Results: A total of 1,129 breast cancer cases were included. Most common subtype was ER+PR+HER2- with 76.0% (858), followed by 13.3% in HER2+ (150) and 10.7% in ER-PR-HER2- tumors (121). The difference in NPV was significant between ER-PR-HER2- and HER2+ tumors (90.2% versus 80.6%, p=0.048) and HER2+ and ER+PR+HER2- tumors (90.2% versus 87.2%, p=0.04). Sensitivity, specificity, NPV, FNR and accuracy did not significantly differ per breast cancer subtype.
Conclusion: The NPV of axillary ultrasound differed per molecular subtype, and was highest in ER-PR-HER2- tumors. The clinical consequence of the difference in NPV between breast cancer subtypes is unknown. Other parameters of diagnostic performance did not significantly differ per breast cancer subtype.

B-0275 15:12

Can documenting the number of abnormal nodes at axillary ultrasound accurately predict axillary nodal burden

N. Sharma[1], M. Wallis[2], R.G. Newcombe[3], S. Puri[4], M. Al-Attar[5], S. Pascaline[6], M. Hajaj[5], B. Elsberger[7], A. Goyal[4]; [1]*Leeds/UK*, [2]*Cambridge/UK*, [3]*Cardiff/UK*, [4]*Derby/UK*, [5]*Leicester/UK*, [6]*Kettering/UK*, [7]*Dundee/UK (Nisha.sharma2@nhs.net)*

Purpose: The aim was to determine if for women with needle biopsy-proven positive node on preoperative axillary ultrasound (AUS), the number of abnormal nodes seen on AUS is a predictor of number of positive nodes at histology.
Methods and Materials: This prospective multicentre cohort study included consecutive patients with early breast cancer who had needle biopsy-proven positive node on AUS and underwent axillary lymph node clearance (ALND) between October2015 and July 2016. The number of abnormal nodes at preoperative AUS was recorded by the scanning radiologist/radiographer.
Results: 123 patients were included in the study. Median age of the women was 62 (range 30 to 93) years. 54/123 (44%) women had one abnormal node while 69 (56%) had multiple abnormal nodes on AUS. 40/123 (33%) women had two or less nodes with metastases at histology after ALND. Tumours 20 mm or less ($P < 0.001$) and one abnormal node on AUS ($P < 0.001$) were associated with two or less nodes with metastases at ALND. Both remained significant in logistic regression analysis. The likelihood of at least three metastases based on the combination of these two factors had 95% sensitivity (79 of 83), 35% specificity (14 of 40), negative predictive value of 78% (14 of 18) and positive predictive value of 75% (79 of 105).
Conclusion: Women with needle biopsy-proven positive nodes, around 3 in 4 women (78%) with invasive tumour size 2cm or less and one abnormal node on AUS have 2 or less positive nodes at ALND. These women are overtreated by upfront ALND and can be offered SNB.

B-0276 15:20

Specification of breast masses according to BI-RADS classification enforced with contrast-enhanced ultrasound

E. Peniaeva[1], A. Sencha[2], Y. Patrunov[1], E. Sencha[2]; [1]*Yaroslavl/RU*, [2]*Moscow/RU (Ellapenyaeva@mail.ru)*

Purpose: To define the diagnostic value of contrast-enhanced ultrasound (CEUS) in specification of BI-RADS category of breast lesions.
Methods and Materials: CEUS with intravenous bolus administration of 2.4ml of Sonovue® was performed in 67 patients of the age 28-67 years. Linear 7-15MHz probes with specialised “contrast” option were used for CEUS. Core needle biopsy after CEUS diagnosed 28 carcinomas and 39 benign lesions.
Results: The following patterns were registered. CEUS BI-RADS 1 - no change. CEUS BI-RADS 2 (conferred 30 benign lesions) - slow or synchronous isoenhancement without perfusion defects and feeding vessels, slow or synchronous hypoenhancement with distinct regular margins without feeding vessels, absence of contrast enhancement of the lesion with distinct regular margins. CEUS BI-RADS 3 (6 benign lesions and 2 carcinomas) - synchronous hyperenhancement without perfusion defects and feeding vessels that does not exceed the grayscale size of the lesion. CEUS BI-RADS 4 (3 benign lesions and 12 carcinomas) - fast hyperenhancement of irregular shape that exceeds the grayscale size. CEUS BI-RADS 5 (14 breast carcinomas) - fast hyperenhancement of regular/irregular shape with perfusion defects that does not exceed or exceeds the grayscale size, or hyper/isoenhancement with/without perfusion defects with feeding vessels. US BI-RADS scale had the sensitivity of 75%, specificity 82.4%, diagnostic accuracy 79.1% in diagnosis of

breast carcinoma. CEUS BI-RADS scale improved the sensitivity up to 92.8%, specificity - 92.3%, diagnostic accuracy - 92.5%.
Conclusion: CEUS improves the diagnostic value of ultrasound in differentiation of breast lesions.

Histogram analysis of ADC maps and FLAIR MR imaging can predict active demyelination in multiple sclerosis
K.Y. Wang, J. Carlton, D. Guffey, F.E. Moron; *Houston, TX/US (femoron@gmail.com)*

Purpose: The aim is to evaluate the discriminatory power of apparent diffusion coefficient (ADC) values and FLAIR signal intensity histogram analysis in differentiating new acute demyelinating lesions (ADLs) and new non-acutely demyelinating lesions (N-ADLs) in multiple sclerosis (MS).
Methods and Materials: A total of 64 lesions from 32 MRIs of patients with clinically definite MS were analyzed. A new ADL was defined as an enhancing lesion. A new N-ADL was defined as a new non-enhancing lesion not present on a prior comparison MRI performed <1 year. Discrete lesions were selected for optimal region-of-interest (ROI) placement. Manual ROIs were drawn on FLAIR and ADC map by maximizing lesion coverage while avoiding volume averaging. Mean, max, min, 10th, 25th, 50th, 75th, and 90th percentile values were calculated. A second ROI was drawn in the contralateral normal-appearing white matter (WM). A ratio was obtained by dividing lesion value by contralateral WM value. Wilcoxon rank-sum test was used to compare ratios between ADL and N-ADL. Logistic regression was used to assess associations between FLAIR ratios and new ADLs. Receiver operating curve analysis evaluated discriminatory power of ADC map and FLAIR ratios. A $p<0.05$ was considered statistically significant.
Results: The data skewness ranged from 1.11 (ratio of 10th percentile diffusivity) to -0.34 (ratio of min FLAIR value). The FLAIR ratios of all descriptive statistics (mean, max, min, and percentiles) were significantly higher for ADLs compared to N-ADLs ($p=0.0002$ to <0.0001). No significant associations between FLAIR ratios and ADLs were noted for all descriptive statistics with logistic regression. The diffusivity ratios of all descriptive statistics (mean, max, min, and percentiles) were also significantly higher for ADLs compared to N-ADLs ($p=0.0309$ to 0.0117). ROC analysis of FLAIR demonstrated an area under the curve ranging from 0.792 (max ratio) to 0.833 (25th percentile ratio). A cutoff of 1.471 for the 25th percentile FLAIR ratio provides a 0.86 sensitivity, 0.70 specificity, and 0.81 accuracy. ROC analysis of ADC demonstrated an area under the curve ranging from 0.669 (min ratio) to 0.698 (90th percentile ratio). A cutoff of 1.543 for the 90th percentile ADC ratio provides a 0.75 sensitivity, 0.70 specificity, and 0.73 accuracy.
Conclusion: The signal intensity of FLAIR and diffusivity on ADC maps may have the potential to discriminate between new ADL and N-ADL in MS.

B-0278 14:08

Proton magnetic resonance spectroscopy (^{1}H-MRS) of the brain in patients with tick-borne encephalitis
R. Zawadzki[1], B. Kubas[1], M. Hładuński[1], J. Zajkowska[1], O. Zajkowska[2], D. Jurgilewicz[1], A. Garkowski[1], S. Pancewicz[1], U. Lebkowska[1]; [1]*Bialystok/PL*, [2]*Warsaw/PL (zaw.radoslaw@gmail.com)*

Purpose: To study the metabolic changes of the brain by ^{1}H-magnetic resonance spectroscopy (^{1}H-MRS) in patients with tick-borne encephalitis (TBE).
Methods and Materials: 22 patients diagnosed with TBE and 24 healthy controls have been enrolled. All of them underwent routine magnetic resonance imaging (MRI) protocol using 3.0 T MRI scanner, which included T1-weighted images, T2-weighted images, fluid-attenuated inversion recovery (FLAIR), and diffusion weighted images (DWI). ^{1}H-MRS examinations were performed with the following acquisition parameters: repetition time (TR), 2000 ms; echo time (TE), 135 ms; number of excitations, 128. Single voxels were manually located bilaterally in the basal ganglia, thalami and in the hemispheres of cerebellum. Metabolites to creatine (Cr) ratios were analysed. The following peaks were assessed: N-acetylaspartate (NAA), choline-containing compounds (Cho), and glutamate/glutamine/γ-aminobutyric acid complex (Glx).
Results: Compared to controls we found statistically significant decrease of the NAA/Cr ratio bilaterally in the right and left thalamus ($p = 0.0002$ and $p = 0.0017$, respectively) and statistically significant increase of the Cho/Cr ratio in the right and left thalamus ($p = 0.03$ and $p = 0,0065$, respectively). We also observed statistically significant increase of the Cho/Cr ratio in the left hemisphere of cerebellum ($p=0.04$). There were no statistically significant brain metabolite alterations within other evaluated areas.
Conclusion: A significant reduction in NAA/Cr ratio and statistically significant increase of the Cho/Cr ratio in comparison with the control group suggests the presence of neuronal damage in patients with TBE.

B-0279 14:16

Altered hippocampal GABA and glutamate levels and functional connectivity in multiple sclerosis
X. Yin[1], F. Gao[2], G. Wang[2]; [1]*Chongqing/CN*, [2]*Jinan/CN (xuntaoyin@gmail.com)*

Purpose: There is growing evidence for dysfunctional glutamatergic excitation and/or gamma-aminobutyric acid (GABA)ergic inhibition in patients with multiple sclerosis (MS). Cognitive impairment may occur during the early stages of MS and hippocampal abnormalities have been suggested as biomarkers. However, researchers have not clearly determined whether changes in hippocampal GABA and glutamate (Glu) levels are associated with cognitive impairment and aberrant neural activity in patients with MS.
Methods and Materials: We used magnetic resonance spectroscopy to measure GABA and Glu levels in the left hippocampal region of 29 patients with relapsing-remitting MS and 29 healthy controls (HCs). Resting-state functional connectivity (FC) with the hippocampus was also examined. Partial correlation analyses of the cognitive performance, hippocampal GABA+ and Glu levels and FC strengths, were performed separately for patients with MS and HCs, while controlling for age and gender.
Results: Compared to HCs, patients exhibited significantly lower GABA+ and Glu levels, which were associated with verbal and visuospatial memory deficits, respectively. Patients also showed decreased FC strengths between the hippocampus and several cortical regions, which are located within the default mode network. Moreover, hippocampal GABA+ levels correlated with the FC strengths in HCs but not in patients with MS.
Conclusion: This study describes a novel method for investigating the complex relationships among excitatory/inhibitory neurotransmitters, brain connectivity and cognition in health and disease. Strategies that modulate Glu and GABA neurotransmission may represent new therapeutic treatments for patients with MS.

Advanced MRI assessment during dendritic cell immunotherapy
A. Gioppo, M. Eoli, D. Aquino, G. Finocchiaro, M.G. Bruzzone, V. Cuccarini; *Milan/IT (andrea.gioppo@istituto-besta.it)*

Purpose: To examine advanced MRI findings encountered in first diagnosis glioblastoma patients treated with dendritic cell immunotherapy.
Methods and Materials: A retrospective analysis was performed on longitudinal MRIs obtained before the first vaccination and every two months, by 22 patients enrolled in the EUDRACT N°2008-005035-15 trial. Tumor volume, mean normalized tumoral CBV (rCBV), mean normalized tumoral ADC (rADCmean), ADC mode (ADCmode), ADC skewness (ADCskew) were collected.
Results: We identified 10 responders and 12 not-responders. In responders, basal rADCmean was significantly higher than in non-responder patients (1.34±0.17 vs 1.14±0.34;p=0.03). After the first four vaccinations, responders showed a significant decrease in rADCmean (1.34±0.17 vs 1.23±0.23;p=0.028) and not statistically differences in ADCskew, when compared to non-responders. A decrease in rADCmean value ≥0.13 and a change in ADCskew ≥-0.14 were significant predictor of longer progression-free survival (PFS) (17.2 vs 10.2;p=0.04/ 15.4 vs 9.3;p=0.02) and overall survival (OS) (33 vs 19.9;p=0.003/ 29 vs 12.4;p=0.002). Regarding follow-up, MRI performed at progression demonstrated a significant increase of rCBV (4.25 vs 5.38;p=0.04) and a significant decrease in rADCmean (1.17 vs 1.01;p=0.004) when compared to basal MRI. MRI performed at pseudo-progression showed no modification of rCBV and rADCmean. A significant decrease in ADCmode was observed comparing value obtained at pseudo-progression time with those obtained at the following exams (0.0012 vs 0.0010;p=0.008).
Conclusion: An early decrease in rADCmean and no significant changes in ADCskew are related to a better survival in GBM patients treated with DC immunotherapy. Modification of rCBV and rADCmean can be useful in distinguishing progression and pseudo-progression.

B-0282 14:32

Cortical vs juxtacortical lesions in multiple sclerosis: an analysis of PSIR performance in comparison to FLAIR

M.R. Lima[1], G. Furlin[1], A. Kupske[1], J.S. Muller[1], M.C.A. de Vecino[1], M.G. Longo[2], K.R.S.B. Nunes[1], B.B. Valentini[1], M.A.G. de Caneda[1]; [1]*Porto Alegre/BR*, [2]*Boston, MA/US (Gabifurlin@gmail.com)*

Purpose: Multiple sclerosis (MS) affects white and grey matter. Imaging differentiation between juxtacortical and cortical lesions can be challenging with the standard magnetic resonance (MRI) sequences. New sequences have demonstrated better performance, like phase-sensitive inversion recovery (PSIR). This study evaluates the performance of PSIR to detect and differentiate cortical plaques in patients with MS, in comparison to FLAIR.
Methods and Materials: Patients with MS confirmed by McDonald criteria (2010) who underwent MRI examination in our service between March 2016 and April 2017 were retrospectively evaluated by two radiologists that quantified the number of lesions detected first by FLAIR and then by PSIR. Later, they estimated how many lesions were reclassified using PSIR.
Results: 71 patients were included with an average of 12.7 years of disease. 52 patients (73.2%) presented juxtacortical lesions in FLAIR. Of these, 43 (82.7%) had lesions reclassified using PSIR, with a median number of 2.55 lesions per patient. 38 (54.3%) presented supratentorial lesions identified only in PSIR, with a median number of 1.44 lesions per patient. 23 (32.9%) presented infratentorial lesions identified only in PSIR, with a median number of 1.43 lesions per patient. PSIR showed better performance than FLAIR in identifying MS lesions in supratentorial and infratentorial compartments ($p<0.001$ for both), detecting an average of 1.5 more lesions in supratentorial and 0.42 more in infratentorial compartment.
Conclusion: The evaluation of MS lesions with PSIR showed greater performance for diagnosis and classification in comparison to FLAIR and its use should be encouraged in the clinical practice.

B-0283 14:40

Neuroimaging manifestations of HIV-AIDS at a reference center in south of Brazil

G.F.D. Castanho, P. Yokoo, J. Geske, G. Michelis, A. Cremoneze, B.C. Teixeira; *Curitiba/BR (gabrielle.castanho@gmail.com)*

Purpose: The nervous system is among the most frequent and serious targets of human immunodeficiency virus (HIV) infection, mainly in patients with profound immunosuppression. This group of patients presents particular aspects of neuroimaging that must be known and recognised by radiologists. We want to present illustrative magnetic resonance imaging (MRI) findings in HIV positive patients.
Methods and Materials: This was a retrospective observational study. We reviewed all orders of Brain MRI at our service, in a two year period (March 2015 to March 2017) with a total of 2089 exams. We included patients with a known HIV diagnosis described in the medical application or summary of hospital discharge. We identified 123 HIV patients (154 Brain MRI) and we studied and correlated with anatomopathological and clinical-laboratory findings.
Results: The majority of patients in our sample were hospitalised (61%). In this group 52% had CD4<200 and 14% was not available, also we observed some overlapping findings, infection was found in 56% (39% toxoplasmosis, 16% PML, 11% syphilis, 11% tuberculosis and 9% HIV encephalopathy), neoplasm in 10% (62% lymphoma and 25% metastasis), 26% had others lesions (45% microangiopathy, 20% infarcts and 5% IRIS) and 17% of patients evolved to death.In the outpatients only 8% had CD4<200 and 8% was not available, we found 6.3% with signs of active infections and 23% with chronic alterations (vascular and infectious), the remainder presented nonspecific or normal findings.
Conclusion: The hospitalised patients presented a more aggressive pattern than outpatients, as expected, because of the larger immunosuppression.

B-0284 14:48

Acute optic neuritis (ON): can magnetic resonance (MRI) in the acute setting help in determining the aetiology?

C. Rosti, M. Cellina, V. Fetoni, M. Pirovano, M. Ciocca, G. Oliva; *Milan/IT (cristina.rosti@gmail.com)*

Purpose: ON is an inflammatory disease of the optic nerve which can be idiopathic or associated with demyelinating or autoimmune diseases. Our aim was to investigate if MRI in the acute setting may help in establishing ON aetiology.
Methods and Materials: 60 previously healthy subjects presented to our emergency department with a first episode of ON, clinically diagnosed. Patients underwent ophthalmologic, neurologic examinations, blood tests and by brain and orbit basal CT. A 1.5T MRI of the orbit, brain and cervical spine was executed within 48 hours from the onset. The protocol included a 3D FLAIR, DWI, T1 and T2 weighted sequences, with fat saturation (FS) on the orbit and, after contrast injection, a T1 3D MPRAGE on the brain, FS T1 SE on the orbit and cervical spine. Neuroradiologists, unaware of clinical data, made an ON aetiological diagnosis based on the MRI datasets. ON were classified as idiopathic or clinically isolated syndrome (CIS), multiple sclerosis (MS) or optic neuromyelitis (NMO) in case of T2 lesions, according to location, morphology, contrast enhancement (CE).
Results: All CT were negative. According to MRI, 22 ON were classified as idiopathic (19 negative MRI, 3 swelling of the optic nerve); 7 as MS (spatio-temporal disseminated T2 lesions); 29 as CIS (T2 lesions without CE with/without cervical and optic nerve involvement), 2 as NMO (brain and cervical lesions with typical characteristics). MRI results confirmed neuroradiologists' diagnosis. NMO was confirmed by the antiaquaporin-4.
Conclusion: MRI findings perfectly matched neurologists' diagnosis confirming ON aetiological diagnosis.

B-0285 14:56

Evaluation of chronic MS lesions with T1 magnetic resonance fingerprinting

E. Springer[1], W. Bogner[1], P. Cardoso[1], M. Nittka[2], J. Pfeuffer[2], G. Koerzdoerfer[2,2], R. Kirsch[2], S. Trattnig[1]; [1]*Vienna/AT*, [2]*Erlangen/DE (elisabeth.springer@meduniwien.ac.at)*

Purpose: MR Fingerprinting(MRF) is a novel approach in data acquisition, post-processing and visualization[1]. Non-enhancing T1-hypointense lesions(black holes) in multiple sclerosis(MS) are chronic lesions characterized by severe axonal damage[2, 3], and with a persistent iron ring are considered slowly progressive lesions[4, 5]. Iron rings are in most cases only visible at 7T due to higher spatial resolution and stronger susceptibility effects[6, 7]. To investigate whether MRF T1 relaxation times may be used to differentiate chronic T1-hypointense lesions with iron ring-deposits from chronic T1-hypointense lesions without iron-deposits.
Methods and Materials: Ten relapsing remitting MS(RRMS) patients were measured on a 3T MAGNETOM-PRISMA MR-scanner with a 64-channel head/neck coil, and on a 7T-MAGNETOM MR-scanner(both Siemens Healthcare, Germany) with a 32-channel head coil (Nova Medical). The comprehensive routine MS protocol, including FLAIR, 3D-FLAIR, T2-TSE, MP2RAGE, diffusion-weighted imaging, post-contrast T1-weighted images, as well as a prototype MRF sequence[8] were performed at 3T, susceptibility-weighted imaging at 7T. MRF T1 relaxation times were measured in regions of interest in FLAIR-hyperintense, T1-hypointense lesions without contrast media uptake, containing iron ring-deposits on SWI, and non-containing iron-deposits, using Syngo Via. Multi-Level Analysis(MLA) was assessed to take clustered multiple measures per patient into account when comparing different regions.
Results: MRF T1 relaxation times were significantly higher in chronic T1-hypointense MS lesions containing iron ring-deposits than in non-iron-containing chronic T1-hypointense MS lesions ($p=0.002$).
Conclusion: MRF T1 relaxation times may be used to differentiate iron-containing from non-iron-containing chronic MS lesions, and thus may facilitate the depiction of a more progressive form of RRMS at 3T.

Brain damage in early adult paediatric-onset MS with no or minimal disability

L. Nichelli[1], A. Giorgio[2], J. Zhang[2], M. Stromillo[2], F. Rossi[2], M. Battaglini[2], M. Mortilla[3], M.P. Amato[3], N. De Stefano[2]; [1]*Modena/IT*, [2]*Siena/IT*, [3]*Florence/IT (lucianichelli@gmail.com)*

Purpose: Paediatric-onset MS (POMS) patients seem to benefit from brain adaptive mechanisms in the short-medium term, although they reach clinical disability at a significantly younger age than adult-onset MS (AOMS) patients. To investigate such unfavourable long-term clinical outcome, we measured structural and functional brain damage in early adult POMS patients with no or minimal clinical disability.
Methods and Materials: 15 POMS patients (age=24.8±7 years; median EDSS=1), 14 age- and disability-matched AOMS patients and 20 normal controls (NC) underwent a 3T MRI examination. We obtained WM-lesion volume (LV) and probability maps (LPM), brain volumes (whole brain, WM, GM, neocortical, deep GM) with SIENAx and performed a voxelwise DTI and resting fMRI analyses with FSL tools, using the statistics of non-parametric permutation testing.
Results: No differences in LV and in brain volumes were found between POMS and AOMS. However, in comparison with AOMS patients, early adult POMS showed (i) at the level of posterior corona radiata (PCR), an eloquent area for motor disability, higher probability of lesion occurrence ($p=0.002$) and higher axial and radial diffusivity ($p<0.001$); and (ii) a reduced long-range functional connectivity between default mode network and secondary visual

network (p=0.0016), whose interaction supports important cognitive functions such as spatial attention and visual learning.
Conclusion: This pattern of structural damage and altered functional connectivity in early adulthood may give insight into long-term outcome of POMS.

