom thickness and a wide range of exposure parameters. SDNR was measured using an iron insert centered in the phantom and afterwards multiplied by MTF based correction factors for focal spot and motion blurring to give SDNR(u): the FOM was $SDNR^2(u)/K_{ref}$. The optimized ADRC settings were then applied and SDNR(u) was measured versus phantom thickness to examine whether the ADRC held image quality at the requested level. Measurements were repeated for tantalum, bismuth, platinum and gadolinium inserts.
Results: Average differences of measured data from the predicted values were 5±4%, 5±4% and 13±7%, for reference air kerma, detector dose and SDNR respectively. Compared to conventional ADRC methods, the new approach increased the FOM (i.e. efficiency) and held SDNR(u) constant to within 3±3% and 5±4% for the different materials, for fluoroscopy and acquisition respectively.
Conclusion: Measurements in this study validated the calculations required to design a FOM based ADRC enabling optimized task-specific control of x-ray parameters and leading to potential increases in imaging efficiency.

Model observer techniques and an innovative statistical method for detectability evaluation in digital angiography: comparison with a 2AFC experiment

R. Villa, N. Paruccini, C. Spadavecchia, A. Baglivi, R. Corso, A. Crespi; *Monza/IT (raffaele.vill@gmail.com)*

Purpose: Interventional radiology procedures are characterised by high dose level for patients and physicians; thus dose management and protocols optimisation are mandatory.We evaluate the feasibility of different less time consuming approaches for protocol optimisation in interventional radiology.
Methods and Materials: CDRAD Phantom has been acquired with a Flat Panel Angiography equipment. Different protocols have been considered: three fluoroscopy modes and cine-coronary angiography. 3 different insert dimensions (1.3, 2, 3.2 mm of diameter) have been selected to characterise low contrast detectability. A 2AFC experiment has been performed by two observers with “Recommended Display Frame Rate”. Furthermore, Low Contrast Detectability has been evaluated with a statistical method using uniform images. This analysis has been performed using an average of 3, 6, 12 images of different runs was calculated, considering 200 ms as the time of noise integration by human eye-brain system. Two different Model Observers has been considered: Non-PreWhitening Eye filter (NPWE) with spatio-temporal contrast sensitivity function and Channelized Hotelling Observer (CHO) with spatio-temporal Gabor filters.
Results: Analysis with both Model Observers and 2AFC experiments suffered from the general low quality of the protocols considered. Nevertheless, a good agreement (within 20%) can be found considering the effects of internal eye noise.Results with the Statistical Method show different degree of accordance related to insert dimension; thus, a single correction factor can be used to obtain an agreement within 30% for every protocols considered.
Conclusion: Every methods show both advantages and disadvantages. Nevertheless, numerical approaches are useful in protocol optimisation involving cine images.

B-0128 11:42

Low-dose protocol in prostatic artery embolisation (PAE): dose assessment

F. Rottoli, C. De Mattia, M. Sutto, P.E. Colombo, A. Rampoldi, A. Torresin; *Milan/IT (frottoli26@gmail.com)*

Purpose: To implement a low dose angiographic protocol for guidance of prostatic artery embolization (PAE) and analyse it in terms of dose, compared with a standard protocol.
Methods and Materials: In our institution, the PAE angiographic procedure showed high Kerma Area Product (KAP) compared to other interventional protocols, associated with high risk of skin lesions. After a retrospective analysis of the exposure values (KAP, entrance dose, Peak Skin Dose (PSD)) using RDIM NEXO[DOSE]® (Bracco, Italy), for 84 patients, a new protocol was introduced with low entrance detector acquisition dose. In this protocol, images are taken at 2 frames per second (fps) (previously 3) with an additional X-ray filtration of 1mmAl+0.1mmCu (previously no filtration) in acquisition mode; in fluoroscopy, frame rate is reduced from 15 to 7.5 fps.
Before introducing the low-dose protocol into clinical practice, it was analysed in terms of entrance dose on a 20cm PMMA phantom.Image quality was assessed quantitatively as low contrast detectability, using a home-made phantom. After optimisation, patient dose was monitored using KAP, entrance dose and PSD.
Results: Protocol optimisation provides a 60% reduction of KAP (from 686 to 276 $Gycm^2$), 49% of entrance dose (from 3829 to 1904 mGy), 50% of PSD (from 3.2 to 1.6 Gy), without any relevant loss of image quality as determined on the phantom.
Conclusion: Optimisation of the PAE procedure led to a significant reduction of patient dose and without relevant degradation of image quality. This was the result of a multidisciplinary team work (physicians, technicians and medical physicists).

B-0129 11:50

Standardisation and optimisation of MRI examination protocols

E. Karavasilis[1], A. Karatopis[1], P. Szatmari[2], R. Illing[2], N. Papanikolaou[2]; [1]*Nicosia/CY*, [2]*Budapest/HU (peter.szatmari@affidea.com)*

Purpose: To present a methodology for standardising and optimising heterogeneous MRI systems improving quality and patient experience.
Methods and Materials: The MRI protocol standardisation project was applied in 5 European countries in 33 MRI sites. A total number of 74 standardised protocols were developed in consensus between 6 experienced radiologists. More than 1500 pulse sequences were included in the standardised protocols and optimised in 8 MRI systems from 3 different MRI vendors by a group of 3 MR application consultants. 8 standardisation workshops were organised with a mean duration of 3 hours and 14 min, where all radiologists by consensus decided which sequences should be included on each different protocol dividing them into four categories. The optimisation part was conducted by a combination of site visits of the MR application consultants and remote access to a protocol exchange platform that was developed to easily transfer optimised protocols to those sites where no site visit was performed. The duration of the whole project was 14 months.
Results: The average examination time reduction after optimisation was up to 42.2% for Philips MRI scanners, 17.1% for Siemens scanners and 22.3% for GE scanners. Image quality of the optimised protocols was graded equal or superior to the old protocols in all cases.
Conclusion: Protocol standardisation although a challenging process is necessary to achieve workflow optimisation and, therefore, improve quality of services. A lot of effort needs to be invested and different stakeholders need to be actively involved for such a project to succeed.

Mammography performance and quality assurance practice among five European countries

A. Henner[1], N. Richli Meystre[2], C. Sá dos Reis[3], B. Strøm[4], J. Pires Jorge[2], T. Kukkes[5], E. Metsälä[6]; [1]*Oulu/FI*, [2]*Lausanne/CH*, [3]*Perth/AU*, [4]*Bergen/NO*, [5]*Tartu/EE*, [6]*Helsinki/FI (anja.henner@oamk.fi)*

Purpose: The purpose of this study was to identify variability in mammography practice focused on approach to select exposure parameters, breast compression, quality control procedures, image quality assessment and guidelines in use in five European countries.
Methods and Materials: This study was cross sectional survey based on an online questionnaire addressed to clinical radiographers in five European countries. Questions were mostly closed-ended with the possibility to add comments. The answers were dichotomous, multiple choice or with a five point Likert Scale. The data collected was analysed and redundant data was disregarded. Statistical data analysis was performed using the software packages SPSS (version 21, IBM) by using descriptive methods, Chi square and independent samples t-test.
Results: Computed Mammography (CR) was used by 10% of the participant institutions and Full Field Digital Mammography (FFDM) by 89%. Recommendations on exposure parameter selection were based mainly on National (23%), EUREF (9 %), ACR (7 %), local (5 %) and IAEA guidelines (4 %). The main techniques selected by radiographers were use of automatic exposure control, molybdenum/rhodium (Mo/Rh) as target/filter combination, compression force from 8 kg to 11 kg and standard mediolateral oblique (MLO) projection angle of 45 degrees. Technical quality control was implemented in 99% of the departments involved in this study.
Conclusion: Practice in mammography varies considering the participant institutions. That reveals the need of further studies to identify if the cause is due to the population characteristics or if it is due to the use of different guidelines.

B-0131 10:38

Validation of applied pressures after clinical introduction of pressure-standardised compression mammography

D.d. Boer, L.A. Dam-Vervloet, M.F. Boomsma, J. van Dalen, L. Poot; *Zwolle/NL (d.den.boer@isala.nl)*

Purpose: Validation of the compression pressure of a pressure-standardized compression mammography (PSCM) system, which aims to reduce discomfort and pain by applying the same force per unit of area to every breast, independent of breast size.
Methods and Materials: We retrospectively studied mammograms of 50 patients acquired with the conventional force-standardized compression mammography (FSCM) technique and intra-individually compared them to mammograms acquired on checkup visits with PSCM technique. Patients received one craniocaudal (CC) and one mediolateral oblique (MLO) compression for both breasts. The contact area between breast and compression paddle enabled the calculation of compression pressures.
Results: A total of 193 FSCM and 193 PSCM images were analysed. The mean compression pressure decreased significantly from 16.6 ± 6.8 to 12.8 ± 3.4 kPa, while also drastically reducing the relative standard deviation of the compression pressure with PSCM. The applied compression pressure is depends very slightly on breast contact area; however, this was likely to be clinically irrelevant. Furthermore, the relative number of compressions of more than 20 kPa reduced significantly from 22.8% 1.6%, benefiting patients with smaller breasts.
Conclusion: The introduction of the PSCM system led to a nearly constant applied compression pressure for different contact areas and a significant reduction in compression pressures. Especially for higher pressures, which are generally applied to smaller breasts and are generally associated with discomfort and pain. This suggests that using PSCM can reduce patient discomfort and pain during mammographic compression and provide a more constant image quality, which could potentially improve diagnostics.

B-0132 10:46

Breast compression between women imaged using digital mammography and breast tomosynthesis in a population-based breast cancer screening programme

G.G. Waade[1], Å.S. Holen[1], B. Hanestad[2], S. Sebuodegaard[1], N. Moshina[1], K. Pedersen[1], S. Hofvind[1]; [1]*Oslo/NO*, [2]*Bergen/NO (Gunvor-Gipling.Wade@hioa.no)*

Purpose: Digital breast tomosynthesis (DBT) leads to longer image recording time. We compared breast compression when screening with digital mammography (DM) or DBT.
Methods and Materials: The study included information about 16,832 women participating in the Bergen Tomosynthesis Trial, as a part of BreastScreen Norway, January 2016 to April 2017. We compared mean values of applied compression force (N) and pressure (kPa), for DM and DBT, by view (craniocaudal, CC, and mediolateral-oblique, MLO). Two-sample t tests were used to test statistical significance.
Results: Half the women were screened with DM (n=8354) and the other half with DBT (n=8478). Mean compression force was statistically significantly higher for DM compared to DBT (CC: 108.6N vs 102.7N; MLO: 122.4N vs 120.8N, $p<0.01$). Mean compression pressure was statistically significantly higher for DM compared to DBT for CC view (13.9kPa vs 13.0kPa, $p<0.01$). There was no difference in compression pressure between the screening techniques for MLO view (DM and DBT: 9.7kPa, $p=0.55$).
Conclusion: Radiographers applied less compression when performing screening with DBT compared to DM. However, the observed differences in breast compression between the screening techniques were negligible. Further research is needed to investigate the clinical implications of these findings.

B-0133 10:54

Breast compression and experience of pain: comparing two compression paddles

S. Hofvind, N. Moshina, G.G. Waade, S. Sebuødegård; *Oslo/NO (solveig.hofvind@kreftregisteret.no)*

Purpose: Women's experience of pain during screening mammography may be related to breast compression and result in non-attendance of the next screening examination. We aimed to compare the pain experienced among women screened using an ordinary flexible paddle and women screened using a fixed paddle, standardizing compression pressure to 10 kilopascal (kPa).
Methods and Materials: Data on experienced pain, compression force (newton, N) and pressure, and related factors (age, breast volume, contact breast area, pain in shoulders and/or neck prior to mammography), were collected via a questionnaire from 1,444 women screened using fixed (n=950) or flexible (n=494) paddle, May-June 2017. Experienced pain was evaluated using a scale from 0 to 10 and presented as no/mild (<3.5) and moderate/severe (≥3.5). We used logistic regression to estimate the odds ratio (OR) with 95% confidence interval (95%CI) for moderate/severe pain associated with type of compression paddle, adjusting for compression force or pressure and related factors.
Results: No difference in experienced pain was observed for women screened using the flexible paddle compared to the study paddle (OR 1.15; 95%CI 0.89-1.49 for compression force; and OR 1.25; 95%CI 0.94-1.65 for compression pressure). Pain in shoulders and/or neck prior to mammography coupled with increasing compression force or pressure during mammography was associated with moderate/severe pain during mammography.
Conclusion: The ordinary flexible paddle and the fixed paddle standardizing compression pressure perform similarly with respect to pain experienced during mammography. Future research on comparing the performance of the paddles should explore the association between breast compression and image quality.

B-0134 11:02

The influence of breast compression on re-attendance in a population-based screening programme

S. Sebuødegård, N. Moshina, G.G. Waade, S. Hofvind; *Oslo/NO (solveig.hofvind@kreftregisteret.no)*

Purpose: A high attendance rate in organized breast cancer screening programs is a prerequisite to achieve a reduction in breast cancer mortality. We aimed to investigate whether breast compression at prior screening was associated with re-attendance among subsequently screened women in BreastScreen Norway.
Methods and Materials: Information about re-attendance were available for 77,674 women aged 52-69 with at least two prior screening exams, 2007-2013. Data on compression force (kg) and pressure (kPa) were available from automated density assessment software. Two-sample unpaired t-tests were used to identify differences in re-attendance. Logistic regression was used to estimate the odds of re-attendance, adjusting for age, county of residence, prior false positive result, breast volume, breast density, and year of screening.

Results: Overall, 71,241 (91.7%) women re-attended. For compression force, re-attendance was highest for women who received <11.3 kg (92.0%) and lowest for women who received >13.3kg (91.5%) (p=0.082). For compression pressure, re-attendance was highest for those who received 11.3-14.3 kPa (92.5%) and lowest for <9 kPa (90.7%) (p<0.001). The adjusted odds of re-attendance did not differ statistically significantly by compression force. The odds for re-attendance was 33% higher for women who received pressure ≥9 kPa relative to <9 kPa (95% CI: 23%-42%).
Conclusion: Compression force did not show any statistically significant influence on re-attendance, while compression pressure ≥9 kPa was associated with a higher odds. Future research focusing on compression variables, experienced pain and image quality is needed to understand this issue.

B-0135 11:10

Impact of contralateral breast shielding on the risk of developing radiation-induced cancer from full field digital mammography (FFDM) screening

R.M.K.M. Ali[1,2], A. England[2], C.E. Mercer[2], A.K. Tootell[2], P.H.Hogg[2]; [1]*Najaf/IQ*, [2]*Manchester/UK (p.hogg@salford.ac.uk)*

Purpose: To investigate the impact of contralateral breast shielding on the risk of developing radiation-induced cancer from 4-view FFDM screening.
Methods and Materials: A breast phantom and adult ATOM dosimetry phantom were used to measure organ dose on 4 FFDM machines using cranio-caudal and medio-lateral oblique projections for each breast. A lead rubber shield was used to protect the contralateral breast. Organ dose, effective dose and effective risk were calculated; for effective risk estimations, the impact of the shield was considered for all known screening programmes worldwide.
Results: The shield can reduce the contralateral breast dose by more than 95%. For each FFDM machine the figures in µGy were (35.20 reduced to 1.93), (41.40 reduced to 0.01), (22.85 reduced to 1.24) and (22.76 reduced to 1.66). A small reduction was identified in sternum bone marrow dose due to the use of contralateral breast shield. The contralateral breast shield can significantly reduce the total effective risk of worldwide screening programme (p<0.05). However, the reduction percent in total effective risk is different for the 4 FFDM machines, ranging between 0.95% and 1.44% with minor differences amongst different worldwide screening programmes.
Conclusion: This novel work demonstrates the value of a contralateral breast shield. More research is required to determine whether such as shield has clinical utility.

B-0136 11:18

Outpointing breasts and hallux valgus: correlation and implications in mammography quality

S. Pacifici, D. Giudice; *Rome/IT (s_pacifici@virgilio.it)*

Purpose: In mammography, the position of the woman and her feet is critical for positioning the breast correctly and, consequently, regarding quality criteria such as the nipple in profile, the PNL perpendicular to the pectoral muscle edge on MLO view and on the breast midline on CC view. These criteria are hard to meet when non-standard breast shapes are in evidence, such as those which are outpointing. In these cases, positioning could require feet intra-rotation. From our working experience, we have observed a consistent co-existence of outpointing breasts and hallux valgus. For this reason, we began to investigate the correlation.
Methods and Materials: 54 women with at least one outpointing breast were selected and asked about the existence of a hallux valgus condition, assigning a 0-2 value to the variables and analysing the data by concordance tests.
Results: The results showed a 99,7% of concordance which called for a PubMed search to find out any scientific evidence in Western medicine, with negative results. In change, in osteopathy and traditional Chinese medicine concepts, we found links between the big toe and the breast-related muscles explained by the biomechanics of the muscle chains and some energy meridians.
Conclusion: The study seems to offer sufficient data to confirm a correlation, the knowledge of which can facilitate the positioning of outpointing breasts, respecting the quality criteria and thus avoiding technical errors which could influence recalls and repeats, comparative evaluations with previous mammograms and congruence between the PNLs. However, a clinical study with postural evaluation and activation points is required.

B-0137 11:26

Learner's perception, knowledge and behavior assessment within a breast imaging eLearning course for radiographers

I.C. Moreira, S.R. Ventura, I. Ramos, P.P. Rodrigues; *Porto/PT (icm@ess.ipp.pt)*

Purpose: ELearning has been revealed to be a useful tool to specific training and continuing education within health professionals, namely by radiographers. This education method needs continuous evaluation in order to validate its effectiveness. One method for this evaluation is Kirkpatrick's framework which consists of four categories: learner perception, knowledge, behavior, and impact on organization. Our aim was to assess an eLearning course on breast imaging for radiographers according to the first three categories.
Methods and Materials: An asynchronous eLearning system was developed for radiographers in order to promote a better knowledge about breast imaging, namely mammography technique and interpretation. The contents of this eLearning course were based on the guidelines proposed by the European Society of Breast Cancer Specialists (EUSOMA). Learner satisfaction was assessed through a questionnaire. Knowledge gain was assessed by using pre- and post-testing. After 6 months finishing the course, learners were contacted through a questionnaire in order to give feedback whether behaviour changed in their profession. Statistical analysis is under progress.
Results: Two editions of the course were performed, totalling 64 learners. In general, learners reported being very satisfied with the experience (above 90%), improved their knowledge, and also changed some attitudes and behaviours (such as communication, positioning, image analysis and processing) within their work routine. These and other results are still being thoroughly analysed.
Conclusion: This course represents an important contribution for the improvement of radiographers' performance in mammography clinical setting, enhancing continuous education models in health professions.

B-0138 11:34

The customised training for radiographers and its importance for image quality improvement and an accurate diagnosis of breast cancer

T.B. Silva, E.C. Mauad, S. Sabino; *Barretos/BR (tbuosi@gmail.com)*

Purpose: To evaluate the impact of a customized training for radiographers on clinical quality of mammography.
Methods and Materials: Radiographers selected for 80 hours training course submitted 15 days before the course starts a portfolio containing 50 examinations conducted by them for review. Through the evaluation of 18 mammographic positioning quality items stipulated by the European Guidelines it is produced a customized practice-oriented training, based on their most frequent positioning failures. Students in these classes were grouped according to their failures and a personalized training program was established for each one of the students, which spends 80% of their time in hands-on training. Subsequently, we evaluate each exam performed by the students during the course and itens in "non-conformity" were counted. The data pre and post-course were tabulated and the performance of the training was assessed.
Results: Since 2012 it was trained 396 radiographers from Brazil. The mean of failures reported per exam was 3.7 at the beginning of the course (portfolio analysis) and 1.1 at the end. The average rate of decrease of failures per exam was 68% (p=0.001). The most common positioning-related failures reported were absence of the pectoral muscle at cranio-caudal incidence (89%) and pectoral muscle to nipple level (49.1%) and non-visualization of infra-mammary angle (43.9%) at Medio-lateral oblique.
Conclusion: The trained professionals become able to perform mammography with higher diagnostic quality, reversing the current national framework, where the majority of mammograms performed have errors that make it difficult to provide an accurate diagnosis.

B-0139 11:42

Dose analytics over large DICOM datasets: a case study in mammography and a quest for meta data quality

M. Rodrigues dos Santos, N. Rocha, A. Silva; *Aveiro/PT (mrs@ua.pt)*

Purpose: The DICOM metadata of the mammographic studies, can contribute to a better knowledge of the exposure to which a population is exposed. The objective of this work was to identify the extent to which the quality of the DICOM metadata stored may contribute to the characterization of the exposure and dose used to perform mammography studies.
Methods and Materials: The studies carried out during the first 12 months of equipment activity were analyzed. The work was carried out in 5 phases: Indexing and extraction of DICOM metadata from PACS archive, image IOD characterization (e.g, Patient Age, Organ Dose), data quality analysis and sample normalization, population and exposure characterization.
Results: An initial sample of 1569 images from 379 studies of 351 patients was obtained. After the normalization process in which 8.55% of patients, 9.76% of the studies and 16.54% of the images were excluded, a final sample consisted of 1302 images, 342 studies performed on 321 patients was obtained. It was possible to characterize the population as well as ESAK (CC = 7.85 ± 4.48 mGy and MLO = 8.86 ± 4.96 mGy) and AGD (CC = 1.67 ± 0.73 mGy and MLO = 2.37 ± 0.14 mGy) as well as the mean compression force and mean breast thickness per age group
Conclusion: It is possible to characterize the exposure to which the population is subject in mammography studies based on the data stored in the PACS file. However, it is pertinent to consider the quality of the stored metadata.

B-0140 11:50

Tomosynthesis-guided vacuum-assisted breast biopsy: a survey of the patient's experience

R. Gullien, A. Haakull, T. Nyborg, B. Sollid, M. Stensvoll, S.M. Ali, J.-G. Andersen; *Oslo/NO (uxraul@ous-hf.no)*

Purpose: To evaluate and measure the patient experience and satisfaction following tomosynthesis-guided breast biopsy.
Methods and Materials: The survey study period was February 3rd-December 21st, 2016. 90 patients were scheduled for tomosynthesis-guided breast biopsy. Of these, 23 patients did not participate in the survey due to cancelled examination, language barriers or they refused. The remaining 67 patients were asked to fill out two questionnaires: part one immediately after the procedure and part two at home two weeks after the examination. Of the 67 participants, 56 participants answered both questionnaires, 11 participants did not answer part two despite reminders. All participants underwent standard procedure for local anaesthesia immediately before the procedure.
Results: 84% (56/67) of the participants answered both surveys. Results part one: 24% (16/67) were much or very much anxious before the examination; 58% (39/67) were a little anxious; 18% (12/67) were not. 69% (46/67) felt the examination uncomfortable; 22% (15/67) did not; 9% neutral. 45% (30/67) felt the examination painful; 42% (28/67) did not; 13% (9/67) neutral. Results from part two: 39% (22/56) no pain five days after; 61% (34/56) had pain or some pain; none had severe pain. 9% (5/56) contacted healthcare (pain, bleeding, infection, discolouration), 91% did not need. 96% (54/56) answered "yes" they received adequate information before, during and after the procedure, 4% (2/56) answered "no". 73% (41/56) was very satisfied with the overall experience of how they were taken care of; 25% (14/56) were satisfied; 2% (1/56) was not satisfied.
Conclusion: Most patients were anxious before examination. They got adequate information, were satisfied and felt they were very well taken care of during the examination.

Paradoxical low-flow, low-gradient severe aortic stenosis: cardiac magnetic resonance (CMR) evaluation

S. Pradella, C. Vignoli, M. Acquafresca, F. Grossi, I. Fusi, V. Miele; *Florence/IT (pradella3@yahoo.it)*

Purpose: Paradoxical low-flow, low-gradient (LFLG) severe aortic stenosis (AS) despite preserved left ventricular ejection fraction (LVEF) is one of the most challenging entities in valvular heart disease. The outcome is not clear. Aortic valve replacement (AVR) may be indicated in these patients.
Methods and Materials: A year (2016) patient's whit LFLG were assessed by clinical data and 2D-3D echocardiography. CMR imaging was performed on a 1.5 T in LFLG AS patient's. The LV outflow tract (OT) minimal and maximal diameters, to calculate the ellipticity index, and area were measured. LV volumes, stroke volume (SV), and LVEF was calculated on short axis cine images. The aortic valve area (AVA) was measured by direct planimetry of the maximal opening of the aortic valve. Late gadolinium enhancement (LGE) was evaluated to exclude focal replacement fibrosis, and T1 mapping for assessing of diffuse patterns of interstitial fibrosis presence (not in all patients).
Results: 72 patients with severe AS, 13 (18%) paradoxical LFLG, mean age: 78.3 ± 9.5 years; male 4-30%, BMI 24.5+2.6, BMI 24.5+2.6, NYHA 1.8+0.6 BNP 487.8+299.0. The ellipticity index was 1.21+0.3. 48% patients were re-classified as moderate AS with CMR. No LGE was found. T1 values were higher than normal.
Conclusion: Assessment of AS severity can be complex because standard resting echocardiography may not reflect the true severity of stenosis. There may be errors and inaccuracies in the calculation of AVA by the continuity equation, which could erroneously suggest the paradoxical phenotype. Information from CMR may be complementary to provides an accurate diagnosis.

B-0142 10:47

The role of topography of valve calcification in degenerative aortic stenosis: a new marker in CT evaluation

J.A.B. Araújo-Filho[1], A. de Santis[1], C.H. Nomura[1], F. Tarasoutchi,[1], M.C. Vieira[1], M. Katz[1], J. Brown[2], E.R. Edelman[3], P.A. Lemos[1]; [1]*São Paulo/BR*, [2]*Cambridge, MA/US*, [3]*Boston, MA/US (ariaraujocg@hotmail.com)*

Purpose: The relationship between calcium location and the severity of aortic valve stenosis (AS) remains poorly understood. The present study aimed at evaluating whether the location of calcium influences the functional severity of AS.
Methods and Materials: Prospective, single-arm study including 97 patients with diagnosed moderate or severe AS. Aortic valve calcium score was calculated from no-contrast multidetector computed tomography (MDCT). "Low-contrast-dose" MDCT images were acquired for segmentation of the cardiac anatomy, with the attenuation at the aortic valve zone used to quantify its calcium content.
Results: The calcium score was higher among patients with severe AS compared to patients without severe AS (3131±1828 Agatston units [AU] vs. 1302±846 AU respectively; p<0.001). Patients with severe AS had significantly higher attenuations at the center of the valve than at its periphery (507.4±181.7 Hounsfield units [HU] vs. 449.8±114.5 HU; p=0.001). Conversely, patients without severe AS had lower attenuation at the center than at the periphery of the valve (308.7±92.9 HU vs. 347.6±84.2 HU; p<0.001). The center/periphery attenuation ratio was significantly higher for patients with severe AS than for those without severe disease (1.14±0.32 vs. 0.89±0.13; p<0.001), and remained significantly associated with the presence of severe AS even after adjusting for the underlying degree of valve calcification.
Conclusion: The severity of degenerative aortic valve stenosis appears to result not only from the degree of calcification but also from the localization of the calcific deposits within the valve.

B-0143 10:55

Dynamic morphological changes of the aortic annulus in patients with bicuspid aortic valves

S. Boccalini, L.R. Bons, A.T. van den Hoven, G.P. Krestin, A.E. van den Bosch, J. Roos-Hesselink, R.P. Budde; *Rotterdam/NL*

Purpose: Bicuspid aortic valve (BAV) consists of a malformation of the aortic valve. Transcatheter aortic valve implantation is increasingly practiced to treat the associated precocious valvular dysfunction. Precise pre-interventional measurements of the annulus are fundamental to avoid potentially lethal complications. However, in the general population the annulus has an elliptic shape that undergoes shape changes during the cardiac cycle. The aim of our study was to investigate dynamic changes of the annulus in BAV patients.
Methods and Materials: BAV patients who underwent an ECG-gated CTA of the aorta between January 2015-March 2016 were included. The annulus plane was manually identified on reconstructions obtained at 5% intervals of the cardiac cycle. Based on semi-automatically defined contours, maximum and minimum diameter, area, perimeter and asymmetry ratio (maximum diameter/minimum diameter) were calculated. Paired samples Student's *t* test was used to assess differences.
Results: In 55 BAV patients (age: 38.4±13.3 years; 58% males) 38 had BAV type 1, 10 type 0 and 7 type 2. Minimum diameter, perimeter and area were significantly higher in systole than in diastole (relative changes: 14%, 6%, 17% respectively), while maximum diameter was significantly higher in diastole (all p<0.001). The asymmetry ratio was >1 in all phases, indicating an elliptic shape, with more pronounced flattening in diastole (p<0.001). When examined separately, the different BAV types showed analogous dynamic changes.
Conclusion: The annulus of BAV patients undergoes significant changes in shape during the cardiac cycle with a wider area in systole and a more elliptic conformation in diastole, affecting pre-interventional measurements.

Does the heart cycle fase of cardiac-MSCT influence the measurement of the aortic root in patients undergoing TAVI placement?

A. Drago, V. Alberotanza, C. Massarelli, L. Mappa, M. Carbone, M. de Ceglie, E. Ventrella, A.A. Stabile Ianora, A. Scardapane; *Bari/IT (angelicadrago87@gmail.com)*

Purpose: To assess the differences between systolic and diastolic dimensions of the aortic root in patients undergoing MSCT before TAVI placement.

Methods and Materials: Coronary-CT examinations of 70 patients, 29 females and 41 males with an average age of 66.2 years were evaluated. Modulated ECG-gated cardiac CTA was performed after the injection of 60-80 ml of iodinate contrast at a flow rate between 4 and 5 ml / sec. Systolic (20% of RR interval) and diastolic (75% RR interval) images were obtained and aortic annulus was measured just below the insertion of the valve leaflets after true axial cuts were obtained aligning the three perpendicular imaging planes. Distances of the coronary ostia were also measured. The differences between systolic and diastolic measure were compared using the T-Test.
Results: The mean diastolic and systolic size of the aortic annulus were respectively 22.28 mm and 22.5 mm in short axis and 27.25 mm and 27.8 in long axis. The distance of the right coronary artery from the aortic valve had a mean diastolic value of 14.37 mm and a mean systolic value of 14.15 mm; The distance of the left coronary artery from the aortic valve had a mean diastolic value of mm 14.21 mm and a mean systolic value of 14.4 mm. No statistically significant differences (p>0.05) were found among these measures.
Conclusion: There was no statistically significant difference between systolic and diastolic measurements, so we believe that measurement should be performed during the best phase of each patient's heart cycle.

B-0145 11:11

Angio-CT: key for landing zone reconstruction in TAVI

D. Araujo Martins, R. Ruiz Salmeron, A. Rivera, C. Caparros Escudero, L. Cueto Álvarez, F. Mateo Carballo; *Sevilla/ES (danielamromeo@gmail.com)*

Purpose: AngioCT has become gold standard for planning TAVI. AngioCT evaluation of aortic annulus is key to define the prosthesis to be implanted. However, anatomical characteristics of TAVI landing zone, the portion between the left ventricle outflow tract and the aortic root receiving prosthesis deployment, have not been fully described. Aim: To describe the anatomical characteristics of the landing zone evaluated by angioCT, and to generate a 3D model to support TAVI procedure strategy.
Methods and Materials: In 83 consecutive patients (56 females) undergoing TAVI, angioCT study of landing zone analysed the values of area (mm2) and eccentricity (1- (Minor Diameter / Major Diameter)) in 5 cut-off points separated by 5mm: lower cut-point located below the aortic ring, next on the aortic annulus, and the remaining three cut-points above, at the aortic root. With those data, SolidWork graphics software generated a 3D geometric model.
Results: Landing zone showed, at each cut-point, inverse relationship between area and eccentricity: ascending from the left ventricular outflow tract towards the aorta, area increased and eccentricity decreased significantly (p 0.001). We found significant differences between male and female gender regarding the dimensions and degree of eccentricity of the landing zone: men showed larger area and a lower eccentricity (p 0.001). For each patient, SolidWork was able to generate and print a 3D landing zone model.
Conclusion: AngioCT allows an accurate description of the landing zone anatomy of TAVI procedures, and its 3D printing model is an attractive tool for the success of the intervention.