B-0287 15:12

Comparison between grey matter-only and white matter-only imaging in the detection of brain multiple sclerosis lesions
Z. Abidi[1], F. Faeghi[2], Z. Mardanshahi[3], J. Abdolmohammadi[4], M. Haghighikaboudkola[5]; [1]*Qaemshahr/IR*, [2]*Tehran/IR*, [3]*Sari/IR*, [4]*Sanandaj/IR*, [5]*Babolsar/IR (abidi4805@sbmu.ac.ir)*

Purpose: We aimed to evaluate two different types of double inversion recovery sequence including grey matter-only (GM only) and white matter-only (WM only) imaging and routine brain MRI sequences in detection of multiple sclerosis (MS) lesions.
Methods and Materials: In this study, 30 patients including 19 patients with RRMS and 11 with SPMS were examined on a 1.5T Philips MRI scanner, using GM only, WM-only imaging and routine brain MRI sequences with same parameters, including field of view, matrix, slice thickness, voxel size and number of signal averaging (NSA). In GM-only imaging two inversion pulses with inversion delay times (TI_1=3400 and TI_2=325 ms) optimized to suppress signal of WM and cerebrospinal fluid (CSF) to image cortex alone and in WM-only imaging two different TI (TI_1=3700 and TI_2=525 ms) are used to suppress signal of GM and CSF to image the WM lonely.
Results: More total number of lesions were displayed on GM-only sequence compared with WM-only imaging (p=0.0001) and FLAIR (p=0.014) and T2W_TSE (p=0.0001). Higher contrast ratio has been observed between the white matter lesions and the normal-appearing white matter (NAWM) in most anatomical regions.
Conclusion: GM-only and WM-only imaging provide additional information compared to routine brain MRI sequences. Although GM-only imaging was superior to routine sequences, but WM-only imaging had a poor detection of MS lesions in brain. So, we highly recommend routine use of GM-only imaging for early detection of MS lesions.

Improved image quality and reduced radiation dose in trauma CT using a custom arm rest pillow
V. Larsen, C.T. Traply, B.R. Mussmann; *Odense/DK (brz9ak@gmail.com)*

Purpose: In multi-trauma CT, assessment of the liver is crucial for the diagnosis, but with current scan procedures the patients are often scanned with the arms down causing artifacts in the abdominal region. We developed a custom arm rest pillow allowing for scans with arms in overhead position. We hypothesized that the arms-over-head position would affect image quality in the parenchymal organs positively, while moderate image quality decrease in the cervical spine was expected. The purpose was to assess dose and image quality implications of the custom pillow in emergency CT.
Methods and Materials: We included 24 multi-trauma patients referred for chest-abdomen scans. Using the trauma pillow 12 patients were scanned feet first, arms over head and 12 were scanned head first, arms down (standard procedure). Subjective image quality was assessed in the parenchymal organs and cervical spine using a five-point scale. Image quality scores < 3 were considered unacceptable. Image scores and dose length products were compared using the two-sided unpaired t test.
Results: Mean DLP decreased from 2360 to 1800 mGy*cm (p=0.06) using the pillow. Mean image quality score in the parenchymal organs increased from 2.4 to 4.3 (p<0.00001). All patients with insufficient image quality were scanned with arms down. Cervical spine image quality decreased from 4.7 to 3.6 (p<0.0001) with no scores below cut-off.
Conclusion: Image quality can potentially be improved in the parenchymal organs and radiation dose can be reduced using the trauma pillow while image quality in the cervical spine is decreased, yet diagnostically acceptable.

B-0289 14:08

Evaluation of the diagnostic potential of the GCS for the indication of whole-body CT in paediatric polytrauma
C. Frellesen, J. Wichmann, P. Tischendorf, T.J. Vogl, K. Eichler; *Frankfurt a. Main/DE (c.frellesen@gmail.com)*

Purpose: To evaluate the diagnostic potential of the Glasgow Coma Scale (GCS) for the indication of whole-body CT (WBCT) in paediatric polytrauma.
Methods and Materials: 100 paediatric polytrauma patients with WBCT were compared according to age, gender, mechanism of injury (MOI), GCS, detected injury and injury severity score (ISS). Correlation between GCS and patient groups with (p+) and without (p-) injury was assessed using Mann-Whitney U Test and ROC analysis to evaluate its predictive potential.
Results: Average age was 9.13 years with predominance of male patients (72 vs 28%). Traffic accidents were the most frequent MOI (63%). Injury was detected in 71% of the patients, most commonly of the head (43%). There was no significant correlation between MOI and ISS. P+ and p- showed significant differences regarding GCS (p<0.001). ROC analysis revealed an optimum discrimination threshold of the GCS at 12.5 with an inaccuracy rate of 21% relating to craniocerebral injuries and 30% to whole-body injuries, respectively.
Conclusion: The indication of WBCT in paediatric polytrauma patients should not be based on the GCS alone. Focused CT of individual body regions is to be preferred. Cranial CT is recommended at a GCS less than or equal to 13.

Who needs a CT scan? Incorporating S100B into existing guidelines in the management of mild traumatic brain injury
L. van den Hauwe, M. Landen, F. Vandereyken, R. Vael, P. Bracke; *Brasschaat/BE (lucvdhauwe@mac.com)*

Purpose: To determine whether S100B, a protein biomarker of brain injury, can predict intracranial abnormalities CT in patients with mild traumatic brain injury (mTBI).
Methods and Materials: Consecutive adult patients with mTBI (GCS 14-15) were included in this study. Patients were managed according to existing guidelines for CT selection based on patient history and clinical examination. S100B was analysed within 4 hours after the traumatic event; results were available within 1 hour. Non-contrast CT was subsequently performed when elevated S100B levels were found.
Results: One hundred seven patients were included during a 12-month period (October 2016-September 2017). Thirteen patients (12%) showed traumatic abnormalities on CT, including skull/facial fractures (n=9), subarachnoid haemorrhage (n=6), cortical contusions (n=4), subdural haematoma (n=3), intracerebral haematoma (n=2), and epidural haematoma (n=1). No patients needed neurosurgical intervention; none died as a result of the TBI. Thirty-three patients (31%) had normal S100B levels and 74 patients (69%) showed elevated S100B levels (≥ 0.105µg/L). Compliance to the new guidelines was not always perfect. As a result over-triage occurred in 4 patients (4%) and under-triage occurred in 11 patients (10%). A false-negative test was observed in 1 demented patient who had a subarachnoid haemorrhage and a subdural haematoma on CT. A false-positive test was observed in a multitrauma patient (liver laceration and rib fractures) without head injury.
Conclusion: Used in combination with clinical decision rules, S100B may reduce the need for CT and as such reduce radiation exposure to the patient and save costs to the society.

B-0291 14:24

Can computed tomography (CT) help in predicting diplopia in orbital blowout fractures (BOFs)?
M. Cellina[1], M. Orsi[1], C. Floridi[2], G. Oliva[1]; [1]*Milan/IT*, [2]*Perugia/IT (m.cellina@yahoo.it)*

Purpose: The management of BOFs is controversial and the assessment of diplopia is the most important criterion for planning surgical repair. Our aim was to determine CT findings that can be used to predict diplopia in patients with BOFs.
Methods and Materials: We retrospectively evaluated orbital CT of all patients presented for blunt craniofacial trauma (N=3500) from January 2014 to June 2016, selecting patients with CT-proven BOFs. For each CT we assessed the following variables: fracture site, bone fragments displacement, extraocular muscle (EOM) swelling, EOM dislocation, EOM entrapment, EOM hooking, intraconal and extraconal emphysema, intraconal and extraconal hematoma, orbital fat herniation. All patients underwent Hess-Lancaster test to establish the presence of diplopia. After performing group comparison with Pearson $\chi 2$ test, we derived our prediction model using logistic regression, with diplopia as the prediction and CT variables as predictors.
Results: We observed 299 patients with BOFs, 46 (15.4%) with diplopia. CT variables with statistically significant difference between the group with diplopia

and the group without diplopia were as follows: floor fracture (p=.014), bone fragments displacement (p=.001), EOM swelling (p=.001), EOM displacement (p<.001), EOM entrapment (p<.001), orbital fat herniation (p=.003). CT variables with significance as predictors of diplopia at multivariate analysis were only: floor location (odds ratio [OR], 2.87; 95% confidence interval [CI]: 1.22, 6.73; p=.01), muscle entrapment (OR, 10.69; 95% CI: 3.76, 30.4; p<.001) and muscle displacement (OR, 11.51; 95% CI: 3.05, 43.3; p<.001).
Conclusion: Diplopia can be predicted on CT findings after an orbital trauma.

B-0292 14:32

Multi-energy CT in patients with thoraco-abdominal bleeding: new techniques to facilitate image reading and to help save dose

J. Kahn[1], G. Böning[1], U. Fehrenbach[1], F. Feldhaus[1], D. Kaul[1], M.H. Maurer[2], D.M. Renz[3], F. Streitparth[1]; [1]*Berlin/DE*, [2]*Berne/CH*, [3]*Jena/DE*

Purpose: CT protocols for the detection of bleeding sources often include native CT series to distinguish between calcifications and contrast-agent extravasation. The study evaluates whether virtual native imaging (VNI) can replace real native imaging (RNI) in the reading of acute thoraco-abdominal bleeding and whether monoenergetic imaging can improve the detection of the bleeding's origin.
Methods and Materials: Out of a total of 107 data sets from patients with clinically suspected bleeding, 20 patients (14 men; age 65.4±14.1 years) showed active visceral or soft-tissue bleeding in multi-energy CT angiography. After acquisition of an RNI series, the multi-energy protocol included VNI, monoenergetic images at 40 and 140keV and iodine mapping. CT numbers of ROIs in liver, pancreas, aorta, kidney, muscle and the bleeding jet were measured for quantitative image analysis (contrast-to-noise ratios, CNR). Two radiologists rated detectability of the bleeding source in different series. Wilcoxon rank test was used to compare related samples.
Results: VNI series showed sufficient, but not complete suppression of iodine (CT number aorta RNI: 33.2±12.3, VNI: 44.8±9.5, p<0.01; bleeding jet RNI: 43.1±16.9, VNI: 56.2±16.7, p<0.05). VNI showed significantly higher CNR than RNI in all measured organ regions. 40keV images showed a CNR in bleeding jets 4 times higher than standard 140keV images and were the best series to detect bleeding sources in qualitative rating.
Conclusion: VNI can safely replace RNI in a CT protocol looking for bleeding sources with a potential dose reduction of 30%. Low keV series may improve detection of the bleeding's origin.

B-0293 14:40

Evaluation of CT and clinical features of bowel and/or mesenteric injury in blunt abdominal trauma: a case-control study

A. Lansier, C. Bourillon, R. Jantzen, E. Ragot, A. Follin, A. Berger, O. Clement, P. Halimi, C.A. Cuenod; *Paris/FR (alexandre.lansier@gmail.com)*

Purpose: To evaluate the multidetector CT and clinical features of bowel and/or mesenteric injuries in blunt abdominal trauma and evaluate the interobserver agreement according to the experience of the radiologist.
Methods and Materials: This retrospective case-control study included 30 cases with surgically confirmed bowel and/or mesentery requiering surgical repair and 52 consecutive controls with blunt abdominal or chest trauma and no surgically important bowel and/or mesenteric injury. CT findings were screened by two radiologists: an 8-year-experimented in abdominal imaging radiologist and a second-year resident blinded to the patients' outcome. Clinical outcomes were analysed by consulting the medical file. Sensitivity and specificity were calculated for each sign and a kappa coefficient were used to establish the interobserver variability.
Results: The CT signs with best positive likelihood ratio were extra luminal air (infinity), bowel wall defect (infinity) and thickening (38.13), decreased bowel wall enhancement (10.4) and mesenteric vessels abnormalities (9.01). The specificity of clinical seat belt sign associated with anterior abdominal wall injury on CT was 98%. The sensitivity of free intraperitoneal fluid was 100% and its density was higher in cases. More than 50% of patients with missed diagnosis on first CT had a visceral injury associated. Diagnosis of mesenteric and/or bowel injury depends on the experience of the radiologist (kappa = 0,6).
Conclusion: Multidetector CT is accurate for the diagnosis of bowel and/or mesenteric injuries in blunt abdominal trauma depending on the experience of the radiologist. The association of clinical seat belt sign and anterior abdominal wall injury on CT is highly specific.

B-0294 14:48

Prognostic and diagnostic value of hyperattenuating adrenal glands on contrast-enhanced computed tomography scans of polytraumatised patients

D. Kildal, T. Erben, M. Beer; *Ulm/DE*

Purpose: The adrenal gland with its endocrinal hormones relates to several reactions due to traumatic injury of the human body. Purpose of this study was to seek possible connections between hyperattenuating adrenal glands on contrast-enhanced CT scans of polytraumatised patients and potentially lethal injuries.
Methods and Materials: This retrospective study includes 379 polytraumatised patients which had a biphasic contrast-enhanced CT. Two radiologists assessed the general pathologies, Hounsfield units (HU) measurements of the adrenal gland [AG], the V. cava inferior [VCI] and the erector spinae muscle [ESM] were registered. Patients were sorted into 2 groups [group 1: HU(AG) ≥ HU (VCI); group 2: HU (AG) ≤ HU (VCI)].
Results: 31 patients exhibited hyperattenuated AGs and were sorted into group 1. 348 patients were sorted into group 2 due to non-hyperattenuated AGs. Density in group 1 was 106.77 ± 29.29 HU, in group 2 density was 83.80 ± 26.50 HU. 11 patients of group 1 suffered from intracranial bleeding [ICB] (group 1: 11/31 ICB, 35.48%) whilst 54 patients of group 2 showed ICB (group 2: 54/348 ICB, 15.52%). Intracranial bleeding and hyperattenuating AGs were noticed in 11 out of 65 cases (11/65, 16.92%). A comparison between group 1 and 2 showed that it is significantly more likely to express/suffer from ICB while expressing hyperattenuated ADs (Fisher's exact test p value: 0.0104, Chi-square test p value: 0.0047).
Conclusion: Hyperattenuating AGs of polytraumatised patients are frequently linked to intracranial bleeding and, therefore, might function as a red flag in contrast-enhanced abdominal examinations of polytraumatised patients.

B-0295 14:56

Dual-phase CT protocol in the assessment of traumatic liver injuries

F. Iacobellis[1], I. Iadevito[2], A. Sorbo[2], M.G. Scuderi[1], S. Daniele[1], A. Sparano[1], G. Russo[1], L. Romano[1], M. Scaglione[2]; [1]*Naples/IT*, [2]*Castel Volturno/IT (iacobellisf@gmail.com)*

Purpose: To examine the role of dual-phase CT protocol in the assessment of traumatic injuries of liver, evaluating the prevalence of parenchymal contusion, active bleeding, and contained vascular injuries between arterial and portal venous phase.
Methods and Materials: Dual-phase CT examinations of 175 patients diagnosed with traumatic liver injury performed were retrospectively reviewed. For each examination, arterial and portal venous phase were compared in the identification of liver parenchymal injuries, active bleeding, and contained vascular injuries.
Results: Of 175 patient, 154 (88%) had parenchymal lesions and 21 (12%) showed associated vascular injuries. Out of these, 16/21 (76.2%) had active bleeding and 5/21 (23.8%) contained vascular injuries. Parenchymal lesions were evident in all the patients in the portal venous phase. In 5/16 patients with active bleeding (30%), the arterial phase was crucial to correctly identify the arterial origin of the bleeding. In 3/5 patients with contained vascular injuries (60%), the detection of vascular lesion was possible only in the arterial phase.
Conclusion: Dual-phase CT examinations increase the possibility, in the arterial phase, to detect contained arterial injuries and to identify the arterial origin of active bleeding, whereas the venous phase is essential to identify the parenchymal injuries, venous vascular injuries, to differentiate contained vascular injuries from active bleeding and to evaluate the bleeding entity.

B-0296 15:04

Correlation between CT-based liver injury scoring and subsequent management

M. Reim[1], A. Lomp[1], V. Mihnovits[1], P. Ilves[1], S. Saar[2], U. Lepner[1], P. Talving[1,2]; [1]*Tartu/EE*, [2]*Tallinn/EE (Reimmartin@gmail.com)*

Purpose: The liver is the second most commonly injured abdominal solid organ. The aim of the study was to determine correlation between CT scoring of liver injuries and subsequent operative management.
Methods and Materials: The data for consecutive trauma admissions to major trauma facilities with liver injuries between 1/2009 and 12/2013 were retrospectively included using ICD 10 codes (S36.10) and the images reviewed from the All-Estonian Picture Archive (PACS). CT scoring per American Association for the Surgery of Trauma organ injury scale stratified liver injuries into minor/moderate (grades I-III) vs. severe (grades IV-V) injuries. The primary outcomes were operative management and in-hospital mortality.
Results: Overall, 81 cases were included. The mean age of the cohort was 31.5 ± 12,2 years and 73.1% were male. Overall, grades I-III injuries 86.4% (n=70) and grades IV-V injuries 13.6% (n=11) were examined. The most common associated injuries involved chest wall (n=44; 54.4%), lung (n=42; 51.8%), lower ribs (n=32; 39.5%), and small bowel at (n=11; 13.6%), spleen (n=9; 11.1%), kidneys (n=7; 8.6 %). Nonoperative management was used in 82.7% (n=67), 84.3% (n=59) of the cases for grades I-III and in 72.7% (n=8) of the cases for grades IV-V. There was no correlation between CT scoring of liver injuries and surgical management (p=0.196). The mortality of the patients with CT scoring was 2.5% (n=2), including one grade V injury.
Conclusion: The majority of the liver injuries were minor or moderate and CT-scoring of liver injuries did not determine subsequent surgical management. Further prospective studies are warranted.

B-0297 15:12

Comparison of the inter-observer reliability of injury severity recording between unstructured and structured CT reports of blunt abdominal trauma

Y.-C. Wong, L.-J. Wang, C.-H. Wu; *Taoyuan/TW (ycwong@cgmh.org.tw)*

Purpose: To compare between unstructured and structured CT reports for the inter-observer reliability of injury severity recording in blunt abdominal trauma (BAT) among different readers.
Methods and Materials: In this IRB-approved study, we randomly selected 30 contrast-enhanced CT examinations of BAT from January 2013 to December 2013. All images were anonymised for viewing by six readers (two attending radiologists, two senior residents, two junior residents) who were blinded to clinical outcome. They recorded CT findings independently on unstructured and structured templates six months apart. We compared injury severity of each item on a 6-point Likert scale and intraclass correlation coefficient (ICC) of all readers between unstructured and structured reports.
Results: Active bleeders were recorded more critical on structured reports by 4 (4/6, 66.7%) readers. Solid organ injuries were recorded more critical on structured reports by 2 (2/6, 33.3%) junior residents. Pelvic and spine injuries were recorded more critical on structured reports by 1 (1/6, 16.7%) junior resident. In contrast, hollow organ injuries were recorded less critical on structured report by 1 (1/6, 16.7%) attending radiologist. The ICC values for hollow organ injuries on unstructured and structured reports were 0.837 and 0.821, respectively. The ICC values for active bleeders, solid organ injuries, pelvic and spine injuries on unstructured and structured reports were all > 0.900.
Conclusion: Structured reports could alter the injury severity recording of active bleeders and solid organ injuries from less to more critical especially among junior residents.

Whole-body multidetector CT in polytrauma patients: incidence and clinical significance of missed diagnoses

F. Ruschi; *Bolzano/IT (francesco.ruschi@gmail.com)*

Purpose: To evaluate the incidence and significance of missed diagnoses at whole body MDCT in polytrauma patients.
Methods and Materials: Whole body (head to symphysis) MDCT reports of 169 polytrauma patients (study group) were retrospectively evaluated and compared with clinical/surgical management. The study group was divided into three subgroups: no missed injuries, missed injuries of no clinical significance, clinically significant missed injuries (requiring medical or surgical treatment). The MDCT exams of second and third subgroups were re-evaluated in order to determine whether the missed lesions were recognisable or truly non-detectable.
Results: The commonest types of injuries were intracranial bleeding (23%), rib fractures (32%), pneumothorax (17%), lung contusions (15%), spine fractures (23%) and midface-skull fractures (11%). In 94.1% of patients all injuries were diagnosed correctly. Eight patients (4.7%) had missed injuries that required no further treatment (non-displaced fractures, spleen/liver/cerebral contusions). Two patients (1.2%) had relevant missed injuries such as carotico-cavernous fistula and diaphragmatic rupture. With secondary interpretation the 80% of these lesions could be diagnosed. The carotico-cavernous fistula was missed probably because during the second survey (MDCT) there were concomitant life-threatening injuries (diffuse subarachnoid hemorrhage, internal carotid artery dissection) to focus on. On the other hand, as the diaphragmatic lesion was detected at laparotomy in a patient with CT diagnosis of complete spleen rupture, this had no additional therapeutic consequence (there was already an indication for an emergent laparotomy).
Conclusion: Missed injuries in CT reports of polytrauma patients have rarely clinical significance and they are often detected at follow up imaging.

Dose optimisation in digital radiography of the hands: evaluation of the GC85A low-dose technology

S. Siepmann, K. Ziegeler, A. Beck, T. Diekhoff, A. Bach, B. Hamm, K.-G. Hermann; *Berlin/DE (stefan.siepmann@charite.de)*

Purpose: Patients with rheumatic conditions are frequently required to undergo follow-up X-ray examinations to measure disease progression. Thus, reduced dose digital radiography may play a role to keep long-time exposure minimal. The aim of this study was to evaluate the GC85A low-dose technology in patients with suspected rheumatoid arthritis.
Methods and Materials: Fixed low-dose (LD) digital radiography protocols at 51.6 kVp were defined with 1.7 mAs and 1.2 mAs, that equal 80% and 64%, respectively, of the standard exposure (SE). LD images were processed further using the feature preserving noise reduction algorithm (S-Vue 3.02) implemented into the GC85A X-ray device (Samsung, Seoul, South Korea). Patients were consecutively enrolled. Randomly, one hand was X-rayed with one of the LD protocols while the opposite hand received the SE protocol. Images were scored independently by two readers blinded to X-ray protocol. Standardised scoring included evaluations of bony contours, spongious bone, joint spaces, soft tissues, image noise and contrast on 0-5 numeric weighting scales.
Results: X-ray images of both hands were acquired in 116 patients. Mean image quality scores were 29.1±2.8 for SE and 28.9±3.1 for LD (no significant difference) for the total population. This result remained when analysing only 80% and 64% LD images, respectively. No major artefacts occurred in any of the X-rays acquired.
Conclusion: Low-dose GC85A digital radiography down to 64% of the standard exposure is a suitable approach to reduce the lifetime X-ray radiation dose in patients with rheumatic conditions, that need to undergo follow-up X-ray examinations every other year.