B-0146 11:19

One-stop high definition 64-row CT coronary angiography in patients with severe aortic stenosis candidate to transcatheter aortic valve implantation (TAVI): a pilot feasibility study

L. Faggioni, M. Gabelloni, M. Bianchi, G. Costa, M. De Carlo, A.S. Petronio, D. Caramella; *Pisa/IT (lfaggioni@sirm.org)*

Purpose: To assess the diagnostic performance of high definition 64-row CT coronary angiography (CTCA) integrated in a one-stop-shop CT protocol for TAVI planning.
Methods and Materials: A retrospectively ECG-gated CTCA examination was performed in 57 nonobese patients with severe aortic stenosis as part of a comprehensive CT protocol for TAVI planning. All studies were carried out on a high definition 64-row CT scanner using 100kV tube voltage and an iterative reconstruction algorithm. Patients with inconclusive or positive CTCA findings (defined as presence of stenosis >50% of the left main artery and/or proximal or mid left anterior descendent, circumflex, or right coronary arteries) underwent invasive coronary angiography (ICA) prior to TAVI, whereas in a subset of patients with negative CTCA findings (7/30, 23.3%) ICA had previously been performed before CTCA. Per-patient sensitivity, specificity, positive and negative predictive value of CTCA compared to ICA as gold standard were calculated. The association between image quality (graded visually as good, adequate or nondiagnostic), coronary calcium score (CCS) and heart rate (HR) was also evaluated.
Results: A total of 47/57 CTCA examinations (82.5%) were of diagnostic quality. Sensitivity, specificity, positive and negative predictive value of CTCA were 100%, 87.5%, 90.9% and 100%, respectively. Image quality was inversely correlated with CCS and HR (p<0.05), and in particular, adequate or good image quality was associated with CCS<350 and HR<74bpm.
Conclusion: One-stop CTCA allows accurate detection of critical coronary artery stenoses and can play a role as a gatekeeper to ICA in selected patients candidate to TAVI.

B-0147 11:27

Comparison of aortic annulus dimensions by multimodal measurement before transcatheter aortic valve replacement

R. Qi; *Hangzhou/CN (tsirea@163.com)*

Purpose: We sought to compare 3 methods of measurements of the aortic root in patients of severe aortic stenosis (AS), transthoracic echocardiography (TTE), transesophageal echocardiography (TEE), and multislice computed tomography (MSCT), and to evaluate their potential clinical impact on transcatheter aortic valve implantation (TAVI) strategy.
Methods and Materials: Aortic root dimensions were measured using TTE, TEE, and MSCT in 138 consecutive patients with severe AS referred for TAVI in our institution. The differences among measurements of aortic annulus diameter were compared. The accuracy of the multimodal measurements before TAVI was evaluated with postoperative follow-up.
Results: Mean aortic annulus diameter was 23.37±2.22mm using TTE and 23.52±1.70mm using TEE (p=0.12) and correlation between TTE and TEE was excellent (r=0.87). The mean of long- and short-axis diameters according to MSCT multiplanar reconstruction did not differ from the diameter derived from cross-sectional area (p=0.08). However, the diameter derived from circumference was larger than the others, and the difference is 0.43±0.62mm, 0.51±0.62mm (p<0.01, respectively). Measurements of the aortic annulus diameter by MSCT were larger than the measurement by TTE and TTE significantly (p<0.01). Implantation was successful in all, but 3 patients with worse than moderate paravalvular leakage and 1 patient with valve-in-valve implantation because of prosthetic valve restenosis.
Conclusion: In patients referred for TAVI, measurements of the aortic root using TTE or TEE were smaller than measurements by MSCT. In the absence of a gold standard, a strategy based on comprehensive consideration would provide good clinical results.

B-0148 11:35

Comparison of cardiovascular magnetic resonance imaging and computed tomography to guide transcatheter aortic valve replacement: a pilot study

A. Mayr, C. Kranewitter, G. Klug, C. Kremser, G. Feuchtner, W. Jaschke, B. Metzler; *Innsbruck/AT (a.mayr@i-med.ac.at)*

Purpose: To compare a comprehensive cardiovascular magnetic resonance (CMR) imaging protocol with contrast-enhanced computed tomography angiography (CTA) for guidance in TAVR evaluation.
Methods and Materials: Non-contrast three-dimensional (3D) “whole heart” CMR imaging for aortic annulus sizing and measurements of coronary ostia heights, contrast-enhanced CMR angiography (MRA) for evaluation of transfemoral routes as well as aortoiliofemoral-CTA were performed in 16 patients referred for evaluation of TAVR.
Results: Aortic annulus measurements by CMR and CTA showed a very strong correlation (r=0.956, p<0.0001; effective annulus area for CMR 430±74 vs. 428±78 mm² for CTA, p=0.629). Regarding decision for valve size there was an excellent agreement between CMR and CTA. Moreover, vessel luminal diameters and angulations of aortoiliofemoral access as measured by MRA and CTA showed overall very strong correlations (r= 0.819 to 0.996, all p<0.001), the agreement of minimal vessel diameter between the two modalities revealed a bias of 0.02 mm (upper and lower limit of agreement: 1.02 mm and -0.98 mm).
Conclusion: In patients referred for TAVR, CMR measurements of aortic annulus and minimal aortoiliofemoral diameters showed good to excellent agreement. Decisions based on CMR measurements regrading prosthesis sizing and transfemoral access would not have modified TAVR-strategy as compared to a CTA-based choice.

B-0149 11:43

Value of left ventricular fibrosis volume as a parameter for long-term survival after TAVI

A.S. Sträter, A. Huber, J. Nadjiri, M. Rasper, M.T. Berndt, E.J. Rummeny, J. Rieber; *Munich/DE (alexandra.straeter@gmail.com)*

Purpose: Patients with severe aortic stenosis develop left ventricular hypertrophy and reduced left ventricular function. Insufficient vascularisation of hypertrophic myocardium may cause development of left ventricular fibrosis. Transcatheter aortic valve implantation (TAVI) is an upcoming procedure to reduce workload and improve left ventricular function. Long-term survival shows huge inter-individual difference. NYHA class 30 days after TAVI has shown to be a strong and independent parameter for long-term survival. This study assesses the value of left ventricular fibrosis volume as a predictive parameter for clinical outcome.
Methods and Materials: The study enrolled 35 consecutive patients for TAVI. The mean characteristics were 81±7 years, NYHA Class 3.2±1.4, EF 48±9.3%. In each patient pre-interventional contrast-enhanced cardiac MRI was performed in a Philips Ingenia 3T. Left ventricular fibrosis volume was

quantified. Functional recovery was assessed using NYHA class 30 days after the procedure.
Results: NYHA class after TAVI was reduced significantly (1.7±1.3; p<0.001). 22 (63%) patients revealed 2 class reduction whereas 12 (34%) patients showed reduction of 1 class and 1 patient remained (this patient had good pre-interventional function: EF 74%). Left ventricular fibrosis volume was inversely related to the reduction of NYHA class (left ventricular fibrosis volume 720.75±43 [NYHA reduction ≥2 grades] vs 1501.6±74 [NYHA reduction <2 grade]; p<0.05).
Conclusion: The left ventricular fibrosis volume shows a strong correlation to the reduction of NYHA class 30 days after successful TAVI implantation. Thus, the quantification of left ventricular volume might possibly be used as a prognostic parameter for long-term survival in TAVI patients.

B-0150 11:51

Left ventricular reverse remodeling after transcatheter aortic valve implantation as assessed by CT angiography
B. Szilveszter, D. Oren, M. Kolossvary, M. Vecsey-Nagy, J. Karady, F. Suhai, A. Apor, B. Merkely, P. Maurovich- Horvat; *Budapest/HU*

Purpose: Transcatheter aortic valve implantation (TAVI) has rapidly emerged as a safe and effective treatment option for high risk patients with severe aortic stenosis. CT imaging provides accurate assessment of left ventricular (LV) dimensions. Therefore, we aimed to assess the impact of TAVI procedure on LV remodeling as assessed by CT angiography.
Methods and Materials: We performed retrospectively gated CT angiography for the planning and follow-up of TAVI procedure in 48 patients. We measured LV mass on serial CT images using a dedicated semi-automated software. Epi- and endocardial contours were manually adjusted. Pre- and post-procedural left ventricular mass and volumes were compared using Wilcoxon signed rank test. Multivariate linear regression analysis was used to establish independent factors related to LV reverse remodeling.
Results: Mean age was 77.1 ± 15.1 years, 58.3% were male. We found significant reduction in LV mass after TAVI procedure: 166.3 [139.2-225.5] grams for pre- and 128.2 [106.2-151.6] grams for post-TAVI, respectively, p<0.001. Mean change in LV mass was 48.9 ± 31.4 grams. On multivariate analysis, baseline LV mass is independently associated with LV reverse remodeling (ß=0.63, p<0.001) above traditional risk factors, age, gender and BMI.
Conclusion: Significant regression of LV mass was observed in almost all cases after TAVI procedure that is presumably associated with the reverse remodeling of the left ventricular structure. In line with previous data larger baseline LV mass was associated with more pronounced remodeling.

Apparent diffusion coefficient (ADC) and its correlation with gestational age (GA) in normal developing foetal brain: preliminary results of a prenatal MRI study
A. Antonelli, S. Capuani, M. Guerreri, S. Bernardo, R. Petrillo, V. Vinci, L. Manganaro, C. Catalano; *Rome/IT (amanda.antonelli@hotmail.it)*

Purpose: To provide a normal comparison base of ADC values in the developing non-pathological foetal brain parenchyma, investigating the potential of ADC as a function of gestational age (GA).
Methods and Materials: Diffusion-weighted imaging (DWI) was performed in 35 pregnancies (GA range: 19-38 weeks) at 1.5T (Siemens Avanto, Erlangen, Germany). A DW-Spin Echo EPI with TR/TE=4000/79; bandwidth=1628 Hz/px; matrix=192x192; FOV 379mm2 was obtained. Eight regions of interest (ROIs) were manually placed in the frontal white matter (FWM), cccipital WM (OWM), thalamus (THAL), caudate (CD), basal ganglia (BG) cerebellum (CH), pons and lateral ventricle cerebral spinal fluid (CSF). ADC values of each ROI were measured and mean values for second and third trimester of gestation were obtained. One-way ANOVA was used to calculate the differences between the mean values and Pearson analysis with Bonferroni correction was used to evaluate the linear correlation between ADC values and GA.
Results: ADC values of CH and pons show significant negative correlations with GA (R =-0.87, -0.80, respectively, all p<0.0001); a positive correlation was found between ADC and GA in FWM (R=0.56, p<0.01). In FWM, the ADC increases in parallel to GA during the second trimester; conversely, ADC decreases with the increasing of GA in the third trimester. ADC mean values of CH, Pons, FWM and BG are significantly different between second and third trimester.
Conclusion: ADC parameters reflect the physiological microstructural changes of myelination, occurring during foetal brain maturation; these ADC results may be useful in the assessment of suspected fetal CNS abnormalities.

B-0152 10:38

A pain in the neck: imaging of the paediatric cervical spine (c-spine) in isolated neck trauma
M. McGill, A. Paterson; *Belfast/UK*

Purpose: To the authors' knowledge there are currently no internationally recognised guidelines which consider the radiological management of focal cervical spine tenderness (FCST) following isolated paediatric c-spine trauma. Our aim was to develop regional guidelines for imaging children with FCST.
Methods and Materials: A retrospective review of 1,000 children (<14yrs) presenting to both tertiary and district general hospitals between 2011 and 16, with isolated c-spine trauma was undertaken to establish current practice with respect to imaging. Guidelines were developed utilising best evidence-based practice in consultation with paediatric spinal and orthopaedic surgeons.
Results: All children evaluated had plain radiograph(s), 39% underwent c-spine CT and 2% c-spine MRI for persistent focal tenderness. Regional differences in local guidelines and practice were identified. Retrospective application of the proposed regional guidelines did not result in the 'miss' of clinically significant c-spine injuries within this study population and would have resulted in a 22% reduction in utilisation of CT and a 45% increase in the utilisation of MRI.
Conclusion: It is possible to decrease the number of CT c-spine exams undertaken in children with FCST. Proposed imaging guidelines are presented for discussion: initially, analgesia is prescribed and consideration of cervical collar placement undertaken by the assessing team. C-spine plain films are obtained and if abnormal, or inadequate, CT is discussed with the radiology team. If pain persists and plain films are normal, referral to the orthopaedic team is undertaken, and a c-spine MRI is organised within 72 hours. Children with focal neurology are all referred for MRI.

B-0153 10:46

Diffusion kurtosis imaging (DKI) can efficiently differentiate low- and high-grade gliomas in paediatric patients
I.P. Voicu, A. Napolitano, L. Lattavo, C. Carducci, M.C. Rossi Espagnet, A. Mastronuzzi, P. Toma, G.S. Colafati; *Rome/IT (paul.voicu@hotmail.it)*

Purpose: To investigate whether diffusion kurtosis imaging (DKI) can be helpful in differentiating low- and high-grade gliomas (LGG and HGG respectively) in paediatric patients.
Methods and Materials: After obtaining informed consent, thirty-two consecutive children (median age 8.5 years, 17 M) affected by histologically confirmed brain gliomas were prospectively studied on a 3T magnet with a 32-channel head coil. Conventional sequences and DKI sequences (30 directions, 3 b values: 0, 1000, 2000) acquired with the simultaneous multislice (SMS) technique were obtained. Mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK) and fractional anisotropy (FA) values were calculated and the corresponding maps were obtained. The enhancing and nonenhancing tumour volumes (VOIs) were segmented semiautomatically. Mean and highest 20 percentile (H20%) DKI values in tumour VOIs were calculated for each metric. Differences among DKI values in the enhancing and nonenhancing VOIs of low and high-grade gliomas (LGG and HGG respectively) were assessed with an independent sample t test.
Results: After excluding three patients for motion artefacts, the scans of twenty-nine children (20 LGG and 9 HGG) were analysed. Significantly different mean RK, H20% RK and mean MK values were found in the enhancing tumour VOI between LGG and HGG (p<0.029, p<0.015 and p<0.05 respectively).
Conclusion: DKI can be helpful in differentiating low and high-grade gliomas in paediatric patients.

B-0159 10:54

Grading of hemispheric gliomas in pediatric patients by using Diffusion Kurtosis MR imaging
I.P. Voicu, A. Napolitano, L. Lattavo, C. Carducci, M.C. Rossi Espagnet, A. Mastronuzzi, P. Toma, G. Colafati; *Rome/IT (paul.voicu@hotmail.it)*

Purpose: To investigate whether diffusion kurtosis imaging (DKI) can help differentiate low- and high-grade hemispheric gliomas (hLGG and hHGG respectively) in paediatric patients.
Methods and Materials: After obtaining informed consent, eighteen consecutive children (median age 9.6 years, 9 males) affected by histologically confirmed hemispheric gliomas were prospectively studied on a 3T magnet with a 32-channel head coil. Conventional sequences and DKI sequences (30 directions, 3 b values: 0, 1000, 2000) acquired with simultaneous multislice

technique (SMS) were obtained. Mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK) and fractional anisotropy (FA) values were calculated and the corresponding maps were obtained. The enhancing and nonenhancing tumour volumes (VOIs) were segmented semiautomatically. Mean and highest 20 percentile (H20%) DKI values in tumour VOIs were calculated for each metric. Differences among DKI values in the enhancing and nonenhancing VOIs of low and high-grade hemispheric gliomas (hLGG and hHGG respectively) were assessed with an independent sample t test.
Results: After excluding one patient for motion artifacts, the scans of seventeen children (12 LGG and 5 HGG) were analysed. Significantly different mean RK, H20%RK, mean MK and H20% MK values were found in the enhancing tumour VOI between hLGG and hHGG ($p<0.003$, $p<0.007$, $p<0.004$ and $p<0.001$ respectively). No significant differences in DKI values were found between nonenhancing tumour VOIs in hLGG and hHGG.
Conclusion: DKI can help differentiate low and high-grade hemispheric gliomas in paediatric patients.

B-0157 11:02

Diffusion kurtosis imaging (DKI) can help differentiate low- and high-grade brainstem gliomas in pediatric patients: a pilot study
I. Voicu, A. Napolitano, L. Lattavo, M. Rossi Espagnet, C. Carducci, A. Mastronuzzi, P. Toma, G. Colafati; *Rome/IT (paul.voicu@hotmail.it)*

Purpose: To investigate whether diffusion kurtosis imaging (DKI) can help differentiate low- and high-grade brainstem gliomas (bLGG and bHGG respectively) in paediatric patients.
Methods and Materials: After obtaining informed consent, fourteen consecutive children (median age 7.4 years, 8 males) affected by histologically confirmed brainstem gliomas were prospectively studied on a 3T magnet with a 32-channel head coil. Conventional sequences and DKI sequences (30 directions, 3 b values: 0, 1000, 2000) acquired with simultaneous multislice technique (SMS) were obtained. Mean kurtosis (MK), axial kurtosis (AK), radial kurtosis (RK) and fractional anisotropy (FA) values were calculated and the corresponding maps were obtained. The enhancing and nonenhancing tumor volumes (VOIs) were segmented semiautomatically. Mean and highest 20 percentile (H20%) DKI values in tumor VOIs were calculated for each metric. Differences among DKI values in the enhancing and nonenhancing VOIs of low and high-grade brainstem gliomas (bLGG and bHGG respectively) were assessed with an independent sample t test.
Results: After excluding two patients for motion artifacts, the scans of twelve children (8 LGG and 4 HGG) were analyzed. Significantly different H20% FA, mean MK, H20% MK, mean AK and H20% AK values were found in the nonenhancing tumor VOI between LGG and HGG ($p<0.05$, $p<0.008$, $p<0.007$, $p<0.045$ and $p<0.001$ respectively). No significant differences in DKI values were found between enhancing tumor VOIs in bLGG and bHGG.
Conclusion: DKI can help differentiate low and high-grade brainstem gliomas in paediatric patients.

B-0154 11:10

High predictive value of MRI imaging in mitochondrial disease
I. De Beaurepaire, D. Grevent, R. Levy, V. Dangouloff-Ros, A. Munnich, A. Rötig, N. Boddaert; *Paris/FR (isaure.debeaurepaire@orange.fr)*

Purpose: Because the mitochondrial respiratory chain is ubiquitous, its deficiency can theoretically give rise to any symptom in any organ or tissue at any age with any mode of inheritance, owing to the twofold genetic origin of respiratory enzyme machinery, i.e. nuclear and mitochondrial. Yet, not all respiratory enzyme deficiencies are primary. Indeed, secondary deficiency is frequently observed, leading to a number of fake conclusions and inappropriate investigations in clinical practice.
Methods and Materials: Starting from a large series of 189 patients at risk of respiratory chain deficiency, for whom both brain MRIs and disease-causing mutations were available, we retrospectively studied the predictive value of brain MRI imaging and its ability to discriminate between two groups: primary deficiency of the mitochondrial respiratory chain machinery (n=152) and phenocopies (n=37).
Results: Although no anomaly was specific, detection of i) brainstem hyper-intensity with basal ganglia involvement ($p \leq 0.001$) and ii) lactate peak with either brainstem or basal ganglia hyper-intensity were highly suggestive of primary respiratory chain deficiency ($p \leq 0.01$). Fourteen items had a positive predictive value > 95% and biallelic *SLC19A3* mutations represented the main differential diagnosis. Non-significant differences between the two groups were found for cortical/subcortical atrophy, leukoencephalopathy, and involvement of caudate nuclei and corpus callosum.
Conclusion: Based on these results and owing to invasiveness of skeletal muscle biopsies and cost of high-throughput DNA sequencing, we suggest giving consideration to brain MRI imaging as a strong predictive marker and the first investigation to be performed in patients at risk of respiratory chain deficiency.

B-0155 11:18

SMI ultrasound of the neonatal brain: comparison with MRI (1.5 T) in a clinical case series
A. Hojreh, G. Kasprian, K.A. Göral, K. Klebermass-Schrehof, K. Vergesslich Rothschild, M. Weber, J.M. Patsch; *Vienna/AT (azadeh.hojreh@meduniwien.ac.at)*

Purpose: Superb microvascular imaging (SMI) is a novel ultrasound application capable of depicting micro-vasculature. Previously, we have reported feasibility and features of brain SMI in healthy neonates. The purpose of this study was to compare SMI ultrasound and MRI in a clinical case series.
Methods and Materials: Following ethical approval and written informed consent, we performed transcranial ultrasound in thirteen neonates with suspected brain pathologies. Routine examinations were performed and documented according to national standards. SMI ultrasound was performed using linear (18mHz and 14mHz) and curved array transducers (4mHz). Superficial and deep scans were acquired in the coronal and parasagittal plane, using the left and right superior frontal gyrus as anatomical landmarks. All subjects underwent 1.5 T MRI. Regarding visibility of microvessels, T2-weighted turbo-spin-echo sequences and susceptibility-weighted sequences were compared with SMI ultrasound.
Results: In all cases (n=13;100%), cortical and medullary were visible on SMI ultrasound and invisible on MRI. In 23 % of cases (3/13), intraparenchymal striatal microvessels were visible on SMI, but invisible on MRI (100%). In a case with mitochondrial disease, medullary micro-vessels were pathologically elongated/tortuous, which was confirmed by histology. Post-ischemic cortical hyperperfusion was detected in an area of cortical infarction/diffusion restriction. SMI detected tortous subarachnoid vessels in a case of osteogenesis imperfecta, which could be confirmed by MRI.
Conclusion: SMI ultrasound opens a new diagnostic window in the assessment of vascular pathologies of the neonatal brain. Abnormalities of cortical, medullary, and striatal micro-vessels that are invisible on 1.5T MRI can be readily detected.

B-0156 11:26

Simultaneous decrease of aspartate and NAA levels in the brain after severe TBI: ^{1}H MRS study
P.E. Menshchikov, M. Ublinskiy, A. Manzhurtsev, T. Akhadov, N. Semenova; *Moscow/RU (peeterem@gmail.com)*

Purpose: N-acetylaspartate (NAA) is a neuronal marker in the brain. Severe TBI is associated with decrease of NAA level. Disturbances in the NAA synthesis from aspartate (Asp) may be the reason of NAA decrease. Thus, the main objective of this study was to estimate simultaneously cerebral Asp and NAA levels in vivo using proton magnetic resonance spectroscopy (^{1}H MRS).
Methods and Materials: Eight children (mean age: 14±2 years) were examined with quantitative ^{1}H MRS after closed severe head injury (5-6 months after TBI). Control group consisted of 11 healthy children (mean age: 15±1 years) without history of any TBIs. MRS protocol included MEGA PRESS (aspartate and pure glutamate signals) and conventional PRESS spectra with TE=115 ms. Voxels in size of 25×25×30 mm were located in the frontal lobe. All investigations were performed on Philips 3.0T Achieva TX MRI scanner.
Results: NAA/tCr as well as Asp/tCr ratios were significantly reduced ($P < .001$) in patients by 34% and 44%, respectively. Cho/tCr was significantly increased (by 36%) in patients. GLX and pure glutamate levels were unchanged.
Conclusion: This study for the first time revealed simultaneously reduced cerebral Asp and NAA levels. This result can be a significant confirmation of NAA synthesis disturbances after TBI. Further investigations on Asp/NAA balance in the acute severe TBI will certainly help in understanding of biochemical changes in injured brain.

B-0158 11:34

Assessment of a 33-point software programme for the identification of vertebral fractures in children
F. Alqahtani, F. Messina, A.C. Offiah; *Sheffield/UK (ffmalqahtani1@sheffield.ac.uk)*

Purpose: To measure observer reliability and diagnostic accuracy in children, of a semi-automated programme using a 33-point technique (Avert™) developed for vertebral fracture (VF) diagnosis in adults, which records percentage loss of vertebral body height and to compare Avert with previous results of a 6-point technique (SpineAnalyzer™).
Methods and Materials: Lateral spine radiographs (RA) and dual-energy lateral vertebral assessment (VFA) images of 50 children were analysed using two different programmes (SpineAnalyzer™ and Avert™; 50 RA analysed with SpineAnalyzer (Group 1), 50 RA analysed with Avert (Group 2) 50 VFA analysed with Avert (Group 3). Diagnostic accuracy (sensitivity, specificity) was calculated by comparing with a previously established consensus arrived at by three experienced paediatric radiologists, using a simplified algorithm based

qualitative scoring system. Levels of agreement were calculated using Cohen's kappa.
Results: Overall sensitivity of Groups 1, 2 and 3 was 26%, 37% and 35% and specificity was 98%, 94% and 92% respectively. Fair agreement was found between different modalities/different software; between Groups 2 and 3 kappa 0.29 (95% CI, 0.06 - 0.53), between Groups 1 and 3 kappa 0.35 (95% CI, 0.12 - 0.59). Moderate agreement was noted between identical modalities; Groups 1 and 2 kappa 0.55 (95% CI, 0.28 - 0.82).
Conclusion: The 33-point technique has slightly higher accuracy for the representation of vertebral morphometry in children when compared to the 6-point technique. However, neither Avert nor SpineAnalyzer are satisfactorily reliable for VF diagnosis in children. Therefore, training of either or both software programmes on paediatric images is required.

B-0160 11:42

Systematic approach to the congenital abnormalities of the posterior fossa: a tertiary paediatric referral hospital experience in last five years (2012-2016)

J. Smiechowicz[1], M. Rebollo Polo[2], M. Gómez Chiari[3], J. Muchart Lopez[3], C. Fons Estupiña[2]; [1]*Girona/ES*, [2]*Esplugues de Llobregat/ES*, [3]*Barcelona/ES (jareksmie@wp.pl)*

Purpose: Congenital abnormalities of the posterior fossa present a wide spectrum of radiological features including normal anatomic variations and severe malformations. MRI permits systematic evaluation of cerebellum and its pathology and employment of the biometric parameters.
Methods and Materials: We reviewed MRI scans of the group of 351 newborns (age: 1-28 days) performed in the tertiary referral hospital in years 2012-2016. 1.5T Signa Excite GE MRI T1 T1 FLAIR, PDT2, DWI , T2 , T2* y T1 3D-SPGR. We have taken measurements of cerebellum transversal diameter, craniocaudal and anteroposterior diameter of the vermis, tegmento-vermian angle and analysed the cerebellar fissures. Moreover, the presence of the supratentorial pathology was also recorded.
Results: The range of the tegmento-vermian angle in a group of control is 3 - 14,5 degrees, meanwhile, a significant number of patients with malformation present an angle value higher than 15 degrees. In addition, the differences of the values of cerebellum craniocaudal diameter of the vermis between both groups has drawn our attention. Abnormalities of posterior fossa such as arachnoid cyst, Blake cyst, cerebellar dysplasia, rhomboencephalosynapsis, Chudley-McCullough syndrome, Joubert syndrome, Dandy-Walker malformation, pontocerebellar hypoplasia or congenital muscular dystrophy with cerebellar affectation were analysed. Anatomic variations such as mega cisterna magna was also recorded.
Conclusion: The systematic revision of the posterior fossa structures increases the sensibility in diagnosing possible congenital malformations. These abnormalities can be classified in order to criteria based in biometric parameters which facilitate suggesting differential diagnosis, genetic disorder orientation and prognostic factors of neurological outcomes.

B-0161 11:50

Dentate and basal ganglia T1-hyperintensity in pediatric patients who had received both linear and macrocyclic Gadolinium-based MRI contrast agents; evidence of a "carry-over" effect

P. Gulino[1], A. Bianchi[1], A. Scionti[2], S. Diciotti[3], E. Bartolini[1], P. Papadopulos[1], C. Defilippi[1], M. Mascalchi[1]; [1]*Florence/IT*, [2]*Pisa/IT*, [3]*Bologna/IT (pietrogulino@yahoo.it)*

Purpose: The capability of macrocyclic Gadolinium-Based Contrast Agents(GBCAs) to determine hyperintensity of dentate nucleus and basal ganglia in pre-contrast T1-weighted images (T1wH) is controversial. Our study intend to demonstrate the "carry over" effect.
Methods and Materials: Two radiologists visually assessed in consensus sagittal T1-weighted SE or TSE images of 140 index-MRI examinations in pediatric patients with at least one prior contrast-enhanced (CE)-MRI and of 123 control-MRI examinations in pediatric patients without prior CE-MRI.
Results: T1wH was identified in 9 (4 "definite" and 5 "faint": 6.4%) of 140 index-MRI and in none of 123 control-MRI (p=0.004). All of them belonged to the group of 86 patients who had received both linear (gadopentetate dimeglumine) and macrocyclic (gadoterate meglumine) GBCAs, whereas none of the 54 patients who had received only the macrocyclic GBCA showed T1wH (p=0.01). Age, number of prior CE-MRI and the cumulative dose of GBCAs were significantly (p<0.01) higher in patients with T1wH as compared to patients without. Region-of-interest (ROI) analysis showed a progressive increase of pallidal/middle cerebellar peduncle (MCP) signal intensity (SI) ratio in the 4 patients with "definite" T1wH and of dentate/MCP SI ratio in 3.
Conclusion: Dentate and basal ganglia T1wH occurs in pediatric patients after CE-MRI with both linear and macrocyclic GBCAs in line with a "carry over" effect.

MRI texture analysis of rectal cancer with mono- and multivariate analysis using machine learning artificial intelligence

R. Ferrari[1], C. Voena[1], C. Mancini[1], M. Zerunian[2], F. Rivosecchi[2], V. Marè[1], R. Paramatti[1], R. Faccini[1], A. Laghi[2]; [1]*Rome/IT*, [2]*Latina/IT (ferraririccardo@gmail.com)*

Purpose: To perform texture analysis (TA) of first and second order of T2 weighted images of the entire volume of rectal cancer acquired pre, intermediate and after the treatment. To perform mono and multivariate analysis of texture parameters using AI by means of machine learning.
Methods and Materials: 55 patients. T2 weighted images were analysed using TA:first order(gray-level histogram) in 2D and 3D dimensions,mean,standard deviation, skewness and kurtosis. Local entropy.The grey level co-occurrence matrix(horizontal direction, 1pixel displacement).The homogeneity, the energy, the contrast and the dissimilarity.Time evolution of these parameters has been studied between the different time-control.The most effective parameters have been combined in a multivariate analysis with the use of the machine learning algorithms.
Results: The most significant parameters are: the ratio of the minimum of the local entropy computed after and before the treatment and some of the parameters extracted from the gray-level co-occurrence matrix computed in the slice where the tumour has maximum area. We also found that the area of the tumour before the treatment, is quite sensitive and it has been included in the multivariate analysis. A cut on the output of the random forest classificator can be placed to separate CR and PR+NR with the performances summarised in the ROC curve.
Conclusion: The use of a automatic multivariate analysis algorithm for analysing values of TA of T2 weighted images in patient with rectal tumour, using 2D and 3D segmentation of the tumour could differentiate *Complete responder* patients and *partial responder/non responder* patients to Radiotherapy and chemiotherapy.