B-0300 14:08

Heels: the higher, the better? Weight-bearing MRI evaluation of the forefoot in women during heeled-shoes wearing

C. Gianneramo, F. Bruno, S. Quarchioni, E. Cannizzaro, P. Palumbo, S. Mariani, F. Arrigoni, A. Barile, C. Masciocchi; *L'Aquila/IT (camillagianneramo@gmail.com)*

Purpose: To evaluate the possible physiological changes of the forefoot in women wearing heels using weight-bearing MRI.
Methods and Materials: We evaluated 22 healthy volunteers (mean age 32.3 years, range 28-36). All women were submitted to MRI examination of the foot in orthostatic weight-bearing position using a dedicated low-field scanner (0.3T). Each examination consisted of 3 acquisitions, respectively without heel (position1, P1), with a 2.3in (6cm)-heel (position2, P2) and with a 4.7in (12cm)-heel (position3, P3). We acquired a sagittal SSFP 3D sequences, with reconstructions on coronal and axial planes.
Results: For each position we measured, on the axial plane, the distance between the centre of the first and the centre of the fifth metatarsal heads (M1-M5D), the transverse arch height (TAL), the distance from the centre of the third metatarsal head to the plane passing from the base of the medial sesmoid to the base of the fifth metatarsal head, and the angle between the first and fifth metatarsal (M1-M5) measured on the coronal plane.Mean values of M1-M5D were 63.4mm (P1), 69.4mm (P2) and 74.8mm (P3) ($p<0.005$).Mean values of TAL were 12.7mm (P1), 10.8mm (P2) and 8.1mm (P3) ($p<0.005$).Mean values of M1-M5 were 21.68° (P1), 28° (P2) and 31° (P3) ($p<0.005$).These alterations resulted into evident modifications of the anatomical relations of the forefoot structures.
Conclusion: Our MRI findings defined the physiological changes of the forefoot structures in women wearing heeled-shoes; these results could represent an important background to evaluate symptomatic subjects with foot pathology exacerbated by heeled-shoes wearing.

B-0301 14:16

MDCT arthrography assessment of the severity of cartilage damage and scapholunate dissociation in regard to specific component tears of the scapholunate ligament

J.-B. Quere, C. Phan, A. Miquel, L. Arrive, Y. Menu, M. Crema; *Paris/FR (quere.jb@gmail.com)*

Purpose: To evaluate the severity of cartilage damage assessed on MDCT arthrography in a sample of patients with scapholunate interosseous ligament (SLIL) tear, in regard to specific dorsal or volar component involvement. The relationships with assessment of scapholunate dissociation were also evaluated.
Methods and Materials: We retrospectively included 43 patients who underwent MDCT arthrography with SLIL tears. Dorsal and volar components of the SLIL were separately assessed for tears and graded as: normal, partial tear, or complete tear. Cartilage damage was assessed in 14 regions of the wrist using a modified WORMS system (grades 0-6). Cartilage damage score was obtained by summing WORMS grades from regions of the radial side. Staging of SLAC (0-3) was performed. Scapholunate dissociation was measured at the tenth of a millimeter. The Student's T and the Wilcoxon rank-sum tests were used to evaluate the differences in cartilage damage scores and scapholunate dissociation when assessing tears of dorsal and volar components of the SLIL.
Results: Cartilage damage scores were greater in patients with complete tears of the dorsal component (12.67; 95%CI 7.63, 17.72) than in patients with no or partial tears (2.83; 95%CI 1.25, 4.41); p values<0.001. Scapholunate dissociation values were also greater in these patients (p values<0.0001). Scapholunate dissociation was more severe in SLAC≥1 than in SLAC 0 (p values<0.0001), with a cut-off value of 3.9 mm for diagnosing SLAC≥1 (sensitivity 79.2%, specificity 94.7%).
Conclusion: The severity of cartilage damage and scapholunate dissociation is greater when the dorsal component of the SLIL is completely ruptured.

MRI patterns of locked metacarpophalangeal joints of the long fingers

L. Lassalle[1], F. Lapegue[2], H. Guerini[1], R. Campagna[1], V. Vuillemin[1], N.E. Regnard[1], A. Buisson[1], J.L. Drape[1]; [1]*Paris/FR*, [2]*Narbonne/FR (louis.lassalle@gmail.com)*

Purpose: Locked metacarpophalangeal (MCP) joints of long fingers may be clinically misdiagnosed with more common trigger fingers. The goal is to describe the MR patterns of locked fingers
Methods and Materials: MRI studies of 13 patients (12-65 yo) : 9 females (69%) and 4 males (31%), with clinical presentation of locked finger (loss of active and passive extension of the MCP joint with preserved interphalangeal joint mobility) were retrospectively reviewed by two MSK radiologists. MRI patterns were described according to the type of the lesion (dorsal or volar locking) and clinical presentation (further flexion possible: type 1 of impossible: type 2). Surgical correlation was available in 6 cases.
Results: In type 1 lesions MR demonstrated osseous prominences or osteophytes of the radial condyle of the MC head and entrapment of the accessory collateral ligament. In type 2 lesions MR depicted intra-articular entrapment of a torn volar plate following an acute trauma. In dorsal locking MRI highlighted an entrapment of either a dorsal interosseous tendon or a torn collateral ligament between the sagittal band and the dorsal interosseous expansion ("stener like" lesion).
Conclusion: MRI allows an accurate evaluation of the anatomical lesions in locked MCP joints. Several different lesions may have the same clinical presentation.

B-0303 14:32

Cartilage damage assessed with dGEMRIC occurs at the zone of 3D CT-based impingement simulation: a pilot study

F. Schmaranzer, T. Lerch, I. Todorski, P. Haefeli, M. Hanke, S. Werlen, K. Siebenrock, M. Tannast; *Bern/CH*

Purpose: For complex cases of femoroacetabular impingement (FAI), CT-based 3D impingement simulation is the current gold standard to determine the impingement location. Delayed gadolinium-enhanced MRI of cartilage (dGEMRIC) allows a noninvasive estimation of cartilage composition. (1) To compare T1 indices between clock-face positions with versus without simulated impingement; (2) to assess whether the clock-face position of lowest T1 index is located at the zone with highest prevalence of impingement.
Methods and Materials: This is a retrospective IRB-approved study. Twenty-one patients (mean age 30 years) with symptomatic FAI and preoperative indirect MR arthrography at 3.0 T (0.2 mmol/kg, Gd-DTPA^{2-}) for dGEMRIC (3D T1 maps, dual-flip angle technique) and 3D CT scans of the pelvis with distal femoral condyles were included. Radial T1 images were reformatted. Regions of interest were placed manually. CT-based 3D models of the bony hip were generated and impingement simulation was performed with in-house developed software. This served as the gold standard. (1) Mean T1 indices between clock-face positions with versus without impingement were compared. (2) Overlap between the clock-face position with lowest mean T1 indices with the zone of highest prevalence of impingement (% of hips) was assessed.
Results: (1) Mean T1 indices for clock-face positions with impingement (482±146 ms) were significantly (p<0.001) lower compared to those without impingement (594±180 ms). (2) Lowest mean T1 indices (472±140 ms) were at the zone of highest prevalence of impingement (2 o'clock position; 21/21 hips, 100%) .
Conclusion: DGEMRIC may be used for impingement detection instead of CT scans in young patients with FAI.

B-0304 14:40

Diagnostic efficacy of a 3D sequence in the standard MR protocol among high risk patients for knee cartilage lesions

M. Vlychou[1], I. Kyriakis[2], K. Vassiou[1], I. Tsougos[1], S. Michalitsis[1], M. Hantes[1]; [1]*Larissa/GR*, [2]*Milton Keynes/UK (mvlychou@med.uth.gr)*

Purpose: Articular cartilage lesions is a common injury among patients between 20 and 40 years of age. 3T MR imaging is the method of choice for detecting traumatic knee lesions; however, its performance remains challenging especially for grade I and II cartilage defects. The purpose of the present study is to assess the diagnostic efficacy of a 3D sequence among high risk patients for knee cartilage lesions.
Methods and Materials: One hundred eleven patients (78 males, 33 females, mean age 34.8 years) were included in the study. All patients underwent the same MR protocol at a 3T MR scanner including T1-weighted and 2D proton density-weighted sequences in three planes and a 3D spoiled gradient-recalled echo (SPGR) sequence. Subsequently all patients underwent arthroscopy. Each articular surface was graded initially at the 2D sequences and subsequently at the 3D sequence and was graded accordingly by two independent radiologists blind to arthroscopic findings. Arthroscopic grading was used as the gold standard. The McNemar test was used to compare sensitivity, specificity, positive and negative predictive values.
Results: There was a statistically significant improvement in both specificity and sensitivity for detecting cartilage lesions by adding the 3D SPGR sequence and also a statistically significant ($p < 0.05$) improvement in the proportion of correctly graded cartilage lesions, especially in cartilage defects located in the femoral trochlea.
Conclusion: The routine protocol of knee may benefit from adding a 3D sequence since it may improve the diagnostic efficacy for detecting and grading cartilage lesions in high risk patients.

B-0305 14:48

Comparison of T2*-weighted gradient-echo sequence with magnetisation transfer contrast, to other MRI sequences in the diagnosis of gonarthrosis

U.Y. Ayaz[1], M.H. Ozturk[2], A. Dilli[3], B. Hekimoglu[3]; [1]*Mersin/TR*, [2]*Trabzon/TR*, [3]*Ankara/TR (umityasarayaz@yahoo.com)*

Purpose: We compared the efficacy of T2*-weighted (W) gradient-echo (GE) sequence with magnetisation transfer contrast (MTC), to those of other MRI sequences in diagnosis of osteoarthritic chondral defects of the knee.
Methods and Materials: In this prospective study, 30 patients with gonarthrosis who would undergo total knee prosthesis operations were included. 1.5-T knee MRI was performed before surgery. T2*W GE with and without MTC, fat-saturated (FS) T1W GE and FS proton density (PD) sequences were obtained. Before surgery, images were evaluated by two radiologists together, in consensus. For verification of MRI, osteoarthritic chondral defects were evaluated and documented both intraoperatively (in vivo) and after their excision by two orthopedic surgeons, together in consensus. T2*W GE sequence with MTC was compared to other MRI sequences in distinguishing the lesioned cartilage. Statistical analysis was made.
Results: In distinguishing lesioned cartilage from the intact one, the sensitivities of FS PD FSE, T2*W GE with MTC, FS T1W GE and T2*W GE without MTC were 82%, 82%, 78% and 78%, respectively. There was no significant difference between FS PD FSE and T2*W GE with MTC (P> 0.05), while there were significant differences between these two sequences (FS PD FSE and T2*W GE with MTC) and the other two sequences (FS T1W GE and T2*W GE without MTC) (P <0.05).
Conclusion: The use of MTC with T2*W GE seems to increase the sensitivity of the sequence in diagnosis of osteoarthritic chondral defects. The contrast between cartilage and synovial fluid is more prominent with MTC.

B-0306 14:56

Knee derangement in the era of total knee replacement epidemic

M. Abd El Bagi, O. Alshehre, H. Alfaleh, S. Ahmed, F. Alorfi, N. Ashraf, A. Thomas, M. Reutener; *Riyadh/SA (othmanzayed@googlemail.com)*

Purpose: To determine the current causes of internal knee derangement that might lead to total knee replacement if not treated at an earlier stage.
Methods and Materials: A retrospective review of consecutive knee MRI scans performed at a tertiary care hospital.The reports and all images were reviewed. Indications were tabulated. Where plain films were performed, their results were registered.
Results: 404 consecutive knee MRI scans were reviewed. Age range was 41 to 81 with a mean age of 39.3 years. 247(61.1) were males. 157(38.8%) were females. Commonest age group was 21-40 (46.6%)of the 404 patients. The commonest abnormality was osteoarthritis in 182 (45%) of the 404 patients with equal number of affected males and females. Osteoarthritis was mild in 126(69.2%), moderate in 44(24.1%) and severe in 12 (6.5%) of the 182 cases. The second commonest abnormality was menisci derangement in 160(39.6%). 93(58.1%) of these 160 patients were males and 67(41.8% were females. Anterior cruciate ligament abnormalities were detected in 146(36.1%), other ligaments injuries in only 34(8.4%). Joint effusion was seen in 110(27.2%). Cartilage lesions detected in 67(16.5%). Trochlear dysplasia was seen in 91 (22.5%) by groove depth. Lateral patellar tilt indicated a higher incidence of 114(28.2 %) possibly exaggerated by collateral ligaments degenerative laxity.
Conclusion: The common findings of current internal derangement are surgically or arthroscopically correctable by simpler and less expensive procedures than total knee replacement. MRI alone or in correlation with plain radiographs, can demonstrate these lesions at an earlier stage.

B-0307 15:04

Diagnostic imaging of haemophilic arthropathy in children: 3T MRI HAMRIS staging scale

K. Bokwa-Dabrowska, P. Łaguna, M. Brzewski; *Warsaw/PL (katarzyna.bokwa@gmail.com)*

Purpose: Haemophilia is a genetic bleeding disorder which leads to many complications including arthropathy. Precise MRI assessment provides valid clinical information and may lead to complementation of primary prophylaxis.
Methods and Materials: The study group included 16 boys (25 large joints) aged 5-19 years with haemophilia who were examined with 3T MRI within HAMRIS programme (haemophilic arthropathy in magnetic resonance imaging-staging programme). Each patient had had an episode of haemarthrosis affecting the examined joint and was supplemented with factor VIII or IX. Some examinations were performed in forced positions due to limited mobility. The HAMRIS protocol included basic sequences in three planes: T1 fse, T2-weighted fse, TIRM, PD, T2 mapping. T2 me2d and T2 fl2d gradient sequences were obtained in 3D. Each examination was complemented with DWI to reassess the osseous oedema.
Results: The HAMRIS scale includes 5 grades which gives a detailed classification of post-haemorrhagic complications. It classifies an injury according to the location and concerns the scope of endosteal oedema. The exacerbation of pathologies may be easily determined with the HAMRIS scale and make it possible to implement early orthopaedic prophylactic treatment.
Conclusion: The implementation of the HAMRIS programme may be a chance to avoid surgery and permanent disability. As MRI diagnostics is becoming more accessible, it is thought that it should be performed on a routine basis in patients with haemophilia.

B-0308 15:12

Fat saturated 3D-flash sequence improves erosion detection on the sacroiliac joints: results from the SIMACT study

T. Diekhoff, J. Greese, J. Sieper, D. Poddubnyy, B. Hamm, K.-G. Hermann; *Berlin/DE (kghermann@gmail.com)*

Purpose: Detection of structural lesions of the sacroiliac joint improves the specificity of magnetic resonance imaging (MRI). Our study applies a three-dimensional 3D-flash sequence (volumetric interpolated breath hold examination; VIBE) for erosion detection to patients with suspicion of axial Spondyloarthritis (axSpA).
Methods and Materials: Low-dose computed tomography (ldCT) and MRI with T1 and VIBE of 110 prospectively included patients with low back pain were acquired and scored for erosions and joint space alterations by three readers. A contingency table analysis using ldCT as standard of reference, a comparison of sum scores using repeated measurements ANOVA with multiple comparisons and the calculation of interrater-reliability using Cohen's kappa was performed.
Results: The erosion sum score was higher for MR-VIBE (8.1 ± 9.3) as compared to MR-T1 (6.7 ± 8.4), $p = 0.003$, similarly, the total number of erosions (15.5 ± 21.8 vs 9.2 ± 12.1, $p < 0.001$). The joint space sum score was 1.8 ± 2.2 for MR-VIBE and 0.8 ± 1.0 for MR-T1, $p < 0.001$. MR-VIBE showed a higher sensitivity for erosions as compared to MT-T1 (95 % vs 79%, respectively) and joint space alterations (88 % vs 76%) without a decrease in the specificity for erosions (93 % each) and only a small decrease for joint space alterations (93% vs 99 %, respectively).
Conclusion: MR-VIBE detected erosions at the sacroiliac joints with higher sensitivity and similar specificity compared to a standard MR-T1 sequence. Therefore, MR-VIBE may be a valuable supplement to standard MR protocols.

B-0309 15:20

Prevalence of fat metaplasia and other structural changes of sacroiliac joints in patients without axial spondyloarthritis: a cross-sectional MRI study

K. Ziegeler, H. Eshkal, C. Schorr, J. Sieper, T. Diekhoff, M.R. Makowski, B. Hamm, K.-G. Hermann; *Berlin/DE (katharina.ziegeler@charite.de)*

Purpose: To determine the prevalence of fat metaplasia and other structural lesions of the sacroiliac joints associated with axial spondyloarthritis in a non-rheumatological patient population.
Methods and Materials: MRI examinations that included the pelvis of patients without known rheumatological disease were used for this retrospective cross-sectional study. These images were evaluated for sacroiliac fat deposition, sclerosis, osteophytes and joint space alterations such as erosions or ankylosis. Patients were divided into 7 age groups (from 15-24 to ≥75). Prevalence of lesions across age groups were calculated. Possible clinical confounders (e.g. status post-radiation, suspected inflammatory bowel disease) were investigated with regard to their impact on lesion prevalence and extent to exclude bias.
Results: A total of 485 patients were enrolled in this study. Fat deposition, was very common, showing a prevalence of 50.6% in the age group <45 which increased with age to 94.4% in patients ≥75 years. Erosions were uncommon: 0.6% of patients <45 and 2.6% of the entire study population exhibited this feature, with no detectable age-dependent increase. Sclerosis and osteophytes were detected in 13.7% and 37.0% of patients, respectively. None of the investigated clinical confounders showed a significant impact on lesion prevalence.
Conclusion: Our study shows a very high prevalence of periarticular fat deposition adjacent to the sacroiliac joint in asymptomatic patients, while erosions are extremely uncommon.

Online platform for fast and accurate calculation of fetus dose in CT

N. Saltybaeva, H. Alkadhi; *Zurich/CH (Natalia.Saltybaeva@usz.ch)*

Purpose: CT examination of pregnant patients is always a challenging task because of the concern about the radiation risk to the fetus (embryo). The methods estimating radiation dose to the fetus are either limited in their accuracy or require complicated measurements and calculations. The purpose of our study was to create online platform for fast and accurate fetal dose assessment.
Methods and Materials: The online tool for fetal dose assessment was based on precalculated data from Monte Carlo simulations (MSC). These simulations were performed on standard phantoms, representing 3-, 6- and 9-month of pregnancy, using generic x-ray spectrum, filtration and scanner geometry. To validate the tool we compared the dose values calculated by the algorithm on standard phantoms against those calculated for the real patients. For this purpose MCS were also performed on 11 pregnant patient (gestational ages 7-35 weeks) previously underwent clinically indicated abdominal CT, using individual kVp, mAs curves, collimation, and scanner geometry.
Results: The algorithm proposed in the study allows estimating dose to the fetus with an accuracy of 32 (STD~17%). The study has shown strong correlation ($p<0.05$) between the accuracy of calculated dose and patients size. The algorithm tends to overestimate fetus dose by 41% in overweight

patients, however, this effect can be corrected (23±11% of accuracy) if patient effective diameter is used as an input parameter.
Conclusion: The proposed algorithm allows for fast and sufficiently accurate assessment of radiation dose to the fetus in CT. The prototype is available online.

B-0311 14:17

Radiation dose for digital breast tomosynthesis: influence of breast composition and breast thickness

N. van der Werf[1], E.-J. van Dijk[2], D. Dickerscheid[1], M.C. Kock[1]; [1]*Dordrecht/NL*, [2]*The Hague/NL (n.r.vanderwerf@asz.nl)*

Purpose: Compared to digital mammography (DM), average glandular dose (AGD) increases for digital breast tomosynthesis (DBT). However, the contribution of breast composition and compression thickness (CT) to the increase in AGD remains unknown. Therefore, the objective of this study was to evaluate the influence of breast composition and CT on differences in AGD between DM and DBT.
Methods and Materials: A total of 2,368 out-patients with low (n=479), medium (n=1689) and high (n=200) glandular fraction (GF) were scanned with the Selenia Dimensions as part of routine clinical practice. Each scan consisted of both DM and DBT acquisition within the same compression. ACR composition A and D correspond with the categories low GF and high GF, respectively. ACR composition B and C were combined and correspond with medium GF. Each GF was subdivided based on the CT into >40, 40-50, 50-60 or <60mm. Statistical significance was analysed using paired T tests between DM and DBT scans, where $p<0.05$ was deemed significant.
Results: For cranio-caudal (CC) views, overall AGD increased significantly ($p<0.0005$) by 0.99, 0.40 and 0.12 mGy for low, medium and high GF, respectively. Low and medium GF showed significant increased ($p<0.0005$) AGD for all CT. For high GF, AGD increased ($p<0.0005$) for 35 and 45 mm, whereas AGD decreased significantly ($p<0.05$) for 55 and 65mm.
Conclusion: Differences in AGD between DM and DBT depends on both GF and CT. AGD for high GF breast of 50-60 or >60mm CT was significantly lower for DBT than for DM.

B-0312 14:25

A national web-based tool for optimisation of radiological protocols

S.J. Thunberg, H. Båvenäs, T. Cederlund; *Stockholm/SE (stefan.thunberg@ssm.se)*

Purpose: All medical examinations using radiation for imaging must be optimized for both adult and paediatric patients. The purpose of this project was to develop a web-based national support for the optimization process for medical exposures.
Methods and Materials: Swedish Radiation Safety Authority has developed and launched DosReg, a web-based tool for registration of imaging protocols and local diagnostic reference levels (LDRL). The user receives a histogram in real-time illustrating other clinics' results as well as the national DRLs for each modality and procedure. DosReg has been developed for six different modalities: computef tomography, nuclear medicine, mammography, interventional procedures, conventional radiology, and dental CBCT.
Results: Five out of DosReg's six modalities were released in 2017. CT was released in September 2016. All the modalities contain registered LDRLs. CT has the most registrations, with 351 (as of October 2017), as this modality has been available for the longest period of time. Several clinics in Sweden have used DosReg in their optimization work in cases where their initially reported LDRLs were higher than those of other clinics. There have been several cases where DosReg's optimization tool has resulted in a dose reduction in the range of 50-80 per cent.
Conclusion: Immediate implementation of this tool by radiological departments needing to optimize some of their protocols will lead to substantially improved optimization of radiological protocols in Sweden, which in turn will result in less variation nationally in doses received by patients from the same kind of examination.

B-0313 14:33

Validation of the DACS-integrated radiation dose monitor skin dose mapping software using XR-RV3 Gafchromic films for fluoroscopically guided procedures

L. Hadid-Beurrier[1], B. Habib Geryes[1], M.-J. Waryn[2], A. Jean-Pierre[1], J. Farah[3]; [1]*Paris/FR*, [2]*Bondy/FR*, [3]*Le Kremlin-Bicêtre/FR (bouchra.habib-geryes@aphp.fr)*

Purpose: To determine the accuracy of a DACS-integrated patient skin dose mapping solution for fluoroscopically guided procedures using on-phantom and on-patient Gafchromic film measurements**.**
Methods and Materials: The DACS-integrated radiation dose monitor® (RDM, Medsquare) software uses radiation dose structured report (RDSR) to calculate cumulative patient skin dose distribution in 1 cm² area taking into account backscattered radiation, table and mattress attenuations. To determine their accuracy, RDM skin dose maps were compared against measurements performed with XR-RV3 Gafchromic films on IGS530 and 540 (GEMS) and ArtisZee-VC21 (Siemens) systems. To validate RDM peak-skin-dose (PSD) calculations and 2D-skin-dose distributions, measurements were first performed considering a PMMA phantom and then in clinical settings for patients undergoing pulmonary angioplasties and AVM/aneurysm neuro-embolizations.
Results: Thanks to a careful calibration of XR-RV3 films using a clinical beam quality, a 11.4% overall measurement uncertainty was achieved. RDM PSD calculations and Gafchromic film measurements performed on the PMMA phantom agreed within 23% for all considered beam projections (PA, R/LAO20°-60°, RAO30°CAU20°, etc.), radiation qualities (60-85 kV), fields-of-view (16-30 cm), collimations and lateral/vertical table positions (-30 to +30 cm from isocenter). Skin dose distributions measured on patients show a 25% agreement with RDM mapping proving its accuracy in complex clinical settings.
Conclusion: This benchmarking study proves the accuracy of RDM skin dose mapping software as a key tool for interventional procedures with high risk of skin reactions. The software is being tested in clinical settings for cardiac and abdominal procedures extending the tests to Philips and Toshiba vascular equipment.

B-0314 14:41

Radiation dose impact of indication- and BMI-based CT protocols vs anatomy-based protocols: prospective multicentre study

H. Brat[1], F. Zanca[2], S. Imsand[1], B. Rizk[3], S. Montandon[4], H. Pasquier[5], D. Fournier[1]; [1]*Sion/CH*, [2]*Leuven/BE*, [3]*Villars-sur-Glane/CH*, [4]*Gland/CH*, [5]*Creteil/FR (hugobene@gmail.com)*

Purpose: To assess impact on dose metrics of indication- and BMI-based CT protocols vs anatomy-based protocols in a prospective multicentre dose optimisation study.
Methods and Materials: A protocol optimisation based on clinical indication and BMI with stepwise dose reduction was implemented on 5 CT scanners (Philips Healthcare, NL). 3215 abdomen CT examinations (mean BMI 26 (13-86)) were prospectively assessed for diagnostic image quality. All data were collected using a dose management software (DoseWatch, GE) after parameter uniformisation and protocol Radlex mapping. Anatomy- and indication-based institutional DRLs (median CTDIvol) were compared to each other as well as to national DRLs, according to BMI. Mann-Whitney tests were used to assess statistical significant differences ($p<0.05$).
Results: (1) All examinations were significantly lower than national P75 DRLs. (2) Per clinical indication, institutional DRLs were significantly lower than national abdomen P25 DRL (10 mGy) for BMI<25 patients. (3) BMI stratification enabled a significant dose impact (BMI<25/BMI>25): appendicitis 5.8/9mGy, colonography 4.1/9.5mGy, diverticulitis 5.9/9.5mGy, kidney stones 5.6/8.6mGy, liver 7.3/13mGy, pancreas 5.6/8.5mGy, renal infection 6.5/8.9mGy, renal tumour 5.8/9.4mGy. (4) Indication: compared to anatomy-based protocols were significantly lower for specific indications: CT colonography, kidney stones and pancreas for BMI<25 and pancreas, kidney stones, renal infection and renal tumour for BMI>25 patients.
Conclusion: This multicentre prospective study showed: (1) a statistically significant reduction in patient X-ray exposure when considering BMI and indication-based abdomen CT protocols compared to anatomical region protocols and national DRLs. (2) A p25 DRL target for BMI<25 abdomen CT achievable in all patients.
Author Disclosures:

B-0315 14:49

CT scan radiation dose evaluation by clinical indication: a multi-centric French study

A. Hornbeck[1], B. Habib Geryes[2], N. Pierrat[2], V. Jarrige[3], S. Dreuil[4], H. Ducou le Pointe[2]; [1]*Strasbourg/FR*, [2]*Paris/FR*, [3]*Bourges/FR*, [4]*Fontenay-aux-Roses/FR (amauryhornbeck@gmail.com)*

Purpose: To propose dosimetric indicators representing French national practices for current adult CT-scan clinical indications.
Methods and Materials: 22 groups of clinical indications (GCI) for diagnostic CT-scan in adult patients were defined jointly by the French Society of Medical Physics (SFPM) and the French Society of Radiology (SFR), based on their frequency and their requirements in terms of image quality. A national call for participation was sent to the medical physicists' community and a data sheet was emailed to the volunteers. Data collection took place from March to June 2017. For each scanner and each GCI, 15 to 30 consecutive exams performed between 2015 and 2017 were required. Collected data included scanner characteristics (model, year, maximum collimation), patient morphological data (age, gender, weight, height), technical settings (kV, scan length, contrast media, tube current modulation, reconstruction algorithm) and dosimetric data (CTDIvol, DLP) for each phase of the CT exam. A two-step validation was

performed: the global coherence of the collected data was checked and the pertinence of the selection method of the examinations was reviewed.
Results: 10753 CT-scan acquisitions, representing 7490 examinations, were collected from 53 public and private French radiology departments. Dosimetric indicators are proposed as examination DLP and acquisition CTDI and DLP for each GCI. Influence of patient morphology or examination technical settings is studied for selected GCIs.
Conclusion: CT-scan dosimetric indicators by clinical indication represent an attempt to provide a tool for CT dose optimization that is better adapted to the everyday clinical practices.

B-0316 14:57

Multicentre CT scanner dose excellence programme: strategies and results

H. Brat[1], C. Dias[2], S. Behzad Imsand[3], C. Thouly[1], S. Montandon[4], B. Rizk[5], D. Fournier[1], F. Zanca[6]; [1]*Sion/CH*, [2]*Buc/FR*, [3]*Epalinges/CH*, [4]*Gland/CH*, [5]*Villars-sur-Glane/CH*, [6]*Leuven/BE (hugobene@gmail.com)*

Purpose: To comply to the revised European Basic Safety Standards Directive to present a radiation dose optimisation and education programme through CT protocol harmonisation and optimisation in a multicentre setting.
Methods and Materials: A dose team was set up with one radiologist and one technologist in each center, a CT field engineer, a physicist and team leader. Data were collected in a dose management software (Dosewatch™, GE). Two-step strategy: 1. harmonisation by designing a clinical indication-based protocol map with 2 categories of patients according to body mass index (BMI < 25 and BMI > 25), after CT parameters uniformisation and protocol Radlex mapping. 2. Optimisation using a 12% step-wise mA reduction for all protocols. Low-contrast resolution was quantified by phantom analysis (QRM™ 401 abdomen phantom, Germany) to guarantee 5mm liver lesion detectability. Image quality was assessed using adapted European image quality guidelines and an electronic voting tool in the dose tracking software.
Results: Protocol harmonisation eliminated redundant protocols and reduced dose globally by 6% for chest and 7% for abdomen at institutional level. Protocol optimisation additionally reduced dose by 26% on average before hitting the low-contrast resolution limit (phantom measurements). Clinical indication- and BMI-based protocols allowed significantly lower dose levels than existing DRLs.
Conclusion: Homogenising CT protocols and optimising radiation doses without compromising image quality can be achieved with a clear road map, leadership, team work, education, regular communication, commitment, continuous dose monitoring and partnership with stakeholders. The use of automatic dose data collection and phantom tests during optimisation are key.

B-0317 15:05

Evaluation of diagnostic reference levels for conventional radiography in Austria

D. Wachabauer, F. Röthlin, P. Homolka, H.M. Moshammer, H. Ostermann; *Vienna/AT (david.wachabauer@goeg.at)*

Purpose: Evaluation of Austrian National Diagnostic Reference Levels (NDRLs).
Methods and Materials: A nationwide survey on common conventional radiography examinations was conducted. In line with Austrian radiation protection standards, all relevant Austrian hospitals and radiology practices were asked to report a minimum sample of 10 representative dose-area products (DAP) together with patient weight. Participants were invited via e-mail, followed up by reminders to increase participation rates. 59% of invited institutions (67% hospitals, 51% radiology practices) submitted DAP data (n=15305), 31% submitted additional data on patient weight. Case numbers presented varied from 1005 to 2121. Plausibility checks were performed to increase data quality. Third quartiles (Q75) of median DAP of participating institutions were calculated and compared to NDRLs.
Results: DAP values and interquartile ranges (IQR) are given in $cGy*cm^2$. Third quartiles (Q_{75}) were considerably lower than existing NDRLs. Highest discrepancies (≥50%) were observed for skull AP/PA (Q_{75}: 49, IQR:21, NDRL:100), skull LAT (Q_{75}:49, IQR:21, NDRL:100), chest PA (Q_{75}:13, IQR:6, NDRL:28) and LAT (Q_{75}:42, IQR:21, NDRL:100). Discrepancies of ≥20% occurred for abdomen AP/PA (Q_{75}:184, IQR:92, NDRL:300), pelvis AP (Q_{75}:194, IQR:96, NDRL:300) and lumbar spine LAT (Q_{75}:310, IQR:149, NDRL:400). For lumbar spine AP (Q_{75}:176, IQR:90, NDRL:200) discrepancy was 12%. Q_{75} for bedside chest X-ray (Q_{75}:20, IQR:10) was significantly ($p \leq 0.01$) higher than thorax PA. Average patient weight was 74kg.
Conclusion: Q75 derived from the survey are on average 40% lower than Austrian NDRLs suggesting an update of NDRLs. Since Q75 correspond nicely to German and Swiss NDRLs, an update would be in accordance with European DRL harmonisation efforts.

B-0318 15:13

Diagnostic reference levels for interventional radiology: quantifying diagnostic cerebral angiography complexity

T. De Bondt[1], F. Zanca[2], X. Lopez Rendon[2], L. Brouhon[1], T. Van der Zijden[1], M. Voormolen[1], O. D'Archambeau[1], P.M. Parizel[1]; [1]*Antwerp/BE*, [2]*Buc/FR (timo.debondt@gmail.com)*

Purpose: To comply with the 2013/59/Euratom guidelines, diagnostic reference levels (DRL) for interventional radiology procedures need to be established. The complexity of procedures influences the delivered radiation dose; hence, a quantitative measure for complexity needs to be defined to stratify dose levels.
Methods and Materials: A complexity form was drafted through a collaboration of 3 interventionalists, a radiographer and a medical physicist. This form contains factors, with grading scale, that contribute to delivered radiation dose in diagnostic cerebral angiography. Complexity data from 27 interventions were acquired, along with automatically collected dosimetric data from a dose-tracking software system (DoseWatch, GE Healthcare). A multiple linear regression model was built to predict air kerma (Kair) and dose area product (DAP), which are the quantities in which DRLs are expressed.
Results: Statistically significant factors to predict Kair and DAP are fluoroscopy time ($p=0.007$; $p<0.001$) and presence of anatomical variant ($p<0.001$; $p=0.002$). Additional parameters are of significant value to predict DAP: weight ($p=0.002$), ease of catheterization ($p<0.001$) and peripheral vessel disease ($p<0.001$). A complexity index based on the regression coefficients was not able to categorize procedures as being easy, medium or difficult with a statistically significant difference.
Conclusion: Adding a complexity factor to define DRLs for interventional procedures poses a significant challenge. Our pilot study shows that relevant complexity factors differ between models for Kair and DAP, which is problematic. Larger datasets with standardized complexity forms need to be acquired to establish robust models to define DRLs for interventional radiology procedures.

B-0319 15:21

Implementation of updated ACR size-specific CT diagnostic reference levels based on water-equivalent diameter and SSDE using automated dose monitoring software

P. Kröpil, C. Thomas, O.T. Bethge, Y. Klosterkemper, J. Aissa, E. Appel, C. Schleich, G. Antoch, J. Boos; *Düsseldorf/DE*

Purpose: To use automatic dose monitoring software to analyse institutional CT dose data regarding the updated American College of Radiology (ACR) diagnostic reference levels (DRLs) based on water-equivalent diameter (Dw) and size-specific dose estimates (SSDE) to detect patient-size subgroups in which dose can be optimised.
Methods and Materials: This retrospective study included all institutional chest CT, pulmonary CT-angiography and abdominopelvic CT from 06/2016 to 03/2017. Dw and SSDE were automatically calculated using in-house-developed Matlab software (The Mathsworks, Natick) and stored into our dose monitoring system (DoseIntelligence®, Pulmokard). SSDE as CT dose parameter was analysed regarding updated ACR DRLs using Dw to group patients (size groups: 21-25cm, 25-29cm, 29-33cm, 33-37cm, 37-41cm).
Results: 30002 CTs were performed during the study period, n=4541 were included in the analysis (age 62.2±16.1 years, Dw 29.0±3.6cm). Mean SSDE relative to updated DRLs were 43.9±21.7% for non-contrast (n=655) and 51.2±24.5% for contrast-enhanced (n=719) chest CT, 66.9±30.6% for pulmonary CTA (n=371), 41.8±28.5% for non-contrast (n=635) and 55.1±21.7% for contrast-enhanced (n=2161) abdominopelvic CT. Lowest dose compared to ACR DRLs was found for Dw-group 21-25cm in non-contrast abdominopelvic CT (31.8±21.3%). The only transgression of ACR DRLs was found for Dw-group 37-41cm in non-contrast abdominopelvic CT (100.3±60.0%).
Conclusion: Mean SSDE of institutional CT protocols were lower than updated ACR DRLs. However, size-specific subgroup analysis revealed slight transgression of DRLs in non-contrast abdominopelvic CT of large patients. Updated ACR size-specific DRLs allow for a comprehensive analysis of CT dose data and help identifying patient subgroups in which dose can be optimised.

Image comparison of virtual non-contrast images and true non-contrast images obtained from dual-energy CT in latest generation dual-source and dual-layer CT for liver
B. Na, S.-J. Lee, H.-J. Jeong, D.-S. Kim; *Seoul/KR (passion3744@gmail.com)*

Purpose: To evaluate the reliability of virtual non-contrast (VNC) images obtained from two different dual-energy CT (DECT) which have different mechanism to produce VNC image.
Methods and Materials: Sixty patients underwent liver CT examination, using both dual-layer detector CT and third-generation dual source CT. Mean attenuation and contrast to noise ratio (CNR) for the relevant tissues were compared between true non-contrast (TNC) and VNC images. Paired student t tests were used for statistical analysis. Under same CT scan parameter, using the both DECT, performance phantom was scanned to evaluate background noise which could influence CNR.
Results: Mean attenuation difference between TNC and VNC image with dual-source CT and dual-layer CT were as follows, respectively: right liver lobe -0.22 and -1.02, left liver lobe -0.99 and 2.12, psoas muscle -0.8 and 1.01, aorta 5.63 and 14.47, spleen 3.92 and 3.9, right kidney 5.17 and 6.59, left kidney 6.35 and 6.23. There was no significant difference in mean attenuation value of liver and psoas muscle from the both DECT scanner (p>0.05). CNR on TNC image was higher than on VNC image because background noise of VNC was almost twice of higher than TNC. However, under same CT scan parameter, in the phantom experiment, same background noise values were shown between TNC and VNC from the both CT scanner.
Conclusion: VNC image obtained from both dual-source and dual-layer CT could potentially be an alternative to TNC image for liver examination.

B-0321 14:17

Acceptable noise levels in abdominal CT examinations of obese paediatric patients
M. O'Connor, J.G. Stowe, S.J. Foley; *Dublin/IE (michelle.oconnor@ucd.ie)*

Purpose: This research investigated acceptable noise levels in abdominal CT scans of obese paediatric patients
Methods and Materials: A MATLAB-based low dose simulation software was developed and validated in-house which enabled simulation of 50mAs stepwise increases in mAs. With ethical permission, a sample of 21 obese abdominal CT datasets, stratified by age (5-, 10- and 15-year olds) was retrospectively collected from Irish paediatric hospitals. Scans were performed on Philips 64 slice Brilliance scanners using weight-based protocols (80-120kVp, AEC, 64x0.625mm collimation, pitch0.891, iDose level 4). A single axial slice at the level of L1 from each scan was modified using the low dose simulation software to imitate scans obtained at lower mAs i.e. higher noise levels. This resulted in a total of 76 scans for review. Objective noise measurements were performed by the lead researcher using identical sized ROI's in three homogeneous locations; (1) liver, (2) subcutaneous adipose tissue, (3) air 2cm anterior to skin. Subjective image quality analysis was carried out by four experienced paediatric radiologists. Diagnostic acceptability, subjective image noise, contrast resolution, spatial resolution and visibility of anatomical structures were scored using a grading system devised from the European Guidelines on quality criteria for CT.
Results: The amount of noise considered acceptable in abdominal scans of obese paediatric patients by all four viewers was; 18.6HU in the 5-year-old group, 16.24HU in the 10-year-old group and 15.91HU in the 15-year-old group.
Conclusion: This research is the first to establish the maximum noise level (16HU) tolerated on abdominal CT scans of obese paediatric patients.

Does body mass index affects radiation dose reduction in prospective electrocardiographic gating cardiac computed tomography?
B. Kara, M. Onur, A. Toker, S. Horoz, D. Akata; *Ankara/TR (tomografi@hotmail.com)*

Purpose: To evaluate the effect of body mass index (BMI) in radiation dose reduction in different cardiac computed tomography (CT) protocols.
Methods and Materials: We retrospectively evaluated cardiac CT examinations of 172 patients (79 female, 93 male; mean age: 64, ranging between 37-81) presented with cardiac symptoms. Patients were grouped according to BMI as group I (BMI < 30) and group II (BMI > 30). Cardiac CT examinations were performed with two different methods as conventional cardiac and prospective ECG gating (PECT) method. Radiation dose levels of patients were recorded as dose length product (DLP) values. We compared the DLP values of two cardiac CT protocols in group I and group II.
Results: PECT and conventional cardiac CT were performed in 32 and 56 patients, respectively in group I. Group II was consisted of 28 and 56 patients, respectively. There were statistically significant differences between mean DLP values of patients underwent PECT (DLP:111.88; DLP: 188.50) and conventional cardiac CT (DLP: 376.54; DLP: 858.54) in group I ($P < 0.0001$) and group II ($P < 0.0001$), respectively. Radiation dose reduction was more significant in group II.
Conclusion: Prospective ECG gated cardiac CT yields significant radiation dose reduction in patients with BMI < 30 and BMI > 30. Reduction of radiation dose is more prominent in patients with BMI > 30.

B-0323 14:33

Metal artefact reduction in the musculoskeletal system with dual-energy CT and spectral imaging
C. Fraga Piñeiro[1], M. González Vázquez[1], M. Monteiro[2]; [1]*Vigo/ES*, [2]*Coimbra/PT (carlosfrapi@gmail.com)*

Purpose: Metal artefacts have been an important limitation in musculoskeletal CT, but with the advent of dual-energy equipment new strategies to reduce metal artefact have been provided. We intended to compare metal artefact reduction and image quality in dual-energy computed tomography (DECT) using polychromatic and high-energy monochromatic images.
Methods and Materials: We collect data from 39 patients with metallic implants in extremities who underwent DECT polychromatic images with 80, 120 and 140kV and post-processing high-energy monochromatic images at 110, 130 and 150KeV were used. Qualitative evaluation of the artefact and image quality was performed by two musculoskeletal radiologists using Likert scale. We use Spearman's Rho for inter-observer correlation. Artefact severity was assessed quantitatively.
Results: The best results were obtained at 140kV as well as in monochromatic series. The inter-observer agreement was (artefact rs=0.73- 0.95 and quality image rs=0.77-0.93). Artefact severity (artefact index): 14.16 (80kV), 11.01 (120kV), 7.74 (140kV), 6.36 (110keV), 5.5 (130keV) and 4.94 (150keV). All results presented statistical significant differences (p<0.05), except for 130 and 150keV which had comparable results.
Conclusion: Metal artefact reduction and image quality were rated superior in monochromatic high energies, compared with polychromatic images and, within these, those with 140kV were considered better than with energies of 80 and 120kV.

B-0324 14:41

Effective dose calculations of trunk CT scans in single-energy CT (SECT) and fast kVp switching dual-energy CT (FKS-CT)
K. Yagami[1], T. Miyoshi[1], S. Shigeyama[1], H. Okada[1], S. Suzuki[2], S.J. Foley[3]; [1]*Gifu/JP*, [2]*Toyoake/JP*, [3]*Dublin/IE (yagami@gifu-u.ac.jp)*

Purpose: To compare effective dose calculations based on dose-length product (DLP), size-specific dose estimate (SSDE) and measured organ doses in SECT and FKS-CT using an anthropomorphic phantom.
Methods and Materials: Two 64-detector row CT systems (Discovery CT750HD; GE and Brilliance 64; Philips) were used for dose measurement. An anthropomorphic phantom (Alderson Rando Phantom) with thermo-luminescent dosimeters (BeO) was positioned inside (n=97) and on the surface (n=60) of various anatomical organs as per ICRP 103 for measuring the effective dose and calculating SSDE according to AAPM 204. The scanning conditions were the same as those used in clinical practice. The scanning range of FKS-CT was chest apices to symphysis pubis and SECT were three different examinations including chest apices to symphysis pubis (whole body), diaphragm to symphysis pubis (abdomen-pelvis) and chest apices to diaphragm (chest).
Results: Measured average effective dose between the two CT systems in whole-body CT was 13 mSv, in abdomen-pelvis CT was 9 mSv, chest CT was 5 mSv, and in FKS-CT was 13 mSv. For both CT systems, the difference between effective dose based on measured organ doses and calculations from

SSDE and k-factors was within 10% for all scan ranges and also FKS-CT. However, the use of DLP and k-factors resulted in 25% differences in effective dose compared to measured organ dose values.
Conclusion: For both SECT and FKS-CT, effective dose from measured organ doses closely approximated effective dose calculated from SSDE but DLP conversion to effective dose consistently underestimated both values.