B-0163 10:38

Radiomic features from pretreatment MRI are associated with prognosis in rectal cancer patients: preliminary findings

S. Yiqun, T.T. Tong, Y.J. Gu; *Shanghai/CN (12211230032@fudan.edu.cn)*

Purpose: Our goal was to investigate the correlation between histopathology and diffusion parameters by utilizing the most repeatable strategy for ROI- and slice-based diffusion parameters in rectal cancer.
Methods and Materials: Sixty-six patients underwent DKI-MR. Two readers independently measured the parameters using three slice protocols including single slice, three slices and whole tumour slice (WTS), combined with one of two ROIs, including outline and round ROI. Kruskal-Wallis, a paired sample *t* test, interclass correlation coefficient (ICC), Bland and Altman, Student's *t* tests, and receiver operating characteristic curves were used for statistical analysis.
Results: There were no significant differences among three slice protocols with regard to diffusion parameters ($p > 0.05$). The ADC and D derived from outline ROI were higher than those from round ROI ($p < 0.05$), while the opposite trend was apparent for K ($p < 0.05$). The WTS-outline ROI method resulted in the most excellent intra- and interobserver ICC. Utilizing the WTS-outline ROI, the AUC for assessment of well-differentiated tumours is greater by K (0.871), compared to ADC (0.809), and AUC for T2 is 0.768 by K.
Conclusion: The most repeatable strategy was the WTS-outline ROI method. In addition to ADC, K correlated with histopathology utilizing the WTS-outline ROI.

B-0164 10:46

Performance of texture analysis in predicting tumoural response to neoadjuvant chemoradiotherapy inrectal cancer patients studied with 3T MR

M. Zerunian, D.M. Bellini, D. Caruso, D. De Santis, T. Biondi, A. Laghi; *Latina/IT (marta.zerunian@gmail.com)*

Purpose: To determine the performance of texture analysis(TA) in predicting tumoural response in colon rectal cancer (CRC).

Methods and Materials: 40 consecutive CRC patients were prospectively enrolled and underwent 3T MRI before, during and after chemoradiotherapy(CRT). A region of interest was manually drawn around the tumour on axial oblique T2 images and analysed using first order statistical texture parameters (Skewness, Kurtosis, Entropy and mean value of positive pixels (MPP)). Receiver operating characteristic (ROC) curve analysis was performed to assess the diagnostic yield of TA parameters to predict complete response (CR).
Results: Thirteen patients showed histological CR, Twenty-two patients partial response(PR) and five patients were non-responders (NRs). Entropy, Kurtosis and MPP showed significant differences before and after CRT in CR's; PR/NR Entropy and Skewness showed significant differences before and after CRT ($p<0.05$). Absolute changes among different texture parameters in CR and PR/NR patients before and after CRT showed significant differences in Entropy, Kurtosis and MPP(0.31±0.35, in CR,-0.02 ± 1.28 in PR/NR, ($p=0.04$); 1.87 ± 2.19, in CR, -0.06 ± 3.78 in PR/NR($p=0.0005$); (107.91 ± 274.40, in CR, -28.33 ± 202.91 in PR/NR, ($p=0.004$), respectively). Kurtosis, evaluated on pre-treatment images, showed significant results in predicting CR ($p=0.04$; optimal cutoff value ≥ 6.68, Se 76.92% and Sp 38.46%).
Conclusion: TA from T2 images potentially play an important role as imaging biomarkers of tumoural response to neoadjuvant-CRT in CRC. Kurtosis is accurate in predicting complete responders.

B-0165 10:54

Evaluation of diagnostic accuracy of diffusion weighted (DW) MRI in mesorectal lymph node staging of rectal carcinoma (ReNoRis)
C.G. Monaco[1], G. Parker[2], R. Little[2], Y. Watson[2], S. Cheung[2], J. O'Connor[2], A.V. Marchianò[1], D. Scaramuzza[1]; [1]*Milan/IT*, [2]*Manchester/UK*
(cristianmonaco87@gmail.com)

Purpose: To assess the pre-operative DW MRI accuracy in detecting mesorectal lymph-node metastasis.
Methods and Materials: 34 patients prospectively enrolled April 2012-May 2014 with newly diagnosed, histologically proven, rectal cancer. T4 and mucinous tumors were excluded. 1.5T MRI Avanto, Siemens, Erlangen, Germany was used with this sequences protocol: pelvis T1 (5mm), T2 sagittal and coronal (3mm), T1 and T2 perpendicular to the rectum (3mm), DWI echo-planar (5mm, b-values 0, 400, 800 mm/s^2), T1 gradient-echo dynamic contrast-enhanced (5mm), T1 VIBE (1mm) and TSE (3mm) post contrast. ADC was evaluated from DWI with ROI's on tumours and mesorectal lymph-nodes. All patients underwent total mesorectal excision within 1 week after MRI, without neoadjuvant-therapy. Surgical specimens were cut at 5mm thickness, TNM classified. The pathologist and the radiologist identified the lymph-nodes location. For predicting mesorectal nodal metastasis we assessed these characteristics using Wilcoxon and Fisher's tests: T stage; lymph-node size, margins, internal homogeneity and location with respect to the upper tumoral border, lymph-node ADC and node to primary tumour (N/T) ADC ratio.
Results: TNM staging: 1 T1, 3 T2, 30 T3 tumours, and 22 N0, 6 N1, 6 N2. Only irregular lymph-node margins ($p=0.002$), lymph-nodes located at least 1cm above the upper tumoral border ($p=0.0004$) and N/T ADC ratio ($p=0.0007$) were significantly associated with metastasis.
Conclusion: Similar cellularity between primary tumour and lymph-nodes is significantly associated to the presence of mesorectum lymph node metastasis, as irregular lymph-node margins. The lymph-node location/distance from tumoral margin is possibly related to the anatomic drainage of rectal tumours.

B-0166 11:02

Prognostic value of bodycomposition parameters assessed at the preoperative CT in patients withcolorectal carcinoma
M. Martinelli, M. Chincarini, G. Zamboni, C. Fabris, C. Conti, C. Pedrazzani, R. Pozzi Mucelli; *Verona/IT (marco.chincarini@gmail.com)*

Purpose: To assess the effects of Body Composition Parametrs (BCPs), measured on the preoperative CT in patients with colorectal cancer (CRC), on overall survival and surgical complications.
Methods and Materials: We reviewed the preoperative CTs of 288 patients who were resected for CRC, and measured the BPCs on the L3-L4 transverse sections using a free software (ImageJ, National Institutes of Health, USA). Total Fat Area (TFA), Subcutaneous Fat Area (SFA), Visceral Fat Area (VFA), Retroperitoneal Fat Area (RFA) and Total Muscle Area (erector spinae + psoas + abdominal wall muscles), were measured. The Skeletal Muscle Index (SMi= TMA/height^2) was calculated to assess for sarcopenia. The clinical features assessed included gender, age, BMI, tumor location, TNM stage, overall survival and surgical complications. Kaplan-Meier curves for survival were calculated. Chi-square was used to assess the association of the parameters with complications.
Results: 194/288 patients (67,4%) were sarcopenic. 3-year survival and 5-year survival were significantly lower for sarcopenic patients than for the non-sarcopenic (83.2% vs 93.7%, and 78.2% vs 90.1%, respectively; $p=0.03$). No significant difference was observed regarding surgical complications. BMI and fat measures did not appear to influence patient survival or surgical complications.
Conclusion: Sarcopenia appears to be significantly associated with a lower overall survival. Amount of visceral, subcutaneous or total fat and obesity did not show any significant correlation with patient prognosis. Assessment of sarcopenia can provide additional prognostic information from the preoperative CT.

B-0167 11:10

Pelvic MRI after induction chemotherapy and before long-course chemoradiation therapy: what are the imaging findings?
I. Blazic, N.M. Campbell, A. Knezevic, M. Gonen, P. Lynn, M. Weiser, J. Garcia-Aguilar, L. Saltz, M.J. Gollub; *New York, NY/US*
(ivanablazic@yahoo.com)

Purpose: To assess the ability of MRI after FOLFOX-based induction chemotherapy (ICT) to predict rectal cancer response to total neoadjuvant treatment (TNT).
Methods and Materials: In this IRB-approved retrospective study, pre- and post-ICT tumour T2 volume and relative T2 signal intensity (rT2SI; tumour/obturator internus muscle) were assessed in 63 patients with 65 tumours by two readers. Node size, signal intensity and border characteristics were recorded. Correlations were made between the reference standard of histopathologic percent tumour response in the primary tumour with tumour volume change, rT2SI and baseline and post-ICT lymph node characteristics.
Results: Post-ICT MRI was obtained within 30 days of completion of ICT. 9/63 (14.3%) patients had a complete response after TNT. Change in T2 volume was not associated with TNT response. Change in rT2SI showed no correlation with TNT response. There was a significant negative correlation between baseline and post-ICT node size and TNT response ($r=-0.25$, $p=0.05$; $r=-0.35$, $p=0.005$, readers 1 and 2, respectively). Both baseline and post-induction median node size were significantly smaller in complete responders and 95% responders ($p=0.03$, 0.001; readers 1, 2, respectively). Median change in largest baseline node size and decrease in post-ICT node signal heterogeneity were associated with 100% tumour response ($p=0.04$).
Conclusion: In this cohort of patients receiving post-ICT MRI, tumour volume and signal intensity did not correlate with TNT response. Lymph node sizes decreased after ICT and were significantly associated with complete response to TNT. This potentially useful prognostic information will require validation in a prospective study.

B-0168 11:18

Tumour volume vs RECIST criteria in re-staging rectal cancer
E. Guidi, C. Giaconi, C. Arena, E. Neri; *Pisa/IT*
(radiodiagnostica3.aoup@gmail.com)

Purpose: To compare MRI tumour volume regression grade vs RECIST criteria in the re-staging of rectal cancer.
Methods and Materials: Thirty-three patients with locally advanced rectal cancer (T3-T4 stage or any N+) underwent MRI for staging and re-staging. MRI acquisition was performed on 1.5T and 3T scanners, with a protocol compliant with the ESGAR guidelines. MR tumour volume was calculated by a semi-automatic tool.All patients underwent neo-adiuvant chemo-radiotherapy, followed by total mesorectal excission. Each rectal specimen, analysed by the pathologist, was classified on the basis of the Dworak tumour regression grade.
Results: In 24/33 patients a complete downstaging from T3 to T-T2 was obtained. Among these 7 patients showed a tumour volume reduction grade > 80%. A statistically significant correlation between tumour regression grade and volume reduction was observed (Spearman rank = 0.3626, p = 0.0189). According to the RECIST criteria 19/33 (57,6%) patients had partial response and only 3 had complete response.
Conclusion: Tumour volume reduction grade showed the best correlation with pathological grading and should be considered as one indicator/biomarker of response to chemo-radiotherapy in restaging locally advanced rectal cancer.

B-0169 11:26

MRI of rectal cancer response to therapy: comparison of T2, DWI and ADC between 3Tand 1.5T
M. Zerunian, D. Caruso, D.M. Bellini, D. De Santis, F. Rivosecchi, A. Laghi; *Latina/IT (marta.zerunian@gmail.com)*

Purpose: To compare signal intensity (SI) on T2, DWI and ADCmaps between 3T and 1.5T MRI of rectal cancer pre, during and post-neoadjuvant-chemoradiotherapy (CRT).
Methods and Materials: Twenty-two consecutive rectal cancer patients were prospectively analyzed on both 3T and 1.5T MRI. All patients underwent to dedicated axial-oblique T2, DWI and ADC performed pre, during and post-CRT. Two expert radiologists selected in agreement the best qualitative single slice where the tumor was detectable for all three chosen sequences of each examination, for a total of 396 slices. Another radiologist, blinded for

histological results, drawn a region of interest of the tumor on the selected slice and registered the corresponding SI of T2, DWI and ADC.
Results: Significant differences were observed for DWI on 3T compared to 1.5T for pre-CRT (324.37±172.21 vs. 70.72±20.83), during CRT (199.86±128.08 vs. 52.59±17.16) and post-CRT (135.53±68.03 vs. 43.17±14.47), and for T2 values between 3T and 1.5T for pre-CRT (599.57±144.83 vs. 339.57±117.87), during CRT (527.24±178.92 vs. 344.76±119.89) and post-CRT (526.19±136.30 vs. 318.91±99.77) (all $p<0.05$), whereas no significant differences were reported for ADC values between 3T and 1.5 T for pre-CRT (0.85±0.21 vs. 0.83±0.19), during CRT (1.11±0.25 vs. 1.18±0.33) and post-CRT (1.24±0.36 vs. 1.27±0.35) (all $p>0.05$). A progressive decreasing trend for DWI and T2 was observed during the three controls, while an increasing trend was noticed for ADC in the three examinations, for both fields strength.
Conclusion: DWI and T2 values were significantly higher on 3T than 1.5T while no significant differences were observed on ADC pre, during and post-CRT.

B-0170 11:34

Correlations between the iodine concentrations from dual-energy computed tomography and molecular markers Ki-67 and HIF-1α in rectal cancer: a preliminary study
S. Fan, X. Li, Z. Ye; *Tianjin/CN (303533681@qq.com)*

Purpose: To investigate whether dual-energy computed tomography (CT) with iodine quantification is correlated with molecular markers Ki-67and hypoxia-inducible factor 1α (HIF-1α) in rectal cancer (RC).
Methods and Materials: Eighty patients (43 males and 37 females) diagnosed with rectal cancer got pelvic contrast-enhanced CT scan with dual-energy computed tomography before any anticancer treatment. The normalized iodine concentration (NIC) values and CT values at each energy level (40-140 keV) from the virtual monochromatic image of the primary lesions were analysed. The postoperative specimens of all 80 patients underwent Ki-67 and HIF-1α immunohistochemistry staining. By SPSS17.0 software package, we analysed the correlations of NIC values and CT values at each energy level (40-140 keV) with Ki-67 and HIF-1α expression. The receiver operating characteristic (ROC) curves of these dual-energy computed tomography parameters were calculated and the diagnostic value were assessed .
Results: There was a weak positive correlation between NIC values and carcinoembryonic antigen level ($r=0.246$, $P=0.028$) in RC. Both the value and the level of Ki-67 expression were correlated positively with the NIC values ($r=0.344$, $P=0.002$ and $r=0.248$, $P=0.026$). HIF-1α expression was correlated positively with the NIC values of the RC ($r=0.598$, $P<0.001$). The best threshold value of NIC values in diagnosing the expression of HIF-1α was 0.5839. The sensitivity was 78%; specificity, 87%; PPV, 86%; NPV, 79%; accuracy, 83%.
Conclusion: The NIC values on dual-energy computed tomography may be used as a measurement of hypoxia in RC and determining the ability of tumour invasion noninvasively.

B-0171 11:42

Utility of CT histogram parameters in discriminating between metastasis and non metastases among colorectal cancer patients with pulmonary lesions
S. Wang, T. Tong, T. Hu, W. Peng, J. Wang, L. Huang; *Shanghai/CN (shengpingwang2007@126.com)*

Purpose: To determine whether whole-lesion histogram parameters of pulmonary nodules based on computed tomography (CT) images can distinguish between lung metastasis (LMs) and non metastases (NMs) in patients with colorectal cancer (CRC).
Methods and Materials: From January 2012 to December 2014, 276 CRC patients with pulmonary lesions were divided into two groups: LM group and NM group which were confirmed by pathology. Whole-tumour texture analysis was performed on CT images, and histogram parameters were derived from the pixel distribution histogram. Potential predictive parameters to differentiate LM from NM were identified by univariate regression analysis and subsequently tested in multivariable logistic regression analysis.
Results: Of 276 nodules, pathologic analysis confirmed 171 LMs,105 NMs(13 PLCs and 92 benign lesions).Kurtosis and sphere value were significantly higher (0.73 versus -0.79, $P<0.0001$; 1.59 versus 0.65, $P<0.0001$, respectively) while skewness was significantly lower (-1.03 versus 0.13, $P<0.0001$) in LM group compared to the group. Multivariate analysis revealed that smaller sphere value (adjusted odds ratio, 0.092) and higher kurtosis (adjusted odds ratio, 3.319) are significant differentiators of LM from NM ($P < .001$). With mean attenuation, the standard deviation of attenuation, volume, kurtosis, and sphere value, the logistic regression model showed excellent accuracy (area under the curve, 0.91) in the differentiation of LM from NM.
Conclusion: In patients with CRC, higher kurtosis and sphere value are significant differentiators of LM from NM, and LM can be accurately differentiated from NM by using CT histogram analysis.

B-0172 11:50

Staging of colon cancer, best technique/modality, a PhD thesis
E. Nerad[1,2], M.J. Lahaye[2], R.G.H. Beets-Tan[2]; [1]*Worcester/UK*, [2]*Amsterdam/NL (nerad19@hotmail.com)*

Purpose: Paradigm shift in the treatment for colon cancer is on the horizon with neo-adjuvant therapy possibly becoming available for operable colon cancer patients (FOXTROT study). Staging will become crucial; the focus of this thesis is to determine what technique/modality has the highest accuracy.
Methods and Materials: Two meta-analyses, computed tomography (CT) and CT colonography (CTC) and an original study using magnetic resonance imaging (MRI) to determine the accuracy in the detection of tumour invasion through the bowel wall and nodal involvement of colon cancer were performed.
Results: The sensitivity, specificity for detection of tumour invasion beyond the bowel wall were 90% (95%CI: 83-95%); 69% (95%CI: 62-75%) for CT, 90% (95% CI: 88-92%); 87% (95% CI: 83-90%) for CTC; 91% (76-98%); 84% (60-96%) for MRI respectively. For nodal involvement the estimates were 71% (95%CI: 59-81%); 67% (95%CI: 46-83%) for CT, 84% (95% CI: 80-88%); 66% (95% CI: 59-72%) for CTC, 91% (76-98%); 84% (60-96%) for MRI respectively.
Conclusion: It appears regular CTC and MRI have a better accuracy in the local staging of colon cancer compared with regular CT techniques.

Early treatment for PE diagnosed on CTPA: does electronic critical report labelling make a difference?
S.L. Dluzewski, N. Patel, S.R. Tincey, S. Hare; *London/UK (sophia_tincey@hotmail.com)*

Purpose: Recent guidance for reporting radiologists emphasises the importance of highlighting studies with significant or abnormal findings to requesting clinicians. Pulmonary embolism (PE) represents a significant cause of morbidity and mortality in the hospital setting. The aim of this study was to assess whether electronic critical report labelling has an impact on the rapidity of initiating anticoagulation treatment for PE diagnosed on CTPA.
Methods and Materials: A retrospective observational study was conducted with regard to CTPA studies performed between August 2015 and May 2016 at a District General Hospital, in the UK. All CTPA studies that identified PE were identified. These reports were grouped into those critically labelled and those that were not. Time to therapeutic anticoagulation was compared between the labelled and unlabelled groups.
Results: 410 CTPAs were performed, 85 of which were positive for PE. 8 out of 85 of these were highlighted as critical (9.4%). Patients with critical report labelling were anticoagulated significantly more quickly than those that were not ($p=0.0249$, $u=24$). Pre-scan clinical suspicion, pulmonary embolism severity, ward location, time of day and staffing levels were not statistically significant.
Conclusion: This research forms the first UK study in standard clinical practice that provides evidence that labelling reports as critical is associated with significantly shorter delay to treatment.

B-0174 10:38

Appropriateness and pattern of imaging modality choice amongst radiologists from different countries
V. Pozdniakova[1], J. Froehlich[2], A. Gutzeit[3]; [1]*Stavanger/NO*, [2]*Zurich/CH*, [3]*Lucerne/CH (v.a.pozdnyakova@gmail.com)*

Purpose: Appropriate use of medical imaging is a key to the effective diagnostic decision making. Heterogeneity of existing radiological standards yields a big number of improper examinations and leads to unnecessary radiation exposure and high health care costs. In this study we investigated an agreement between radiologists from different countries on imaging modality choice and an appropriateness of selected procedures.
Methods and Materials: A web-based questionnaire with 15 clinical cases was sent to radiologists from 11 European and 3 non-European countries. Responders had to choose the most relevant imaging modality for the suggested clinical situation. Responses appropriateness was ranked according to American College of Radiology (ACR) Appropriateness Criteria from 1 to 9.

The agreement between responders was analyzed using graphical statistics made in R software program. Descriptive statistics were realized in SPSS.
Results: There were significant discrepancies in ACR scores amongst 183 responders who completed the survey. The questions with the worst agreement were related to imaging in blunt abdominal trauma, stroke, physical child abuse and microscopic hematuria. The best agreement was achieved on imaging of lung nodules, cervical spine injury, pyelorostenosis and deep vein thrombosis. 56% (n=1247) of responses were ranked as usually appropriate, 13% (n=684) as may be appropriate and 31% (n=295) as not appropriate.
Conclusion: There is a low agreement between radiologists from different countries on preferred imaging modality. It emphasizes a need for an active development and implementation of common radiological guidelines.

B-0175 10:46

Preliminary analysis of a computer tool to avoid repetition of radiological tests

P. Fraga Rivas[1], L. Garcia del Salto[1], J. de Miguel Criado[2], F. Aguilera del Hoyo[1], C. Benito Vicente[1], A. Marco Sanz[1]; [1]*Madrid/ES*, [2]*Coslada/ES (fragarivas@gmail.com)*

Purpose: To submit a computer tool implanted in the electronic medical history of the notification of repetition of the request of radiological test to analyse the results obtained in the first 10 months after its implantation.
Methods and Materials: In November 2016, this tool was established in the electronic history of our hospital. When a physician requests a radiological test, which was already requested in the previous 180 days, the tool generates a test repetition warning alert. The faculty decides if he continues with the creation of that request, or if he considers that this test should not be repeated.
Results: In these 10 months there have been 8646 notices of repeated radiological request, representing 6.5% of the total of 131593 requests generated. In 3197 notices (36.9%) the physician decided not to request the test again (1273 cases of ultrasound scan, followed by 1109 cases of simple x-ray) and in 5449 (63.02%) he made a new request (3572 were simple radiographs, and 801 cases of ultrasound. 78.2% of simple RX corresponded to trauma).
Conclusion: A large number of unnecessary tests are consequences of ignorance that the patient has a previous and recent one. The tool has proven useful since it has managed to avoid a large number of unnecessary repetitions. The simple x-ray and the traumatology service are the scenes of the greatest number of repetitions of the test. Ultrasonography has been the modality in which more repetitions have been avoided.

B-0176 10:54

Making the best of clinical radiology: a single-institution review of imaging referral appropriateness including cumulative monetary and dose estimates for inappropriate scans

J. Ryan, A. Hollywood, A. Stirling, L. O' Hora, M. Glynn, A. Brady, A. Dolan, L. Lawler, F. Bolster; *Dublin/IE (jamesryannchd@gmail.com)*

Purpose: There has been a dramatic year on year increase in imaging requests at our academic institution. The iRefer guidelines are produced by the Royal College of Radiologists (RCR) in the UK and are designed to prevent inappropriate imaging and radiation exposure. These guidelines have been available to general practitioners and hospital physicians in Ireland since June 2015. We performed a large retrospective review of radiographs performed in 2015 and 2017 to determine the proportion of inappropriate referrals before and after guideline availability.
Methods and Materials: 1173 radiographs were reviewed. A validated RCR audit template was used for data collection. Emergency department, in-patient and general practitioner referrals were reviewed. Cost and cumulative effective dose estimates were calculated.
Results: The inappropriate abdominal radiograph referral rate was 37% in January 2015 and 47% in January 2017. The inappropriate spinal radiograph referral rate was 48% in 2015 and 39% in 2017. The predicted cost of inappropriate abdominal and spinal radiographs for 2017 was 12,720 euros, the predicted cumulative dose was 927mSv. Paranasal sinus and nasal bone radiographs are considered inappropriate. Over the past 4 years, 573 such scans were performed with an estimated cost of 2,868 euros and a cumulative dose of 8.6 mSv.
Conclusion: Despite the availability of the iRefer guidelines there remains a significant proportion of inappropriate imaging requests. The cost of these scans is significant, as are dose estimates. Interventions are needed to decrease inappropriate referrals. Clinical decision support software may help achieve this.

B-0177 11:02

Metformin and intravenous contrast medium: a systematic review of international radiological societal guidelines

A. Weir[1], B.S. Kelly[1], A. Liew[2], P. McCarthy[2]; [1]*Dublin 4/IE*, [2]*Galway/IE (arleneweir88@gmail.com)*

Purpose: A systematic review was performed to assess the current international radiological societal guidelines on metformin and the risk of lactic acidosis in patients receiving IV contrast media. The quality of supporting evidence was also assessed.
Methods and Materials: Evidence-based guidelines created by established international radiological societies were searched using search terms relating to metformin, contrast media and lactic acidosis in PubMed, Cochrane Library, Embase and Google Scholar databases. Two reviewers assessed the quality of the guidelines using the AGREE collaboration instrument and relevant supporting evidence.
Results: Five international radiological societal guidelines met the inclusion criteria. All guidelines have low scores on many criteria assessed using the AGREE collaboration instrument. Four of the five guidelines had revised their recommendations recently, despite the absence of high-quality evidence. All guidelines, except that of the Royal College of Radiologists, had lowered their threshold for withholding metformin. Despite a lack of agreement between the guidelines in regard to the exact threshold to stop metformin, an improvement in clarity and consistency was noted in relation to the type of renal function assessment, duration for withholding metformin and timing of renal function re-assessment. The data used to support these recently revised guidelines was derived from observational studies alone.
Conclusion: This systematic review showed a significant change in current recommendations for metformin use and IV contrast media, with specific focus on lower renal thresholds for withholding metformin, despite absence of high-quality evidence. Furthermore, there are substantial inconsistencies in the recommendations from various international guidelines.

B-0178 11:10

Study of the current situation of patient information in the example of a CT scan: what are improvement options?

D. Kildal[1], S. Schmidt[1], M. Beer[1], O. Schöffski[2], T. Blasenbrey[1]; [1]*Ulm/DE*, [2]*Nürnberg/DE*

Purpose: The yearly number of CT shows a steady increase in Germany. Patient information is a significant part of radiologists' daily work. Additionally, in 14% of the legal issues patients complain are focused on the information given by the doctor before the radiological examination. That shows the special importance of correct information and documentation prior to the CT examinations. This study explores the quality, patient satisfaction, doctor satisfaction and spent efforts.
Methods and Materials: 1438 questionnaires from 4 hospitals with different care levels were analysed. Additionally, 512 patients and 106 physicians throughout Germany were asked regarding quality, satisfaction, spent efforts and opportunities for improvement with regard to the patient knowledge concerning CT examination and the acceptance of a computer-assisted Information.
Results: Up to 40% of the patients declared that they received no radiological information by a physician. Patients and physicians rate current situation only as "moderately content". 22% of the patients wish extended information. 85.3% of the doctors said that medical information is heavily impacting their daily workflow. Patient information given by radiologists was better than those given by non-radiologist doctors. Finally, the quality of the patient information seems to depend on the size of the staff.
Conclusion: The study shows, that patient information for radiological services is time consuming and currently not very effective. New media (like video-based information and computer-assisted methods) might be promising to set new quality standards and to reduce needed efforts for medical staff.

B-0179 11:18

Patient-adapted communication between radiologist and patient: should radiologists rethink their patient care?

A. Gutzeit; *Lucerne/CH (agutzeit2000@gmail.com)*

Purpose: The aim of this study was to investigate how patients' perception changes when the radiologist communicates the findings after an examination.
Methods and Materials: After a routine MRT patient group 1 (101 patients) was given the opportunity to discuss the findings with the radiologist. Patient group 2 (101 patients) left the radiological institute without any personal communication. By means of a questionnaire both groups could be compared in terms of stress level, emotional attachment to the institute, and the feeling of competence regarding the radiologist.
Results: 77 % of all patients were concerned about the findings without any difference between the two groups ($p>0.05$). Significant more patients in group 1 (81%) appreciated that a discussion of these findings represents a good

radiological consultation service in comparison to group 2 (14%)(p<0.005). Patients in group 1 had a significantly higher binding rate and wanted to be examined in department with communication only (p<0.05)(93.1% group, 1/75% group 2). After the interview significantly more patients in group 1 considered the radiology department as being a competent department than in group 2 without a discussion (p <0.001).
Conclusion: Communication and reporting between radiologists and patients after an examination leads to a much better perception of patient well-being, feeling of competence and binding factor between patient and radiologist.

Significant quality improvement of results and patient satisfaction in medical information for radiological examinations applying video information techniques

D. Kildal[1], S. Schmidt[1], M. Beer[1], O. Schöffski[2], T. Blasenbrey[1]; [1]*Ulm/DE*, [2]*Nürnberg/DE*

Purpose: Correct medical information for radiological examinations is very important and simultaneously expensive and time consuming. Additionally, 14% of legal issues are associated with an incorrect medical-information process. Legal requirements and wishes of patient representatives increase steadily, on the other side, yearly CT examinations in Germany strongly increase. Actually German doctors spend on average 17.7 years only for the CT information procedures. Despite this time effort, patients and physicians are only moderately satisfied with the current situation. This study explores the acceptance of patients and doctors regarding the implementation of using information videos and computer-assisted anamnesis methods for the patient information.
Methods and Materials: 512 patients and 106 doctors throughout Germany were asked regarding the current situation, satisfaction and acceptance of technical innovation. Another survey relating an information video was conducted for validation. It was analysed how many risks and side effects were remembered by the patients depending on the method information was given.
Results: Patients and doctors showed a great acceptance for technical innovation. The second survey (information video) showed a significant rise in all test areas. Patients could better remember the radiation risk, side effects of contrast agents or risk in general after video-based information. The satisfaction after the video information was significantly higher than after a conventional given medical Information.
Conclusion: The video-information is future oriented. Patients could be enlightened with higher quality and more satisfactory medical learnings. It is to be expected that the medical-information conversation will be more well prepared, more focused and at least shorter - the last point is also important for cost savings.

B-0181 11:34

Radiologists as co-author in case reports containing radiological images: does their presence influence quality?

E. Luyckx[1], J.M.L. Bosmans[2,1], B. Broeckx[3], S. Ceyssens[1], P.M. Parizel[1], A. Snoeckx[1]; [1]*Antwerp/BE*, [2]*Ghent/BE*, [3]*Merelbeke/BE*
(elisaluyckx1@gmail.com)

Purpose: Imaging plays a crucial role in many diagnostic processes. It is, therefore, not surprising that medical case reports often include radiological images. Cui honorem, honorem deberi ("honour to whom honour is due") seems straightforward, but such is not always the case where it concerns including radiologists as co-authors. Clinical specialists often see radiologists as 'image providers', not as clinical colleagues. The purpose of our study was to investigate how often radiologists are mentioned as co-authors in case reports containing radiological images, and to assess if their involvement influences quality.
Methods and Materials: We searched PubMed using "Case report" as search term. Criteria for inclusion were: publication in a non-radiological journal and availability of full text in English. We included 400 case reports, 218 of which contained medical images. The images and figure legends of these 218 case reports were scored by two radiologists and a nuclear medicine physician in consensus, using a self-defined scoring system.
Results: In 21% (45/218) of case reports a radiologist was included as a co-author. In 79% (173/218) of case reports there was no radiologist as co-author. In 7 of those, a radiologist was mentioned in the acknowledgements. The median quality score in case reports with and without a radiologist as co-author was 74% and 51%, respectively; this difference was statistically significant (p<0.05).
Conclusion: In a minority of non-radiological case reports containing radiological images, a radiologist was listed as co-author. The participation of a radiologist as co-author did, however, have a significant impact on quality.