B-0325 14:49

Impact of scanner type and acquisition parameters on the accuracy of displayed computed tomography dose index

C. Dionisi, B. Cannillo, R. Matheoud, L. Vigna, G. Fusco, M. Brambilla; *Novara/IT (clizia.dionisi@gmail.com)*

Purpose: According to the EU directive 2013/59, CT scanners shall be able to inform the practitioner of relevant parameters for assessing the patient dose. The aim of this study was to measure the accuracy of the displayed CTDI on ten different CT scanners of various vendors and to assess the impact of acquisition parameters on CTDI accuracy.
Methods and Materials: CT scanners from 4 vendors (16 slices n=6, 32 slices n=1, 64 slices n=3) were included in the study. The accuracy of the displayed CTDI was checked using a dosimeter. The impact of the independent variables, CT model (16, 32, 64 slices), phantom size (head/body), kVp (80, 100, 120, 140 kVp) and primary collimation (≤3mm, 3-10mm, 10-20mm, >20 mm) on the dependent variable, accuracy of the displayed CTDI (derived from user manual), assessed by a four-way factorial ANOVA.
Results: All the factors had a statistically significant impact on CTDI accuracy ($p<001$). In a head to head comparison, the lower accuracies were found on average for 16 slices CT (-10±5%), for HeadPhantom (-8±8%), for 80kV (-14±11%) and for thick collimation (-9±12%), whereas maximum accuracies were found for 64 slices CT (-5±10%; $p<0.001$), BodyPhantom (-5±9%; $p=0.05$), 140 kV (-5±9%; $p<0.01$) and thin collimation (-6±7%; p=NS).
Conclusion: In the case of 16CTs and acquisition protocols involving the use of the HeadPhantom with low kV and a wide primary collimation, the displayed CTDI inaccuracies may be higher than 20% (suspension level in the EC RP N.162).

B-0326 14:57

Dose values in interventional computed tomography procedures: a multicentre study

A.R. Costa[1], I. Gomes[1], A.S. Pimenta[2], C. Oliveira[1], C.M. Almeida[3], G.N. Paulo[1], J. Santos[1]; [1]*Coimbra/PT*, [2]*Porto/PT*, [3]*Lisbon/PT (araquel.costa@hotmail.com)*

Purpose: The number of computed tomography (CT)-guided interventions had increased exponentially on the last decade. The aim of this study was to analyse the frequency of examinations, protocols and patient dose values.
Methods and Materials: The study was carried out in three Portuguese centres of reference of excellence. Retrospective analysis of the frequency of interventional CT procedures, patient data (age, gender and examination body region), exposure parameters and dose values, in terms of CT dose index (CTDIvol) and dose length product (DLP) were directly collected from picture archiving and communication system (PACS).
Results: Local DRLs were obtained for the most common interventional CT procedures per each centre (76% chest, 10% bone, 8% pelvic and 6% abdomen). Lung biopsy revealed to be the most frequent procedure. The exposure parameters and dose values vary across the centres. The found acquisition modes for intervention CT are 2D in (axial and helical mode) and CT fluoroscopy. The highest interventional acquisition dose values were found for CT fluoroscopy. The majority of the obtained dose values are similar to other studies.
Conclusion: The first national approach of interventional CT dose values was performed. Different approaches to these procedures were verified. A lack of standardisation of practice was identified justifying further research to protect the staff and decrease the risk of patient's over-exposure and procedure complications.

B-0327 15:05

One-stop imaging for triple-rule-out CT angiography using 16-cm wide-detector CT: a preliminary study

K. Liu, Z. Li; *Chengdu, Sichuan/CN (634270986@qq.com)*

Purpose: To investigate the feasibility of one-stop imaging for triple-rule-out (TRO) CT angiography (CTA) using 16-cm wide-detector CT in patients with acute chest pain.
Methods and Materials: Totally 23 patients with requests for examinations of thoracic vessels underwent TRO CTA on a 256-row, 16-cm wide-detector CT using a protocol consisting of an axial, ECG-gated cardiac acquisition followed by a spiral chest CT acquisition from the thoracic inlet to the diaphragm bottom in a free breathing condition. Heart rate was not controlled. The total volume of iodinated contrast medium (370mg/ml) for a biphasic injection protocol was 60-75ml (30-45ml based on the weight of patients; then another 30ml). Attenuation values and standard deviations in pulmonary artery, thoracic aorta, coronary artery and muscle were measured to calculate contrast noise ratio (CNR) for vessels as objective indicators to evaluate the image quality. The subjective image quality was evaluated independently by two readers. Effective dose was recorded.
Results: All patients gained satisfactory image quality for diagnosis. There was no statistically significant difference between the scores of two readers ($P>0.05$). Mean attenuation values were adequate at 464.3±146.1HU in the pulmonary trunk, 313.1±50.4HU in the aortic arch, 378.5±64.9HU and 410.3±58.3HU in the right and left coronary artery, respectively. Noise was 16.6±1.8 and CNR were 27.1±8.6 in the pulmonary trunk, 18.0±3.2 in the aortic arch, 22.1±5.1 and 23.8±3.7 in the right and left coronary artery, respectively. Effective radiation dose for the entire scan was 4.5±0.9 mSv.
Conclusion: One-stop imaging for TRO CTA using 16-cm wide-detector CT can improve image quality, with low radiation dose and contrast medium volume.

B-0328 15:13

Optimisation of computed tomography practice: phantom and patient approach

F. Pires, T. Patrão, F. Alves, J. Santos; *Coimbra/PT (fspires.11@gmail.com)*

Purpose: Computed tomography examinations are responsible for a large proportion of effective collective dose across the countries, and concern about potential effects increased in the last years. The aim of this study was to analyse the exposure parameters and dose levels of the most common CT procedures to audit and implement optimisation measures.
Methods and Materials: This study was carried out in four phases: (1) establishment of local diagnostic reference levels (DRLs) base on the 75th percentile dose value of the most common CT examinations; (2) analyse of the practice and literature comparison; (3) anthropomorphic phantom experimental tests with PBU-60; (4) subjective and objective image quality analysis, based on visual grading characteristic (VGC) of the radiologist opinion of the guideline criteria and on the standard deviation value of the Hounsfield units in homogeneous regions of interest, respectively.
Results: Local DRLs were obtained for head, chest, abdomen and lumbar column. The majority of the values were higher than the recommendation. The optimisation experimental tests allowed the definition of new exposure parameters with radiologist approval. The optimised local DRLs are according to the recommend values in most of the body regions. Image quality analyses revealed an expected increase of noise; however, no significant differences were founded for the majority of criteria.
Conclusion: The most common CT procedures were optimised. Dose reductions were obtained with diagnostic imaging criteria fulfilment and radiologist approval.

B-0329 15:21

Assessment of image quality criteria from chest CT examinations

R. Carrasquinho[1], A.M. Ribeiro[1], L.P. Ribeiro[1], O. Lesyuk[2], R.P. Almeida[1], A.F. Abrantes[1]; [1]*Faro/PT*, [2]*São Brás de Alportel/PT (oksanalesyuk@gmail.com)*

Purpose: To assess the image quality criteria from chest CT examinations based in quality control charts and to demonstrate the importance of implementing an image quality control system.
Methods and Materials: A retrospective study was conducted in a public CT unit using a random sample of 750 chest CT examinations grouped into 30 smaller samples, each one with 25 exams. Using a checklist based on CT quality criteria, the conformities and non-conformities found were recorded and used to establish three types of quality control: (1) the proportion of conformities and non-conformities (p chart); (2) the total number of non-conformity exams (np chart) and (3) the total number of non-conformities in each sample (c chart), in order to suggest corrective actions for improvement.
Results: Considering all exams, 186 (24,80 %) are non-conformity exams. 265 non-conformities were identified and the "absence of data relating to examination" presented the highest number of non-conformities (55,09%), followed by the group "image quality criteria" (17,36 %), "artefacts" (13,96%) and the "incorrect positioning" (13,58 %).
Conclusion: This research allowed the identification of different types of non-conformities found in chest CT images, which have impact on image quality. Therefore, the existence of suitable quality control of the image is essential to achieve high quality standards in CT departments. It is recommendable to do training courses regularly improving radiographer's performance and strategies to improve image Quality in CT must be implemented.

Obesity and type 2 diabetes: cardiovascular and cerebral aspects

R.L. Widya; *Leiden/NL (R.L.Widya@lumc.nl)*

Purpose: This thesis focuses on cardiovascular and cerebral dimensions and function in people with obesity and type 2 diabetes.
Methods and Materials: Extensive cardiovascular, abdominal and cerebral phenotyping by magnetic resonance imaging (MRI), magnetic resonance spectroscopy and functional MRI was performed in healthy, overweight and obese subjects, and type 2 diabetes patients. Statistical analysis included multivariate linear regression models to investigate the complex interrelationships between fatty liver, visceral and subcutaneous adiposity, metabolic syndrome, and several cardiovascular and cerebral outcome measures.
Results: In a large population-based cohort, hepatic triglyceride content was associated with left ventricular diastolic function and aortic pulse wave velocity after adjustments for several cardiometabolic risk factors. Studies with type 2 diabetes patients showed right ventricular remodeling and impaired systolic and diastolic function, in a similar manner as changes in left ventricular dimensions and function. A 6-month exercise intervention induced tissue-specific changes in ectopic fat compartments. Short-term caloric restriction normalized hypothalamic responsiveness to glucose ingestion in patients with type 2 diabetes. Obesity was associated with larger amygdalar and hippocampal volumes, and increased abdominal visceral adipose tissue rather than subcutaneous adipose tissue was associated with microstructural brain tissue damage.
Conclusion: Cardiovascular and cerebral impairments in obesity and type 2 diabetes are influenced by several metabolic abnormalities. Fatty liver itself could pose a risk of myocardial dysfunction and subclinical vascular impairment above and beyond known cardiovascular risk factors that are clustered within the metabolic syndrome. Exercise and caloric restriction show beneficial effects on ectopic fat deposition and hypothalamic glucose response.

B-0331 14:08

CT dose reduction for epicardial fat measurement in obese patients: effects of low-dose cardiac CT and adaptive statistical iterative reconstruction

S. Mirafzal, C. Lahaye, A. Mulliez, P. Morin, M.A. Vaz Touret, Y. Boirie, L. Boyer, L. Cassagnes; *Clermont-Ferrand/FR (sonia_mirafzal@hotmail.fr)*

Purpose: To evaluate the effects of radiation dose reduction—120 kV versus 100 kV—and the reconstruction algorithm used—adaptive statistical iterative reconstruction (ASIR)—on the variability and reproducibility of EFV (epicardial fat volume) in obese patients.
Methods and Materials: Standard dose CT (120 kV) and low-dose (100kV) calcium artery scoring CT (CAS-CT) examination were performed in 80 obese patients. The standard dose CT images were reconstructed using ASIR 30% (reference standard in our center); the low-dose CT images were reconstructed using ASIR 30%, 50% and 100%. In the 320 images series obtained, the EFV was measured using a semi-automatic software. Two observers independently quantified EFV and inter-observer agreement was evaluated.
Results: Radiation dose of the low-dose CAS-CT examinations was 67% (mean) lower than standard dose CT examinations. The mean noise on standard dose CT, ASIR 30 low-dose CT, ASIR 50 low-dose CT, ASIR 100 low-dose CT were 22.5, 35.5, 30.3, and 22.8, respectively. Excellent correlations were observed between the EFV measured on standard dose CT and EFV measured on low-dose CT ASIR 50/EFV measured on low-dose CT ASIR 100 ($r=0.96$, $p<0.01$ and $r=0.97$, $p<0.01$, respectively). Inter-observer agreement was excellent too: $r=0.97$, $p<0.01$.
Conclusion: A 67.0% reduction of the radiation dose would be possible in CT for the measurement of EFV in obese patients using low-dose CT and the reconstruction algorithm ASIR instead of 120 kV standard dose CT.

B-0332 14:16

Computer-aided semi-automatic quantification of epicardial fat volume on angio-CT images

M. Codari[1], C. De Angelis[2], M. Scarabello[2], F. Secchi[1], F. Sardanelli[1]; [1]*San Donato Milanese/IT*, [2]*Milan/IT (marina.codari@grupposandonato.it)*

Purpose: The quantification of epicardial adipose tissue (EAT) on angio-CT images is still limited in clinical routine due to the post-processing time. To this aim, we proposed a semi-automated method for EAT quantification and evaluated its reproducibility.
Methods and Materials: Twenty-one consecutive angio-CT, performed from February 2017 to May 2017, were retrospectively selected. Our local Ethics Committee approved this study. A semi-automatic approach was developed to detect the pericardial sac through the 3D interpolation of contours manually identified on different views and segment the EAT contained therein. Two operators segmented all images using a double-blinded approach. One operator performed it twice. The number of contours and EAT volume (cm^3) were recorded for all images. Data are presented as median and interquartile range. Wilcoxon signed rank test was used for comparisons while Bland-Altman analysis was used to assess operator reproducibility.
Results: Intra- and inter-operator analysis showed: a bias of 1.0 cm^3, a coefficient of repeatability of 14.0 cm^3, an average measurement of 90.2 cm^3, and a reproducibility of 84%; 1.1 cm^3, 21.0 cm^3, 90.9 cm^3, and 77% respectively. The median number of drawn contours was 12 (10-14), with statistically significant difference between the number of segmented contours by each operator ($p=0.018$), but not between the corresponding volume values ($p=0.875$).
Conclusion: The proposed method allows segmenting a whole angio-CT images, with submillimetric resolution, using few contours with an acceptable level of reproducibility. The significant difference in contours number seems to not affect volume segmentation accuracy, allowing to further reduce them.

B-0333 14:24

Epicardial fat volume as a potential imaging biomarker for coronary artery disease in symptomatic patients

G. Milanese[1], M. Silva[1], L. Bruno[2], M. Goldoni[1], E. Maffei[3], F. Cademartiri[4], N. Sverzellati[1]; [1]*Parma/IT*, [2]*Palermo/IT*, [3]*Urbino/IT*, [4]*Rotterdam/NL (gianluca.milanese@studenti.unipr.it)*

Purpose: Epicardial adipose tissue is a visceral fat depot with paracrine activity that may associate with increased coronary artery disease (CAD). We tested if individuals with increased epicardial fat volume (EFV) - as quantified by cardiac CT angiography (CCTA) - show a higher amount of coronary artery calcifications (CAC) and a higher prevalence of CAD.
Methods and Materials: Patients with clinical indication to CCTA were retrospectively selected. EFV was quantified as the sum of voxels with density between -190 and -30 HU, within the volume outlined by the epicardial sheet. CAC was quantified according to the Agatston score (AS) and patients were stratified in four groups: AS=0; 1≤AS<100; 100≤AS<400 and AS≥400. CAD was classified as absent, non-obstructive, and obstructive (lumen reduction≥50%). Parameters were reported as median and interquartile range (IQR). Correlation was tested by Spearman test. Multivariable analysis tested association between CAD and morpho-clinical metrics.
Results: In 1,351 patients, median EFV was 90.92 ml (IQR=66,2); median CAC was 58 (IQR=452). CAD was absent in 848, non-obstructive in 325 and obstructive in 170 patients. EFV and CAC were moderately correlated ($r_s=0.34$;$p<0.001$). EFV was significantly higher in patients with higher CAC ($p<0.001$) and in patients with obstructive CAD ($p<0.001$). CAC ($p<0.001$), but not EFV ($p>0.05$), was a significant predictor of CAD category. When adjusting for traditional clinical cardiovascular risk factors, EFV was not a significant predictor of CAC.
Conclusion: EFV is higher in patients with obstructive CAD, its role in the development of CAD is probably due to shared risk factors.

B-0334 14:32

Intra- and interobserver variability of MR-based assessment of myosteatosis as a biomarker for metabolic diseases in subjects from the general population

L.S. Kiefer[1], J. Fabian[1], R. Lorbeer[2], J. Machann[1], C.L. Schlett[3], S. Rosplecz[4], A. Peters[5], F. Bamberg[1]; [1]*Tübingen/DE*, [2]*Munich/DE*, [3]*Heidelberg/DE*, [4]*Oberschleißheim/DE*, [5]*Neuherberg/DE (lena.kiefer@med.uni-tuebingen.de)*

Purpose: To determine the reproducibility of skeletal muscle adipose content quantification by magnetic resonance imaging (MRI) as a metabolic biomarker in subjects from the general population.
Methods and Materials: Subjects without cardiovascular disease from a population-based cohort study underwent a whole-body 3T MRI protocol, including a T2*-corrected, multi-echo 3D-gradient-echo Dixon (TR 8.90 ms, six echo times, flip angle 4°). Skeletal muscle adipose content was quantified as mean proton-density fat fraction in % in M. psoas major (MPM), M. quadratus

lumborum (MQL), autochthonous back muscles (ABM) and M. rectus abdominis (MRA) on the right (R) and left (L) side at level L3 by two independent readers. Variability was assessed using Bland-Altman plot analysis of absolute differences and intra-class-correlation coefficients (ICC) from two-way random-effects ANOVA.
Results: Among 40 subjects (mean age 54.8±8 years, 62.5% males, mean BMI 28.7±5.3) a total of 320 measurements were performed. Inter-reader agreement was excellent for all muscle compartments (MPMR: ICC 0.91, MPML: ICC 0.98, MQLR: ICC 0.98, MQLL: ICC 0.91, ABMR ICC 0.97, ABML: ICC 0.98, MRAR: ICC 1.00, MRAL: ICC 0.98) with only minor absolute differences (-0.3±1.0%, -0.1±0.5%, 0.2±0.7%, -0.2±0.8%, -0.9±1.5%, -0.4±1.3%, -0.3±1.5% and -0.3±1.5%; respectively). Similarly, intra-reader reproducibility was excellent for all included muscle compartments (ICC 0.95 to 1.00, absolute differences -0.2 to 0.3%). All agreement was independent of BMI and body height (ICC 0.90 to 0.99).
Conclusion: Skeletal muscle adipose content by MRI is highly reproducible and may therefore serve as a robust metabolic biomarker in larger cohort studies to determine its prognostic role.

B-0335 14:40

Cardiovascular function in relation to abdominal adipose tissue distribution

E.H.M. Paiman, R. de Mutsert, R.L. Widya, J.W. Jukema, F.R. Rosendaal, H.J. Lamb; *Leiden/NL (e.h.m.paiman@lumc.nl)*

Purpose: To assess the relation of abdominal subcutaneous (SAT) and visceral adipose tissue (VAT) with left ventricular (LV) remodeling, cardiac function and aorta stiffness.
Methods and Materials: This is a cross-sectional analysis of 1076 participants of the Netherlands Epidemiology of Obesity study, who underwent abdominal and cardiovascular MRI. We used linear regression to examine the associations of SAT and VAT area with LV ejection fraction (EF), LV mass/end-diastolic volume (concentricity), the ratio of mitral early and late filling rate (E/A) and aorta pulse wave velocity (PWV), adjusted for sex, age, ethnicity, education, smoking, menopausal status, use of hormone therapy and either VAT or SAT.
Results: Participants (47% men) had a mean (SD) age of 56 (6) years, SAT: 237 (97) cm^2, VAT: 91 (56) cm^2, LVEF: 64 (6)%, LV concentricity: 0.66 (0.13) g/ml, E/A ratio: 1.32 (0.50), PWV: 6.7 (1.4) m/s. Per SD of SAT, LV concentricity was 0.02 (95%CI: 0.01, 0.03) g/ml lower, and LVEF was 0.79 (0.30, 1.29)% lower. Per SD of VAT, LV concentricity was 0.02 (0.01, 0.03) g/ml higher, and E/A ratio was 0.07 (0.03, 0.11) lower. SAT and VAT were not associated with PWV (beta: 0.00 (-0.11, 0.11) m/s per SD SAT and 0.06 (-0.07, 0.19) m/s per SD VAT).
Conclusion: In this middle-aged population-based cohort, SAT was associated with LV eccentric remodeling and lower systolic function. In contrast, VAT was associated with LV concentric remodeling and lower diastolic function. For cardiovascular risk assessment, it is essential to differentiate between abdominal subcutaneous and visceral adiposity.

B-0336 14:48

MRI-based epi- and para-cardial fat depots in a cohort of prediabetics, diabetics and healthy controls from a general population without cardiovascular disease

S.D. Heber[1], R. Lorbeer[2], S. Gatidis[1], J. Machann[1], S. Auweter[2], S. Sellner[2], A. Peters[3], F. Bamberg[1], C.L. Schlett[4]; [1]*Tübingen/DE*, [2]*Munich/DE*, [3]*Neuherberg/DE*, [4]*Heidelberg/DE (sophiaheber@web.de)*

Purpose: The quantification of the pericardial fat depots by MRI in a cohort of prediabetics, diabetics and healthy controls from a population without cardiovascular disease and relation to different fat depots and cardiovascular risk factors.
Methods and Materials: Assessment of the cardial fat depots was conducted in the MR cine steady-state free precession (SSFP) sequence (TR 29.97 ms, TE 1.46 ms) in 400 subjects from the KORA FF4 cohort. Epi- and pericardial fat were segmented manually in a single slice at end-systole and end-diastole. Median regression was conducted to examine the relationship of epi- and paracardial fat to impaired glucose metabolism.
Results: Of 400 subjects, 372 (93%) were included in the analysis (median age 57 years; 59.4% male), including 220 healthy controls, 100 prediabetics, and 52 diabetics. Fat measurements correlated strongly between end-systolic and end-diastolic slices while measurements were on average slightly larger when derived from systolic (+11.3% for epicardial- and +10.8% for paracardial fat). Both, epi- and para-cardial fat increased stepwise from healthy controls to subjects with prediabetes and diabetes (7.7 vs. 9.2 vs. 10.3 cm^2 for epicardial- and 14.3 vs. 20.3 vs. 27.4 cm^2 for paracardial fat, retrospectively; both $p<0.001$). While paracardial fat is independent of BMI (p=0.03) or SAT (p=0.048) in diabetics, none of the cardial fat depots are associated to the diabetic status independent of VAT.
Conclusion: There is an increase for epi- and paracardial fat from healthy controls to subjects with prediabetes and diabetes, which is only partially independent of other, abdominal MR-based fat depots.

B-0337 14:56

Coronary CT angiography-based fractional flow reserve in diabetic patients: results from the MACHINE consortium

F. Nous[1], A. Coenen[1], M. Kruk[2], J. De Geer[3], U.J. Schoepf[4], D. Yang[5], A. Kurata[6], R.P. Budde[1], K. Nieman[1]; [1]*Rotterdam/NL*, [2]*Warsaw/PL*, [3]*Linköping/SE*, [4]*Charleston, SC/US*, [5]*Seoul/KR*, [6]*Ehime/JP (f.nous@erasmusmc.nl)*

Purpose: Coronary CT angiography (CCTA)-derived fractional flow reserve (FFR) (CT-FFR) simulates the hyperaemic state to evaluate the haemodynamic impact of coronary artery disease (CAD), assuming a normal coronary microvascular response. Coronary microvascular dysfunction, however, is frequently present in diabetic patients. We assess the diagnostic performance of a machine learning (ML) application for on-site computation of CT-FFR in diabetic patients.
Methods and Materials: The diagnostic performance (sensitivity, specificity, negative predictive value, positive predictive value, accuracy) of ML-based CT-FFR was analysed per patient and per vessel in patients with and without diabetes, who were enrolled in the MACHINE consortium. Invasive FFR was used as a reference and FFR ≤0.8 was considered haemodynamically significant for CAD. Per-patient and per-vessel discrimination of lesion-specific ischaemia by CT-FFR were assessed by the area under receiver operating characteristic (ROC) curves.
Results: 75 out of 351 patients had diabetes (21%), involving 110 of the 525 vessels (21%). Per-vessel diagnostic accuracy of ML-based FFR in diabetic patients was 85% (95% CI: 72-91%) and 76% (72-80%) in non-diabetic patients (p=0.136). On a per-patient level, the accuracy of ML-based FFR in diabetic patients was 86% (77-94%) and in non-diabetic patients 85% (80-89%) (p=0.884). The area under curve of per-vessel and per-patient ROC curves of diabetic and non-diabetic patients was comparable (per-vessel: 0.88 (0.82-0.95) vs 0.82 (0.78-0.86); per-patient: 0.88 (0.80-0.96) vs 0.82 (0.77-0.87)).
Conclusion: The diagnostic performance and the discrimination of ischaemia by on-site ML-based CT-FFR analysis are similar in diabetic patients and non-diabetic patients.

The right ventricular strain assessment in type 2 diabetes mellitus patients: insights from cardiac magnetic resonance feature tracking

B.-Y. Hu, Z.-G. Yang, X. Liu, K. Shi, H.-Y. Xu, Y.-K. Guo; *Chengdu/CN (237772342@qq.com)*

Purpose: To investigate the feasibility of cardiac magnetic resonance (CMR)-derived feature tracking for assessing right ventricle (RV) myocardial deformation in type 2 diabetes mellitus (T2DM), and to determine if these parameters are correlated to biochemical markers.
Methods and Materials: A total of 57 T2DM patients, including 14 with impaired right ventricle ejection fraction (RVEF), 43 with preserved RVEF and 22 healthy controls were studied. Cardiac volumes and function, right ventricular feature tracking parameters [the global longitudinal, circumferential, and radial peak strain (PS), peak diastolic strain rate (PDSR), and peak systolic strain rate (PSSR)] were determined by CMR. The intraclass correlation coefficient (ICC) was used to evaluate the inter- and intra-observer variabilities.
Results: Compared with controls, significantly lower values of longitudinal PS in the T2DM with impaired RVEF (-23.90±4.06% vs -27.22±2.37%, p=0.009) and preserved RVEF groups (-25.27±3.37% vs -27.22±2.37%, p=0.009) indicates impairment of RV function. Furthermore, the circumferential and radial PDSR in the impaired RVEF group decreased significantly compared with controls (both $P<0.05$). In the T2DM cohort, longitudinal PS correlated with HbA1c (r=0.470, P=0.001) and low-density lipoprotein (r=0.355, P=0.027), and had weak correlation with RV end-diastolic volume (r=0.279, P=0.013), RV end-systolic volume (r=0.262, P=0.020), and RV myocardial mass (r=0.226, P=0.045). The ICCs for intra- and inter-observer variabilities were 0.798-0.905 and 0.701-0.897.
Conclusion: In adults with T2DM, abnormal RV myocardial deformation can be monitored using CMR feature tracking, even in those with preserved RVEF; and the diastolic dysfunction was associated with HbA1c and low-density lipoprotein.

B-0339 15:12

Assessment of the left ventricular myocardial strain in type 2 diabetes mellitus patients with hypertension using MR tissue tracking

L. Xie, Y. Guo, Z. Yang; *Chengdu/CN (xielinjun2016@163.com)*

Purpose: To investigate the left ventricular myocardial strain in type 2 diabetes mellitus (T2DM) patients with hypertension using cardiac magnetic resonance tissue tracking.
Methods and Materials: Thirty-six T2DM patients with hypertension (Group 1), 39 cases of T2DM without hypertension (Group 2) and 26 normal control individuals were enrolled. All patients underwent cardiovascular magnetic resonance (CMR), including cardiac cine sequence (short-axis, long-axis two-chamber and four-chamber image). Cardiac function indexes and tissue tracking parameters were all measured by CVI42 and compared statistical. Pearson's correlation between the left ventricular ejection fraction (LVEF) and the left cardiac strain parameters were also investigated.
Results: All the patients recruited finished CMR and the baseline characteristics were recorded. The Group 1 presented lower LVEF than Group 2 and normal group (LVEF: Group 1: 57.17±9.30%, Group 2: 61.11±5.73%, normal group: 62.22±3.44%; *P*=0.032, 0.004). Compared with the normal group, the global radial, circumferential and longitudinal peak strain (PS) of the Group 1 were significantly reduced (all *P*<0.05). Group 2 presented with lower longitudinal PS value than control group (Group2: -16.50±2.27%; control group: -18.10±1.85%, *P*=0.004). Pearson correlation analysis indicated a significant and positive correlation between the LVEF and radial PS (r = 0.746, *P*<0.001) and circumferential PS (r = 0.786, *P*<0.001). A positive correlation existed between the longitudinal PS and LVEF (r = 0.587, *P*<0.001).
Conclusion: The myocardial strain decreased in T2DM patients with hypertension were more obvious than control group. The myocardial strain appears to be more sensitive than LVEF for assessing LV dysfunction in T2DM patients without hypertension.

B-0340 15:20

Phenotypic multi-component involvement of subclinical disease as quantified by MRI in subjects with prediabetes, diabetes and normal glucose tolerance

C. Storz[1], S. Rosplecz[2], R. Lorbeer[3], W. Rathmann[4], M.F. Reiser[3], U. Hoffmann MD MPH[5], A. Peters[2], C.L. Schlett[6], F. Bamberg[1]; [1]*Tübingen/DE*, [2]*Neuherberg/DE*, [3]*Munich/DE*, [4]*Düsseldorf/DE*, [5]*, Boston, MA/US*, [6]*Heidelberg/DE (corinna.storz@med.uni-tuebingen.de)*

Purpose: To compare whole-body subclinical disease phenotypes by magnetic resonance (MR) imaging to study differences between subjects with prediabetes, diabetes, and controls with normal glucose tolerance.
Methods and Materials: Overall, 400 subjects from a western general population without prior cardiovascular disease were enrolled in a prospective case-control study and underwent whole-body MR between June 2013 and September 2014. The MR protocol was tailored to the assessment of metabolic and arteriosclerotic alterations, including age-related white matter changes, hepatic proton-density-fat-fraction, visceral adipose tissue volume, left ventricular remodeling index, carotid plaque, and late-gadolinium enhancement. MR features were summarized in an ordinal phenotypic-based metric (score range: 0-6). Univariate, multivariate correlation, and unsupervised clustering were performed.
Results: 243 subjects with complete multi-component MR datasets were included in the analysis (55.6±8.9 years, 62% males), 48 were classified as subjects with prediabetes and 38 as subjects with diabetes. The MR phenotypic score was significantly higher in subjects with diabetes and prediabetes as compared to controls (mean score, 3.00±1.04 and 2.69±0.98 vs 1.22±0.98, p<0.001, respectively), also after adjustment for potential confounders. Clustering analysis identified two clusters of MR phenotype patterns associated with glycaemic status (p<0.001), independent of the MR phenotypic score (Cluster II: odds ratio: 2.49; 95%-CI: [1.00, 6.17], p=0.049).
Conclusion: Subjects with prediabetes and diabetes have significantly higher phenotypic-based metric as compared to subjects with normal glucose tolerance, and feature a diabetes-specific pattern of MR phenotypes.

Detection of bridging vein thrombosis at computed tomography: a specific sign of shaken baby syndrom?

S. Nahmani, D. Grevent, K. Beccaria, N. Boddaert; *Paris/FR (sarah.nahmani@gmail.com)*

Purpose: Shaken baby syndrom (SBS) also known as abusive head trauma (AHT) is a major cause of head trauma in infants. Bridging vein rupture caused by anterio-posterior movements has proofed to be responsible of subdural hematoma (SDH). The resulting thrombosis, following the rupture can be seen in CT and MRI. The objective is to evaluate the specificity of bridging vein thrombosis (BVT) seen in cranial CT (cCT) in SBS compared to a cohort of infants victims of accidental head trauma.
Methods and Materials: A total of 173 cCT of children under 36 months of age, performed between 2010 and 2016 in Necker hospital (92 who were diagnosed AHT and 81 with accidental head trauma) were analyzed retrospectively and independently by two radiologists who were blinded to the diagnosis.
Results: BVT were found in 69/92 AHT, sensitivity = 75%, (95% CI : 64.8-83.4%)) and 6/81 accidental head trauma, specificity =93% (95% CI : 84.6-97.2%) by the senior reader (and respectively 65, sensitivity =71%, (95% CI : 60.2-79.6) and 11, specificity = 86% (95% CI : 76.9 - 93) by the junior reader), p<0.05. Further analysis showed that the 6 BVT in the accidental group were consecutive to 2 road traffic accidents, 1 defenestration, 1 polytraumatism, and 2 traumatisms eventually reclassified as AHT.
Conclusion: BVT, seen in cCT, is a very sensitive and specific sign of AHT. This finding is not compatible with a minor alleged trauma and should suggest AHT in infants brought spontaneously to emergency room without polytrauma.

B-0342 14:08

The estimation of radiation dose in suspected child abuse imaging

H. Niiniviita, E. Saukko, J. Saunavaara; *Turku/FI (hannele.niiniviita@tyks.fi)*

Purpose: To assess the radiation doses related to imaging in suspected child abuse with patients under the age of 2 years and to estimate the additional radiation dose, if follow-up images are taken according to the new guidance of the Royal College of Radiologists.
Methods and Materials: There were 60 suspected child abuse patients, who were imaged between the years 2013 and 2016. The number of studies, radiation doses and image parameters for calculating effective dose (voltage, tube current-time product, image area, additional filtration) were collected from PACS. The radiation dose was recorded as DAP-value (dose area product, $mGycm^2$) and the effective dose of skeletal survey was estimated by PCXMC-software for nine patients. The effective dose of suggested follow-up images were estimated from these calculations.
Results: We reviewed 154 x-rays studies, where the main protocols used were skeletal survey (22%), femur (17%) and thorax (10 %). In skeletal survey there were at mean 19 exposures and the mean DAP was $261mGycm^2$. The highest DAP-values were observed in skull (AP+LAT, $102.7mGycm^2$), spine (LAT, $34.8mGycm^2$), thorax (oblique, $17.1mGycm^2$) and pelvis (AP, $15.4mGycm^2$). The mean effective dose in skeletal survey was 61µSv and the effective dose of follow-up images including extremities, thorax AP and two obliques was estimated to be approximately 25µSv. The effective dose of extremities contribute 25% of total dose in control images.
Conclusion: The highest radiation doses related to suspected child abuse imaging are generated from skull and spine. The additional radiation dose of follow-up images is low.

B-0343 14:16

Optimising imaging in suspected child abuse: a five-year prospective study in a tertiary referral children's service

I. Moorthy, K. Iliadis, T. Diacon, L. Moon, L. Vitta; *Brighton/UK (kyriakos.iliadis@bsuh.nhs.uk)*

Purpose: Imaging teams are crucial in assisting paediatric and social service professionals when child abuse is suspected. This study aims to consolidate guidance on best practice in imaging these vulnerable children, while remaining sensitive to the rights of their carers.

Methods and Materials: Prospective data were collated for every skeletal survey performed over a five-year period (April 1, 2012 to March 31, 2017) as part of an ongoing audit, using a pre-designed data collection form. Accuracy of reporting of bony injury, and bony density and morphology were studied (audit standard: 100% compliance). As double reporting and timely follow-up imaging contribute to diagnostic accuracy, this was also studied (audit standard: 100% compliance). Our neuroimaging practice was also audited.
Results: Total number of children studied = 88 (100%); number of positive initial skeletal surveys = 48 (55%); number where bone morphology and density were commented on = 80 (91%); number of double reports of initial skeletal surveys = 80 (91%); number where second reporter disagreed with first reporter = 3 (3%); interval to follow-up imaging = 11 to 33 days (mode 14 days); number of follow-up surveys = 72 (82%); number of follow-up surveys with new findings = 4 (5%).
Conclusion: Multidisciplinary teamwork and clear imaging protocols (including double-reporting, follow-up imaging, and relevant neuroimaging) are crucial to making the correct diagnosis in suspected child abuse. Ongoing audit of imaging practice optimises diagnostic accuracy.

B-0345 14:24

Quantitative bone ultrasound: low sound wave propagation in cortical bone as a novel, non-invasive imaging biomarker in children and adolescents with hypophosphatemic rickets

J. Schneider[1], A. Raimann[2], A. Boni-Mikats[2], M. Krssak[2], R. Klepochová[2], G. Häusler[2], K. Raum[1], J.M. Patsch[2]; [1]*Berlin/DE*, [2]*Vienna/AT*
(janina.patsch@meduniwien.ac.at)

Purpose: The assessment of ultrasound wave propagation in cortical bone is a novel, non-invasive quantitative imaging tool in bone research. The purpose of this study was to determine sound wave propagation properties in the distal extremities of paediatric patients with hypophosphatemic rickets and healthy controls.
Methods and Materials: Following study approval by institutional review and written informed consent, we performed quantitative bone ultrasound in children, adolescents and young adults with xlh (n=8), and healthy controls (n=13). The majority of patients and controls also underwent high-resolution peripheral quantitative computed tomography (HR-pQCT) of the radius and tibia as a standard of reference. Bone ultrasound was performed at the distal radius and the distal tibia according to a structured examination protocol, using a dedicated 1MHz transducer with one receiver arrays and two transmitter array. Based on bidirectional axial transmission and propagation of ultrasound waves, the 'first arriving signal velocity' (vFAS) was measured and post-processed. HR-pQCT images were reviewed by a board-certified radiologist, data were evaluated by the manufacturer's quantification software.
Results: Quantitative bone ultrasound of wave propagation was feasible in all study participants. At the distal radius, we found vFAS to be significantly lower in in XLH patients than in healthy controls (-6.8%; ANOVA: p = 0.0013). A similar reduction of vFAS was observed in the distal tibia (-6.5%; ANOVA: p = 0.0009). HR-pQCT scans revealed microstructural deficits in both cortical and trabecular bone.
Conclusion: Sound wave propagation in cortical bone is a promising imaging biomarker in children and adolescents with hypophosphatemic rickets.

B-0346 14:32

Evaluation of a new computer-aided diagnosis system for automated bone age assessment in comparison to the Greulich Pyle atlas method: advanced results of a multireader study

C. Booz, J.L. Wichmann, S. Böttger, A. Al Kamali, S.S. Martin, D. Leithner, L. Lenga, T.J. Vogl, B. Bodelle; *Frankfurt a. Main/DE*
(boozchristian@gmail.com)

Purpose: To investigate a novel computer-aided diagnosis (CAD) software for bone age (BA) assessment in comparison to the Greulich Pyle (GP) method regarding its accuracy and precision. In addition, we evaluated the influence of carpals on bone age assessment.
Methods and Materials: Data from clinically indicated left hand and wrist radiographs of 305 children were included. Total BA, BA of the distal radius and BA of the carpals were determined by three radiologists using the GP method and additionally assessed by the CAD software (BoneXpert). Pearson product-moment correlation, Bland-Altman plot, root-mean-square (rms) deviation and further agreement analyses were calculated.
Results: Mean total BA was 9.76 years (CAD) and 9.81 years (GP) showing very high correlation between both approaches (r=0.985; rms deviation 0.49 years). Mean BA of the distal radius was 9.50 years (CAD) and 9.82 years (GP) (r=0.963). Mean BA of the carpals was 9.94 years (GP). Statistical analysis demonstrated a significantly higher correlation between total BA and BA of the distal radius (r=0.969) than between total BA and BA of the carpals (r=0.923). Assessment of the carpals showed only good inter-reader agreement (κ=0.79), while the agreement in analysing the distal radius was excellent (κ =0.98).
Conclusion: The evaluated CAD system allows for precise BA assessment compared with the GP method. Assessment of the carpals is challenging and leads to comparatively lower precision and inter-reader agreement. Methods assessing BA without analysing the carpals should be more accurate than methods including the carpals in analysis like the GP method.

Role of imaging in the diagnosis of glenohumeral deformity following obstetric brachial plexus injury

A.N. Parimalai[1], A. Chelladurai[1], K. Damodaran[2], P. Muthayan[1]; [1]*Chennai/IN*, [2]*Coimbatore/IN (anand7687@gmail.com)*

Purpose: To study the use of imaging in the assessment of glenohumeral deformity following obstetric brachial plexus injury. To study the usefulness of CT in the measurement of glenoid version angle and humeral head dislocation and to propose a grading for the severity of glenohumeral deformity.
Methods and Materials: This was a prospective study, conducted in the Department of Radiodiagnosis at Stanley Medical College between August 2015 and July 2016. The study group included 21 children below the age of 10 years presenting with posterior dislocation of the shoulder, with a past history of obstetric brachial plexus palsy. The children were examined with modified Mallet score and Naraka's neurological grading. CT of both shoulders using GE Optima 128 slice scanner and MRI using 1.5 Tesla Siemens unit were done. MR myelogram of the cervical spine was done.
Results: In our study, glenoscapular angle, percentage of humeral head anterior to the scapular line, scapular height and scapular width were analysed by paired Student's t test and were statistically significant [p<0.05]. We classified the children according to Waters and proposed radiological grading. We also classified according to the joint's stability. 3 affected joints were stable, 9 were subluxated and 9 dislocated. The higher the grade of deformity, the more difficult will be the shoulder movements and the scores worse in the Modified Mallet scale.
Conclusion: CT clearly identifies glenohumeral deformities such as increased glenoid retroversion, posterior subluxation or dislocation of the humeral head, smaller humeral head size and smaller size of the scapula as deviations from the normal status.

B-0348 14:48

Relationship between cranio-orbital volume changes and the severity of skull base dysmorphology in infants with anterior synostotic plagiocephaly: a quantitative analysis

M. Panfili, R. Calandrelli, L. Massimi, S. Gaudino, C. Colosimo; *Rome/IT*
(panfilimarco@gmail.com)

Purpose: The premature fusion of one coronal suture causes skull and orbital alterations in terms of side-to-side asymmetry. This study aimed to quantify the relationship between cranio-orbital complex changes and the severity of skull-base dysmorphology in patients with unicoronal synostosis.
Methods and Materials: We analysed CT images of 21 infants (mean age 156 days) with unicoronal synostosis, subdividing them into three subgroups according to severity of skull-base dysmorphology. Cranial fossae lengths, intracranial volume (ICV), each half-skull ICV (synostotic and non synostotic side), whole brain volume (WBV), orbital volumes (OV) were measured. ICV/WBV, $ICV_{affected}/ICV_{unaffected\ side}$ and $OV_{affected}/OV_{unaffected\ side}$ ratios were evaluated. Our results were compared with those of 21 age-matched healthy subjects.
Results: In all subgroups: reduced lengths and asymmetry of the anterior (CX) and the middle (XM) cranial fossae and asymmetry between $ICV_{affected}/ICV_{unaffected}$ and between $OV_{affected}/OV_{unaffected}$ were significant (p<0,05); ICV, WBV and ratio ICV/WBV were not significantly altered (p>0,05); OV on the affected side resulted significantly reduced only in group III (p<0,05). OV on the synostotic side were found to correlate with CX and XM lengths.
Conclusion: Skull and orbital changes revealed a side-to-side asymmetry but only the OV of the affected side, in group III, was found significantly reduced. It implies a relationship between the major severity of skull base dysmorphology and orbital alterations on affected side probably related to earlier timing of synostotic process; the lack of reduced ICV on synostotic side, in group III, suggests a different plasticity of skull cavity respect to orbital one.

B-0349 14:56

Detailed evaluation of a completely automatic, computer-assisted (CAD) analysis of hand X-ray examinations by including four different paediatric collectives

D.M. Renz[1], A. Schröder[1], J. Böttcher[2], A. Pfeil[1], F. Streitparth[3], U.K. Teichgräber[1], H.-J. Mentzel[1]; [1]*Jena/DE*, [2]*Gera/DE*, [3]*Berlin/DE*
(diane.renz@med.uni-jena.de)

Purpose: The CAD system BoneXpert (Visiana) determines the bone age of children and adolescents on hand X-ray examinations. Furthermore, the CAD

method calculates bone parameters of the metacarpals, among others the ,,bone health index" (BHI). The study purpose was a detailed evaluation of the CAD method, focusing on bone parameters, by including paediatric collectives with the following disorders: obesity, underweight, hypothyroidism, or chronic inflammatory bowel disease.
Methods and Materials: In the investigation, 325 children and adolescents (151 boys, 174 girls) between 3 and 18 years were included. All X-ray examinations were analysed visually and with the CAD system. The bone parameters of the CAD analysis were compared with age- and gender-matched normative values by using Z-scores; these Z-scores were calculated for the calendar as well as the skeletal age.
Results: High correlations were achieved between the visual determination of bone age and the CAD analysis, ranging between 0.848 and 0.956 ($p<0.001$) for the different paediatric collectives. The Z-scores of the BHI were significantly reduced in all four cohorts (Student´s t-tests, $p<0.01$), if the bone age was the reference. In the case of using the calendar age, the BHI Z-scores were also significantly lower compared to the normative collective ($p<0.01$), with one exception of female obese patients.
Conclusion: One major benefit of the CAD method is the calculation of parameters of bone health without using any additional radiation exposure. To early identify paediatric patients with osteopenia can induce prevention strategies to reduce the risk of developing osteoporosis, also in later life.