B-0182 11:42

Remote radiological audit: a regional quality assurance system

E. Guseva, S. Morozov, D.V. Burenchev, I. Trofimenko, N. Ledikhova, T. Rostovtseva; *Moscow/RU (e.guseva@npcmr.ru)*

Purpose: To evaluate the effectiveness of electronic quality assurance system in radiology departments.
Methods and Materials: Currently, 75 outpatient clinics are connected to the Unified Radiological Information Service (URIS). The service comprises 130 CT and MRI units, 422 radiologists, and 321 technicians. In 2016, we developed remote quality assurance system and discrepancy detection module (DDM). The software is designed to review studies, provide feedback and accumulate "big data". We have compared the number of discrepancies before and after DDM implementation (4473 anonymized CT and MRI studies). P<0.05 was considered statistically significant.
Results: We observed a decrease in significant and non-significant discrepancies from 6.4±2.9% (64) to 2.8±0.8% (104) and from 19.6±3.0% (197) to 9.5±0.7% (352). The number of reports without any discrepancies increased from 51.7±2.9% (520) to 69.1±0.7% (2560). The number of general remarks (terminology, scan protocol) remained roughly the same, 22.4±3.0% (226) vs 18.6±1.59% (691). We have conducted 2622 consultations. Clinics received daily updates and 804 monthly reports. Radiologists with high discrepancy rates were personally notified. 67 training courses and 89 webinars were conducted with 1955 and 10244 participants.
Conclusion: Regional remote quality assurance system improved department effectiveness. In 12 months, the number of discrepancies decreased by more than a half.

B-0183 11:50

Affidea imaging metrics platform: a comprehensive dashboard providing key performance indicators for optimisation of image quality and throughput

N. Papanikolaou[1], G. Papaioannou[2], A. Iliopoulos[2], P. Szatmari[1], R. Illing[1]; [1]*Budapest/HU*, [2]*Nicosia/CY (rowland.illing@affidea.com)*

Purpose: To present a web-based imaging analytics platform that can calculate several metrics, the so-called key performance indicators (KPIs) to assess both quality of MRI exams and patient throughput.
Methods and Materials: The Affidea imaging metrics is a web-based system comprised of agents and a central server communicating with the agents to collect, process, quantify and present metrics on an interactive dashboard. Agents were installed in14 MRI departments in 3 European countries. 18 MRI scanners were connected to the agents through local network and all MRI examinations were sent to the agents through setting an auto-transfer dicom service in the background of the MR scanners. Agents extracted metadata from the dicom headers of each image and transmitted them through secure FTP to a central server. Meta data were compared with a reference database and compliance to standardised protocols was calculated. In addition, deviation was defined as the percentage of sequences not included in the standardised protocols. Other KPIs including number of exams, voxel size, examination time and waste time were also quantified.
Results: All KPIs were presented as info tablets including the name of the KPI, the average value over a user-defined time interval, its percent change comparing to a user-defined time interval in the past. In addition, each KPI was presented on a chart for different countries, sites, MRI models and types of exams.
Conclusion: A comprehensive web-based platform monitoring the performance of MRI scanners by means of several KPIs is presented.

Differences in liver imaging reporting and data system categorisation between MRI with hepatobiliary-specific vs primary-extracellular agents

V. Bura[1], H. Nguyen[2], S. Lee[2], T. Tirkes[3], C. Lall[2]; [1]*Cluj-Napoca/RO*, [2]*Orange, CA/US*, [3]*Indianapolis, IN/US (vlad.t.bura@gmail.com)*

Purpose: The purpose was to assess whether liver lesions are categorised differently using Liver Imaging Reporting and Data System (LI-RADS), in chronic-hepatitis patients at risk for hepatocellular carcinoma (HCC), when undergoing liver-MRI with two different contrast agents: primary-extracellular (ECa) versus hepatobiliary-specific (HBa).
Methods and Materials: We retrospectively selected patients, provided they underwent liver-MRI with both agents within a three-month time interval. The cases were reviewed by two radiologists. The images were downloaded and anonymised, for blinding the radiologists to patient demographics/agents used and further remove any implicit bias. Multiple enhancement and wash-out characteristics, as well as capsule visualisation, were studied throughout arterial, venous and equilibrium MRI-phases. A final category was assigned using LI-RADS-v2014-guidelines.
Results: We reviewed 22 patients, and a total of 36 lesions. For 44% of the lesions, the ECa-MRI upgraded LI-RADS by one or even two categories (5 lesions), based on better wash-out visualisation and/or the presence of a partial/full capsule. Arterial enhancement was assessed as more robust with ECa-MRI in 42% cases. Seven lesions not seen with HBa-MRI were LI-RADS 3 (5/7) or 4 (2/7) category on ECa-MRI.
Conclusion: Although performed on a small number of patients, the present study reveals superiority of EC-agents in a more precise LIRADS categorisation of liver lesions for patients at risk for HCC. There is an improvement in the visualisation of arterial-enhancement, venous wash-out and capsule with an EC-agent. Pertinent negative of the study was the smaller number of patients which showed better characterisation and LI-RADS with the HB-agent MRI (5%).

B-0191 14:08

Prospective evaluation of dynamic MR with gadoxetic acid for the non-invasive diagnosis of HCC in newly detected nodules smaller than two centimetres on US in cirrhotic patients

C. Ayuso, A. Darnell, J. Rimola, A. García-Criado, R. Vilana Puig, A. Forner, J. Bruix; *Barcelona/ES (cayuso@clinic.cat)*

Purpose: To evaluate the diagnostic accuracy of gadoxetic acid-enhanced MR (GA-MR) for non-invasive hepatocellular carcinoma (HCC) diagnosis in nodules ≤2cm detected by US screening programme.
Methods and Materials: Cirrhotic patients with newly detected solitary nodules ≤2cm by screening US were included. Extracellular contrast-MR (EC-MR) and GA-MR were performed in less than 1 month. Final diagnosis was based on the EASL/AASLD guidelines criteria (specific vascular profile on EC-MR or biopsy). Blind, double reading was performed in all GA-MR studies. The criterion for HCC diagnosis using GA was arterial contrast uptake and washout in the portal phase or hypointensity in the hepatobiliary phase (HBp).
Results: 62 consecutive cirrhotic patients Child-Pugh A (53) or B (9) were included. Final diagnosis was: 41 (66.1%) HCC, 2 intrahepatic cholangiocarcinoma (ICC), 1 colo-rectal cancer metastasis, and 18 benign lesions. Benign lesions were followed up during a median of 23 months to discard malignancy. The EC-MR diagnosed 26 out of 41 HCC nodules (sensitivity 63.4%, CI95%: 46.9-77.9). Sensitivity and specificity for GA-MR were 56.1% (CI95%: 39.7-71.5) and 90.5% (CI95%: 69.8-98.8), respectively, with a PPV of 92 (CI95%: 74-99) and NPV of 51.4 (CI95%: 34.4-68.1). False positives were observed in the two ICC. In GA-MR, wash-in was present in 82.9% and portal wash-out in 42%. Low signal intensity in the 20 minutes HBp was observed in 63.4% of HCC nodules, whereas the remaining 15 HCCs were iso- or hyperintense.
Conclusion: GA-MR is not superior than EC-MR for non-invasive diagnosis of HCC in nodules ≤2cm in cirrhotic patients.

Diagnostic accuracy of LR-M criteria for differentiating combined hepatocellular cholangiocarcinoma on gadoxetate-enhanced MRI

H. Lee, C. An, M.-J. Kim; *Seoul/KR (iitrue9hsii@yuhs.ac)*

Purpose: To determine the diagnostic accuracy of LR-M criteria of LI-RADS version 2017 for differentiating combined hepatocellular cholangiocarcinoma (cHCC-CC) on gadoxetate-enhanced MRI.
Methods and Materials: Preoperative gadoxetate-enhanced MRI of 33 cHCC-CC and 66 hepatocellular carcinoma (HCC) were reviewed by two radiologists, who assessed the presence of nine imaging features favoring other malignancy (LR-M features) and 10 favoring HCC. The sensitivity and specificity of LR-M features for differentiating cHCC-CC from HCC were calculated from consensus opinions..
Results: At least one LR-M feature was seen in 31 (93.9%) of 33 cHCC-CC and 34 (51.5%) of 66 HCC. The sensitivity and specificity for the diagnosis of cHCC-CC using any of LR-M features were 93.9% and 48.5%. Among the LR-M features, the rim arterial phase hyperenhancement (APHE), progressive concentric enhancement, peripheral washout, adjacent biliary obstruction, mixed pattern, and infiltrative margin were significantly more common in cHCC-CC (p<0.05). Three or more LR-M features were seen in 18 (54.5%) cHCC-CC, while two or less were seen in 62 (93.9%) of HCCs. For lesions 2 cm or larger, the presence of all three major features of HCC including non-rim APHE, washout, and distinct rim showed sensitivity of 46.7% and specificity of 100% for the diagnosis of HCC, regardless of LR-M features.
Conclusion: Current LR-M criteria showed high sensitivity and moderate specificity for the diagnosis of cHCC-CC. Presence of all three major HCC features including distinct rim showed moderate sensitivity and perfect specificity for the diagnosis HCC for tumours of 2 cm or larger.

An imaging and clinical scoring system to predict early mortality in spontaneous ruptured hepatocellular carcinoma treated with transarterial embolisation

K.H. Lee, M.L.D. Tse, A.K.C. Cheng, H.Y.F. Wong, M.L. Yu, Y.L. Li, P.Y.C. Chien, Y.C. Ho, F. Chu; *Hong Kong/HK (viclkh88@gmail.com)*

Purpose: Spontaneous ruptured hepatocellular carcinoma (rHCC) is an emergency associated with significant mortality, and treatment includes transarterial embolisation (TAE). We aim to develop a scoring system using a combination of clinical and imaging parameters to predict 30-day mortality.
Methods and Materials: Retrospective review was performed of all patients with rHCC who underwent abdominal computed tomography (CT) and subsequent TAE between January 2007 and December 2016. CT features were reviewed by two radiologists blinded to patient outcome. Clinical parameters included serum bilirubin, albumin, INR and scores of individual measures according to Child-Pugh score. Independent risk factors for 30-day mortality after TAE were identified using multivariate binary logistic regression, for development of a scoring system.
Results: 98 patients with mean age 65.1 years were included. 30-day mortality rate was 40.8%. Bilobar distribution (p<0.001), maximum tumour size (p=0.03), bilirubin score (p=0.01) and albumin score (p=0.02) were independently associated with 30-day mortality. A 12-point score, based on 1-3 points for each of the four factors, was derived to predict 30-day mortality, and yielded area under receiver operating characteristic curve of 0.905 (95%CI: 0.843, 0.964). A score ≥7 was associated with 30-day mortality with sensitivity 100% and specificity 60%; a score ≥10 showed sensitivity 55% and specificity 92%. This stratified patients into low-, intermediate- and high-risk groups, with 0%, 45% and 92% 30-day mortality, respectively.
Conclusion: Clinical and imaging parameters can be combined into a scoring system to accurately predict 30-day mortality after TAE in rHCC patients. This may help identify and counsel high-risk patients.

B-0194 14:32

Can gadoxetic acid-enhanced MRI predict that a solitary HCC (cT1) is pT1 or pT2?

I.C. Chou, Y.-T. Kuo, I.H.W. Lao, P.-L. Hsieh, Y.-Y. Su, C.-W. Mak, D.-P. Sun, M.-J. Sheu, H.-T. Kuo; *Tainan/TW (yichenchou@hotmail.com)*

Purpose: To determine which imaging findings can predict pathology T2 stage of a single hepatocellular carcinoma (HCC, cT1) on gadoxetic acid-enhanced MRI.
Methods and Materials: Pre-operative gadoxetic acid-enhanced MRI were reviewed in a retrospective cohort of patients with solitary HCC. The reference standard of tumour staging was surgical pathology. Univariate and multivariate analyses were performed to identify predictors of microvascular invasion or satellite nodules in patients with HCC. Diagnostic performance of different MR findings was investigated.
Results: There were 39 (34.2%; 39 of 114) pathologically staged T2 HCCs (either with microvascular invasion, satellite nodules or combination of both).

75 HCCs (65.8%; 75 of 114) were staged T1. Large tumour size (>=2.3cm) had higher risk of pT2. In multivariate analysis, two MR findings, i.e. corona enhancement (odds ratio: 2.67; 95% CI: 1.101-6.480), and peritumoural hypointensity on hepatobiliary phase (odds ratio: 2.203; 95% CI: 0.961-5.049), were associated with high risk of pT2 HCCs. Positive likelihood ratio was 6.25 (95% CI: 1.788-21.845) and sensitivity to diagnose pT2 HCC on EOB MRI was 86.2% when a HCC was met with two or three of these MR findings. On the other hand, small tumour size and hypointense rim on hepatobiliary phase were 'protective' findings. When small HCCs were with hypointense rim and without aggressive findings, most of them were pT1 lesions (specificity was 100%).
Conclusion: There are 'protective' and 'aggressive' imaging findings of solitary HCCs on MRI. When combining size and imaging findings, gadoxetic acid-enhanced MRI could predict solitary HCC (cT1) as pT1 or pT2.

B-0195 14:40

Liver imaging reporting and data system (LI-RADS) version 2017 with gadoxetic acid-enhanced MRI: utility of ancillary features in diagnosis of hepatocellular carcinoma

H. Chang, H. Park, Y. Kim, M. Yu, S. Jung, H. Jeon; *Seoul/KR (20150113@kuh.ac.kr)*

Purpose: To investigate the utility of ancillary features of liver imaging reporting and data system (LI-RADS) version 2017 using gadoxetic acid-enhanced MRI in the diagnosis of hepatocellular carcinoma (HCC).
Methods and Materials: Our institutional review board approved this retrospective study and informed consent requirement was waived. Between August 2008 and May 2017, 154 high-risk patients with 180 pathologically confirmed HCC nodules who underwent gadoxetic acid-enhanced MRI were included. Two radiologists retrospectively assigned a LI-RADS category for all pathologically proven HCC observations in consensus, before and after considering ancillary features on MRI. For the cases in which category change was observed, ancillary features that caused category upgrade or downgrade were assessed.
Results: Based on major HCC features without considering ancillary features, 13.3% (24/180), 21.7% (39/180), and 65% (117/180) of nodules were categorized as LR-3, LR-4, and LR-5, respectively. After considering ancillary features, 11.1% (20/180) of nodules underwent category change, with all nodules upgraded from LR-3 to LR-4. No cases were downgraded after considering ancillary features. Mild-moderate T2 hyperintensity and hepatobiliary phase hypointensity were the most frequently found ancillary features in nodules with upgraded category (60%, n=12), followed by the restricted diffusion (50%, n=10).
Conclusion: In the diagnosis of HCC on gadoxetic acid-enhanced MRI using LI-RADS version 2017, ancillary features increased the confidence of HCC diagnosis in approximately 10% of the cases. The presence of mild-moderate T2 hyperintensity, hepatobiliary phase hypointensity, or restricted diffusion were found to be useful ancillary features favouring HCC in nodules with intermediate probability for HCC (LR-3).

B-0196 14:48

Liver vein infiltration in patients with hepatocellular carcinoma: impact on survival

S. Schotten, F.-I. Meyer, A. Mähringer-Kunz, A. Weinmann, C. Düber, R. Kloeckner; *Mainz/DE (sebastian.schotten@gmail.com)*

Purpose: Portal vein tumour thrombosis (PVTT) significantly impairs the prognosis of patients with hepatocellular carcinoma (HCC) and classifies them as advanced stage (BCLC-C). However, the relevance of liver vein infiltration (LVI) remains unclear. The aim of this study is to compare the prognosis of patients with different forms of macrovascular infiltration as this might influence the choice of treatment.
Methods and Materials: 1378 HCC patients were extracted from the clinical registry of our tertiary referral centre treated between 01/2005 and 01/2017. Macrovascular infiltration was diagnosed by re-evaluation of all available CT or MRI studies by two experienced radiologists in consensus reading. Overall survival (OS) was calculated from the date of initial diagnosis for all subgroups (no infiltration, PVTT, and LVI). In case of macrovascular infiltration, OS was additionally calculated from the date of its first appearance.
Results: 1341 patients could finally be included. 807 patients had no infiltration, 491 showed PVTT, and 43 an isolated LVI. OS from initial diagnosis was 37.29, 6.53, and 16.03 months, respectively (p<0.001). The OS calculated from the first appearance of macrovascular invasion was 4.9 months for PVTT and 7.33 month for isolated LVI (p=0.018).
Conclusion: Isolated LVI showed significantly better survival compared to patients with PVTT. This renders the question if patients with isolated LVI should be classified and treated like patients with portal vein infiltration (BCLC-C, mainly systemic therapy), or if a local approach is justified in selected patients.

B-0197 14:56

Diagnostic efficacy of conventional gadolinium-enhanced MRI in the detection of recurrent hepatocellular carcinoma: intra-individual comparison with gadoxetic acid-enhanced MRI

J.-H. Yim, Y. Kim; *Seoul/KR (jh111.yim@samsung.com)*

Purpose: To compare the efficacy of extracellular contrast media (ECCM) MRI to gadoxetic acid-enhanced MRI for detection of recurrent hepatocellular carcinoma (HCC) in patients previously treated.
Methods and Materials: One hundred and sixty patients who were suspected of having tumour recurrence after multiple treatments for HCCs (surgery, transarterial chemoembolization, and radiofrequency ablation) underwent ECCM MRI and gadoxetic acid-enhanced MRI with 10- to 30-day interval. A total of 105 liver lesions were diagnosed as HCC recurrence. The ECCM MRI and the gadoxetic acid-enhanced MRI were retrospectively analysed by two observers for detection of HCCs using receiver operating characteristic analysis. The diagnostic accuracy and sensitivity were calculated.
Results: For both observers, the ECCM set showed superior sensitivity and accuracy than the gadoxetic acid set (p<0.005, both). In addition, observer 2 represented higher negative predictive value with the ECCM set (52.3%) than the gadoxetic set (33.3%) (p=0.031). Pooled data for two observers also showed higher sensitivity, accuracy, and negative predictive value with the ECCM set (90%, 90.9%, and 51.1%, respectively) than the gadoxetic set (77.6%, 79.7%, and 31.8%, respectively) (p<0.003). We achieved excellent degree of interobserver agreement for both MRIs (k=0.804 and 0.891).
Conclusion: In detection of recurrent HCC in patients with history of multiple treatments, conventional ECCM MRI showed superior diagnostic efficacy in sensitivity, accuracy, and negative predictive value than gadoxetic acid-enhanced MRI.

B-0198 15:04

Differentiation between hepatocellular carcinoma showing uptake of gadoxetic acid and focal nodular hyperplasia

A. Kitao[1], O. Matsui[1], N. Yoneda[1], R. Kita[2], K. Kozaka[1], S. Kobayashi[1], T. Minami[1], W. Koda[1], T. Gabata[1]; [1]*Kanazawa/JP*, [2]*Osaka/JP*

Purpose: To clarify the imaging differentiation points between hepatocellular carcinoma (HCC) showing uptake of gadoxetic acid enhanced MRI and focal nodular hyperplasia (FNH)/FNH like nodule.
Methods and Materials: We enrolled the pathologically diagnosed 49 HCC with hypreintense area constituting more than two thirds of the nodule on hepatobiliary phase and 15 FNH/FNH like nodule, and compared findings of dynamic CT and gadoxetic acid enhanced MRI between them using Mann-Whitney test, Chi square test and univariate logistic regression analysis
Results: The enhancement pattern of dynamic CT was significantly different between HCC and FNH (P<0.0001): arterial enhancement/washout pattern (89.8% vs 13.3%) and arterial enhancement/no-washout pattern (4.1% vs 86.7%), respectively. Enhancement ratio on arterial phase of dynamic CT was higher in FNH than in HCC (P<0.0001). The frequency of corona like enhancement on portal to equilibrium phase (83.7% vs 13.3%, P<0.0001) and arterial phase enhancement of adjacent hepatic vein (6.5% vs 46.7%, P=0.001) were significantly different between HCC and FNH. Apparent diffusion coefficient (ADC) value was lower in HCC than in FNH (P=0.002). The signal distribution on hepatobiliary phase were significantly different between HCC and FNH (P=0.0002): homogenous hyperintensity (59.2% vs 73.3%), hyperintensity mixed with hypointensity (26.5% vs 0%), hyperintensity with peripheral hypointensity(14.3% vs 0%) and hyperintensity with central hypointensity (0% vs 26.7%).
Conclusion: For the differentiation between HCC with uptake of gadoxetic acid and FNH/FNH like nodule, presence of washout on dynamic CT, corona enhancement, ADC value, distribution of signal intensity on hepatobiliary phase would be important.

B-0199 15:12

T2 mapping and diffusion-weighted imaging of hepatocellular carcinoma: prediction of tumour histological grades

L. Cao, B. Song; *Chengdu/CN (clk2089@icloud.com)*

Purpose: To investigate and compare the diagnostic performance of T2 relaxation time value and apparent diffusion coefficient (ADC) for non-invasive preoperative prediction of the histological grade of hepatocellular carcinoma (HCC).
Methods and Materials: The study consisted of 30 patients with surgically resected HCCs who underwent preoperative MRI exams including DWI and T2 mapping which was acquired using T2-prepared TrueFISP sequence. T2 values and ADC were measured and averaged over ROIs placed in HCC solid regions on T2 mapping and ADC map, respectively. ANOVA was used to evaluate the statistical difference of the mean T2 value and ADC among three histological grades, and the diagnostic performance of T2 value and ADC was

also evaluated and compared using receiver operating characteristic-based positive test. The sensitivity, specificity, and accuracy were calculated.
Results: The mean T2 values of poorly differentiated (Edmondson grade III and IV), moderately differentiated (Edmondson grade II) and well-differentiated HCC (Edmondson grade I) were (38.4±2.40) ms, (44.4±3.0) ms and (49.6±3.9) ms, respectively, and there were differences in statistical meaning among them. The sensitivity, specificity, and accuracy, when an ADC of 0.972 or higher was considered as an indicator of well-differentiated tumours, were 73.1%, 72.9%, and 0.729, respectively, while when T2 = 41.85ms, the sensitivity, specificity, and accuracy were 81.3%, 68.4%, and 0.706. Using both methods, the AUC was elevated to 89.6%.
Conclusion: Higher tumour T2 in combination with higher ADC is a potential biomarker in the prediction of histological grades before treatment.

B-0200 15:20

Prediction of pathological differentiation for hepatocellular carcinoma: preoperative Gd-EOB-DTPA-enhanced MRI and histopathological correlation
K. Huang; *Guiyang/CN*

Purpose: Our aim of the study is to investigate the feasibility of prediction for pathological differentiation of hepatocellular carcinoma (HCC) using preoperative Gd-EOB-DTPA enhanced magnetic resonance imaging (MRI).
Methods and Materials: 91 patients with solitary HCC who underwent preoperative Gd-EOB-DTPA enhanced MRI were prospectively analyzed. Features including tumor size, signal homogeneity, tumor capsule, tumor margin, intratumoral vessels, peritumor enhancement in mid-arterial phase, peritumor hypointensity during hepatobiliary phase, apparent diffusion coefficient (ADC), T1 relaxation times and the reduction rate between pre- and post-contrast enhancement images were assessed. HCC pathological differentiation in excision specimens were evaluated using Edmanson criterions. Correlation between these MRI features and HCC pathological differentiation were analyzed by chi-square test and multivariate logistic regression so as to establish a prediction model. Receiver operating characteristic (ROC) curve was used to assess the predictive effectiveness for the model.
Results: Univariate analysis showed that tumor margin (p=0.007), intratumoral vessels (p=0.041), peritumoral low signal (p=0.017), maximum tumor diameter (p=0.014) significantly correlated with pathological differentiation. Those HCC lesions with the greater size, the more irregular margin, presence of intratumoral vessels and peritumoral low signal indicated high degree pathological differentiation. There was no relationship between venous thrombosis, tumor signal, tumor capsule, peritumoral enhancement, ADC value, T1 reduction ratio and pathological differentiation. Multivariate logistic regression analysis demonstrated that the maximum tumor diameter (p=0.007, OR=1.0019, 95% CI: 1.005~1.032) was an independent risk factor of HCC with poor differentiation.
Conclusion: Gd-EOB-DTPA contrast-enhanced MRI could noninvasively predict pathological differentiation of HCC before surgery.

Evaluation of hepatic warm ischaemia-reperfusion injury and intervention effect of Lipo-PGE1 in rabbit models: 3.0T BOLD MRI study
Q. Ji[1,2], Z.-Q. Chu[2], J.Y. Li[2]; [1]*Nanjing/CN*, [2]*Tianjin/CN (jiqianq@aliyun.com)*

Purpose: To investigate the diagnostic value of blood oxygen level-dependent (BOLD) MRI in the grade of hepatic warm ischaemia-reperfusion injury, and to evaluate the intervention effect of liposome-carried prostaglandins E1 (Lipo-PGE1) in rabbit models.
Methods and Materials: Seventy rabbits were randomly divided into sham-operation group, three test groups and three corresponding intervention groups (n=10 for each group) according to different hepatic warm ischaemia time. BOLD MRI was performed on a 3.0 T MR scanner with 9 TE (2.57 to 24.25 ms). Rabbits were sacrificed for biochemical and histomorphological analysis. In vivo R2* values of hepatic parenchyma were compared between different groups and matched with biochemical parameters.
Results: R2* values had excellent interobserver agreement with ICC of 0.805. There were significant differences of R2* values between all of groups, between sham-operation group and test groups, between sham-operation group and intervention groups, between test groups and corresponding intervention groups (P<0.05). With the prolonged of warm ischaemia time, R2* values showed a gradual increasing tendency; after the intervention of Lipo-PGE1, the reduction of R2* values was increasingly obvious. R2* values corresponded well with biochemical parameters (r>0.5, P<0.05).
Conclusion: BOLD MRI is a non-invasive and valuable technique in assessing the pathophysiologic changes of hepatic WIRI and relieved degree of Lipo-PGE1 in a rabbit model.

B-0202 14:08

Ultrasonic adaptive sound speed estimation for the diagnosis and quantification of hepatic steatosis
M. Dioguardi Burgio[1], M. Imbault[2], M. Ronot[1], A. Faccinetto[1], B. Van Beers[1], P.E. Rautou[1], L. Castera[1], M. Tanter[2], V. Vilgrain[1]; [1]*Clichy/FR*, [2]*Paris/FR (marco_dioguardi@hotmail.it)*

Purpose: to evaluate the ability of a new ultrasound (US) method based on Sound Speed Estimation (SSE) in detection, quantification, and grading of hepatic steatosis using magnetic resonance (MR) proton density fat fraction (PDFF) as reference standard and to calculate one US fat index based on the patient's SSE.
Methods and Materials: we consecutively included N=50 patients as study cohort and further N=50 as validation cohort who underwent both SSE and abdominal MR. Hepatic steatosis was classified according to MR-PDFF cutoffs as: S0 ≤6.5%, S1 from 6.5 to 16.5%, S2 from 16.5 to 22% and S3≥ 22%. Receiver operating curve analysis was performed to evaluate the diagnostic performance of SSE in diagnosis of steatosis. Based on the optimal data fit derived from our study, we proposed a correspondence between the MR-PDFF and an US fat index. Coefficient of determination R^2 was used to evaluate fit quality, and was considered as robust when R2 >0.6.
Results: study and validation cohort presented mean SSE value of 1.570±0.026 and 1.568±0.023 mm/µs for S0 and 1.521±0.031 and 1.514±0.019 mm/µs for S1-S3 (p<0.01) patients respectively. SSE threshold of ≤1.537 mm/µs had 80% sensitivity and 85.7% specificity in diagnosis of steatosis in the study cohort. Robust correspondence between MR-PDFF and the US fat index was found both for the study cohort (R2= 0.73) and the validation cohort (R^2= 0.76).
Conclusion: SSE can be used to detect, quantify and grade liver steatosis and to calculate an US fat index.

B-0203 14:16

Performance of a 2D-SWE method for predicting different stages of liver fibrosis, using transient elastography as the reference method
I. Sporea, F.B. Bende, A.S. Popescu, R. Sirli, M. Danila, S. Nistorescu, R. Fofiu, V. Baldea; *Timisoara/RO (isporea@umft.ro)*

Purpose: To evaluate the performance of 2D shear-wave elastography from General Electric(2D-SWE-GE), implemented on the LOGIQ S8 system, for the noninvasive assessment of liver fibrosis and to identify liver stiffness(LS) cut-off values for predicting different stages of fibrosis using Transient Elastography(TE) as reference.
Methods and Materials: We included 179 consecutive subjects with or without chronic hepatopathies in whom LS was evaluated in the same session by 2 elastographic techniques: TE(FibroScan, EchoSens) and 2D-SWE-GE(LOGIQ S8, GE Healthcare). Reliable LS measurements were defined for TE as the median value of 10 measurements with a success rate of ≥60% and an interquartile range/median ratio(IQR/M)<0.30 and for 2D-SWE-GE as the median value of 10 measurements acquired in a homogenous area and an IQR/M<0.30. To discriminate between TE fibrosis stages we used the following cut-offs: F2-7; F3-9.5 and F4-12 kPa.
Results: Reliable LS measurements were obtained in 97.2% subjects by 2D-SWE-GE, and 98.3% by TE(p=0.72). 171 subjects were included in the final analysis. Based on TE cut-off values we divided our cohort into four groups: F<2: 51(29.8%); F=2: 40(23.4%); F=3: 31(18.1%); F=4: 49(26.7%). A good positive correlation was found between the LS values obtained by the 2 methods: r=0.72, p<0.0001. The best 2D-SWE-GE cut-off value for F≥2 was 6.9 kPa(AUC 0.93, Sensitivity 85.8. Specificity 90.2), for F≥3 it was 8.2 kPa(AUC 0.93, Sensitivity 87.5, Specificity 86.8) and for F=4 it was 9.3 kPa(AUC 0.91, Sensitivity 85.7, Specificity 81.2).
Conclusion: The best 2D-SWE-GE(S8) cut-off values for predicting F≥2,F≥3 and F=4 were 6.9, 8.2 and 9.3 kPa.

Associations between liver fat, visceral fat and microalbuminuria in the general population

I. Dekkers, A. de Vries, A. de Roos, T. Rabelink, F.D. Rosendaal, H.J. Lamb, R. de Mutsert; *Leiden/NL (I.A.Dekkers@lumc.nl)*

Purpose: Abdominal obesity is an established risk factor for metabolic disorders. Our objective was to investigate the relative contributions of visceral adipose tissue (VAT) and hepatic triglyceride content (HTGC) to microalbuminuria in a middle-aged population.
Methods and Materials: In this cross-sectional analysis, VAT was assessed by magnetic resonance imaging, and HTGC by proton spectroscopy. Microalbuminuria was defined as urinary albumin-creatinine ratio ≥2.5/3.5 mg/mmol in men/women. With logistic regression we calculated odds ratios (OR) of microalbuminuria, adjusted for age, sex, ethnicity, education, smoking, alcohol consumption, total body fat, hormonal status in women, and stratified by sex and the patatin-like phospholipase domain-containing (PNPLA3) gene.
Results: Of the 2,023 participants 53% were women, 39% carried a PNPLA3-risk allele, 29% had fatty liver (HTGC>5.56%), and 2% microalbuminuria. In adjusted models, VAT was associated with a two-fold increased risk of microalbuminuria (per SD=55.4 cm^2, OR: 2.16, 95% CI: 1.29, 3.62). Per SD HTGC (7.9%) the OR of microalbuminuria was 1.34 (95% CI: 1.02, 1.77). In joint models, the OR of microalbuminuria per SD VAT was 2.02 (1.18, 3.47), and per SD HTGC it was 1.20 (0.85, 1.70). Associations of VAT, but not HTGC, were stronger in women and in non-carriers of the PNPLA3-risk allele.
Conclusion: Both liver fat and visceral fat were associated with microalbuminuria. In joint models VAT was more strongly associated with microalbuminuria than HTGC fat and may, therefore, be more important in the development of microalbuminuria. Prospective analyses need to study associations of VAT, fatty liver and the development of chronic kidney disease.