B-0350 15:04

Movie projection systems for paediatric CT examinations: effects on examination time, motion artefacts, and the need for restraints
N. Nagasawa, K. Kitagawa, K. Hashizume, A. Yamazaki, H. Maki, H. Sakuma;
Tsu/JP (nagasawa@clin.medic.mie-u.ac.jp)

Purpose: It is important to reduce the anxiety of children for successful diagnostic and therapeutic procedures. The purpose of this study was to develop and assess the usefulness of a handy movie projection system for CT examinations.
Methods and Materials: We designed a handy movie projection system consisting of a mobile projector (MP-CL1; Sony, Tokyo, Japan) connected with a tablet device (iPad; Apple, Cupertino, USA) that was placed on the patient couch near the child's head. Movies were projected onto the upper wall of the CT gantry aperture with a projection size of 35 x 26 cm at 32 lumens. The system was implemented for head CTs in 54 paediatric patients aged 3-10 years (projection system group, 6.5±2.6 y.o.) and animated movies were projected during the CT examination. Examination time, motion artefact, and the need for restraint were compared with 46 paediatric head CTs scanned without the system (conventional group, 6.6±1.8 y.o., p=ns).
Results: Examination time (from topogram to end of scan) of the projection system group was significantly shorter compared to the conventional group (63.0±37.1 sec vs 92.4±42.4 sec, $p<0.001$). The projection system group had no motion artefacts, while 15.2% (7/46 cases) of the conventional group had motion artefacts ($p<0.001$). The projection system group less frequently required restraint to complete the examination, compared to the conventional group (3.8% (2/52) vs 15.2% (7/46), $p<0.05$).
Conclusion: We developed a handy movie projection system that can shorten examination time, decrease motion artefacts, and reduce the need for restraint in paediatric CT.

B-0351 15:12

Parents wish more information on radiation exposure of their children
H. Oikarinen, H. Mahajan, A. Perttu, L. Ukkola, A.-.L. Jussila, A. Henner;
Oulu/FI (helja.oikarinen@ppshp.fi)

Purpose: To find out parents' experience and wishes for information in connection with their child's examination exposing to radiation.
Methods and Materials: A questionnaire was prepared and provided to parents of paediatric patients up to 12 years in a university hospital. Information received from the referring physician prior to their child's x-ray examination as well as wishes for future communication were enquired. Forty-one parents responded to the survey. Twenty-five children were referred for plain radiography of extremities, the others for dental, body or skull area examinations.
Results: Twenty-one patients had been referred from primary care and 17 from the hospital. Altogether 34/41 parents had received enough information on the purpose of the examination, 3/41 on the dose of radiation and 8/35 on other possible options. In all, 11/41 parents were aware of radiation use, and previous examinations were discussed in 7/41 of the cases. The parents scored the overall communication as 6.5 (mean) on a Likert scale from 4 (poor) to 10 (excellent). Altogether 38 out of 40 parents wish to receive information on the purpose, 35 on the dose and 31 on other possible options. Symbols of radiation and corresponding period of natural background radiation are preferred to reveal the dose. In all, 32 out of 38 parents would like to receive the information from the referring physician, 19 from a radiographer.
Conclusion: Parents wish to receive more information on radiation exposure prior to their child's radiography examination.

B-0344 15:20

Ultrasound of the limping child
D. Grant, E. Quinn, R. Gordon Boyd, C. Lee, K.A. Platt, K. Partington;
Oxford/UK (davidjamesgrant@live.co.uk)

Purpose: Septic arthritis (SA) is an emergency with potential long-term sequelae if diagnosis/treatment is delayed. Kocher determined four predictors which help distinguish between SA and transient synovitis: nonweight-bearing (non-WB), fever, raised white cells (WC), and Erythrocyte Sedimentation Rate (ESR). Singhal showed that C-Reactive Protein (CRP) may also be predictive. Ultrasound with aspiration and microscopy remains the gold standard. Although not irradiating, ultrasound represents a time, resource and opportunity cost. Aspiration may prove upsetting for a child and poses its own risks. This study assesses whether clinical predictors may help determine the need for US.
Methods and Materials: Retrospective analysis of all paediatric lower limb ultrasound performed over 12 months at a Tertiary Hospital. Studies were manually filtered for clinical concern of SA. Data obtained from Electronic Patient Records and Radiology Information Systems.
Results: Of 142 cases, joint effusion was present in 46 (32.4%). 14 aspirations performed. There were 6 cases of SA. Pre-determined risk factors were as follows: 'non-WB' (6/6 in SA, 84/136 in non-SA); fever (SA 5/6, non-SA 54/136, p=0.035*); CRP>20mg/L (SA 5/6, non-SA 35/128, p=0.004*); ESR>40mm/hr (SA 3/5, non-SA 25/112); and WC>12x10^9/L (SA 4/6, non-SA 31/130, p=0.019*). All cases of septic arthritis demonstrated at least 2 risk factors. 68 (50%) of non-SA cases demonstrated fewer than 2 risk factors.
Conclusion: Requiring at least 2 SA clinical risk factors would have obviated the need for 68 ultrasounds, including 3 aspirations, whilst maintaining 100% sensitivity. We propose that this represents a resource-efficient addition to the diagnostic algorithm in a limping child.

Radiomics as a novel tool for primary nodal staging in rectal cancer
J.J.M. van Griethuysen[1,2], D.M. Lambregts[1], S. Trebeschi[1], M. Maas[1], M.J. Lahaye[1], G.L. Beets[1,2], F.C. Bakers[2], R.G.H. Beets-Tan[1,2], H.J. Aerts[3];
[1]*Amsterdam/NL*, [2]*Maastricht/NL*, [3]*Boston, MA/US (j.v.griethuysen@nki.nl)*

Purpose: To assess the potential of quantitative MR-imaging analysis using radiomics for nodal characterization in primary rectal cancer staging.
Methods and Materials: 226 lymph nodes (from 34 rectal cancer patients who underwent MRI followed by surgical resection) were analyzed and matched node by node with histopathology. The short axis was measured for each node (on T2W-MRI) and nodes were manually segmented on T1W and T2W-MRI to extract 748 radiomic features (using PyRadiomics). Using principal feature selection, we selected the 25 features providing the best complementary information to routine nodal size measurements. Performance to distinguish between malignant and benign nodes was assessed with areas under the curve (AUC) per feature using a binomial mixed effects logistic regression model, correcting for patient number. False detection rate correction set at 10% was applied to correct for multiple testing.
Results: 17/226 nodes were malignant. The selected features were compared to (and combined with) nodal size measurements using a bootstrap method with 100 iterations; the model was trained on a random subset of patients and tested on the remaining patients (train:test ratio 80:20). The average performance for nodal size measurements was AUC 0.82. The best performing radiomic feature after FDR correction (GLCM-difference average; a measure of heterogeneity) resulted in an AUC of 0.83; the combination of this feature with nodal size resulted in an AUC of 0.85.
Conclusion: Radiomics may provide valuable quantitative information to characterize rectal cancer lymph nodes, particularly features reflecting nodal heterogeneity are promising. Although radiomics slightly improves staging performance, the added benefit compared to routine size-based staging appears to be limited.

B-0353 14:17

CT radiomics signarure for preoperative esophageal cancer patients lymph node metastasis prediction

J. Qu[1], C. Shen[2]; [1]*Zhengzhou/CN*, [2]*Xi'an/CN (qjryq@126.com)*

Purpose: To build and validate a radiomics signature for the prediction of pre-operation lymph node (LN) metastasis in esophageal cancer (EC).
Methods and Materials: A total of 189 EC patients were enrolled in this study, and their LN metastases have been pathologically confirmed. The data was collected from January 2016 to April 2016, patients in the first three months were set in the training cohort, and patients in April 2016 were set in the validation cohort. 789 radiomics features were extracted from CT images of patients. The lasso approach was exploited for dimension reduction and selection of the feature space. The multivariable logistic regression analysis was adopted to build the radimics signature. The area under receiver operating characteristic curve (AUC) were adopted to estimate the signatures' discrimination power.
Results: Thirteen radiomics features were selected to build the radiomics signature. The radiomics signature was significantly associated with the LN metastasis (P<0.001). The area under the curve (AUC) of radiomics signature performance in the training cohort is 0.763 (95% CI: 0.680-0.847), and in the validation cohort is 0.738 (95% CI: 0.677-0.793). The model showed good discrimination, with a C-index of 0.754 (95% CI: 0.686 to 0.822) in training cohort and 0.741 (95% CI: 0.663 to 0.819) in the validation cohort. Decision curve analysis showed the threshold probability is larger than 0.15, our model will receive benefit.
Conclusion: The present study proposed a radiomics signature, which can be potentially applied in the individual preoperative prediction of LN metastasis status in EC patients.

B-0354 14:25

CT texture features of adrenal tumours: the answer to indeterminate adrenal lesions?

J. Gariani, M.M. Siddique, G. Cook, V.J. Goh; *London/UK (Joanna.Gariani@hcuge.ch)*

Purpose: To identify the potential discriminating global and locoregional CT texture features of adrenal tumours.
Methods and Materials: Following an institutional review board waiver, portal-phase enhanced CT scans (120kV, variable mAs, soft tissue reconstruction, matrix 512, FOV 350mm, 2/5mm slice thickness) of 58 consecutive incidentally discovered adrenal lesions (>2.0cm, 21 benign adenomas and 37 malignant tumours) in 48 patients (28 male-20 female, mean age 66.35 years) were assessed with the final diagnosis based on imaging follow-up (>6months) or adrenal CT/MRI. Manual segmentation of each lesion was performed, using an in-house software, by a radiologist (>8 years experience) who was blinded to the final diagnosis, and 92 features encompassing histogram, fractal, second and high-order features were recorded.
Results: Significant differences were found for 46 features including histogram mean, median and skewness (p=0.004, p=0.029 and p=0.013); fractal dimension standard deviation and Hurst exponent (p=0.014, p=<0.001); GLCM (grey-level co-occurrence matrices) autocorrelation and cluster shade (p=0.003, p=0.003); and NGTDM (neighbourhood grey tone difference matrices) coarseness, contrast, busyness and complexity (p<0.001, p=0.001, p<0.001, p=0.03). There was a significant difference in volume between malignant and benign lesions (48.5cm^3 vs 13.3cm^3, p=<0.001).
Conclusion: CT texture differs between benign and malignant adrenal lesions. Texture analysis may be a useful adjunct for the characterisation of indeterminate adrenal lesions.

B-0355 14:33

Machine learning and radiomics analysis of multi-parametric PET/MRI: characterisation of primary cervical cancers

J. Grueneisen, F. Nensa, A. Demircioglu, M. Forsting, K. Herrmann, L. Umutlu; *Essen/DE (johannes.grueneisen@uk-essen.de)*

Purpose: To investigate the prediction potential of PET/MR-derived parameters of patients with cervical cancer assessed with radiomics and machine-learning algorithms.
Methods and Materials: A total of 30 patients with previously untreated cervical cancers underwent a simultaneous 18F-FDG PET/MR examination. The study protocol comprised the acquisition of morphological (T1w-, T2w-images), functional (DWI, DCE-MRI) and metabolic (18F-FDG PET) parameters. After tumour segmentation, quantitative imaging features (n=631) were extracted using the Radiomic Image Processing Toolbox. Statistical analysis and modeling were performed using Python 3.5 and the scikit-learn software machine learning library for the Python programming language.
Results: Correlation analysis of the full set of 631 image features revealed strong correlations between image features, representing redundant information. Therefore, feature selection methods were applied to identify the 20 highest ranking features, which were used for further analysis. For the determination of N-stage, receiver operating characteristic (ROC) analysis revealed an area under the curve (AUC) of 0.85 with a sensitivity and specificity of 79% and 75%. Furthermore, statistical analysis revealed a higher performance for the determination of the M-stage with a 94% sensitivity and 90% specificity and an AUC of 0.97.
Conclusion: The present data show strong correlations between certain PET and MRI-derived quantitative features and major prognostic factors of cervical cancers assessed with radiomics and machine learning algorithms. Therefore, radiomics analysis based on multiparametric PET/MR data offers a large number of non-invasive biomarkers, potentially facilitating a new platform for improved cancer detection, prediction of prognosis and determination of treatment response.

B-0356 14:41

Radiomics as a predictive biomarker of metastatic response to immunotherapy

S. Trebeschi[1], S.G. Drago[2,1], I. Kurilova[1], F. Lalezari[1], D.M. Lambregts[1], E. Smit[1], C.U. Blank[1], H.J. Aerts[3,1], R.G.H. Beets-Tan[1]; [1]*Amsterdam/NL*, [2]*Monza/IT*, [3]*Boston, MA/US (s.trebeschi@nki.nl)*

Purpose: Immunotherapy represents a major breakthrough in cancer treatment. Various predictive biomarkers are currently under investigation, but none with conclusive results yet. With this study, we aim to evaluate the performance of radiomics imaging biomarkers to predict response to immunotherapy (PD-1 blockade) in specific to discriminate non-responders.
Methods and Materials: We retrospectively retrieved baseline and follow-up CE-CTs of 213 metastasized patients (131 NSCLC, 82 melanoma) undergoing immunotherapy at our institution. Patients were divided in a discovery (n=143) and independent validation set (n=70). Target lesions (1-43 lesions/patient, median 3, 1055 total) were delineated on baseline and first follow-up. Radiomics features were extracted from each lesion. Evolution in lesion diameter on FU-CT was the main response outcome (non-response>20% increase). A random forest with wrapper feature selection was trained on the discovery set and optimized via sequential model-based optimization.
Results: The radiomic classifier revealed coarse texture features (GLCM), compactness, elongation and sphericity to be the best predictive features. When tested in the independent validation set, AUCs up to 0.83 were reached to predict non-response in the NSCLC group, with results better compared to predicting response based on routine pre-treatment lesion volume measurements (AUCs<64). In the melanoma group, results were considerably poorer with similar results for radiomics features (AUCs<0.65) and lesion volume (AUC<0.65).
Conclusion: (1) Radiomics analysis of routine clinical CE-CT-imaging could provide viable biomarkers to predict non-response to immunotherapies in melanoma and NSCLC before treatment; (2) the differences in performance between melanoma and NSCLC suggest that both immune-generic and cancer-specific models are required.

B-0357 14:49

CT-derived texture analysis in predicting tumoral response to immunotherapy in patients with lung cancer and correlation with iRECIST

F. Rivosecchi, D. Caruso, D. De Santis, D.M. Bellini, N. Panvini, M. Rengo, A. Laghi; *Latina/IT (flaminiarivosecchi@gmail.com)*

Purpose: To investigate whether CT-derived texture features (TFs) correlate with tumoral response in patients with lung cancer (LC) undergoing immunotherapy.
Methods and Materials: Twelve patients with lung adenocarcinoma who underwent contrast-enhanced CT before and after immunotherapy with Nivolumab were retrospectively analysed. Tumoral first-order TFs (mean, attenuation, standard deviation, mean value of positive pixels [MPP], entropy, skewness, and kurtosis) were assessed with TexRAD software using 5 scale filter (SF) as 0, 1, 1.5, 1.8, and 2. Response assessment was obtained by using Response Evaluation Criteria in Solid Tumours in Immunotherapeutic Trials (iRECIST) using appropriate software (mint lesionTM). Paired *t*-student test was performed to compare the texture results and Pearson correlation with iRecist was performed as well.
Results: Seven patients showed progressive disease (PD) and 5 patients showed stable disease (SD) with iRECIST. Kurtosis was significantly higher for all the SFs in patients with PD compared to SD (P=0.007). Mean attenuation at SF0 was higher in PD compared to SD (12.1 ± 12.2 and -67.7 ± 60.0, P<0.001). Standard deviation at SF1 and SF1.5 in PD (139.2 ± 1.9 and 192.8 ± 2.5) was lower than SD (387.8 ± 180.7 and 501.8 ± 214.1). MPP at SF1.5 in PD was lower than SD (121.5 ± 3.9 vs 457.1 ± 260.2) (all P <0.05). No significant differences were found among the other TFs. A positive correlation was observed between kurtosis and PD using iRecist (r=0.56, P<0.05).
Conclusion: CT-derived TFs could serve as imaging biomarkers of tumoral response to immunotherapy in patients with LC.

B-0358 14:57

Evaluating response to chemotherapy in colorectal liver metastases: correlation between CT texture analysis and RECIST criteria

N. Panvini, D. Caruso, D. De Santis, D.M. Bellini, F. Rivosecchi, M. Rengo, A. Laghi; *Latina/IT (npanvini88@gmail.com)*

Purpose: To evaluate potential role of CT texture analysis (TA) based quantitative imaging biomarkers in predicting response of colorectal liver metastases (CRLM) to chemotherapy in comparison to response evaluation criteria in solid tumours 1.1 (RECIST 1.1).
Methods and Materials: This preliminary study evaluated eleven patients who underwent MDCT before and after chemotherapy (FOLFIRI or FOLFOX). According to RECIST 1.1 criteria computer-aided response assessment of target lesions was performed as reference standard using appropriate software (mint lesion™). For each measured target lesion the software automatically derived statistical texture parameters (mean value of positive pixel (MPP), uniformity of distribution of positive pixel (UPP), skewness, kurtosis, uniformity and entropy). TA parameters were compared between patients with partial response (PR) and progressive disease (PD). Correlation analysis between % change in TA parameters and in sum of diameters (SOD) of target lesions was performed.
Results: Four patients were classified as PR based on RECIST 1.1 while seven patients showed PD at follow-up. Mean follow-up time was 63.4 ± 6.6 days. Kurtosis and skewness significantly increased in patients who showed PD and were reduced in those who responded to treatment ($p<0.05$). No correlation was observed between response to therapy and MPP, UPP, uniformity and entropy.
Conclusion: Kurtosis and skewness significantly correlated with variation of target lesions' largest diameters. These TA parameters may play a relevant role in predicting response to therapy of CRLM.

B-0359 15:05

Histogram analysis of T1-weighted, T2-weighted, and postcontrast T1-weighted images in primary CNS lymphoma: correlations with histopathological findings

H.-J. Meyer, S. Schob, B. Münch, C. Frydrychowicz, U. Quäschling, K.-T. Hoffmann, A. Surov; *Leipzig/DE (jonas90.meyer@web.de)*

Purpose: Previously, some reports mentioned that magnetic resonance imaging (MRI) can predict histopathological features in primary CNS lymphoma (PCNSL). The reported data analysed diffusion-weighted imaging findings. The aim of this study was to investigate possible associations between histopathological findings, such as tumour cellularity, nucleic areas and proliferation index Ki-67, and signal intensity on T1-weighted and T2-weighted images in PCNSL.
Methods and Materials: For this study, 18 patients with PCNSL were retrospectively investigated by histogram analysis on precontrast and postcontrast T1-weighted and fluid-attenuated inversion recovery (FLAIR) images. For every patient, histopathology parameters, nucleic count, total nucleic area, and average nucleic area, as well as Ki-67 index, were estimated.
Results: Correlation analysis identified several statistically significant associations. Skewness derived from precontrast T1-weighted images correlated with Ki-67 index (p=- 0.55, P=0.028). Furthermore, entropy derived from precontrast T1-weighted images correlated with average nucleic area (p=0.53, P=0.04). Several parameters from postcontrast T1-weighted images correlated with nucleic count: maximum signal intensity (p=0.59, P=0.017), P75 (p=0.56, P=0.02), and P90 (p=0.52, P=0.04) as well as SD (p=0.58, P=0.02). Maximum signal intensity derived from FLAIR sequence correlated with nucleic count (p=0.50, P=0.03).
Conclusion: Histogram-derived parameters of conventional MRI sequences can reflect different histopathological features in PSNCL.

B-0360 15:13

Added value of radiomics signature to predict pulmonary metastasis in colo-rectal cancer patients with lung nodules

T. Hu, T. Tong, S. Wang; *Shanghai/CN (h16211230001@163.com)*

Purpose: To evaluate the added value of radiomics signature in the development and validation of nomograms to predict pulmonary metastases in colorectal cancer (CRC) patients with lung nodules.
Methods and Materials: A total of 266 CRC patients with pulmonary nodules were identified between January 2010 and October 2016 to analyze the clinical characteristics and texture parameters from chest CT images. Clinical features identified by the logistic regression analysis were used to construct a clinical nomogram, radiomics signature built by a LASSO regression model were added to the selected clinical features to develop the clinical-radiomics nomogram. The nomograms performance was assessed through discrimination and calibration. Decision curve analyses were applied to compare the clinical usefulness.
Results: The logistic regression analysis identified the primary tumor site, chronicity, and carcinoembryonic antigen as independent predictors. The LASSO model built the radiomics signature with four predictive texture parameters. The clinical nomogram was developed with good discrimination (c-index of 0.808 in the primary set and 0.776 in the validation set) and poor calibration. The clinical-radiomics nomogram showed an incremental prognostic value with superior discrimination (c-index of 0.944 in the primary set and 0.922 in the validation set) and calibration. The decision curve analyses demonstrated that the clinical-radiomics nomogram showed clinical usefulness.
Conclusion: In CRC patients with pulmonary nodules, the clinical-radiomics nomogram which was created by the clinical features and radiomics signature had exhibited superior discriminatory ability and accuracy for a metastases prediction. The clinical-radiomics nomogram is a reliable clinical treatment tool to predict pulmonary metastases.

B-0361 15:21

Personalised radigenomic medicine: prostate cancer gene 3 and PI-RADSv2 team up to predict clinically significant prostate cancer

M. Nguyentat[1], V. Bura[2], A. Ushinsky[1], S. Fardin[1], C. Green[1], E. Uchio[1], T.K. Lee[1], C. Lall[1], R. Houshyar[1]; [1]*Orange, CA/US*, [2]*Cluj-Napoca/RO (vlad.t.bura@gmail.com)*

Purpose: Multiparametric-MRI (mpMRI) utilizing PI-RADSv2 has been shown to detect prostate cancer (PCa) with high diagnostic accuracy. Genomic data, such as prostate cancer Gene 3 (PCA3) is known to be overexpressed in PCa. However, studies combining the two are lacking. We propose a radiogenomic model combining prostate imaging and PCA3 data for detecting clinically significant PCa (csPCa).
Methods and Materials: We retrospectively reviewed patient charts of those who underwent urinary PCA3 testing, mpMRI, and MRI/TRUS fusion-biopsy from 09/2014-12/2016. PI-RADSv2 was utilized for mpMRI. csPCa was defined as Gleason Score ≥ 7. PCA3 data were recorded as both qualitative (positive/negative) and quantitative (absolute number) results. Logistic regression and ROC analysis were performed to assess correlation and diagnostic accuracy of our radiogenomic model for detecting csPCa.
Results: A binomial logistic regression of 62 men with 96 prostate lesions was performed to ascertain the effects of PCA3 and PI-RADSv2 scores on the likelihood that subjects have csPCa. The logistic regression model was statistically significant, $\chi^2(3) = 33.029$, $p < .0005$. Sensitivity of our model was 53.3%, specificity was 95.1%, positive predictive value (PPV) was 66.7% and negative predictive value (NPV) was 91.7%. The AUC of quantitative-PCA3 was 0.720 (95% CI 0.585-0.855, p = 0.009), while for PI-RADSv2 was 0.818 (95% CI 0.705-0.931, $p < 0.001$). Combining the two into one multivariate model produced an AUC of 0.920 (95% CI 0.860-0.979, $p < 0.001$).
Conclusion: Combining PI-RADSv2 and quantitative-PCA3 into one radiogenomic model achieves an excellent specificity, NPV, and a larger AUC for detecting csPCa.