B-0205 14:32

Use of 2D shear-wave elastography in predicting different stages of liver fibrosis according to METAVIR scoring system: a histopathological correlation study

M. Aksakal, S. Ozhan Oktar, G. Esendaglı Yılmaz, S. Özenirler, M. Cindoruk, K. Hızel, F.N. Baran Aksakal, C. Yucel; *Ankara/TR (mehmetaksakalmd@gmail.com)*

Purpose: In this study, we investigated accuracy of 2D shear-wave elastography (2D SWE) in detecting liver fibrosis by using histopathological analysis as the reference method.
Methods and Materials: Our single-center prospective study included 53 consecutive adult patients who had liver biopsy within 14 months of elastographic examination. A real time SD SWE evaluation was performed using LOGIQ E9 system (GE Medical Systems, Wisconsin, USA). The median of 10 valid liver stiffness measurements in kPa for each patient were obtained and were compared with the METAVIR scores obtained from the liver biopsy, using Kendall's rank correlation test. The diagnostic performance of real time 2D SWE was assessed and cut-off values were set by ROC curve analysis.
Results: A significant correlation was found between liver stiffness kPa values and degree of liver fibrosis (Kendall's tau=0.53, p=0.0001). AUROCs were 0.97 (95% confidence interval:0.93-1; SD: 0.02) (p= 0.0001) and 0.98 (95% confidence interval:0.95-1, SD: 0.14) (p= 0.0001) when comparing F0-1 versus F2-3-4 and F0-1-2 versus F 3-4, respectively. When we compare F0-1 versus F2-3-4 and F0-1-2 versus F 3-4 groups, optimal cut-off values were determined as 6.5 kPa (sensitivity:%100, specificity %84) and 8.8 kPa (sensitivity:%83, specificity %92), respectively.
Conclusion: Our findings suggest that 2D-SWE can be used for the assessment of liver fibrosis, especially in identifying patients with no or minimum/mild fibrosis and those with severe fibrosis. Studies on larger groups of biopsied patients are required in order to establish the most appropriate cut-off values for each particular stage of liver fibrosis.

B-0206 14:40

Preliminary exploration of the application of super microvascular imaging in focal liver lesions

H. Meng-Na, T.-A. Jiang; *Hangzhou/CN (monahe@163.com)*

Purpose: To explore the ability of super microvascular imaging (SMI) to differentiate diagnose focal liver lesions.
Methods and Materials: 31 FLLs consisted of haemangioma (HE) (*n* = 17), hepatocellular carcinoma (HCC) (*n* = 5), metastatic lesions (*n* = 5), primary hepatic lymphoma (n = 1), focal nodular hyperplasia (FNH) (*n* = 2) and adenoma (*n* = 1). 9 lesions were pathologically diagnosed and 22 lesions were radiological confirmed. All patients had been done SMI. The patients were divided into subgroups based on the diagnostic results to analyse the SMI manifestations. We also compared the SMI manifestations between the most common FLLs of HCCs, metastatic lesions and HEs.
Results: The HEs were described as three SMI subgroups: diffuse dot-like type (*n* = 6); strip rim type (*n* = 8); nodular rim type (*n* = 3), the size of the three groups were obviously different (*P*=0.00,<0.05); The HCCs were described as two subgroup: diffuse honeycomb type (*n* = 2); non-specific type (*n* = 3). Four of the metastatic lesions were like strip rim type of HE; the other one shared the same type of thick rim type with lymphoma. The FNH was described as spoke-wheel type and the adenoma was diffuse honeycomb type. The SMI types were significantly different between HCCs and metastatic lesions with HEs (*P*=0.048, <0.05).
Conclusion: SMI technology made the evaluation of micro-vascular of focal liver lesions possible without any enhanced agents. SMI had the potential to add useful information to differential diagnosis between HCCs and metastatic lesions with HEs.

B-0207 14:48

Intraoperative shear wave elastography for assessment and staging of liver fibrosis and cirrhosis during open liver tumour surgery in correlation with histopathology: first results

N. Platz Batista da Silva, L.P. Beyer, M. Hornung, S. Brunner, H.J. Schlitt, P. Wiggermann, E.-M. Jung; *Regensburg/DE (natascha.platz-batista-da-silva@klinik.uni-regensburg.de)*

Purpose: Evaluation of feasibilty of intraoperative shear wave elastography (SWE) for quantitative assessment and staging of liver fibrosis/cirrhosis during liver tumour surgery in correlation with histopathology after partial liver resection.
Methods and Materials: Retrospective analysis of intraoperative ultrasound (IOUS) data of 103 patients was performed who underwent liver tumour surgery between 08/2015-07/2017. IOUS was performed by one experienced examiner using multifrequency linear/T-shaped probes from 6-9MHz on the freely mobilized liver. SWE images of parenchyma were stored for assessment of shear wave speed (SWS,m/s) and stiffness (kPa). Five ROIs were placed each to measure SWS/stiffness out of which a mean value was calculated. Findings were correlated to histopathology after partial liver resection. For histopathological staging of liver fibrosis/cirrhosis Ishak score (F0-F6) was used. Statistical analysis was performed using ROC analysis.
Results: 103 patients (M:66, F:37) aged 29-87 years (mean 60y, sd±11,8) were included. Postoperative histopathology showed no fibrosis in 52, F1-4 fibrosis in 30, (in)complete cirrhosis (F5-6) in 21 cases. Patients without fibrosis showed a mean of 2.69m/s(1.5-3.8m/s)/19.9kPa(4.6-45.9kPa). In patients with fibrosis (F1-F4) mean was 2.85m/s(1.8-3.96m/s)/ 26.91kPa(3.7-53.1kPa). Patients with cirrhosis presented a mean of 3m/s(1.8-4.3m/s)/29.03kPa(11.7-66.7kPa). By ROC analysis a cut-off of 2.46m/s/20.4kPa was calculated for diagnosis of relevant fibrosis/cirrhosis (≥F3). $Sensitivity_{SWS}$ was 94%, specificity 54.3%, accuracy 67%, NPV95%, PPV49.2% (AUC 0.745,95%CI:0.6482-0.8419). $Sensitivity_{Stiffness}$ was 94%, specificity 57.4%, accuracy 69.3%, NPV95.1%, PPV51.7% (AUC 0.7643,95%CI:0.6706-0.8579).
Conclusion: Intraoperative SWE enables staging of liver fibrosis/cirrhosis during liver surgery. Stiffness measurements were superior to SWS. Thereby surgical extent could be adapted individually to prevent postoperative hepatic insufficiency.

B-0208 14:56

Intraoperative CEUS for localisation and characterisation of liver lesions during open liver tumour surgery: a single centre's 7 years experience

N. Platz Batista da Silva, M. Hornung, S. Brunner, C. Hackl, H.J. Schlitt, C. Stroszczynski, E.-M. Jung; *Regensburg/DE (natascha.platz-batista-da-silva@klinik.uni-regensburg.de)*

Purpose: To evaluate the accuracy of intraoperative contrast-enhanced ultrasound (IoCEUS) for localization, characterization and differentation of focal liver lesions (FLL) during liver tumor surgery in correlation with postoperative histopathological results.
Methods and Materials: A retrospective analysis of IoCEUS of 166 patients with 202 liver lesions was performed who underwent liver tumor surgery between 10/2010-07/2017. IoCEUS was conducted by one experienced examiner on the freely mobilized liver using multifrequency linear/T-shaped probes (6-9 MHz) after i.v.-application of 2.4-10 ml sulphurhexaflouride microbubbles. FLL were characterized dynamically during arterial (15-45s), portal venous (45-90s) and late venous phase (2-5min). An irregular hypervascularization during arterial phase and/or increasing wash out from portal venous to late phase were considered signs of malignancy. Findings of IoCEUS were correlated to postoperative histopathological findings after partial liver resection or biopsy. Statistical analysis was performed using cross-tables, chi-square- and fisher's exact test with p<0.05 as level of significance.
Results: IoCEUS data of 166 patients with 202 FLL (m:104, f:62) aged between 2-81 years (mean 60.5y, sd±12.2y) were retrospectively analyzed. FLLs' size ranged from 0.1-8.88cm (mean 2.51cm, sd±1.44cm). Postoperative histopathology showed 183 malignant and 19 benign FLL. IoCEUS could correctly characterize 180/183 malignant and 15/19 benign FLL. Four benign lesions were mistaken for malignant by IoCEUS, 3 malignant lesions for

benign. Sensitivity was 98.4%, specificity 79%, accuracy 96.5%, PPV 97.8%, NPV 83.3% (p<0.0001).
Conclusion: Intraoperative CEUS is a highly valuable tool for localization and characterization of preoperatively known or unknown FLL during open liver surgery and should be used routinely.

B-0209 15:04

How safe are percutanous liver biopsy procedures? Complication rate and seeding risk in an oncological setting

K.N. De Paepe[1], L. Bonne[2], E. Raimondi[3], N. Fotiadis[1], D.-M. Koh[1], N. Starling[1], I. Chau[1], G. Brown[4], D. Cunningham[1]; [1]*London/UK*, [2]*Leuven/BE*, [3]*Ferrara/IT*, [4]*Sutton/UK (katjadepaepe@gmail.com)*

Purpose: Percutaneous biopsy of liver metastases is common practice in the setting of oncological clinical trials, where it serves as a relatively non-invasive method to obtain sufficient tissue for genetic analyses. Complications can occur, including seeding of the tumour along the biopsy track; however, literature on the incidence of seeding is scarce. The aim of this study was to evaluate the technique's safety.
Methods and Materials: Patients with ultrasound or CT-guided liver biopsy between 2012 and 2016 were included. Medical records were reviewed retrospectively for post-biopsy complications and all follow-up imaging was re-assessed for the presence of seeding, defined as tumoural deposits in the biopsy needle track.
Results: In 550 patients (282 women, 268 men; mean age of 61y), 782 biopsies were performed, 43.9% (343/782) for trials and 56.1% (439/782) for diagnostic purposes. 93.7% (733/782) were diagnostic, revealing malignancy in 96.9% (710/733). Patients had 1 (n=387) to 7 (n=1) biopsies; a co-axial system was used in 70.6% (552/782) and multiple passes in 29.4% (230/782). Complication rate was 8.8% (69/782), namely pain (4.7%) and vasovagal reaction (2.3%). Less frequent severe complications were bleeding (1.0%), sepsis/fever (1.1%), pulmonary embolism (0.3%) and pneumothorax (0.4%). Seeding rate was 1.1% (8/782) [2/44 melanoma, 1/9 GIST, 1/39 cholangiocarcinoma, 1/248 colorectal, 1/14 oesophagus, 1/97 breast, 1/31 prostate], mean seeding time was 208 days, mean post-biopsy survival time was 495 days and 349 days in the seeding and non-seeding groups, respectively.
Conclusion: Percutaneous liver biopsy is an effective and safe method for tissue collection, with a minimal risk of seeding.

B-0210 15:12

Role of interventional radiology in the scope of liver transplantation

M. Pitton, F. Becker, S. Schotten, R. Kloeckner, T. Zimmermann, J. Mittler, P.R. Galle, G. Otto, C. Düber; *Mainz/DE (michael.pitton@unimedizin-mainz.de)*

Purpose: To analyse the role of interventional radiology (IR) in the complex scenario of liver transplantation (LTx).
Methods and Materials: Patients with history of liver transplantation (LTx) were analysed for number and type of interventional procedures in the scope of liver transplantation. The institutional data base was searched for all interventional procedures during the time on waiting list, in the perioperative phase, and during follow-up after LTx. All interventional procedures were categorised in image-guided punctures (e.g. biopsies, drainages), local tumour treatment (e.g. ablations, TACE, SIRT), biliary interventions (e.g. in ischaemic or ischaemic type biliary lesions [IBL/ITBL]), vascular interventions (portal, venous, arterial recanalisation or embolisation), TIPS, and others. The numbers and time point during the patient´s course were analysed.
Results: 815 patients who received liver transplantation between 1996 and 2016 were included. 24.4% of patients had no interventions at all. 44.7% of patients received interventions during time on the waiting-list (in 20.4% <=3 procedures per patient, in 24.3% >3 procedures per patient, e.g. TACE etc). 23 patients (2.8%) received procedures within the perioperative phase (<= 3 days after LTx). During 30d-Follow-up, a total of 60% of patients received some IR-procedures: 56.4% <= 3 per patient (28.7% only one per patient). However, 3.6% of patients received >3 procedures per patient (range 4-8).
Conclusion: Interventional procedures are an integral part in the scenario of liver transplantation and cover the whole scope of IR, particularly TIPS and local tumour treatment before LTx, peri-/postoperative vascular issues, as well as biliary interventions in IBL/ITBL during follow-up.

B-0211 15:20

Transient elastography (TE), shear wave elastography (SWE) and magnetic resonance elastography (MRE) for fibrosis assessment in chronic viral hepatitis: preliminary data

L. Cevasco, S. Perugin Bernardi, L. Bacigalupo, F. Paparo, M. De Cesari, G. Siri, G. Cenderello, V.M. Pinto, G.A. Rollandi; *Genoa/IT (dott.luca.cevasco@gmail.com)*

Purpose: Verify if TE, SWE and MRE obtain comparable results in the measurement of fibrosis in patients affected by chronic viral hepatitis.
Methods and Materials: We have evaluated 30 consecutive patients (of 100 expected) affected by HCV or co-infected by HCV+HIV. Acquisition of TE, SWE and MRE was performed the same day. Interdisciplinary consensus reference, performed by a panel of experts, determined the real fibrosis stage of each patient, taking into consideration clinical and laboratory features, serum biomarkers of fibrosis and a comprehensive assessment of all non-invasive stiffness imaging methods. Weighted kappa (with Landis & Koch categorization), Bland-Altman plot and Pearson correlation were adopted.
Results: All the techniques, compared independently with the interdisciplinary consensus reference, showed substantial agreement (at least 64%). In particular the agreement resulted almost perfect (93%) in case of MRE. Comparing the techniques with each other the agreement resulted at least moderate (46%) and, in the case of TE vs. MRE, substantial (66%). BMI (Pearson: 38.3%, p=0.028) and Dual-Dixon-Fat-Fraction (48.6%, 0.008) were positively correlated with a higher difference among values. Bland-Altman plot showed that the mean difference between obtained METAVIR scores ranged from a minimum of 0.0, 95%CI (-1.0; 1.0) MRE vs SWE, to a maximum of 0.1, 95%CI (-0.7; 0.8) fibroscan vs. MRE.
Conclusion: The preliminary data showed that TE, MRE and SWE obtain comparable results in the measurement of fibrosis in patients affected by chronic viral hepatitis. MRE showed the best agreement with our consensus reference. These data must be confirmed at completion of enrollment.

Association of non-alcoholic fatty liver disease with increased carotid intima-media thickness considering other cardiovascular risk factors

A. Mohammadzadeh, M. Mohammadzadeh, V. Shahkarami, M. Shakiba, P. Sabetrasekh; *Tehran/IR (psrpsr82@gmail.com)*

Purpose: Non alcoholic fatty liver disease (NAFLD) is the most common liver disease (%6-35) while associated with cardiovascular risk factors and metabolic syndrome (age, diabetes, hyperlipidemia , hypertension and smoking). Here, we want to evaluate association of increased carotid intima-media thickness with NAFLD considering other cardiovascular risk factors to see if NAFLD is independently associated with increased carotid IMT.
Methods and Materials: Totally 300 patients [150 NAFLD - 150 normal] referred to 4 academic hospitals were enrolled. Patients with history of alcohol use, hepatitis, HIV, chemotherapy and other organ failures were excluded. A single radiologist performed abdominal sonographies[3-5MHz probe] and carotid sonography[7.5 MHz probe](measuring posterior wall of both common carotids and calculating mean value). NAFLD was diagnosed based on sonographic findings in absence of acute or chronic liver and kidney diseases and malignancies.
Results: Mean age was 51.2±14.8[20-97] and 184[%61.3] were male. Mean IMT was greater in patients with diabetes, hypertension, hyperlipidemia and NAFLD[all Ps<0.001] and these variables with age were statistically significant in univariate models for estimating IMT. Among NAFLD patients, 38[%25.3] had increased IMT [unilateral or bilateral;considering 0.8 as cutoff point] while this frequency was 8 [%5.3] among normal subjects [P<0.001, odds ratio=6, 95%CI=2.7-13.4].In multivariate regression models[IMT as dependent variable], NAFLD, age and HLP were independent significant variables in linear model[R^2=0.41] and NAFLD showed highest odds ratio[16.4] among significant variables[age, BMI,NAFLD and HLP] in logistic model
Conclusion: Increase carotid IMT is highly associated with NAFLD independent of other cardiovascular risk factors and should be considered in these patients.

B-0213 14:08

Carotid intima-media thickness (CIMT) as a window to atherosclerosis

D.J. Petrovic; *Belgrade/RS (dusanpetrovic736@gmail.com)*

Purpose: The objective of the survey was to establish the relation between the carotid intima-media thickening (CIMT) and the coronary artery disease (CAD) among the patients tested by coronary angiography due to suspecting the coronary artery disease.

Methods and Materials: Eighty respondents with angiography-diagnosed coronary disease (40 men and 40 women varying between the age of 30 and 80) were tested by the ultra-sound Doppler angiography and compared to the identical number of healthy respondents of the same gender and age structure and without risk factors in terms of the coronary disease.
Results: Statistically, the thickness of CIMT is significantly higher for the respondents of both sexes with the presence of CAD ($p< 0.01$). The respondents with the multi-vessel coronary disease have significantly higher CIMT than the respondents with the one-vessel or two-vessel coronary disease ($p< 0.05$). Statistically, the cross-sectional surface area of the a. carotis communis (CSA) is significantly larger among the respondents with CAD in comparison with the control group.
Conclusion: The evaluation of CIMT is a reliable parameter for detecting the degree of vascular remodelling in the process of arteriosclerosis (pre-atherosclerosis or subclinical atherosclerosis) while changes on coronary and carotid arteries correlate to a high degree. Carotid duplex ultrasonography can be used as an important screening method owing to several advantages such as ease of use, reproducibility, no radiation exposure, and high correlation with atherosclerosis. Early diagnosis of carotid artery disease is of utmost importance, and ultrasound plays a pivotal role therein.

B-0214 14:16

Development and validation of a pathlength calculation for carotid-femoral pulse wave velocity

M. Bonnici-Mallia, J. Weir-McCall, L. Brown, J. Summersgill, P. Talarczyk, S. Chin, F. khan, A.D. Struthers, G. Houston; *Dundee/UK (mbonnicimallia@nhs.net)*

Purpose: Carotid-femoral Pulse Wave Velocity (PWV) is the gold standard for measuring arterial stiffness and is predictive of future cardiovascular events. The purpose of this study was to generate a formula from easily obtainable clinical metrics in order to determine the carotid-femoral pathlength component of PWV calculation.
Methods and Materials: 1183 participants, free from cardiovascular disease, underwent whole-body MRI (WBMRI) as part of the TASCFORCE study. Distance between carotid and femoral vessels was obtained by tracing the arterial centreline from the bifurcation of the common carotid to that of the common femoral artery. A backward linear regression model was used to generate a formula for calculating pathlengths based on age, sex, heart rate, height and weight. This calculation was then validated in an external cohort of 128 participants from the SUMMIT study who had also undergone WBMRI.
Results: Applied within the TASCFORCE cohort, the formula provided moderate agreement with true distance ($r=0.59$, $p<0.001$), with a mean difference of 0.04mm (limits of agreement=-55.5-56.3mm, $p=0.96$ for difference). Compared with the measured arterial pathlength on MRI in the SUMMIT cohort, there was a small underestimation of the pathlength distance by the formula with a mean difference of 10.1mm (limits of agreement=-39-59mm), $p<0.001$, and a moderate correlation between the two measures ($r=0.61$, $p<0.001$).
Conclusion: Using simple allometric measures, arterial pathlength for PWV can be calculated with less variability and greater accuracy than current body surface techniques, holding promise for improving interstudy and intercentre reproducibility, thus expanding the utility of PWV calculation in clinical practice.

Lumen dynamics of spontaneous arteries dissection

M. Dreval, L. Kalashnikova, M. Krotenkova, L. Dobrynina; *Moscow/RU (dreval-marina83@yandex.ru)*

Purpose: To estimate the possibility of recanalization of internal carotid (ICA) and vertebral arteries (VA) with spontaneous dissection treated with conservative management
Methods and Materials: The study included 46 patients (46% males, mean age 36,83±7,61 years) with artery dissection manifested by ischaemic stroke or isolated head or neck pain. MRI was performed on 1.5 T scanner. Data of 3D-TOFMRA of the cervical arteries and T1fat-sat of the neck were obtained. The examinations were carried out twice: in the course of the first two weeks and after two months. The size of an internal lumen at the level of dissection and at the level of unchanged artery were measured, degree of the stenosis was evaluated
Results: At the 1st study lumen stenosis of ICA was revealed in 60% of cases, lumen stenosis of VA in 90% (35), occlusion in 40% (10) and 5% (2), respectively. The mean stenosis degree was 45% for ICAD and 50% for VA. MRI Follow-up study showed that in patients with initial stenosis lumen diameter of dissected arteries increased with the time in all cases. In patients with initial luminal occlusion due to dissection recanalization of VA occurred in 50%, spontaneous recanalization of ICA - in 40%. Residual stenosis in all cases was haemodynamically insignificant (20-25%).
Conclusion: Cervical arteries dissection is a dynamic process, stenosis is completely or partially resolved in all cases in two months. In contrast, occlusions are resolved in less than a half of cases and the residual stenosis is considered haemodynamically insignificant.

B-0216 14:32

Relationship between ICA geometry and plaque composition

G. Corrias[1], M. Porcu[2], M. Laino[3], L. Saba[1], A. Mereu[1]; [1]*Monserrato/IT*, [2]*Cagliari/IT*, [3]*Rome/IT (ale.mereu7@studenti.unica.it)*

Purpose: The aim of our study is to demonstrate whether there is a relationship between the geometry of the ICA and atherosclerotic plaque composition in terms of fat, mixed, calcific plaque and volume.
Methods and Materials: This is a prospective single institution pilot study enrolling 55 patients, for a total of 110 carotids, who were scheduled to perform a MDCTA of the supra-aortic vessels. The institutional review board approval for this study was obtained. Plaque composition was quantified either as absolute volume or as percentage of each different component to the total plaque. Associations between ICA curvature and plaque development were statistically investigated. The variables relationship was calculated using correlation coefficient r.
Results: There is a strong correlation between ICA curvature and the volume of each plaque component in absolute values. Fat plaque volume and curvature correlation coefficient r: 0.3390 (significance level p: 0.0006). Fibrous plaque volume and curvature correlation coefficient r: 0.2295 (significance level p: 0.0217). Calcium plaque volume and curvature correlation coefficient r: 0.2820 (significance level p: 0.0045).
Conclusion: We have found a strong correlation between the ICA curvature and the presence of a plaque in the proximal tract of ICA, of any composition. The bigger the curvature value, the highest is the probability to find a plaque, in terms of absolute volume representation. In particular, analysing the percentage of the plaque composition we have found that the higher the curvature value, the bigger the probability to find a plaque composed with mostly fat (with a significancy level $p= 0.0027$).

B-0217 14:40

Are there any differences in radiation-induced and non-radiation-induced carotid atherosclerosis?

T.-C.M. Ying[1], Y. Li[1], W.C.V. Wu[1], C. Yuan[2], L.W.D. Kwong[1], S.P. Yip[1], K.W.H. Law[1], W.Y.S. Lee[1]; [1]*Hong Kong/HK*, [2]*Hunan/CN (htmying@polyu.edu.hk)*

Purpose: Carotid atherosclerosis is common in both post-radiotherapy (RT) nasopharyngeal carcinoma (NPC) patients and individuals with cardiovascular risk factors (CVRF). This study aimed to use ultrasound to investigate the differences in radiation-induced and non-radiation-induced carotid atherosclerosis with focus on the number of carotid plaque, carotid intima-media thickness (IMT) and plaque echogenicity.
Methods and Materials: Carotid ultrasound was performed on 20 post-RT NPC patients and 20 CVRF subjects. In each patient/subject, the IMT of common carotid arteries was measured. The common, internal and external carotid arteries were examined, and the number of carotid plaque detected was recorded. Ultrasound images of carotid plaques were analysed with a computer software to quantify the plaque echogenicity which was expressed as grey scale median (GSMedian) and mean (GSMean).
Results: Post-RT NPC patients (0.78±0.24mm) had significantly larger carotid IMT than CVRF subjects (0.69±0.16mm) ($p<0.05$). Carotid plaques were more commonly found in post-RT NPC patients (n=48) than CVRF subjects (n=36). Carotid plaques in post-RT NPC patients (31.1±11.8 and 35.3±12.5 respectively) had significantly lower GSMedian and GSMean than those in CVRF subjects (39.5±16.2 and 43.6±17.2 respectively) ($p<0.05$).
Conclusion: Radiation-induced carotid atherosclerosis tended to be more severe than non-radiation-induced carotid atherosclerosis as evidenced by larger carotid IMT and higher incidence of plaque formation in post-RT NPC patients. When compared to CVRF subjects, carotid plaques in post-RT NPC patients were more hypoechoic as evidenced by the lower GSMedian and GSMean, and thus were relatively more unstable leading to higher risk of cerebrovascular diseases.

B-0218 14:48

Carotid IMT and haemodynamic indices in evaluation of atherosclerosis in hypertensives

S.F. Kenis; *Zaria/NG (shedrackkenis@yahoo.com)*

Purpose: To evaluate carotid intima media thickness and haemodynamic indices as sonographic markers of atherosclerosis in a resource limited environment.
Methods and Materials: The study involved 130 hypertensive patients and 130 age-matched controls. All underwent carotid Doppler examination using

Mindray DC-8 ultrasound machine. Blood samples were taken after an overnight fast for lipid profile and blood sugar (FBS). The Framingham risk score (FRS) was calculated from patients' information. The data was analysed using SPSS version 20.0, and T-test was used to assess the difference between variables. Pearson correlation was used to determine correlation between duplex finding and FRS. p<0.05 was considered statistically significant.
Results: The mean age of the hypertensive patients was 50.20 ± 10.30years, and the mean age for control is 49.39 ± 9.89 years. The mean carotid intima-media thickness (CIMT) was significantly higher in hypertensives compared to control. Common carotidartery (CCA) pulsatility index (PI), CCA resistive index (RI), internal carotid (ICA) PI and ICARI were not significantly different between hypertensive patients and control. It was observed that the value of carotid haemodynamic indices increases with increasing age in the hypertensive, but the relationship of increasing age and haemodynamic indices was less clearly demonstrated in the control. There was a strong correlation between CIMT and FRS in the hypertensives and only in the ICA was there a moderate to weak correlation between haemodynamic parameters and FRS.
Conclusion: CIMT appears to be the best sonographic marker of atherosclerosis. Though carotid haemodynamic indices correlate less clearly than CIMT, there appears to be a gradual increase in the carotid haemodynamics with age, particularly in the hypertensives.

B-0219 14:56

Magnetic resonance imaging-based assessment of carotid atheroma: a comparative study of patients with and without coronary artery disease
A. Usman, U. Sadat, Z. Teng, M. Graves, J. Boyle, J. Gillard; *Cambridge/UK (ammara.usman2013@gmail.com)*

Purpose: Functional magnetic resonance (MR) imaging of atheroma using contrast media enables assessment of the systemic severity of atherosclerosis in different arterial beds. Whether black-blood imaging has similar ability remains widely unexplored. In this study, we evaluate whether black-blood imaging can differentiate carotid plaques of patients with and without coronary artery disease (CAD) in terms of morphological and biomechanical features of plaque vulnerability, thereby allowing assessment of the systemic severity nature of atherosclerosis in different arterial beds.
Methods and Materials: Forty-one patients with CAD and 59 patients without CAD underwent carotid black-blood MR imaging. Plaque components were segmented to identify large lipid core (LC), ruptured fibrous cap (FC), and plaque haemorrhage (PH). These segmented contours of plaque components were used to quantify maximum structural biomechanical stress.
Results: Patients with CAD and without CAD had comparable demographics and comorbidities. Both groups had comparable prevalence of morphological features of plaque vulnerability (FC rupture, 44% versus 41%, P = .90; PH, 58% versus 47%, P = .78; large LC, 32% versus 47%, P = .17), respectively. The maximum biomechanical stress was not significantly different for both groups (241 versus 278 kPa, P = .14) respectively.
Conclusion: Black-blood imaging does not appear to have the ability to differentiate between the morphological and biomechanical features of plaque vulnerability when comparing patients with and without symptomatic atherosclerotic disease in a distant arterial territory such as coronary artery.

B-0220 15:04

DCE-MRI demonstrates less microvasculature in symptomatic carotid atherosclerosis
G.A.J.C. Crombag[1], R. van Hoof[1], F.H. Schreuder[2], R.J. van der Geest[3], W.H. Mess[1], R. van Oostenbrugge[1], P.A. Hofman[1], J.E. Wildberger[1], M. Kooi[1]; [1]*Maastricht/NL*, [2]*Nijmegen/NL*, [3]*Leiden/NL (g.crombag@maastrichtuniversity.nl)*

Purpose: Rupture of a vulnerable carotid atherosclerotic plaque is an important underlying cause of stroke. Increased leaky plaque microvasculature may contribute to plaque vulnerability. These immature microvessels may facilitate the entrance of inflammatory cells into the plaque. As dynamic contrast-enhanced (DCE) magnetic resonance (MR) imaging is a non-invasive method to study leaky plaque microvasculature, we investigated the difference in plaque microvasculature between the symptomatic and contralateral asymptomatic carotid plaque.
Methods and Materials: 88 symptomatic patients with >2mm carotid plaque underwent 3T MRI (including DCE-MRI) to identify the presence of a lipid-rich necrotic core (LRNC) and to assess plaque microvasculature. K^{trans} was calculated for the entire symptomatic and contralateral asymptomatic plaque, using a pharmacokinetic model (Patlak model). K^{trans} represents the contrast medium transfer rate from the microvasculature to the extracellular space. The presence of an LRNC was assessed on the post-contrast black-blood T1W MR images. Differences in K^{trans} between the symptomatic and asymptomatic side were assessed using a paired samples *T* test. Independent samples *T* test was used to compare the means between plaques with and without LRNC.
Results: A significantly lower K^{trans} was found in the symptomatic carotid plaque compared to the asymptomatic side (0.062±0.0017 min^{-1} versus 0.057±0.0020 min^{-1}, p=0.033). Furthermore, there was a significant lower K^{trans} in plaques with an LRNC (0.061±0.017 min^{-1} versus 0.054±0.014 min^{-1}, p=0.041).
Conclusion: Unexpectedly, the symptomatic carotid plaques had a significantly lower K^{trans}, indicative of a decrease of leaky plaque microvasculature in symptomatic plaques. This may be related to a larger amount of necrotic tissue in symptomatic plaques.

B-0221 15:12

New 3D-arterial analysis software to evaluate carotid atherosclerotic plaque in comparison with CEUS, CTA and histological examination
V. De Soccio[1], V. Cantisani[1], M. Di Segni[1,2], N. Di Leo[1], A. Rubini[1], V. Forte[1], D. Fresilli[1], F. D'Ambrosio[1], C. Catalano[1]; [1]*Rome/IT*, [2]*Civitavecchia/IT (valerio.forte@gmail.com)*

Purpose: To assess the accuracy of ultrasonographic 3D-Arterial Analysis in characterizing stenosis percentage and vulnerability of carotid plaques.
Methods and Materials: Sixty seven patients were enrolled with the following criteria: (1) asymptomatic stenosis of carotid artery &gt70% but &lt100%; or (2) recent transient ischemic attack or ischemic stroke, and ipsilateral carotid stenosis &gt50%. Eventually all patients underwent endarterectomy and samples were histologically assessed for instability features. 3D-Arterial Analysis provided a colour map to evaluate plaque vulnerability and a 3D volumetric stenosis evaluation. Its diagnostic performance has been compared to histological examination for plaque's vulnerability and to CEUS and CTA for stenosis' grading.
Results: Histological examination identified 47 vulnerable plaques with at least one of the following criteria: fibrous cap &lt200 µm, presence of lipid core, intra-plaque haemorrhage, leukocyte recruitment or angiogenesis. 3D-Arterial Analysis software, CEUS and CTA were able to detect 42, 41 and 41 of these 47 vulnerable plaques respectively, with 89%, 87% and 87% sensitivity and 100% specificity. 3D-Arterial Analysis software and CEUS were able to evaluate stenosis percentage with 88% sensitivity and 100% specificity compared to CTA, identifying 59/60 severe stenosis.
Conclusion: 3D-Arterial Analysis software and CEUS seem effective tools to assess plaque's vulnerability and stenosis severity, providing useful information for surgery planning.

MR imaging shows an inverse association between the microvasculature and intraplaque haemorrhage in atherosclerotic carotid lesions
G.A.J.C. Crombag[1], R. van Hoof[1], S. Heeneman[1], P. Nederkoorn[2], W.H. Mess[1], R. van Oostenbrugge[1], M.J. Daemen[2], J.E. Wildberger[1], M. Kooi[1]; [1]*Maastricht/NL*, [2]*Amsterdam/NL (g.crombag@maastrichtuniversity.nl)*

Purpose: Rupture of a vulnerable atherosclerotic plaque is an important cause of clinical ischaemic events. The presence of intraplaque haemorrhage (IPH) is associated with plaque rupture and plaque progression, and predicts cerebrovascular events. However, the underlying mechanisms contributing to IPH are not fully understood. The dominant view is that IPH is caused by leakage of erythrocytes from immature microvessels. Alternatively, it has been suggested that plaque rupture/fissures are important in the development of IPH. The goal of this study was to investigate the association between leaky atherosclerotic plaque microvasculature and the presence of IPH in a large prospective cohort study of patients with symptomatic carotid plaques.
Methods and Materials: 101 symptomatic patients underwent MRI of the symptomatic carotid plaque for detection of IPH and dynamic contrast-enhanced (DCE)-MRI for assessment of plaque microvasculature. K^{trans}, an indicator of microvascular flow, density and leakiness, was estimated using pharmacokinetic modeling. Statistical analysis was performed using an independent samples *T* test and logistic regression, correcting for clinical risk factors.
Results: A decreased vessel wall K^{trans} was found for IPH-positive patients (0.033±0.001 min^{-1} versus 0.040±0.001, p=0.001), which remained significant after correction for confounding factors. No difference in adventitial K^{trans} was found in patients with and without IPH (0.040±0.002 min^{-1} versus 0.039±0.001).
Conclusion: We identified an inverse association between IPH and the microvasculature in symptomatic carotid plaques. Alternative and additional factors, such as disrupted plaque surface and fissures, may contribute to the development of IPH.

Hybrid repair of aortic pathology involving aortic arch
Y. Xue, L. Huang; *Beijing/CN (xueyuguo2006@163.com)*

Purpose: To evaluate the safety and efficacy of hybrid repair for aortic lesions involving aortic arch.
Methods and Materials: From February 2009 to September 2016, 81 consecutive patients (70 men; mean age 63.4±7.9 years, range 32-79) underwent brachiocephalic bypass combined with stent-graft implantation ("hybrid") and were enrolled in the study. Aortic pathologies included Stanford type B aortic dissection (n=22), aortic arch aneurysm (n=26), aortic arch pseudoaneurysm (n=14), aortic arch penetrating ulcer (n=11) and proximal endoleak (n=5) or pseudoaneurysm formation (n=3) after TEVAR. Hybrid repair comprised 3 landing in zone 0, 44 landing in zone 1 and 34 landing in zone 2. Simultaneous procedures included left subclavian artery embolization (n=57), endovascular abdominal aortic repair (n=1), coronary artery bypass (n=1), left common carotid endarterectomy (n=1) and renal stenting (n=4). Follow-up was performed at 1 month, 3 months, 6 months, 1 year and annually thereafter to investigate endoleak, patency of vascular graft and exclusion of aortic pathology.
Results: Technical success was 100%. Instant endoleak was observed in 9 (11.1%, 7 type I, 2 type II) cases on postoperative angiography. Early morbidity was 8.6% (7/81). Early death occurred in 5 cases (6.2%). Follow-up was complete in 100% for 39.4±14.5 months (range 1 -81 months). During follow-up, all the vascular grafts were patent. Late mortality was 6.2% (5/81) and morbidity was 14.5% (8/81).
Conclusion: Hybrid repair of aortic pathologies involving aortic arch is safe and effective with good short- and mid-term results, greatly expanding the indication of endovascular aortic repair.

B-0224 14:17

Overall survival and factors predicting long-term outcome after thoracic aortic endovascular repair
B. De Coster, S. Houthoofd, A. Laenen, I. Fourneau, G. Maleux; *Leuven/BE (bruno.decoster@uzleuven.be)*

Purpose: To assess overall survival and to determine factors predicting outcome after thoracic endovascular aortic repair.
Methods and Materials: This is a retrospective analysis including a cohort of 212 consecutive patients (165 males and 47 females; mean age 64 years) who underwent thoracic endovascular aortic repair (TEVAR) in a tertiary referral centre for aortic disease. Main indications were true thoracic aortic aneurysm (TTAA) (n=58; 27.6%), traumatic aortic rupture (n=33; 15.7%), anastomotic pseudoaneurysms (n=23; 10.9%), dissecting thoracoabdominal aneurysm (n=22; 10.5%) and symptomatic, acute type B dissection (n=21; 10.0%). In 79 patients (37.3%), a hybrid procedure, including supra-aortic rerouting, was performed. Kaplan-Meier estimates are used for overall survival and Cox regressions models are used for univariable analysis of the association between risk factors and survival.
Results: Proximal landing zone were predominantly zone 3 (n=66; 31.3%), zone 2 (n=63; 29.9%) and zone 1 (n=38; 18%). In-hospital mortality was n=18 (8.5%). Overall survival was 79.6%, 65.9% and 51.1% at 2, 5 and 10 years, respectively; better overall survival was revealed for traumatic aortic rupture, chronic posttraumatic pseudoaneurysms and anastomotic pseudoaneurysms (P<0.05). Clinical risk factors influencing overall survival include prior coronary bypass surgery, atrial flutter, arterial hypertension, renal failure, chronic obstructive pulmonary disease and associated abdominal aortic aneurysm (P<0.05).
Conclusion: TEVAR is an effective treatment option for various thoracic aortic diseases with highest survival rates for traumatic aortic rupture and anastomotic pseudoaneurysms. Several clinical parameters are identified as risk factors for overall survival.

B-0225 14:25

Analysis of remodeling in abdomial aortic branch perfusion patterns complicated by type B aortic dissection after thoracic endovascular aortic repair
T. Li, X. Han; *Beijing/CN (litiezhengaz@163.com)*

Purpose: To evaluate the efficiency of thoracic endovascular aortic repair in dealing with visceral malperfusion based on the image-analysis of type B aortic dissection.
Methods and Materials: Retrospective analysis to 32 patients from September 2015 to March 2016 in our department, who were diagnosed type B aortic dissection with visceral malperfusion, the information of clinic and image, as well as the following-up were collected. By observing the image of computed tomography angiography of aortic dissection in preoperative, we analyzed the type of branch perfusion patterns in four abdominal branches (celiac trunk, superior mesenteric artery, bilateral renal artery) in statistical.
Results: Four abdominal branches (total 128 branches), 78 branches (67%) expressed with Class I patterns, in which Class I-b presented with 1%, Class I-c presented with 5%; 14 branches (11%) expressed with Class II patterns, in which Class II-b-1 presented with 4%, Class II-b-2 presented with 3%; 16 branches (13%) expressed with Class III patterns, in which Class III-a presented with 13%, without Class III-b and III-c presentation; the remaining 12 branches with normal. Successful rate of TEVAR was 100%. The mean following-up was 4 months. Postoperative CTA showed that among 14 high-risk abdominal branches, 13 branches (92.9%) preserved improvement, the remaining one branch (7.1%) with I-b showed ischemic malperfusion in progress to I-c.
Conclusion: In comparison to the perfusion of ischemic branches complicated by aortic dissection in pre- and post- operative, there was profound benefit in the reconstruction of abdominal branches to extend the redefined branch type by Nagamine.

B-0226 14:33

Evaluating aortic endograft (EVAR) fate according to anatomical instruction (IFU) compliance: which anatomical feature has the most impact on graft fate?
N. Güner, A. Gulcu; *Izmir/TR (baturalpguner@gmail.com)*

Purpose: In today's practice, abdominal aortic aneurysms (AAA) are prevalently repaired endovascularly (EVAR). Because of its applicability on high-morbidity patients, a large group of EVAR patients have anatomic features that do not comply with endograft device specifications. Our research evaluates the follow-up complication rates of EVAR patients with device-compliant and device-non-compliant anatomical features.
Methods and Materials: Patients treated with EVAR between 2009 and 2015, and having follow-up studies in our institution are included in our study (50 patients). Patients were grouped according to their IFU (instructions for use) compliance, and later each of the seven IFU anatomic criteria individually. Treatment efficiency were observed by aortic/iliac enlargement, type 1 and 3 endoleaks and reintervention obligations during follow-up.
Results: Of patients, 48% had IFU compliant and 52% had non-compliant anatomy. Mean follow-up time was 23 months. There were not any differences between compliant and non-compliant groups in complication rates and treatment efficiency. When each of the IFU anatomic criterias was used for grouping, proximal properties and iliac diameter did not yield any statistical difference. In patients with inadequate iliac fixation (<15mm), endoleak and reintervention rates were statistically higher (P 0.002 and 0.008).
Conclusion: Proximal aneurysmal features were for long considered the most important factor in endograft fate. New design features in endografts may have changed this. Our study claims that distal fixation properties represent a very important and possibly strongest factor on the fate of an endograft. Small number of studies found on distal fixation properties had similar outcomes with our study.

B-0227 14:41

Role of intra-vascular ultrasound (IVUS) in EVAR planning
G. Falcone, C. Raspanti, G. Gabbani, E. Casamassima, F. Mondaini, M. Citone, F. Fanelli; *Florence/IT (gianmarcofalcone@gmail.com)*

Purpose: To evaluate accuracy and safety profile of Intravascular Ultrasound (IVUS - PhilipsVolcano) in pre-treatment EVAR planning for Aortic Abdominal Aneurysm(AAA)
Methods and Materials: In 36 consecutive patients(mean age 70.1 +/- 5.9; 15 male) with AAA pre-procedural EVAR evaluation was performed with CT angiography (CTA). IVUS intra-operative evaluation of proximal neck diameter, sac diameter , distal neck and iliac artery diameter was performed. Endoprosthesis sizing was grounded on CTA data in 18 pts and on IVUS data in 18. IVUS evaluation of endoprosthesis apposition was performed at the end of the procedure. A comparison between IVUS and CTA data was performed.

Results: IVUS was technically feasible in all cases. Mean proximal aortic neck diameter was 28mm (range 21-34mm) on CTA evaluation while on IVUS evaluation was 26mm (range 20-31); Mean Iliac artery diameter on CTA was 12mm (range 11-15mm) and 12mm on IVUS (10-13mm). In 5 cases a mismatch >2.5mm between CT and IVUS measurement of the proximal neck was observed. Technical success was achieved in all EVAR cases. No type I endoleaks were observed in the IVUS group. In the CTA group one type I endoleak was observed due to infolding of the fabric. In this case proximal aortic neck diameter was 26 on CTA and 21mm on IVUS evaluation. No IVUS related complication were reported.
Conclusion: IVUS is a safe evaluation tool and allows a better measurement of aortic diameters in the EVAR planning, reducing the complication rate.

B-0228 14:49

Interventional treatment of visceral artery aneurysms: single centre experience over 16 years

P. Reidler, M. Lerchenberger, M. Rentsch, C.G. Trumm; *Munich/DE (Paul.Reidler@med.uni-muenchen.de)*

Purpose: To evaluate treatment efficacy, complications and short-term mortality after primary interventional treatment of visceral artery aneurysms (VAAs).
Methods and Materials: From 71 consecutive cases of treated VAAs during the years 1999-2015 we selected all patients who had undergone primary endovascular treatment in elective or emergency settings. Aneurysm location and size were assessed by CTA with multiplanar reconstructions. Complications were classified according to Clavien-Dindo (CD) from Grade 0 to V. Mortality was assessed at follow-up after 30 days.
Results: Thirty-two patients (mean age: 57.5 years, female/male: 12/20) who received primary emergency (12) or elective (19) endovascular treatment for single VAA were included. VAAs occurred at the coeliac trunk (1), splenic (8), gastroduodenal (8), hepatic (7), superior mesenteric (3), gastric (3), pancreatic (1) and pancreaticoduodenal artery (1). Aneurysm size varied between 7 and 116mm (Median: 23mm). Primary intervention was successful in 29 patients (91%). 25 patients (78%) did not show any or only insignificant postinterventional complications (CD 0 and I). Pharmacologically treatable complications (CD II) were found in 1 patient (3%). 6 patients (19%) needed further interventional (4) or surgical (2) treatment (CD III) due to residual aneurysm perfusion (1), re-bleeding (2), splenic infarction (2), hepatic abscess (1), stent dislocation (1) or complications due to severe pancreatitis (1). 30-day mortality was 0%.
Conclusion: Interventional therapy of VAA presented a high rate of primary therapeutic success and no to minor complications in a majority of cases. As more severe complications might require interventional or surgical approach, management should include both specialties.

B-0230 14:57

Endovascular repair of 40 Visceral Artery Aneurysms (VAAs) and Pseudoaneurysms(VAPAs) with the Viabahn Stent-Graft: technical aspsects, clinical outcome and mid-term patency

P. Marra, M. Venturini, M. Colombo, G. Brembilla, M.M. Panzeri, M. Salvioni, S. Gusmini, F. De Cobelli, A. Del Maschio; *Milan/IT (marra.paolo@hsr.it)*

Purpose: Endovascular repair of VAAs and VAPAs with Stent-Grafting (SG) can simultaneously allow aneurysm exclusion and vessel preservation, minimizing the risk of ischemic complications. We report a single-center experience on SG of visceral aneurysms, focusing on technical aspects, clinical outcome and mid-term patency.
Methods and Materials: Patients affected by VAAs or VAPAs and treated between 2003 and 2017 with SG using a self-expandable peripheral Viabahn stent-graft were retrospectively reviewed. Aneurysm type, patient number, SG clinical setting, procedural data, peri-procedural complications, technical success, clinical success, 30-day mortality, and follow up (aneurysm exclusion, stent-graft patency, ischemic complications) were analysed.
Results: SG was performed in 40 patients (22 VAPAs/18 VAAs) with 44 procedures (25 in emergency, 19 in election), via transfemoral approach in 37 cases and transaxillary in 7. SG was associated with coil-embolization in 6 cases. One peri-procedural complication was recorded (a splenic artery dissection successfully converted to transcatheter embolization). The overall technical and clinical success rates were respectively 96% and 84%, with excellent trend in election procedures (both 100%). Overall 30-day mortality was 12.5% always due to septic shock after pancreatic surgery. Stent-graft thrombosis occurred in 2 patients within 3 months, with aneurysm exclusion and without ischemic complications. Stent-graft patency and aneurysm exclusion were confirmed at 6, 12 and 36 months in 18, 12 and 7 patients, respectively.
Conclusion: SG of VAAs and VAPAs was safe and effective, particularly in election setting. The Viabahn stent-graft, flexible and without shape memory, is suitable for endovascular repair of tortuous visceral arteries.

B-0231 15:05

Endovascular treatment of visceral artery aneurysms and pseudoaneurysms: extravascular stent graft migration as a possible long-term complication

L. Mascagni[1], M. Tipaldi[1], M. Pignatelli[1], M. Cappucci[1], M. Krokidis[2], G. Orgera[1], M. Rossi[1]; [1]*Rome/IT*, [2]*Cambridge/UK (luca.nero@hotmail.it)*

Purpose: Immediate- and long-term result analysis of endovascular visceral aneurysm and pseudoaneurysm treatment with stent grafts.
Methods and Materials: From February 2006 to Octuber 2011, we deployed 23 stent grafts in 21 patients (12 males and 9 females, mean age 58,2 years) affected by aneurysm or pseudoaneurysm of the splenic artery (n=13), hepatic artery (n=5), gastroduodenal artery (n=1) and renal artery (n=2). The aneurysmal sack dimensions ranged from 9 to 60 mm. We evaluated the technical success, stent patency, possible migration, breakage and aneurysmal reperfusion. The follow-up, performed with CECT, was repeated at 1, 6 and 12 months, then yearly (range 12-72 months).
Results: We achieved complete aneurysmal exclusion in 20/21 patients (95%). In one case, we had incomplete sealing and splenic artery's hilar branch fissuration during the procedure and thus treated with coils and ruled out of the follow-up. We reported complete aneurysmal exclusion in 20/20 patients in follow-up. In 4 cases, we observed stent occlusion, although without organ-related ischemia; in 3 of these 4 cases, stent occlusion was associated with stent graft migration: one inside the gastric antrum at the 36th month during follow-up (confirmed with endoscopy) and two in the lesser omentum at the 12th and 60th month follow-up.
Conclusion: Endovascular treatment of aneurysmal and pseudoaneurysmal pathology of visceral arteries with stent grafts is a safe and effective technique with good immediate- and long-term results. Extravascular migration of the stent graft after its occlusion is a rare, yet possible late complication. According to our evidence, we recommend follow-up even in case the stent is occluded.

Multicentre experience in endovascular treatment of aorto-iliac-femoral anastomotic pseudoaneurysms: evaluation of long-term follow-up

G. Guzzardi[1], B. Del Sette[1], P. Cerini[1], G. Carrafiello[2], F. Fusaro[1], D. Laganà[3], C. Stanca[1], A. Carriero[1]; [1]*Novara/IT*, [2]*Milan/IT*, [3]*Catanzaro/IT (guz@libero.it)*

Purpose: The purpose of this study is to assess the effectiveness of anastomotic pseudoaneurysms (APAs) endovascular treatment following aorto-iliac-femoral surgical reconstruction confronting technical and clinical success in patients with aortic lesions versus iliac-femoral lesions.
Methods and Materials: Were retrospectively evaluated 54 patients that had underwent aorto-iliac-femoral by-pass (72APAs). All patients were evaluated before treatment with CTA to assess the characteristics of the lesions. Follow up was performed with Eco-color-Doppler and/or CTA at 1, 3, 6 months after theprocedure and than yearly. Patients were divided in two groups if they presented pseudoaneurysms in aorta or only in iliac-femoral district.
Results: Immediate technical success was 100%. No periprocedural complications occurred. Six patientsdied during follow-up due to APA-non related causes and 5 for sepsis 3 months after the procedure.During a mean follow up of 25,5 months (range: 3-72), 3/47 occlusions of stent-graft leg occurred respectively 7days, 3 days and 24 months after the procedure, 2 type I endoleak and 1 type III endoleak. Primary clinical success rate was 87.2% and secondary clinical success was 95.7%. We witnessed a higher mortality in patients with aortic pseudoaneurysms even though it did not reach statistical significance (P>0.05).
Conclusion: Endovascular treatment of APAs is a valid alternative to open surgery and could be proposed as treatment of choice especially in patients with high surgical risk.

Correlation analysis of quantitative CT parameters and pulmonary function in COPD patients

Q. Yu[1], X. Quan[1], X. Lu[2]; [1]*Guangzhou/CN*, [2]*Shenyang/CN*

Purpose: To explore the correlation between quantitative CT parameters and clinical pulmonary function in COPD patients using a new COPD automatic analysis software.
Methods and Materials: There were 60 patients with COPD (male 51, median age: 65.9y) who underwent thin-slice chest CT scans both at end-inspiratory and end-expiratory. Airway measurement was provided average values along center line between start and end in the bronchiole of right upper apica lobes by software. ① Indirect indicators of air trapping were measured (end-inspiratory/end-expiratory), which included relative volume change ($RVC_{-860\ to\ -950}$, the expiration to inspiration ratio of mean lung density ($MLD_{E/I}$); ② Direct indicators of airway were measured (end-inspiratory,filter D), which included the following parameters: wall thickness (WT), lumen diameter (LD), Pi10, wall area (WA), lumen area (LA), wall area ratio (WA%), lumen area ratio (Ai%), WA/LA. Spearman rank correlation test and multiple variable analysis were used to evaluate the relationship between the above quantitative CT parameters and pulmonary function (airflow limitation: FEV1%, FEV1/FVC; airway resistance: Z5, R5, R20, Fres; diffusion capacity: DLCOSB).
Results: ① The correlation between indirect index of air trapping ($RVC_{-860\ to\ -950}$, $MLD_{E/I}$) and airflow limitation (r=-0.898 to -0.906, P<0.001), diffusing capacity (r=-0.830, -0.802, P<0.001),airway resistance (r=0.725-0.815, P<0.001) was statistically significant. ② The correlation between direct indicators and airflow limitation (r=-0.305 to -0.623, <0.01), diffusing capacity (r=-0.325 to -0.482, P<0.01), airway resistance (r=0.280 to 0.591, P<0.01) also was significant. Obviously, the correlation between the indirect index and pulmonary function is good (r^2>0.5), which was better than the direct index (r^2<0.5), the best of those was -0.906 (between $RVC_{-860\ to\ -950}$ and FEV1/FVC).
Conclusion: COPD software provides accurate and reproducible measurement of quantitative CT parameters, in which the correlation between indirect indicators of air trapping ($RVC_{-860\ to\ -950}$, $MLD_{E/I}$) and pulmonary function is good.

B-0234 14:08

Using a neuronal network-based software to predict lung function values from qCT parameters in patients with COPD

J.F.M. Gawlitza, T. Sturm, K. Spohrer, T. Henzler; *Mannheim/DE (joshua_gawlitza@yahoo.de)*

Purpose: Quantitative computed tomography (qCT) is an emerging technique for diagnostics and research in patients with COPD. qCT parameters show strong correlation with lung function tests and symptoms. Nevertheless, it is often criticised that qCT only provides anatomical and not functional information. We evaluated a neuronal network-based tool to predict lung function parameters from qCT values against actual lung function tests.
Methods and Materials: 75 patients with diagnosed COPD underwent body plethysmography and a dose-optimised qCT examination on a third-generation dual-source CT (Somatom Force, Healthineers, Forchheim, Germany) in inspiration and expiration. Four qCT parameters were acquired and used within a neuronal-network based dashboard software (PrediCT, Mannheim, Germany) to predict FEV1, FEV1/VC and RV/TLC. The predicted lung function values were then evaluated against the actual tested lung function parameters from body plethysmography.
Results: The mean relative error of the predicted values compared to the lung function tests was 9% for FEV1/VC, 10% for RV/TLC and 17% for FEV1. The root mean squared error was 9.3 for FEV1/VC, 10.5 for RV/TLC and 16.9 for FEV1, respectively.
Conclusion: Novel neuronal-network based software allows the prediction of lung function values from static qCT parameters within a reasonable margin of error. Therefore, qCT parameters may contain more information than we currently utilise and can potentially augment standard functional lung testing.

B-0235 14:16

Quantitive assessment of lung volume and lung density distribution in lung transplant patients: progression pattern in chronic lung allograft dysfunction

S. Dettmer[1], H. Suhling[1], T. Kaireit[1], J.-M. Kuhnigk[2], J. Gottlieb[1], J. Vogel-Claussen[1], F. Wacker[1], H.-o. Shin[1]; [1]*Hannover/DE*, [2]*Bremen/DE (dettmer.sabine@mh-hannover.de)*

Purpose: To evaluate lung volume and density distribution as quantitative CT parameters for progression of chronic lung allograft dysfunction (CLAD) following lung transplantation.
Methods and Materials: 120 lung transplant patients with 327 CT (baseline 6 months after transplantation and during follow up) were evaluated. Following calculation of lung volume and density histogram features (mean lung density, peak, full-width-at-half-maximum, percentiles) skewness und kurtosis were calculated. Longitudinal analysis was performed using the difference of measurements between baseline and follow-up examinations. Patients with and without CLAD (matched 1:3) were compared with independent t-test. Three different time points in regard to CLAD diagnosis were evaluated: the last examination (<1year) before CLAD onset, the first examination after CLAD onset (<1year), and the first examination with severe CLAD / BOS stage 3.
Results: Of these 120 lung transplant patients 16 patients developed CLAD during the follow-up period. Measurements were significantly different between patients with and without CLAD and increase with disease progression. Major differences are the expiratory and inspiratory lung volume (p<0.001-p=0.014), the ratio of expiratory and inspiratory lung density (p=0.001-p=0.236) and the percentiles on expiration (p<0.001-p0.36). Measurements reveal a progressive hyperinflation of the lung and a reduced respiratory dynamic.
Conclusion: Longitudinal changes of lung volume and density distribution measured on CT were significantly different between patients with and without CLAD and reveal a progressive hyperinflation of the lung which begins in the lower lobes and expands to the whole lung with disease progression.

B-0236 14:24

Quantitative CT and machine learning methods can predict eventual development of bronchiolitis obliterans syndrome after lung transplantation

E.J.M. Barbosa Jr.[1], M. Lanclus[2], W. Vos[2], C. Van Holsbeke[2], W. De Backer[3], J. De Backer[3], J.C. Lee[1]; [1]*Philadelphia, PA/US*, [2]*Kontich/BE*, [3]*Antwerp/BE (eduardo.mortani@gmail.com)*

Purpose: Long term survival after lung transplantation (LTx) is limited by bronchiolitis obliterans syndrome (BOS), defined as sustained decline in FEV_1 not explained by other causes. Machine learning (Support Vector Machine - SVM) applied to baseline quantitative CT metrics (qCT) and pulmonary function testing (PFT) was used to predict eventual development of BOS.
Methods and Materials: Paired inspiratory-expiratory CT scans of 41 patients who underwent LTx were analysed retrospectively. All were disease free at initial CT; 15 patients developed BOS at follow up, whereas 26 patients remained BOS free (BOS was defined as sustained reduction in FEV_1>10% compared to baseline FEV_1 after LTx). SVM was applied to baseline qCT features and PFT, to predict LTx patients' probability of eventual development of BOS.
Results: A total of 23 baseline FRI parameters could significantly distinguish between non-BOS patients and eventual BOS developers (p < 0.05), whereas no PFT parameters could. Using machine learning methods (SVM), LTx patients with smaller lung volumes (p<0.001), smaller airway volumes (p=0.01) and surface (p=0.04) and higher airway resistance (p=0.03) had greater probability of developing BOS. A combination of lobar resistance, surface area of the central airways and regional lobar volumes could predict BOS development with an accuracy of 85%.
Conclusion: Baseline qCT biomarkers may allow, via machine learning methods, accurate prediction of eventual onset of BOS from baseline qCT features, whereas baseline PFT metrics cannot. This may optimise the management paradigm of LTx patients.

B-0237 14:32

Temporal subtraction of serial-computed tomography images for visualisation and quantification of disease progression in idiopathic pulmonary fibrosis

H.-O. Shin, M. Minkler, L. Jaeger, C. Caliskan, S. Dettmer, J. Vogel-Claussen, F. Wacker, A. Prasse; *Hannover/DE (shin.hoen-oh@mh-hannover.de)*

Purpose: To evaluate temporal subtraction (TS) as an imaging biomarker for monitoring disease in idiopathic pulmonary fibrosis (IPF).
Methods and Materials: In 54 paired volumetric computed tomography scans (CT) of 27 patients with IPF, a semi-automatic lobe-based segmentation and a non-linear registration were performed warping the follow-up CT scan to the baseline CT scan. A TS image was calculated by subtracting the baseline CT from the warped follow-up CT. A colour look-up table was used for visualisation

of the TS image showing areas of decreased/increased density in shades of blue and red, respectively. CT-quantification was performed calculating the percentage volume change (PVC) of areas with decreased/increased density using a threshold of ± 150 HU in the TS images together with density histogram measures (changes in skewness and kurtosis). CT measurements were correlated with changes in pulmonary function test (PFT): FVC%, FEV1%, and KCO.
Results: In TS images, even subtle changes in parenchymal patterns could be visualised. Considering the complementary nature of CT features and PFT, a good correlation was found between PVC (increased/decreased/ total density change) and KCO (-0.36/-0.56 /-0.5, p<0.1). No significant correlation was found for FVC% and FEV1% . Density histogram features (skewness / kurtosis) showed no significant correlation with PFT for KCO, FEV1% and FVC%.
Conclusion: TS facilitates visual assessment of longitudinal CT scans displaying morphological changes in the colour-coded TS image. PVC may allow for objective quantification of regional morphological changes in IPF patients.

Subtraction CT of the lungs: accuracy of motion correction software
D. Grob[1], L.J. Oostveen[1], J. Rühaak[2], S. Heldmann[2], B. Mohr[3], M.M. Prokop[1], M. Brink[1], I. Sechopoulos[1]; [1]*Nijmegen/NL*, [2]*Lübeck/DE*, [3]*Edinburgh/UK (Dagmar.Grob@radboudumc.nl)*

Purpose: To compare the performance in registration between pre- and post-contrast computed tomography (CT) chest images of two algorithms using an anthropomorphic digital phantom to evaluate the potential accuracy of temporal subtraction to generate pulmonary iodine maps.
Methods and Materials: We used a recent version of the XCAT phantom, with enhanced airway and pulmonary vessel structures, to simulate pre- and post-contrast CT images (voxel size: 0.6x0.6x1.0 mm^3) at different inspiration levels with realistic system noise. We varied the difference in diaphragm position between the two scans from 0 to 20 mm because this value exceeded the 95th percentile found in 100 clinical subtraction CT datasets. Registration was performed using two different lung algorithms (SURE Subtraction Lung, Toshiba Medical Systems and NLR, Fraunhofer MEVIS). For each registration, we calculated the voxel-by-voxel difference between the true deformation and the algorithm-estimated deformation.
Results: Between respiratory phases, the median displacement in the phantom was 5.2mm (interquartile range: 2.3mm - 11.6mm). At 20 mm difference in diaphragm position, the median residual error in registration was 0.93mm (0.52mm - 1.58mm) with SURE Subtraction Lung, and 0.97mm (0.50 mm - 1.84 mm) with the NLR algorithm. The largest errors were seen in the paracardiac regions.
Conclusion: Both tested registration algorithms can compensate for respiratory motion with a median residual error below 1 mm. This level of accuracy opens up new applications such as direct detection of emboli in segmental arteries or evaluation of pulmonary nodule enhancement.

Quantitative CT assessment in patients with desquamative interstitial pneumonia: correlations with pulmonary function parameters
S. Hong, S. Lee, N. Kim, S. Lee, J. Seo; *Seoul/KR (sanghyeop.hong@gmail.com)*

Purpose: To evaluate the correlations between quantitative CT parameters and pulmonary function parameters in patients with desquamative interstitial pneumonia (DIP).
Methods and Materials: From April 2002 to April 2014, 40 patients with DIP were included in our study (39 men and 1 woman; mean age 58.5 years). For quantitative assessment on CT, a texture-based in-house software was used to quantify six regional CT patterns: normal, ground-glass opacity (GGO), reticular opacity (RO), honeycombing, emphysema, and consolidation. The total abnormal opacity was defined as the sum of extents of GGO, honeycombing, and emphysema. Correlations between the quantified CT parameters and the physiologic parameters were evaluated using the Pearson correlation coefficient.
Results: The mean values of FEV_1, FVC, FEV_1/FVC ratio, $FEF_{25-75\%}$, and DLco were 85.0%, 86.7%, 74.9 %, 79.2%, and 65.6%. The mean 6-minute walking distance and lowest SpO_2 during the 6-minute walking test were 514.2 m and 92.7%. The mean extents of GGO, consolidation, emphysema, RO, honeycombing, and total abnormal opacity were 14.3%, 3.0%, 3.6%, 8.9%, 2.6%, and 20.5%. The total abnormal opacity showed significant correlations with DLco (r = -0.466; P = 0.002) and SpO_2 (r = -0.534; P = 0.001), but no correlations with FEV_1, FVC, FEV_1/FVC ratio, and $FEF_{25-75\%}$ (P = 0.391, 0.366, 0.281, and 0.681, respectively).
Conclusion: Quantitative assessment of regional disease patterns in DIP patients showed significant correlations with DLco and SpO_2.

B-0240 14:56

Use of quantitative computed tomography to assess post-interventional long-term changes after bronchial thermoplasty in patients with severe asthma
P. Konietzke, O. Weinheimer, M. Wielpütz, W. Wagner, P. Heussel, C. Heussel, H.-U. Kauczor, F.J. Herth, M. Schuhmann; *Heidelberg/DE (p.konietzke@gmx.de)*

Purpose: Bronchial thermoplasty (BT) can be considered in the treatment of severe asthma. By reducing smooth muscle mass, and thus reducing bronchial wall thickening and bronchoconstriction, asthmatic symptoms may be controlled. We hypothesized that quantitative computed tomography (QCT) is an appropriate tool to measure long-term effects of BT on airway dimensions and air-trapping.
Methods and Materials: 32 paired inspiratory and expiratory CT scans of 16 patients were acquired before and after BT. The fully automatic YACTA software calculated wall thickness (WT), wall percentage (WP), lumen area (LA) and total diameter (TD) in a generation-based as well as total lung volume (TLV) and air-trapping parameters (E/I, $RVC_{856-950}$, A1-A3) in a lobe-based approach, respectively.
Results: WT decreased after performing BT significantly by 3.75% (p=0.035) with a subsequent significant increase in LA by 5.39% (p=0.046) and a decrease of 3.67% in WP (p<0.001) for the combined airways generations 2nd-7th. TD increased by 0.69% on average (p=0.706). After BT media TLV decreased by 68 cm^3 (p=0.459), air-trapping had a significant reduction for the parameter IE (p=<0.001), $RVC_{856-950}$ (p=<0.001), and A1-A3 (p=<0.003, p=<0.001 and p=<0.001), respectively.
Conclusion: QCT was able to show long-term post-interventional changes in patients treated with BT. Significantly reduced WT and WP with an increase in the lumen can be interpreted as direct therapeutic effects caused by a reduction in airway-smooth muscle mass and changes in neuronal innervation. QCT also showed a significant reduction in air-trapping. QCT parameters may be used in therapy guidance and monitoring.

B-0241 15:04

Accuracy of emphysema volume and airway measurements according to FBP, HIR, MIR, and virtual monoenergetic reconstruction images at both low- and standard-dose settings
M. Ha[1], C. Kim[1], K.Y. Lee[1], C. Shin[1], E.-Y. Kang[2], Y.-W. Oh[2], C. Ko[1], J. Cha[1]; [1]*Ansan/KR*, [2]*Seoul/KR (gkahdls89@gmail.com)*

Purpose: To evaluate the accuracy of emphysema volume (EV) and airway measurements (AMs) produced by various iterative reconstruction (IR) and virtual monoenergetic images (VME) at both low- and standard-dose settings.
Methods and Materials: CT images were obtained on phantom at both low and standard doses (30mAs vs 100mAs at 120kVp). Each CT scan was reconstructed using filtered back-projection (FBP), hybrid IR (iDose^4), model-based IR (IMR-R1, IMR-ST1, IMR-SP1), and VME at 70 keV (VME70). The EV of each air column and wall area percentage of each airway tube were measured in all algorithms. Absolute percentage measurement errors of EV (APE_{vol}) and AM ($APE_{WA\%}$) were then calculated. Repeated measures analysis of variance (ANOVA) was performed on repeated measured data.
Results: EV was most accurately measured in IMR-R1, and AM was the most accurate in IMR-SP1 on both low- and standard-dose CT (all P<0.05). There were no significant differences in the APE_{vol} of IMR-R1 between low and standard doses (all P>0.05). VME70 showed a significantly higher APE_{vol} than iDose4, IMR-R1, and IMR-ST1 (all P<0.004). VME70 also showed a significantly higher $APE_{WA\%}$ compared with the other algorithms (all P<0.001).
Conclusion: The measurement of EV and AM via application of IMR on both low- and standard-dose CT showed reliable accuracy in a phantom study. However, VME did not result in any improvement of measurement accuracy. Among these algorithms, IMR was the most accurate modality for measurement of both emphysema volume and airway wall thickness.

B-0242 15:12

Qualitative and quantitative comparison of lung nodules in an ex-vivo system on a high-pitch dual source CT and a standard CT in free breathing
C.A. Burgard; *Munich/DE (caroline.burgard@med.uni-muenchen.de)*

Purpose: To analyse the image quality of lung nodules using two different CT protocols (high pitch dualsource or standard CT) in free breathing and in full inspiration and expiration stimulating a non-compliant patient.

Methods and Materials: Three porcine lungs were prepared with 28 artificial nodules (mean diameter 10.4 mm) and subsequently placed into a dedicated CT compatible chest phantom (PROdesign artiCHEST). Images were obtained in static full inspiration and expiration breath hold, and as well as in free breathing, with two different CT protocols. Quantitative analysis was carried out with a semiautomatic volumetric program (LungCARE, Syngo.via, Siemens, Erlangen, Germany). The reproducibility of nodule volumetry was calculated. Motion artifacts were semi quantitatively assessed by two readers (from 0 or absent to 3 or relevant and non-diagnostic).
Results: In the qualitative analysis, the artefacts in the examinations performed with standard CT intensified with increasing number of respiratory acts per minute, whereas they were negligible in the highpitch dualsource CT examinations. These differences were statistically significant (P <0.005). In quantitative analysis, the relative differences (Δ between the value of the volume calculated with standard and high pitch minus the inspiration value divided by the inspiration value) in the volumetric volume measured in standard CT were statistically significant in the 9, 15 and 18 breaths per minute scans.
Conclusion: While a standard CT examination for nodule volumetry relies on a steady breath-hold of the subject, the presented study demonstrated the feasibility of a high-pitch, dualsource CT acquisition in free breathing i.e in non-compliant patients.

B-0243 15:20

Quantitative CT as a one-stop shop to describe status and outcome of patients with acute respiratory distress syndrome (ARDS)
P. Leiser, J. Schoettler, F.S. Centner, T. Kirschning, J. Krebs, M. Hagmann, C. Weiß, S.O. Schönberg, H. Haubenreisser; *Mannheim/DE (p.leiser@stud.uni-heidelberg.de)*

Purpose: The aim of this study was to establish quantitative CT (qCT) parameters for pathophysiological understanding and clinical use in patients with ARDS. The most promising parameter is introduced.
Methods and Materials: 28 intubated patients with ARDS obtained a conventional and dual-energy CT scan in end expiratory breathhold. Following manual segmentation, 138 volume-, perfusion- and lung weight-related qCT parameters were correlated with 71 anaesthesiological parameters such as applied ventilation pressures (PEEP, Pdrive) and established status and prognosis scores (SOFA, SAPS II). Multiple regression analysis was then performed to enable the prediction of these scores by a single CT scan.
Results: Of all examined qCT parameters, excess lung weight (ELW) displayed the most significant results. ELW correlates positively with the amount of extravascular lung water (r=0.72), atelectatic lung volume (r=0.92), applied PEEP (r=0.37) and negatively with the lung's mean CM enhancement (r=-0.65; all p<0.05). More significantly than any other anaesthesiological parameter it correlates with the patient's SOFA- (p<0.0001, r=0.69) and SAPS II-Score (p=0.0005, r=0.62). A combination of ELW, mean CM and Pdrive can predict SOFA up to r^2=87.95%.
Conclusion: ELW constitutes the best parameter to assess pathophysiology, status and outcome of patients with ARDS and should be considered a first-range diagnostic tool during the first hours of ICU treatment, providing better correlation to relevant clinical parameters than the current standard Horovitz index (PaO_2/FiO_2).

Analysis of clinical and economic management optimisation of multiparametric-MRI as the first line tool in men with high clinical suspicion of prostate cancer
M. Pecoraro[1], A. Padhani[2], R. Campa[1], M.C. Valerio[1], C. Catalano[1], V. Panebianco[1]; [1]*Rome/IT*, [2]*Middlesex/UK (pecoraro.martina1@gmail.com)*

Purpose: Determine diagnostic and treatment costs, and effectiveness of the pathways incorporating multiparametric MRI biopsy (mp-MRI/Bx), compared with transrectal ultrasound-guided biopsy (TRUS/Bx), in men at high risk of prostate cancer (PCa).
Methods and Materials: A cost and time analysis, based on data from a published randomized, single centre study. 1140 patients with total PSA > 4 ng/mL divided in 2 groups: 570 patients underwent a TRUS/Bx, while 570 patients underwent a mp-MRI/Bx.
Results: Mp-MRI/Bx diagnosis costs were 14.6% greater than TRUS strategy (228,946 € vs 199,750 €), and 5.2-6.0% higher for therapy (1,912,000 € vs 1,802,800 €). Mp-MRI/Bx strategy was highly effective for excluding clinically significant disease (Gleason ≥7); sensitivity and NPV both 100% (95% CI 98-100%). If verification of negative mp-MRI was not undertaken, differential cumulative therapy costs for mp-MRI/Bx strategy remained higher (8.4%), despite potential savings in active surveillance costs, because of increased radical therapies (mp-MRI/Bx =409; TRUS/Bx = 373). Time-to-diagnosis was shorter for the mp-MRI/Bx strategy (median 4.0 months (IQR 3-6); TRUS/Bx (median 6 months (IQR 4-12): p < 0.001).
Conclusion: Our analyses suggest mp-MRI/Bx strategy is effective for diagnosing patients with suspected PCa, providing faster and more accurate diagnoses.

B-0245 14:08

Impact of upfront risk stratification on the negative predictive value of multiparametric MRI in patients with no history of prostate cancer
M. Abihanna[1], C. Melodelima[2], P.-C. Moldovan[1], R. Souchon[1], A. Ruffion[3], M. Colombel[1], S. Crouzet[1], O. Rouviere[1]; [1]*Lyon/FR*, [2]*Grenoble/FR*, [3]*Pierre Benite/FR (m_abihanna@hotmail.fr)*

Purpose: To assess the impact of upfront risk stratification on the negative predictive value (NVP) of multiparametric MRI (mpMRI) with patients without history of prostate cancer.
Methods and Materials: We retrospectively analysed a prospective database of 646 patients (456 biopsy naïve, 189 referred for repeat biopsy) who underwent mpMRI before biopsy. The prediction of clinically significant prostate cancer (csPCa) at biopsy by clinical (age, digital rectal examination, PSA density [PSAd], history of prior negative biopsy) and imaging (Likert score, extracapsular extension [ECE], magnetic field strength, experience of radiologist and presence of a concordant hypoechoic lesion [Concord-Echo]) variables was assessed by multivariate analysis. Significant clinical variables were included in a 'clinical model'. Three definitions for csPCa were used (csPCa1: USIP grade group ≥3; csPCa2: USIP grade group ≥2; csPCa3: csPCa2 and USIP grade group 1 with cancer invasion length ≥5 mm).
Results: Age, PSAd, history of prior negative biopsy, Likert score, ECE and Concord-Echo significantly predicted the presence of csPCa1-3. Adding the Likert score to the clinical models significantly increased the models' performance. Omitting biopsy in patients with negative mpMRI would have avoided 28.9% (Likert ≤3/5) or 45.7% (Likert ≤4/5) of biopsies while missing 9.2-11.5% of csPCa1, 11.9-18.5% of csPCa2 and 19.5-28% of csPCa3. mpMRI NPV decreased when the csPCa probability given by the clinical models increased. Therefore, considering clinical models' output allowed defining scenarios missing <5% of csPCa and omitting biopsies in 24.1-39.8% (csPCa1), 20.4-26.2% (csPCa2), and 10.2-12.8% (csPCa3) patients.
Conclusion: Upfront risk stratification of patients allows rational use of mpMRI NPV.

B-0246 14:16

Diagnostic performance of biparametric MR imaging for detection of prostate cancer: a systematic review and meta-analysis
X. Niu; *Chengdu/CN (niu19850519@163.com)*

Purpose: To perform a systematic review and meta-analysis to estimate the diagnostic performance of biparametric MR imaging (bp-MRI) for the detection of prostate cancer (PCa).
Methods and Materials: Two independent reviewers performed a systematic review of the literature published as of June 1, 2017, using predefined search terms. The standard of pathological reference was established at prostatectomy or prostate biopsy. The number of true- and false-positive, true- and false-negative results were extracted. The quality assessment of diagnostic accuracy studies tool was used to assess the quality of the selected studies. Statistical analysis included pooling of diagnostic accuracy, meta-regression, subgroup analysis, head-to-head comparison and identification of publication bias.
Results: Thirty-three studies were used for general data pooling. Overall sensitivity was 81% (95% confidence interval [CI]: 76%, 85%), and overall specificity was 77% (95% CI: 69%, 84%). As for clinically relevant prostate cancer (cr-PCa), multiparametric MRI (mp-MRI) maintained high diagnostic value [AUC=0.85 (95% CI: 0.82, 0.88)]. There was no evidence of publication bias (*P*=0.673). From head to head comparison, mp-MRI demonstrated significantly higher pooled sensitivity of 0.85 (95% CI: 0.78, 0.93) compared with 0.80 (95% CI: 0.71, 0.90) for bp-MRI (P=0.01). However, the pooled specificity was not significantly different [0.77 (95%CI: 0.58, 0.95) vs 0.80 (95%CI: 0.64, 0.96), respectively; P = 0.82].
Conclusion: Results of this meta-analysis suggest that bp-MRI has high diagnostic accuracy in detection of PCa, and maintained high detection rate for crPCa. However, owing to high heterogeneity among the included studies, caution is needed in applying our results.

B-0247 14:24

Diffusion-weighted MRI in prostatic lesions: diagnostic performance of normalised ADC using normal peripheral prostatic zone as a reference

T.F.T. Ali; *Zagazig/EG (tamerfathi2008@yahoo.com)*

Purpose: To evaluate the potential value of using the normal peripheral prostatic zone (PZ) as a reference site to improve the performance of DWI in the evaluation of prostatic lesions.
Methods and Materials: 38 patients with clinical suspicion of cancer prostate and who are scheduled to undergo a TRUS-guided biopsy were subjected to DW-MRI with ADC calculation. The normalised ADC (nADC) value was calculated by dividing the ADC of lesion by ADC of reference site (healthy peripheral zone). DWI-MRI results were compared to that of biopsy. Data were analysed and ROC was used to evaluate the performance of ADCs and nADCs.
Results: The patients were classified histopathologically into non-malignant group (16 patients) and malignant group (22 patients). Significant negative correlation between each of ADC and nADC and malignancy was detected. There was no significant difference between the mean ADC of peripheral healthy PZ in benign and malignant cases. There was significant difference between the mean ADC and mean nADC in benign and malignant lesions (1.049±0.217 versus 0.659±0.221x$10^{-3}$$mm^2$/sec, p<0.001) and (0.475±0.055 versus 0.328±0.044, p<0.001), respectively. There was a significant higher diagnostic performance of nADC than ADC with ADC cut-off value 0.75×$10^{-3}$$mm^2$/sec and nADC cut-off value 0.39 could significantly differentiate between benign and malignant lesion with sensitivity, specificity, PPV, NPV of 86.36, 75, 82.61 and 80%, respectively, p<0.0001 for ADC and 95.45, 93.75, 95.45 and 93.75%, p<0.0001 for nADC.
Conclusion: The diagnostic performance of nADC using normal peripheral zone is higher than ADC in the discrimination between cancerous and non-cancerous lesions of the prostate.

B-0248 14:32

Dynamic contrast-enhanced MRI (DCE) for prostate cancer detection: are qualitative and quantitative analyses the key to success?

F. Ziayee, T. Ullrich, R. Rabenalt, P. Albers, G. Antoch, L. Schimmöller; *Düsseldorf/DE (farid.ziayee@med.uni-duesseldorf.de)*

Purpose: DCE remains an integral part of the multi-parametric MRI of the prostate. The aim of this study was to evaluate the importance of qualitative and quantitative analyses of dynamic contrast-enhanced MRI (DCE) with regard to prostate cancer (PCa) detection.
Methods and Materials: DCE data of 103 consecutive patients with multi-parametric MRI (T2WI, DWI, DCE) and subsequent MRI-(in-bore)-biopsy of the prostate were retrospectively analysed. Qualitative (curve type, PI-RADS v2) and quantitative (K_{trans}, K_{ep}) analyses of in total 206 lesions (87 cancer positive and 119 benign lesions) were performed. Cancer detection, discrimination of significant cancer, and localization was assessed and compared to histopathologic findings.
Results: Regarding discrimination between PCa and benign lesions, differences between K_{trans}, K_{ep}, and curve types were not statistically significant (p=0.2-0.9). Subdivided in peripheral zone (PZ) and transition zone (TZ) K_{trans} (p<0.01; p=0.04) and K_{ep} (p=0.04, p<0.01) were significantly different between PCa and benign lesions. The PI-RADS *v2* overall score could discriminate PCa and benign lesions in both, PZ and TZ (p<0.01), whereas PI-RADS single scores of DCE could differentiate PCa better in PZ (p<0.01) than in TZ (p=0.5). All perfusion parameters could not differentiate between insignificant and significant (≥4+3=7b) prostate cancer (p=0.5-0.8).
Conclusion: PI-RADS *v2* criteria for DCE discriminate well between benign lesions and PCa in the peripheral zone. Qualitative (curve type) and quantitative parameters (K_{trans}, K_{ep}) provide no additional improvement in PCa detection compared to PI-RADS scoring alone. DCE-MRI alone did not allow differentiation between significant and insignificant PCa.

B-0249 14:40

Prostate tumour volume analysis on MRI as a predictor for aggressive disease

N.M. Hughes, C. O'Neill, F.M. O'Brein, N. Mayer, P. Kelly, J.G. Buckley, K. O'Regan; *Cork/IE (nicolahughes@rcsi.ie)*

Purpose: Patients with high Gleason grade (GG) prostate cancer have been shown to have radiological indicators of increased tumour aggressiveness on MRI. The aim of this study was to evaluate tumour volume on MRI as a potential predictor of aggressive disease by correlating with Gleason grade.
Methods and Materials: We performed a retrospective review of prostate MRI in patients with HG-PCa (GG8-10) over a three year period. An age-matched and PSA-matched number of patients with GG7 Pca (GG 3+4 and 4+3) was also reviewed. Volumetric tumour analysis was performed on T2-weighted (T2W) sequences and on diffusion-weighted MRI using Osirix® software.
Results: Seventy-five (n=38 GG7, n=17 GG8, n=17 GG9, n=3 GG10) MR studies were included in total. Average tumour volume for GG 7 disease was 1.96 cc on T2W sequences (range: 0.14-21.0159 cc) and 1.81 cc on ADC maps (range: 0.0763-17.1745 cc). HG-PCa (GG 8 and above) had an average tumour volume of 6.95 cc (3.29 cc GG8, 9.31 cc GG9, 14.39 cc GG10) on T2W sequences (range: 0.0891-54.3883) and 7.83 cc (3.27 cc GG8, 11.04 cc GG9, 15.47 cc GG10) on diffusion MRI (range: 0.0778-72.7619). There was a positive correlation between tumour volume and GG using both T2W sequences (p<0.001) and ADC maps (p<0.001).
Conclusion: This study has shown a positive correlation between tumour volume and Gleason grade. Volumetric analysis of prostate cancer on MRI may have a role in predicting more aggressive disease.

B-0250 14:48

Prostate volume estimation at MRI: reproducibility and limits

M. Bonatti[1], F. Lombardo[1], M. Simioni[2], G. Avesani[1], G. Bonatti[1]; [1]*Bolzano/IT*, [2]*Verona/IT (matteobonatti@hotmail.com)*

Purpose: To evaluate reproducibility of prostate volume estimated with the ellipsoid formula and to show its correlation with PSA density risk class.
Methods and Materials: We included in our IRB-approved retrospective study 60 consecutive patients who underwent prostate MRI for the detection of cancer at our Institution between July and September 2017. Two readers independently estimated prostate volume by means of the ellipsoid formula using axial and sagittal T2-weighted images. A third reader measured prostate volume by means of manual segmentation on axial T2-weighted images using commercially available software (iTK-SNAP). PSA density was calculated for each patient according both to the measured and estimated prostate volumes. Data were compared using paired t-test.
Results: Mean prostate volume calculated with manual segmentation was 54+-20 cc. Mean prostate volume estimated with ellipsoid formula was 50+-19 cc for reader 1 and 52+-20 cc for reader 2. Prostate volume estimated with the ellipsoid formula was significantly different between the two readers (p=0.015). Prostate volume estimated with the ellipsoid formula was significantly different from prostate volume calculated with segmentation for reader 1 (p=0.0016) and not significantly different for reader 2 (p=n.s.); the mean volume difference was 14% for reader 1 and 13% for reader 2. For both readers, 5/60 (8.3%) patients would have changed their PSA density risk class (<or≥0.15) when comparing data obtained from estimation with those obtained from measurement.
Conclusion: Prostate volume estimated with the ellipsoid formula shows poor reproducibility and might lead to errors in PSA density evaluation.

B-0251 14:56

Prevalence and significance of incidental extraprostatic findings in patients undergoing magnetic resonance imaging of the prostate for detection of prostate cancer

F.M. Schäfer, P. Asbach, M. Haas, B. Hamm, A. Baur; *Berlin/DE (Frederik.Schaefer@charite.de)*

Purpose: Multiparametric magnetic resonance imaging (mpMRI) of the prostate can detect prostate cancer with high accuracy. Imaging depicts a wide array of pelvic and abdominal tissues in addition to the prostate. In this study we evaluated the prevalence as well as the clinical significance of incidental extraprostatic findings that can be detected on mpMRI.
Methods and Materials: We retrospectively identified 300 patients (median age, 64 years; range, 46-76 years) who had undergone mpMRI of the prostate at 3 Tesla as a first-line test before prostate biopsy between October 2016 and August 2017 using a standardized examination protocol in accordance with the current Prostate Imaging - Reporting and Data System recommendations. One experienced reader blinded to clinical data analyzed imaging with a focus on incidental extraprostatic findings. Findings that necessitated further work-up were rated as clinically significant.
Results: Of all extraprostatic findings diverticulosis (n=103; 34.3%) and inguinal herniation of fat (n=85; 28.3%) were most common. In 13 patients (4.3%) extraprostatic findings were rated as clinically significant including suspicion for a neoplasm of the bladder (n=1), neoplasms of the sigmoid and rectum (n=3), femoral head necrosis (n=1), chronic diverticulitis of the sigmoid (n=5), and subacute inflammation of an aortic aneurysm (n=1).
Conclusion: Whilst incidental extraprostatic findings were commonly detected on mpMRI, findings rated as clinically significant were only found in a small number of patients. However, awareness of these findings as well as their correct description in imaging reports is important in order to initiate further work-up.

Mp-MRI of the prostate: anti-peristaltic hyoscine butylbromide significantly decreases motion artefacts and allows better delineation of anatomic structures

T. Ullrich, L. Schimmöller, M. Quentin, K.A. Schmaltz, C. Rubbert, C. Arsov, R. Rabenalt, P. Albers, G. Antoch; *Düsseldorf/DE (Tim.Ullrich@med.uni-duesseldorf.de)*

Purpose: To prospectively evaluate the effect of hyoscine butylbromide (HBB) on visualisation of anatomical details and motion-related artefacts in mp-MRI of the prostate at 3.0 Tesla.
Methods and Materials: One hundred and three consecutive patients (65±10years) received high-spatial resolution axial T2-weighted TSE sequences at 3.0T without a spasmolytic agent, repeated after application of 40mg HBB and followed by routine mp-MRI. Secondary endpoints were (1) susceptibility to side effects assessed on 5-point Likert scales by two blinded readers, (2) dependence of spasmolytic effect on patients' weight, and (3) prostate volume.
Results: In 68% of the patients, HBB significantly improved the anatomic score (mean 3.4±0.9 before and 4.4±0.7 after HBB for both readers, p=<0.001). In 67% HBB significantly enhanced the artefact score (mean 3.2±1 before and 4.2±0.8 after HBB for reader 1, p=<0.001; 3.2±1 and 4.1±0.8 for reader 2, p=<0.001). Subgroup analyses revealed no statistically significant difference between patients with different bodyweight or prostate volume. Inter-reader agreement was excellent (k=0.95-0.98).
Conclusion: Administration of anti-peristaltic medication (hyoscine butylbromide) significantly improved image quality and relevantly reduced motion-related artefacts in mp-MRI of the prostate in over 2/3 of the patients. The anti-spasmolytic effect is independent of body weight and prostate volume. No side effects of HBB were reported.

B-0253 15:12

Texture analysis of prostate MRI: utility for differentiating patients combined intraductal carcinoma of the prostate from prostate adenocarcinoma

L. Chu, R. Liu; *Chengdu/CN (710341139@qq.com)*

Purpose: To investigate texture analysis of prostate MRI for cancer differentiation between patients combined intraductal carcinoma of the prostate (IDC-P) and prostate adenocarcinoma.
Methods and Materials: 3.0T multi-parametric MRI was performed on 41 significant prostate cancer patients prior to prostatectomy. Twenty-one patients had prostate adenocarcinoma and twenty patients combined intraductal carcinoma of the prostate. Histogram-based parameters and textural features were extracted from the region of interests delineated around tumor outline on T2 and the T1-TSE DCE sequence based on pathological information and diffusion weighted imaging(DWI). The resulting data were processed with Mann-Whitney U test and binary logistic regression models. Diagnostic accuracy was assessed by area under the receiver operating characteristic curves (ROC-AUC).
Results: Texture features have no significant difference on T2WI between two groups. IDC-P showed lower Skewness(p=0.016) with ROC-AUC 0.724, Cluster Shade(p=0.013) with ROC-AUC 0.732 and higher HaraEntroy(p=0.015) with ROC-AUC 0.726 compared to prostate adenocarcinoma. Combining Cluster Shade and HaraEntroy yielded ROC-AUC 0.803.
Conclusion: Several texture features on DCE series appear useful for differentiating intraductal carcinoma of the prostate from prostate carcinoma and GS assessment. The role of DCE in prostate MRI diagnosis may be underestimated for various DCE features in distinct pathology types of prostate cancer.

B-0254 15:20

Cell cycle progression genomics and MRI features of prostate cancer: radiogenomic correlation and prognostic synergism

A.G. Wibmer[1], N.L. Robertson[1], B. Ehdaie[1], S. Stone[2], M. Brawer[3], H. Hricak[1], H. Vargas[1]; [1]*New York, NY/US*, [2]*Salt Lake City, UT/US*, [3]*Irvine, CA/US (wibmera@mskcc.org)*

Purpose: To explore correlations of the Prolaris© genetic test with magnetic resonance imaging (MRI) features of prostate cancer; and to assess both tests' capabilities to predict adverse features on prostatectomy histopathology.
Methods and Materials: 122 patients undergoing prostate biopsy, Prolaris© test, and MRI from 08/2013-11/2015 were included. The Prolaris© test encompasses 46 genes associated with cell cycle progression (CCP). MRI features included PI-RADSv2 scores, extracapsular extension (ECE), and quantitative metrics (i.e. tumour length, volume, apparent diffusion coefficient). In a sub-group analysis of 42 patients (34.4%) undergoing prostatectomy, results of both tests were correlated with adverse histopathologic features, i.e. Gleason Group ≥3, ECE, and lymph node metastases.
Results: According to the American Urologic Association guidelines, 54 (44.3%) were 'low risk', 64 (52.5%) 'intermediate risk', and 4 (3.3%) 'high risk' patients. Tumour volume (p=0.032) and ECE (p= 0.015) on MRI were associated with higher CCP scores, while PI-RADSv2 scores were not. In the subgroup analysis, ECE on MRI (p=0.009) and Prolaris© CCP scores (p=0.017) were independently associated with Gleason group ≥3 on surgical specimen. ECE on MRI was the only independent predictor of histopathologic ECE (p=0.003) and nodal metastases (p=0.025).
Conclusion: We found a radiogenomic association of cell cycle progression genes with tumour volume and ECE on MRI. Gene expression levels and ECE on MRI were independent predictors of adverse histopathologic tumour features. Both tests may therefore provide synergistic prognostic information.

The diagnostic value of ultrasonography in assessing temporomandibular joint disc position

D. Talmaceanu[1], L.M. Lenghel[1], G. Baciut[1], M. Baciut[1], H. Rotar[1], N. Bolog[2], S. Buduru[1], L. Daniel[1], S. Dudea[1]; [1]*Cluj-Napoca/RO*, [2]*Munchenstein/CH (manu_2416@yahoo.com)*

Purpose: The purpose of this study was to assess the diagnostic value of high-resolution ultrasound (US) in temporomandibular joint (TMJ) disc displacements, compared to magnetic resonance imaging (MRI).
Methods and Materials: 74 patients (with 148 TMJs) with signs and symptoms of TMJ disorders were included in this study. All patients underwent US and MRI of both TMJs 1 to 5 days after the clinical exam. MRI examinations were performed using 1.5 T equipment. Ultrasonographic examination was performed using a high-resolution (13 MHz) linear transducer. The diagnostic characteristics of the tests (sensitivity, specificity, positive and negative predictive values, accuracy and Youden Index) were computed along with 95% confidence intervals.
Results: MRI depicted 68 (45.95%) normal joints, 47 (31.76%) with disc displacement with reduction, 33 (22.3%) with disc displacement without reduction and 34 (22.97%) with degenerative changes. US detected 78 (52.7%) normal joints, 37 (25%) with disc displacement with reduction, 33 (22.3%) with disc displacement without reduction and 21 (14.19%) with degenerative changes. Compared to MRI, US showed a sensitivity of 93.1%, specificity of 87.88%, accuracy of 90.32%, a positive predictive value of 87.1% and a negative predictive value of 93.55% for overall diagnosis of disc displacement. The Youden Index was 0.81.
Conclusion: Based on the results of the study, high-resolution ultrasonography showed high sensitivity, specificity and accuracy in the diagnosis of TMJ disc displacement, being a valuable imaging technique in assessing TMJ disc position.

B-0256 14:08

Is condyle morphology a factor for anterior temporomandibular disc displacement?

I. Camlidag, A.T. Sayıt, M. Elmali; *Samsun/TR (ilkayozaydin@hotmail.com)*

Purpose: To investigate morphological features of the mandibular condyle and its association with anterior temporomandibular disk displacement.
Methods and Materials: 133 patients who underwent temporomandibular MRI examination with presumed diagnosis of temporomandibular dysfunction between January 2015 and December 2016 were retrospectively involved. Patients with marked osteoarthritis, posterior disk dislocation, tumour, abscess and motion artefacts that would hamper evaluation were excluded. Three radiologists evaluated all MR images in consensus. Temporomandibular disc locations were classified as normal, anteriorly displaced with reduction (ADr) and anteriorly displaced without reduction (ADwr). Condylar shapes were classified as flat, rounded and angled on sagittal oblique images. Condyle anteroposterior width (c-APW) was measured on sagittal oblique T1-weighted images in closed-mouth positions.
Results: 106 discs were in normal position, 80 discs were ADr, 80 discs were ADwr. 93 discs were flat, 109 were rounded and 64 were angled. Mean cAPW

was 6.9 mm in normal cases, 5.9 mm in ADr and 5.8 mm in ADwr patients. c-APW were significantly smaller than normal cases in patients with ADr and ADwr (p=0.00); however, no significant difference was found between ADr and ADwr patients. Flat and rounded type condylar shape was equally common among normal discs; however, rounded type was common among ADr and angled type was common among ADnr. ADr cases were significantly younger from normal cases; however, no age difference was found between normal and ADwr patients and ADr-ADwr patients. ADr and ADwr were more common among female gender.
Conclusion: Mandibular condyle shape and its anteroposterior width is associated with anterior disc displacement.

B-0257 14:16

Fast and accurate diagnosis of oval or round window perilymphatic fistula on CT and MRI without contrast injection on 101 patients with surgical confirmation

A. Venkatasamy, Z. Al Ohraini, A. Charpiot, C. Debry, F. Veillon;
Strasbourg/FR (aina.vnkt@gmail.com)

Purpose: We evaluated the usefulness of temporal bone CT and/or T2W steady-state free precession sequence (SSFP) MR images for the positive diagnosis of perilymphatic fistula (PFL) of the round (RW) and/or oval windows (OW), with surgery as gold standard.
Methods and Materials: We enrolled patients who presented for a suspicion of PLF after a barotrauma, imaged by either a temporal bone CT and/or a high-resolution T2W SSFP MR sequence. All patients underwent exploratory surgery and surgical findings served as gold standard. Two radiologists, analysed the RW and OW on the side of the clinical symptoms on CT and MR.
Results: A fluid filling of the RW and OW on non-contrast CT or T2W MR was a good sign of PFL with high sensitivity and specificity. For the OW, if a fluid filling was the best sign of PFF, indirect CT signs were also helpful. The combination of CT and MR had the best sensitivity (95.6%) and specificity (100%) for the diagnosis of PFL.
Conclusion: Non-injected CT or MRI is highly reliable for the fast and accurate diagnosis of PLF. Sensitivity and specificity increased when both techniques are combined, thus we recommend starting the explorations with CT, followed by a T2W sequence on MRI.

B-0258 14:24

Effect of varying tube potentials for the assessment of cochlear implants using advanced cone-beam CT

I. Burck, I. Yel, M.H. Albrecht, S.S. Martin, J.L. Wichmann, S. Balster,
T. Stöver, B. Kaltenbach, T.J. Vogl; *Frankfurt a. Main/DE (iris.burck@gmx.de)*

Purpose: To evaluate the diagnostic value of 120 kilovolt (kV) compared to 96 kV acquired cone-beam CT images in patients after cochlear implantation (CI).
Methods and Materials: In this retrospective study, 75 postoperative cone-beam CT examinations obtained with 120 kV versus standard 96 kV were independently reviewed by four radiologists. Depiction of bone structures of the otocapsule were rated including the ossear spiral lamina, inner and outer wall of the cochlea, vestibule and semicircular canals. Furthermore, metal and motion artefacts, visualisation of single electrode contacts on the CI array, as well as overall image quality were assessed. Criteria were analysed using 5-point Likert-scales. Radiation dose was measured.
Results: Visualisation of bone structures of the otocapsule (mean score, 2.2 vs 3.1; P<0.01), and motion artefacts (mean score, 1.7 vs 2.4; P<0.01) were both rated higher using 120 vs 96 kV images. In addition, overall image quality showed higher scores for 120 kV settings (mean score, 2.1 vs 2.8; P<0.01). No significant differences were found for subjective evaluation of metal artefacts (mean score, 2.6 vs 2.7; P=0.33). Radiation dose of 96 kV images was significantly lower compared to 120 KV images (0.082 mSv vs 0.141 mSv, P<0.01).
Conclusion: Most recent cone-beam CT at 120 kV significantly improves the depiction of temporal bone structures and single electrode contacts compared to standard kV settings.

Radiation exposure imparted during multidetector and cone-beam CT scans for the perioperative cochlear implant evaluation

N. Guberina, U. Dietrich, D. Arweiler-Harbeck, M. Forsting, A. Ringelstein;
Essen/DE

Purpose: To examine radiation doses imparted during 128-, 256-, 384-multislice CT-scanners (MSCT) and cone-beam computed tomography (CBCT) for the perioperative cochlear implant insertion.
Methods and Materials: Radiation doses were evaluated during standardized petrous bone CT protocols at different MSCTs ((I) single-source CT-scanner Somatom Definition AS+, (II) 2nd generation of dual-source CT-scanner Somatom Definition Flash, (III) 3rd generation of dual-source CT-scanner Somatom Force (all Siemens Healthcare GmbH, Erlangen, Germany)) and at the CBCT Ziehm Vision RFD 3D (Ziehm Imaging GmbH, Nuremberg, Germany) ((IV) (a) RFD 3D (standard modifier) and (b) RFD 3D (low-dose modifier)). Image quality was independently examined by two experienced radiologists appraising various important parameters (electrode array placement, quality control of cochlear implant surgery and evaluation of the temporal bone in case of complications) based on real patients' examinations (n=78). Wilcoxon signed rank test was used to determine statistically significant differences (p<0.05). Interrater reliability was determined by calculating k values.
Results: In MSCT setting, the following radiation doses were assessed ($CTDI_w$; DLP_{mean} of different positions, top, center, bottom, right and left): (I) 21.5mGy; 216mGycm; (II) 19.7mGy; 195mGycm; (III) 12.7mGy; 127mGycm; in the CBCT setting, radiation doses were distributed as follows: (IV) (a) 1.9mGy; 19.4 mGycm; (b) 1.2mGy; 12.9mGycm. Overall, image quality was evaluated as good for both, MSCT- and CBCT-examinations, with a good interrater reliability (r = 0.81).
Conclusion: For the perioperative examination of cochlear implant insertion CBCT bears considerable dose-saving potential. Radiation doses are considerably lower during petrous bone CT protocols in the CBCT setting compared to MSCT setting while maintaining adequate image quality.

B-0260 14:40

Diagnostic performance of digital tomosynthesis as compared to conventional radiography in evaluation of craniovertebral junction

P. Kala, R. Avantsa, G. Gowda; *Bangalore/IN (prachi_kala@yahoo.com)*

Purpose: Overlying bony structures limit the assessment of CVJ anatomy. CT provides more precise information but with potential radiation hazards and high costs. Digital tomosynthesis (DTS) improves visualization by removing visual clutter of overlying anatomy. Purpose of the study is to assess the diagnostic performance of DTS in evaluation of CVJ.
Methods and Materials: In an approved prospective study, CT, conventional radiography and DTS were performed in 30 controls and 26 patients with CVJ pathology. Standard radiographs and DTS were performed on GE Discovery XR650 system with "VolumeRAD™. An automatic exposure control technique was used. Image quality was scored for conspicuity and pathology detection by two independent radiologists with experience of more than 3yrs in DT. Radiation dose of the all exams was compared.
Results: DTS was superior to radiography with sharper delineation of anatomy and detection of pathology of occipital condyles (89.6%), odontoid process (95%), C1 (86%) and C2 (100%) vertebrae in the coronal and atlanto-axial junction (92.4%) and dento-axial distance(92.4%) in sagittal slices. The results were found comparable to CT for the same. There was gross reduction in the radiation dose compared to CT (from 28 mGy to 3 mGy), and no significant rise compared to plain radiographs (from <2 mGY to 4 mGy).
Conclusion: DTS improved evaluation of CVJ anatomy. It has the potential to cut in number of views required, providing rapid diagnosis and savings on further imaging, radiation exposure, imaging costs that could mean reducing anxiety and discomfort for the patient.

Thesphenoid ostium and its relationship to other endoscopic landmarks inacromegaly: a CT-based morphological study

V. Hegde[1], N. Rajgopalan[2], S. Thakar[2]; [1]*Chennai/IN*, [2]*Bangalore/IN*
(verahegde@gmail.com)

Purpose: Acromegalic pituitary adenomas are known to cause disproportionate enlargement of the craniofacial and skull base structures (both soft tissue and bony) and thus complicate the trans-sphenoidal surgical approach. Morphological assessment of various landmarks, relevant to the endoscopic pituitary surgeon was done on thin section CT-PNS in operated cases of pituitary adenoma. The data was analysed with respect to growth hormone (GH) levels.
Methods and Materials: The medical records, thin section (1mm) CT-PNS images and their 2D reformations of 15 acromegalic patients (GH) were compared with 15 non-acromegalic patients (n-GH). Various morphological data (size of sphenoid ostium (SO), displacement of SO, depth of sphenoid and sella from piriform aperture, turbinates, sella and inter-carotid distance) and anatomical variations (middle turbinate, sphenoid sinus) were documented and compared between the two groups and in correlation with serum growth hormone levels. Image analysis was done using ImageJ software (ver 1.49).
Results: The ostium size in GH group was significantly larger than n-GH group (p=0.005). A moderate trend for an upward (r=-0.45) and lateral (r=0.34) displacement of the SO in the sphenoid face was observed in patients with increasing GH values. The width of the sellar floor, sphenoid rostrum and inter-carotid distance positively correlated with GH levels (r = 0.40, 0.43, 0.35 respectively).

Conclusion: The anatomical distortion in acromegalic pituitary adenoma poses a challenge to endoscopic pituitary surgeon. Prior knowledge and anticipation may prevent failures and complications.

B-0262 14:56

Comparing subjective and objective image quality at two different radiation exposure ranges of the paranasal sinus CT examinations using a volumetric 320-row detector CT system

M. Kantarci, A. Levent, S. Eren, B. Pirimoglu; *Erzurum/TR (akkanrad@hotmail.com)*

Purpose: To evaluate image quality of protocol including 135 kVp, 5 mAs and 80 kVp, 5 mAs in the paranasal sinus CT examinations using single volumetric 320-row multidetector CT technique.
Methods and Materials: From September to December 2016, both of our control group including 135 kVp and 5 mAs and our study group including 80 kVp and 5 mAs paranasal CT protocols were simultaneously performed on 40 patients using single volumetric 320-row multidetector CT device. Image quality for bony structures, air-filled structures and soft tissues were independently assessed for each group by three blinded observers using a 3-point grading scale.
Results: The effective radiation dose calculated for the control group scans was 0.037 ± 0.003 mSv. But, it was 0.0099 ± 0.001 mSv for the study group scans. The effective radiation dose of study group was statistically significantly lower than control group ($p < 0.001$). Despite significant lowering of the radiation doses, image qualities were sufficient for evaluating all the bony structures, air-filled structures and soft tissues except for eye muscle, retrobulbar fat and eye bulb.
Conclusion: Our results present that our protocols for study and control group provide significant dose reduction without the loss of diagnostic image quality for paranasal sinus CT. Paranasal sinus CT imaging can be performed at very low radiation exposure maintaining high image quality using a single volume 320-row detector CT device using 135 kVp and 5 mAs.

B-0263 15:04

"How much radiation do my baby get sick?" Answering to worried moms about dental radiology in childhood

F. Testa, N. Angaramo, M. Marchisio, R. Olivero, D. Fraire, V. Verna; *Bra/IT (frates@gmail.com)*

Purpose: To evaluate the impact on the pediatric population of radiological examinations such as OPT and cephalometry and to provide practical answers to parents often in trouble about radiation risk.
Methods and Materials: We considered a series of 345 OPTs and 165 cephalometries on children 4-12 yo, calculating the effective dose using an anthropomorphic phantom, according to MonteCarlo algorithms. We estimated the exposure rate of the pediatric population of our country. For each procedure, we optimized parameters in order to dose and image quality.
Results: OPTs not rightly optimized administered a cumulative effective dose of 34.368 mSv, that could be reduced of an amount of 4.096 mSv, (-11.9%); unoptimized cephalometries administered a cumulative dose of 14.15 mSv, that could be reduced of 0.49 mSv, (-3.46%). We calculated an Odds Ratio to undergo OPTs between children 0-12 and adults as 2.24 ($p<0.0000$) ad to undergo to cephalometries as 15.08 ($p<0.0000$). We estimated 31.5% of the children of our country undergo to an OPT during their childhood in public health service; nowadays it is impossible to estimate how many children are studied at private dental practice.
Conclusion: Empirically, considering an average annual Italian environmental dose of 3.3 mSv, an optimized cephalometry is estimated equal to about one week of environmental exposure, but it can reach the three months if not optimized; an OPT equals one month if optimized but until one year if unoptimized. Therefore, optimization is a must and, if implemented, the parents can be quietly relaxed.

B-0264 15:12

High-resolution dental MRI for planning palatal graft surgery: a clinical pilot study

T. Hilgenfeld, T. Kästel, A. Heil, P. Rammelsberg, S. Heiland, M. Bendszus, F.S. Schwindling; *Heidelberg/DE (tim.hilgenfeld@med.uni-heidelberg.de)*

Purpose: Because previous studies have revealed high variability of palatal masticatory mucosa thickness, preoperative evaluation before tissue graft harvesting is recommended e.g. by cone beam computed tomography. To evaluate whether high-resolution, non-contrast-enhanced dental MRI can be used for accurate determination of palatal masticatory mucosa thickness (PMMT) and to locate the greater palatal artery (GPA).
Methods and Materials: Two independent raters measured PMMT by use of dental MRI in 180 positions for five human volunteers. For comparison, clinical bone sounding was performed. To ensure identical measurement positions in MRI and bone sounding, tooth-supported resin splints were fabricated. The GPA was identified in two MRI sequences. Intra- and inter-observer agreement for MRI measurements and agreement between MRI and bone sounding were calculated by using the intra-class correlation coefficient (ICC) and Cohen's kappa (κ).
Results: Reliability of dental MRI measurements was high (intra-observer ICC 0.962; inter-observer ICC 0.959). Agreement of MRI measurements with bone sounding was moderate (ICC 0.744) and the GPA could be identified in 85% of measurement points. Good intra-observer agreement was observed for GPA identification (κ 0.778).
Conclusion: PMMT thickness measured by high-resolution, non-contrast-enhanced dental MRI is comparable with that obtained by bone sounding. Dental MRI enables reliable, non-invasive, and radiation-free planning of palatal tissue harvesting and can also be used for precise location of the GPA, which might help reduce complications during surgery.

MRI profile of sinonasal mucosal melanoma: analysis of 46 cases

E. Tononcelli, L. Calabretta, M. Ravanelli, D. Lombardi, D. Farina, R. Maroldi; *Brescia/IT (tononcelli.elena@gmail.com)*

Purpose: To assess the MR imaging profile of sinonasal mucosal melanoma (SMM) and to compare it with intestinal-type adenocarcinoma (ITAC) and squamous cell carcinoma (SCC).
Methods and Materials: Retrospective analysis of MRI signal pattern was performed in 46 patients affected by SMM, correlating with histology on surgical specimen in 41/46. In all lesions, quantitative assessment was performed on T1 sequences -normalising tumour signal to a pterygoid muscle- and on the ADC map, comparing findings with 28 ITAC and 9 SCC. Enhancement homogeneity and bone changes in SMM were qualitatively assessed. Statistical analysis was performed applying Student's T-test, exact-Fischer test and ANOVA-test.
Results: Statistically significant difference was seen between normalised T1 signal of amelanotic (avg.0,88) and melanotic (avg.1,23) SMM and between each subtype and SCC (avg.1,05) and ITAC (avg.1,06) ($p<0.05$). No significant difference was seen between normalised T1-signal of ITAC and SCC. ANOVA with pairwise comparison showed significant difference between the ADC value of SMM (avg.0,875 mm2/s), ITAC (avg.1,125 mm2/s) and SCC (avg.0,941 mm2/s). Inhomogenous enhancement was significantly more frequent in larger SMM ($p<0,05$). Bone remodelling was significantly more frequent in primary than in recurrent SMM ($p<0,05$), associated with focal erosion in primary and extensive erosion in recurrent SMM.
Conclusion: SMM is a rare and highly aggressive histotype displaying some specific MR signs that may differentiate it from the most common ITAC and SCC. MRI pattern is related to histology, particularly in the melanotic type.

Breast lesions characterisation: prospective comparison of strain and shear wave elastography as additional tool to BIRADS classification

V. De Soccio, V. Cantisani, G. Alagna, M. Di Segni, V. Forte, N. Di Leo, S. La Morte, F. D'Ambrosio; *Rome/IT*

Purpose: To evaluate the diagnostic performance of strain elastography (SE) and shear-wave elastography (SWE), in combination with US, to improve the differentiation of benign and malignant breast lesions
Methods and Materials: 130 histopathologically proven breast lesions were prospectively evaluated by using US, SE and SWE. Each lesion was classified according to the BIRADS lexicon and SE semi-quantitative dynamic features (strain ratio), and SWE through quantitative techniques (expressed in k/Pa). Histology was used as reference standard. 2x2 contingency tables and ROC curve analysis were used to assess the diagnostic performance and Pearson's χ^2 test was used to assess the significance of differences, with $p=0.05$ significance threshold
Results: Histological examination revealed 83 benign and 47 malignant breast lesions. US showed 80% sensitivity and 70% specificity. SWE kPa yielded a sensitivity of 72%, a specificity of 66% and ROC area of 0.691. US plus SR showed a sensitivity of 88%, a specificity of 76.6% and ROC area of 0.823. US plus SWE m/s had a sensitivity of 74%, a specificity of 76% and ROC AUC of 0.750.

Conclusion: Our experience suggests that SE and SWE in combination with B-mode US, are valid tools to improve BIRADS category assessment and the differentiation of benign from malignant breast lesions. According to our results, SE was more accurate than SWE.

Meta-analysis of 3 methods to analyse breast strain elastography
R.G. Barr[1], A. DeSilvestri[2], V. Scotti[2], F. Manzoni[2], C. Tinelli[2];
[1]*Rootstown, OH/US*, [2]*Pavia/IT (rgbarr@zoominternet.net)*

Purpose: There are 3 methods of interpreting strain breast elastography; E/B ratio, 5-point color scale and strain ratio. This meta-analysis was performed to determine if one methods was superior.
Methods and Materials: A systematic search of the medical literature was performed on July 2017. The following terms were used for the bibliographic strategy: Breast Neoplasm, Ultrasonography, mammary, elastic imaging techniques, strain elastography, real-time elastography, strain imaging, sensitivity, and specificity. Studies eligible for inclusion had biopsy proven results, utilised either E/B, 5-P, or SR and had at least 50 cases.
Results: 505 records were retrieved (220 after duplicates removal); of them 60 full-text were carefully examined and 46 papers were included in the metanalysis, publication year ranged from 2007 and 2017 (median year 2012). Quality of studies was generally high. Mean age of woman was 48 years; 12398 lesions (4242 malignant) were analysed. For the 5p methods the sens was 77%, spec 87%, LRP 5.3, LRN 0.24. For the strain ratio the sens was 87%, spec 81%, LRP 4.8, and LRN 0.16. For the E/B the sens was 96%, spec 87%, LRP 7.6 and LRN 0.03.
Conclusion: Of the three methods the E/B ratio has the highest sensitivity and E/B and 5P have the highest spec. With a LRN of 0.03 the E/B ratio can conclusively exclude a malignancy.

Anatomic factors affecting shear wave elastography of malignant and benign breast lesions
L. Plonski, E. Carmon, E. Chernovsky, G. Zeltzer, T. Sella; *Jerusalem/IL (tamarse@hadassah.org.il)*

Purpose: Shearwave elastography (SWE) characterizes breast lesion stiffness by measuring waves propagating through the surrounding tissue. The purpose of this study was to evaluate how anatomic factors of the breast affect the performance of SWE.
Methods and Materials: SWE was measured in 349 breast masses undergoing biopsy. Variables analyzed were density of the surrounding breast tissue (fatty n=130 or dense n=219) and depth of the lesion (superficial n=79, mid-breast n=137 or deep n=117). Data analysis evaluated the ability of SWE to differentiate benign from malignant as compared to histology. Statistical analysis included ROC curves, student's T test and the Kruskal-Wallis test.
Results: The optimal cutoff point to distinguish benign from malignant was 58.5kPa (AUC= 0.923) in dense tissue and 60.2kPa (AUC =0.932) in fatty tissue. Average Emax was higher for malignant masses: 144.4 kPa vs 34.8 kPa in dense tissue and 134.3 kPa vs 34.2 kPa in fatty tissue ($p<0.001$). There was no difference in PPV and NPV of SWE for dense vs fatty tissue (70.7% and 94.9% vs 87% and 90.2%). In all three depth groups ave Emax was higher for malignant compared to benign lesions (superficial 152.1 kPa vs 31.8 kPa, mid 129.1 kPa vs 30.6 kPa, deep 143.4 kPa vs 43kPa; $p<0.001$). PPV and NPV of SWE in superficial lesions were 72.4% and 93.9%, at mid-depth 81% and 92.4% and for deep lesions 78.1% and 94.3%.
Conclusion: SWE is not significantly affected by anatomic factors of the breast, differentiating malignant from benign lesions with high accuracy.

B-0269 14:24

Breast sonoelastography: comparison of the accuracy of the computer assisted diagnosis (CAD) classifier system using two values of different cut-off values with the visual classifier
E.F. Fleury[1], A.C. Gianini[1], V.J. Ayres[2], L. Ramalho[1], J. Sousa Neto[1], K.D. Marcomini[3]; [1]*São Paulo/BR*, [2]*Santo André/BR*, [3]*São Carlos/BR (edufleury@hotmail.com)*

Purpose: To evaluate the diagnostic accuracy of a CAD system to classify breast masses by elastography, using cut-off values for 75% and 80% stiffness areas, comparing with the results of the visual analysis.
Methods and Materials: Prospective evaluations were performed in accordance to local ethical committee. It was included 85 consecutive breast masses evaluated by strain elastography, of which 33 were malignant and 52 were benign. The masses were classified according to stiffness: 1. Soft; 2. Intermediate; 3. Rigid. The rigid lesions (3) were considered suspicious. First, the visual classification was performed. To evaluate the CAD system, the radiologist needs to delimit the edges of the lesion so that the computer automatically classifies the lesion. For classification with the CAD system the radiologist needs to delineate the mass margins so that the computer automatically classifies the lesion. For classification, the CAD system values the percentage of rigid area of the mass. Cutting values of 75% rigidity (CAD75) and 80% rigidity (CAD80) were compared. The ROC curves for the 3 classifiers were determined.
Results: The sensitivity and specificity obtained for each classifier were as follows: CAD75 90.9% and 67.3% respectively, CAD80 90.9% and 65.4%, and VISUAL 87.9% and 63.5%. The ROC curves were as follows: 0.837, 0.832, 0.817. There was no statistically significant difference for the ROC curves, however the CAD75 was the classifier that presented the best ROC curve.
Conclusion: Our results show that CAD using 75% cutoff for rigid area is the classifier with the best diagnostic accuracy.

B-0270 14:32

Role of elastography in the characterisation of subcentimeter breast lesions
S. Sampangi, S. Shivalingappa, M. Ashok Kumar, I. Desai, A. Kesari, D. Basavalingu, A. Verma, K. Kallur, P. Asokan; *Bangalore/IN (dr_sudhakar79@yahoo.com)*

Purpose: To characterize subcentimeter breast lesions on elastography and to determine it's utility for differentiating benign from malignant lesions.
Methods and Materials: 60 patients aged between 25 to 60 years and a total of 65 subcentimeter isoechoic or hypoechoic breast lesions were evaluated with elastography (Siemens Acuson S2000) between 2014 to 2016. Elastography was performed using Virtual Touch imaging (VTI) and Virtual Touch quantification (VTQ) applications. E/B ratio (Elastography/B-mode size ratio) was recorded from the VTI image and an average VTQ value (average of 5 measurements in m/s) were obtained. All the lesions underwent percutaneous ultrasound guided core biopsy.
Results: Of the 65 lesions biopsied, 41 lesions were malignant and 24 lesions were benign. The mean E/B ratio of malignant masses (1.28± 0.21) was significantly higher than that of benign masses (1.07 ± 0.09), with p value less than 0.001.There was no statistically significant difference between the mean VTQ value of malignant masses (2.71 ± 0.75) and benign masses (2.79 ± 1.03), with p value more than 0.05. With the use of ROC curve, the cut off E/B ratio was estimated to be 1.2 with sensitivity of 73.2%, specificity of 82.7%, and accuracy of 79.2 %.
Conclusion: Ultrasound elastography (VTI and VTQ) is a noninvasive technique to characterize tissue stiffness. E/B ratio of subcentimeter breast lesions can be used for differentiating between benign and malignant breast lesions and for potentially correlating with tumor desmoplastic reaction.

Chemoresponse assessment in locally advanced breast cancer patients: comparison of grey scale ultrasound and ultrasound elastography
A. Katyan, M.K. Mittal, C. Mani, A.K. Mandal, S.B. Grover; *New Delhi/IN (amitkatyan@icloud.com)*

Purpose: The study was conducted to compare the role of grey scale ultrasound and strain wave elastography in evaluating the response to neo-adjuvant chemotherapy (NACT) in patients with locally advanced breast cancer (LABC).
Methods and Materials: In this IRB approved study, eighty three patients of LABC were investigated with greyscale ultrasound and strain wave elastography. Women receiving NACT had the affected breast scanned by greyscale ultrasound and elastography before each cycle of chemotherapy and immediately before surgery. Changes in ultrasound size and elastographic parameters (size ratio, strain ratio) were documented and then compared to clinical and pathologic tumour response as evaluated after mastectomy.
Results: Mean strain ratio and mean size ratio for responders was significantly lower in responders in comparison to non-responders. Elastographic strain ratio parameters demonstrated high sensitivity and specificity for determining response even after the first cycle of chemotherapy. Strain wave elastography was found to detect treatment response earlier as compared to greyscale ultrasound in patients of LABC receiving NACT.
Conclusion: Tumour strain ratio was found to be the best predictor of treatment response in patients of LABC. Elastographic parameters showed significant change in its parameters earlier as compared to change in greyscale ultrasound size measurements. Serial imaging with elastography has the potential to predict treatment response early during the course of NACT, which may prove vital in management of patients with breast cancer.

B-0272 14:48

Can a hyperechogenic breast lesion be malignant?

E. Horvath, E.H. Castillo Balladarez, M.F. Pizzolon, C. Silva, M. Gallegos, M.A. Pinochet, M. Galleguillos, M. Uchida, P. Gonzalez; *Santiago/CL (eliette88@hotmail.com)*

Purpose: Hyperechogenic breast lesions have been described as generally benign and are rarely biopsied. The aim of this work was to evaluate the frequency of malignant hyperechogenic breast lesions, describe their imaging findings and histopathological characteristics.
Methods and Materials: IRB approved, retrospective, descriptive case series. Biopsied hyperechogenic lesions were selected from a database of 3.394 consecutive US-guided breast Core biopsies (1,020 malignant, 299 high-risk and 2,075 benign lesions) performed between 2006 and 2016. Any lesion that presented greater echogenicity than subcutaneous cellular tissue of more than 90% of its volume, was considered hyperechogenic. Demographical data, US and histopathological characteristics were recorded.
Results: In total 27 (1,08%) lesions biopsied were hyperechogenic: 21 (57%) of them had benign results. Sixteen patients (mean age: 52 years; range: 26-80) had hyperechogenic cancers, representing 1,5% (16/1,020) of all malignancies: 1 CDIS and 15 invasive carcinomas (81% ductal and 19% lobular histology). Mean size = 2 cm, range: 7-30 mm. All of them exhibited a small central hypoechoic foci and were partially or completely surrounded by fatty tissue. Shape, margins, orientation and vascular architecture were highly suggestive of malignancy on US, mammogram and MRI (features BI-RADS 4 and 5). In histopathological exam these cancers were surrounded by adipose tissue (not by fibroglandular tissue); also, they presented a hypocellular collagenous center and were hypercellular on its periphery, intermixing with fatty tissue, fibrous tracts and collagen.
Conclusion: Hyperechogenic cancers are very rare (less than 2% of breast cancers), but it is important to recognise them to avoid misdiagnosis.

B-0273 14:56

Texture feature analysis can support breast lesions identification and characterisation in images acquired by automated breast ultrasound systems

M. Marcon, A. Becker, N. Berger, M. Wurnig, M. Wagner, T. Frauenfelder, A. Boss; *Zurich/CH (Magda.Marcon@usz.ch)*

Purpose: To demonstrate how texture feature analysis(TA) can support the management of breast imaging findings in automated breast ultrasound imaging.
Methods and Materials: In this prospective IRB-approved study 644 images acquired with an automated breast ultrasound system(ABUS) in 24 consecutive patients with biopsy-proved malignancy(230 images from cancer, 53 glandular tissue, 53 fat) and in 21 with fibroadenoma with follow-up longer than 18 months or biopsy(211 images from fibroadenoma, 49 glandular tissue, 48 fat) were evaluated. After ROI placement, TA was performed applying 19 features computed from histogram and higher-order features for differentiation of cancer, fibroadenoma, glandular tissue and fat.ANOVA was used for the evaluation of differences among the four categories. In case of significant differences, ROC curve calculation and logistic regression analysis were performed to determine sensitivity and specificity. Bonferroni correction was applied using a p-value<0.05.
Results: Entropy values were different among the four categories(mean+/-sd, cancer 5.27+/-0.40, fibroadenoma 5.67+/-0.15, glandular tissue 5.73+/-0.30, fat 5.56+/-0.23, p<0.00001) and the ROC curve obtained comparing malignant lesions versus other findings had AUC=0.84(C.I. 0.81-0.88); using a cut-off value of 5.48 a sensitivity of 86% and specificity of 70% was obtained. Using contrast and energy_mean to differentiate lesions (cancer and fibroadenoma) from normal tissue (fat and glandular tissue) AUC=0.86(C.I.0.83-0.89) und AUC=0.88(C.I.0.85-0.91) were obtained, respectively, and binary logistic regression of the two variables results in AUC=0.92(C.I.0.89-0.94).
Conclusion: Texture feature analysis has the potential to support the differentiation between breast lesions and normal tissue as well as to distinguish cancer from fibroadenoma in automated breast ultrasound imaging.

B-0274 15:04

Does breast cancer subtype affect the diagnostic performance of axillary ultrasound for nodal staging in breast cancer patients

M.L.G. Vane[1], T. van Nijnatten[1], P.J. Nelemans[1], M.B. Lobbes[1], L. van Roozendaal[2], L. Kooreman[1], K. Keymeulen[1], M. Smidt[1], R. Schipper[1]; [1]*Maastricht/NL*, [2]*Heerlen/NL (thiemovn@gmail.com)*

Purpose: Physical examination followed by axillary ultrasound is routinely performed to assess preoperative axillary lymph node status in breast cancer patients. However, the accuracy of axillary ultrasound to assess nodal status for different subtypes of breast cancer is unknown. The aim of this study was to determine whether the diagnostic performance of axillary ultrasound is affected by breast cancer subtype.
Methods and Materials: All newly diagnosed breast cancer patients between 2008 and 2016 in MUMC+ with axillary ultrasound prior to axillary surgery were retrospectively included. Diagnostic performance of the axillary ultrasound (sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), false-negative rate (FNR) and accuracy) was determined for each of the following subtypes:ER+PR+HER2-, HER2+, and ER-PR-HER2-. Histopathology of axillary surgery specimens served as gold standard. Differences in diagnostic performance between breast cancer subtypes were calculated using Chi-squared test.