Whole-body diffusion-weighted MRI in Hodgkin Lymphoma: 3D texture analysis for early treatment response assessment

K.N. De Paepe[1], I.F. Vieira[2], F. De Keyzer[2], P. Wolter[3], O. Bechter[2], D. Dierickx[2], R. Oyen[2], G. Verhoef[2], V. Vandecaveye[2]; [1]*London/UK*, [2]*Leuven/BE*, [3]*Verviers/BE (katjadepaepe@gmail.com)*

Purpose: To evaluate feasibility and predictive utility of early treatment response assessment n Hodgkin lymphoma (HL) using 3D texture analysis of whole-body diffusion-weighted MRI (WB-DWI/MRI).
Methods and Materials: Twenty-six patients with HL underwent 3-T whole body (WB) DWI/MRI before and 4 weeks after start of chemotherapy (1 treatment cycle). Responses after 1 treatment cycle, were assessed by the apparent diffusion coefficient change relative to baseline (ΔADC_{avg}), change of first-order-statistics (FOS) ADC histogram features (ΔADC_{hist}) and change of second-order-statistics (SOS) textures (ΔADC_{text}), generated by grey-level co-occurrence matrices. The discriminative capability of ΔADC_{avg}, ΔADC_{hist} and ΔADC_{text} to identify refractory/recurrent lesions versus responding lesions was determined using Mann-Whitney U tests, supplemented by Monte Carlo (MC) permutation tests for statistical robustness. Correlation of the response

variables with progression-free survival (PFS) was assessed with Kaplan-Meier and log rank tests.
Results: At a median follow-up time of 43 months (range 3-79 m), 21/26 patients had complete remission and 5 patients persistent/ recurrent disease (8 non-responding and 47 responding lesions). The ΔADC_{avg} (p=0.84) and ΔADC_{hist} (p>0.05) didn't correlate significantly with lesion response. The ΔADC_{text} showed significant differences for energy (ΔADC_E; p=0.001), local homogeneity (ΔADC_{LH}; p=0.002), and entropy (ΔADC_H; p=0.001), which also correlated significantly with PFS (ΔADC_{LH},p=0.031; ΔADC_E,p=0.013; ΔADC_H,p=0.002).
Conclusion: Early response assessment after 1 cycle of chemotherapy by WB-DWI/MRI texture analysis (ΔADC_{text}) correlates significantly with PFS, showing substantially stronger association with tumor response than ΔADC_{avg} or ΔADC_{hist}.

B-0363 14:04

Dynamic glucose-enhanced MRI: clinical perspectives and challenges
D. Paech[1], P. Schuenke[1], C. Köhler[1], P. Bachert[1], M. Ladd[1], M. Bendszus[1], H.-P. Schlemmer[1], M. Zaiss[2], A. Radbruch[1]; [1]*Heidelberg/DE*, [2]*Tübingen/DE (d.paech@dkfz.de)*

Purpose: To investigate dynamic glucose-enhanced (DGE) magnetic resonance imaging (MRI) at 7 Tesla (7T) in the healthy human brain and newly diagnosed untreated glioblastoma patients.
Methods and Materials: Eleven newly diagnosed glioblastoma patients and eight healthy volunteers were included in this prospective ethic approved study. DGE MRI was performed at a 7T whole-body scanner (Siemens,Healthcare,Erlangen,Germany) using an in-house developed adiabatically-prepared chemical exchange sensitive spin-lock (CESL) sequence (temporal resolution = 7 sec). 100ml of 20% D-glucose were injected intravenously during DGE MRI. Gadolinium contrast-enhanced T1-w images were obtained along the clinical standard MRI protocol at 3T. Mean signal intensities of (1)the tumor regions vs. normal appearing white matter, and (2)gray matter vs. white matter, were compared by using the *Student's t-test.*
Results: No adverse effects were observed in patients and volunteers related to glucose injections. The DGE contrast allowed for the identification of pathophysiologically increased glucose uptake in the tumor area in all patients. The mean signal intensity of the glucose enhancing tumor region over all patients (DGEρ=3.57±1.79%) was significantly higher than in contralateral normal appearing white matter (DGEρ=0.22±0.80%) (p<0.01). Futher, DGE MRI revealed an increased glucose uptake in gray matter regions compared to white matter of the normal human brain (p<0.001).
Conclusion: DGE MRI may provide complementary information about the metabolic heterogeneity of tumors, with implications for biopsy targeting, patient therapy and response monitoring. Furthermore, glucose enhanced MRI could open up the field of metabolic imaging without the limitations set by ionizing radiation and high expenses associated with radioisotopes.

Compressed sensing accelerated 3D magnetic resonance cholangiopancreatography: application in pancreatic diseases
L. Zhu, Z.-y. Sun, H.-d. Xue, T.-y. Qian, Z.-y. Jin; *Beijing/CN (zhuliang_pumc@163.com)*

Purpose: To prospectively evaluate image quality, duct visibility and diagnostic performance in duct-related pathologies of compressed-sensing (CS) accelerated 3D MRCP, and compare to conventional 3D MRCP in patients with suspected pancreatic diseases.
Methods and Materials: Eighty patients (47 men and 33 women, median age, 57 years, range, 24-87 years) underwent 3D MRCP at 3.0T. Three protocols were performed in each patient: CS breath-hold (BH) protocol, CS navigator-triggered (NT) protocol, and conventional NT protocol. Acquisition time of each protocol was recorded. Image quality and duct visibility were independently rated in random order on a 5-point scale by two radiologists, who were blinded to the protocols. Receiver operating characteristic curves were generated, and area under the curve (A_z value) was used to compare the diagnostic performance of each protocol in duct-related pathologies.
Results: Acquisition time was 17 seconds for CS-BH protocol and 134.1±33.5 seconds for CS-NT protocol, both being significantly shorter than the conventional NT protocol (364.7±78.4 seconds, both p<0.01). CS-BH protocol showed significantly less artefacts compared to both NT protocols (both p<0.01). Visualization of bile ducts was comparable with all three protocols, whereas CS-NT and conventional NT protocol depicted pancreatic duct better than CS-BH protocol (for proximal, middle and distal segment, all p<0.05). CS-NT MRCP had highest diagnostic performance for detecting ductal anomalies, long-segment duct stenosis, abnormal branch ducts, and communication between cystic lesion and pancreatic duct (mean A_z value 0.943-0.983).
Conclusion: CS-MRCP is feasible in patients with suspected pancreatic diseases. CS-NT MRCP demonstrated superior diagnostic accuracy for duct-related pathologies.

B-0365 14:12

Multiparametric MRI to predict response to external beam radiotherapy in locally advanced cervical cancer: comparison of MRI volumetry, diffusion-weighted MRI and MR texture analysis
L.A. Min[1,2], L.L.G.C. Ackermans[1], M.E. Nowee[1], J.J. van Griethuysen[1,2], S. Trebeschi[1], W. Vogel[1,1], M. Maas[1], R.G.H. Beets-Tan[1,2], D.M. Lambregts[1]; [1]*Amsterdam/NL*, [2]*Maastricht/NL (lisaannamin@gmail.com)*

Purpose: Locally advanced cervical cancer (LACC) patients who respond very well to external beam radiotherapy (EBRT), i.e. with near-complete tumour regression, might be candidates for early start of subsequent brachytherapy and dose de-escalation in the future. Goal was to investigate if we can predict upfront which patients will achieve a near-complete response using multiparametric MRI.
Methods and Materials: N=41 LACC patients were retrospectively included. Two readers in consensus analysed the pre-treatment MRIs (3.0T) and delineated whole-tumour volumes on T2-weighted and high b-value diffusion-weighted imaging (DWI). The following parameters were calculated: T2W-volume, DWI-volume, apparent diffusion coefficient (ADC), and texture parameters mean, SD, entropy and uniformity (LoG-filter 1.5). Areas under the ROC curve (AUC) to predict a near-complete response (tumour volume reduction >90% on T2W-MRI after EBRT) were calculated.
Results: AUC to predict a near-complete response was 0.58 for T2W-volume and 0.54 for DWI-volume. ADC rendered an AUC of 0.66. Texture measurements resulted in AUCs of 0.53 (mean), 0.69 (SD), 0.65 (entropy) and 0.63 (uniformity). The improvement in AUCs for the ADC and texture measures compared to T2W-volumetry were not statistically significant. Combining volume with ADC and/or texture parameters did not improve performance.
Conclusion: Pre-treatment tumour volumetry (T2W- or DWI-based) is not useful to predict a near-complete response. Quantitative diffusion and texture parameters may help to improve predictive performance, although results were not statistically significant and remained suboptimal in this small cohort. For future research it would be worthwhile to see if combining quantitative MRI with FDG-PET/CT can further improve results.

B-0366 14:16

Is there rationale for the routine inclusion of chest CT in gastric cancer staging? Evidence from a single-institution cancer registry
A.-H. Chen[1], C.-M. Chen[2]; [1]*Taoyuan/TW*, [2]*Taipei/TW (angel08141@gmail.com)*

Purpose: ESMO 2016 and AJCC 8th edition guidelines recommend routine inclusion of chest CT in gastric cancer staging. We assessed the necessity and clinical value for such routine inclusion.
Methods and Materials: This is a retrospective review of Chang Gung Memorial Hospital, Linkou, Taiwan gastric cancer registry (between 2008 and 2014). We evaluated the inclusion of chest CT at initial staging, patterns of metastases at initial presentation and at recurrence following surgery. Overall survival was calculated from Kaplan-Meier estimates.
Results: A total of 1675 cases were reviewed. Between the review period, there was a doubling trend in the inclusion of chest CT (18.0% - 32.0%); however, the incidence of pulmonary metastases (0.8% - 2.6%) is rare. 478 patients (28.5%) had metastatic disease at presentation. The most common metastases was intra-abdominal (90.0%). 27 (3.2%) and 20 (2.4%) patients had pulmonary and cytologic-proven pleural metastases, respectively. Of all pulmonary metastases, 11 patients (40.7%) had primary lesions located at cardia/fundus. There was no solitary metastasis to lung or pleura and all the lesions could be identified in lower lung fields. Of the 203 patients (16.2%) recurrence, 15 (4.4%) pulmonary and 7 (2.1%) pleural metastases were found. There was no isolated pulmonary metastasis. No demonstrated significant difference in the median overall survival with or without lung metastases at initial presentation (p=0.78) and at recurrence (p=0.85).
Conclusion: Our findings do not support routine inclusion of chest CT in gastric cancer staging because of the rarity of pulmonary metastasis, absence of solitary metastasis and lack of survival difference.

MR texture analysis: potential imaging biomarker for prediction of chemotherapy response in patients with colorectal liver metastases
H. Zhang, T.T. Tong; *Shanghai/CN (17081376182@163.com)*

Purpose: The purpose of the study was to determine if pre-treated MR texture features of colorectal liver metastases (CRLMs) are predictive of chemotherapy response after the first-line chemotherapy.
Methods and Materials: The study included 26 consecutive patients (a total of 193 liver metastasis) with unresectable CRLMs at our institution from August 2014 to February 2016. All patients underwent baseline MRI within 3 weeks before chemotherapy. Lesions were classified as either responding group or non-responding group according to changes in size. Texture analysis was quantified on T2-weighted images by two radiologists with an agreement on

regions of interest which were manually drawn on the largest cross-sectional area of the lesions. Five histogram features (mean, variance, skewness, kurtosis, entropy1) and five grey level co-occurrence matrix features (GLCM; angular second moment (ASM), entropy2, contrast, correlation, inverse difference moment (IDM)) were extracted. The texture parameters were analysed statistically to find the differences between the two groups and receiver operating characteristic curves were depicted to characterize each parameter value for evaluating treatment outcome.
Results: 107 responding and 86 non-responding lesions were evaluated. Higher variance, entropy1, contrast, entropy2 and lower ASM, correlation and IDM were independently (P<0.05) associated with good response to chemotherapy with area under the ROC curve (AUCs) of 0.602-0.784. However, mean (P=0.186), skewness (P=0.311) and kurtosis (P=0.763) did not show a significant difference.
Conclusion: MR texture features on pre-treated T2 images seem to be a promising tool for predicting the chemotherapy response of patients with colorectal liver metastases.

B-0368 14:24

Patterns of responses in metastatic NSCLC during immunotherapy: comparison of RECIST 1.1, irRECIST and iRECIST criteria
M. Tazdait, F. Bidault, S. Ammari, C.S. Balleyguier, D. Planchard, J.-C. Soria, A. Marabelle, B. Besse, C. Caramella; *Villejuif/FR (melodie.tazdait@orange.fr)*

Purpose: Immune checkpoint inhibitors are an important tool in the therapeutic strategy against metastatic non-small cell lung cancer (NSCLC), however radiological evaluation is challenging due to the emergence of atypical patterns of responses. Several evaluation criteria have been proposed, RECIST 1.1, irRECIST and iRECIST, but have not been systematically compared in a homogeneous population.
Methods and Materials: We conducted a monocentric retrospective analysis of consecutive advanced NSCLC patients treated with an anti-PD1 or anti-PD-L1. Response patterns and the discordance between RECIST1.1, irRECIST and iRECIST guidelines were described, and associations of response patterns and clinical outcome were explored.
Results: Overall 160 patients treated between February 2013 and October 2016 were included. Atypical responses were observed in 20 patients (13%), including 8 pseudoprogressions (5%) and 12 dissociated responses (8%). Thirteen of the 20 patients demonstrated clinical benefit. Per RECIST 1.1, 37 patients (23%) showed an objective response or stable disease and 123 patients (77%) exhibited progression. Eighty progressive patients were assessable for irRECIST and iRECIST: 15 patients were assessed differently however only three (3.8%) mismatches with a theoretical impact on the therapeutic decision were identified. Patients with pseudoprogression or dissociated response had higher overall survival than patients with true progression.
Conclusion: Atypical responses (pseudoprogression/dissociated response) occurred in 13% of NSCLC patients under immune checkpoint inhibitors. Based on survival analyses, RECIST 1.1 evaluation underestimated the benefit of immune checkpoint inhibitors in 11% of progressive patients. irRECIST and iRECIST identified these unconventional responses, with a 3.8% discrepancy rate.

B-0369 14:28

Diagnostic value of automated breast volume sonography (ABVS) in breast cancer detection in women with different ACR types
M. Efremova, V.E. Gazhonova; *Moscow/RU (frem13@mail.ru)*

Purpose: To evaluate ABVS diagnostic performance in comparison with hand-held ultrasound (HH-US) and X-ray mammography MMG for breast cancer detecting depending on ACR breast type.
Methods and Materials: 171 women with 251 morphologically verified lesions were examined. For each woman ABVS, HH-US, MMG were performed. Two independent examiners evaluated the ABVS data separately on different workstations without any prior knowledge of patients' history. Bi-RADS classification for ABVS examination was used.
Results: In patients with ACR III, ACR IV the sensitivity (SE) of ABVS was significantly higher among all the methods and amounted to 96.5%, specificity (SP) was 84.1%, the area under the curve (AUC) had the highest value of 0.9 which indicated an excellent quality of the method. For ACR III, ACR IV breast type patients MMG had significantly greater SE 92% and SP 84,6% versus ABVS diagnostic performance (SE-76%, SP-40%, AUC-0,58). Cohen's kappa for inter-rater agreement for BI-RADS evaluation for ABVS in total was $\kappa = 0.62 \pm 0.05$ - good. For malignant tumours $\kappa = 0.82 \pm 0.07$ - very good, for benign $\kappa = 0.39 \pm 0.05$ - satisfactory. Thus, the possibility of missing malignant tumour by ABVS is extremely low but the chance of getting false-positive result is high.
Conclusion: ABVS can be recommended as a reliable imaging method for breast cancer detecting in patients with dense breasts (ACR III, ACR IV). Second look follow-ups may be required in cases of benign findings.

B-0370 14:32

Prognostic significance of different MRI modalities for evaluation of neoadjuvant chemoradiation treatment of locally advanced rectal cancer
O. Ganych; *Kyiv/UA (ganich1@gmail.com)*

Purpose: In a current study we assess the prognostic significance of a widely used tumor regression grade (mrTRG) and the approach that uses grey-scale evaluation of T2 WI aided by the software developed by us (EmrTRG).
Methods and Materials: During the years 2016-2017, 74 patients with primary diagnosed locally advanced rectal cancer (LARC) (mrT3mrf+-4N1-2M0) had been enrolled. All patients completed a course of neoadjuvant chemoradiation therapy (NCRT) with a total dose of 50,4 Gy with capecitabin and underwent curative surgery. 8-10 weeks after completion of the NCRT course an MRI examination with mrTRG and EmrTRG for evaluation of NCRT response was performed. MRI data had been compared with pathological TRG (pTRG), calculated by Dworak grading system.
Results: We observed no cases of tumor progression. Pathologic complete response (pTRG-5) was observed in 6 (7%) of patients, pTRG-4 - 10 (13%), pTRG-3 - 20 (26%), pTRG-2 - 24 (37%), pTRG-1 - 10 (13%), pTRG0 - 4 (4%). There were 12 (16%) patients with complete radiologic response according to mrTRG and 8 (11%) according to EmrTRG, 20 (27%) and 12 (16%) (p<0.05) with mrTRG and EmrTRG grade 4 , 12 (15%) and 18 (24%) (p<0.05) with grade 3, 10 (13%) and 22 (31%) (p<0.05) - grade 2, 14 (22%) and 10 (14%) - grade 1, 6 (7%) and 4 (4%) - grade 0 respectively.
Conclusion: EmrTRG demonstrated superior accuracy in detecting pTRG-2-4 grade of response to NCRT comparing to mrTRG. Both mrTRG and EmrTRG showed insignificant accuracy level in detecting pathological complete response.

B-0371 14:36

Prediction of response to transarterial radioembolisation by means of MRI-based texture analysis as a potential radiomics tool
R. Reimer[1], P. Reimer[2], A. Mahnken[1]; [1]*Marburg/DE*, [2]*Karlsruhe/DE (robertpeterreimer@gmail.com)*

Purpose: To evaluate whether assessment of tumor heterogeneity by means of MRI based texture analysis in patients with liver metastases may predict progress to transarterial radioembolization (TARE) earlier than by morphologic criteria.
Methods and Materials: 37 patients with liver metastases treated by TARE underwent dynamic contrast enhanced and hepatocellular phase MRI with gadoxetic acid after TARE (mean 2.2 days). Response was evaluated on follow-up imaging scheduled in intervals of 3 months (median follow-up, 221 days) based on Response Evaluation Criteria in Solid Tumors 1.1 (RECIST 1.1). Results of texture analysis (mean (m), standard deviation (sd), skewness (s), kurtosis (k), entropy (e), uniformity (u)) of the ROI were compared between patients with and without progressive disease. Receiver operating characteristics including the area under the curve (AUC) were calculated.
Results: According to RECIST 1.1, 24 patients (64.9%) had progressive disease and 13 (35.1%) stable disease or partial response. Median k (2.88vs.2.33) in arterial phase MRI and median s (0.48 vs.0.3) and median k (2.85vs.2.45) (p<0.05) in venous phase MRI derived from texture analysis showed earlier significant differentiation (p<0.05) than RECIST 1.1 between patients with and without progressive disease. The AUC for k in arterial phase was 0.77 (p<0.05) and for s and k in venous phase 0.71 (p>0.05) and 0.72 (p<0.05).
Conclusion: Texture analysis indicating tumor heterogeneity of liver metastases after TARE has the potential to predict progressive disease earlier than by morphologic criteria. Earlier prediction of response to TARE may optimize individual therapy in clinical medical and interventional oncology.

B-0373 14:40

Comparison of whole-body MRI (wbMRI) and bone scintigraphy in oncologic follow-up
A. Malich[1], I. Papageorgiou[1], D. Kovacevic[1], A. Kott[1], D. Wiech[1], U.K. Teichgräber[2]; [1]*Nordhausen/DE*, [2]*Jena/DE (ansgar.malich@shk-ndh.de)*

Purpose: Scintigraphy is still first line method in the detection of osseous metastases. Whole body MRI, however, is increasingly more available at various MR-scanners and thus could fill the gap of reduced availability of nuclear medicine departements. Only few data compare both technologies.
Methods and Materials: 1633 whole body MRI were retrospectively evaluated using a double blinded setting. An unsusipicious MRI was scored true in case of continued unsuspicious follow up, true positive results were accepted in case of histopathology, or initiazation of treatment due to proven metastases with related clinical signs. All cases were evaluated regarding the existence and report of scintigraphic analyses within 1 year after MRI.
Results: 285/1633 wbMRI-cases had a bone scintigraphy; 264/285 had a verification of the imaging modalities. In 208/264 cases scintigraphy and wb-MRI revealed same results (86tp, 122tn). In total WbMRI vs scintigraphy had

the following results: tp: n=102/n=88; tn: n=136/n=146; Fp: n=25/n=14; fn: n=1/n=16. Sensitivity, specificity, PPV, NPV, accuracy are (wbMRI/scinti): 99.0%/84.6%; 84.5%/91.3%; 80.3%/86.3%; 99.3%/ 90.1%; 91.8%/88.0%. Other then bone metastases were found in 18.3%, other incidentally detected tumor like structures were reported in 11.3%. Additional findings in scintigraphy were reported in 1.5%.
Conclusion: Whole body MRI is valuable in oncologic follow up and can replace bone scintigraphy in case of availability. Significant number of additional metastatic findings and incidental tumor like lesions could be found by wbMRI compared to scintigraphic analysis.

B-0374 14:44

Does second reader opinion affect pancreatic adenocarcinoma management?

G. Corrias[1], S. Huicochea Castellanos[1], V. Balachandran[1], L. Saba[2], L. Mannelli[1]; [1]*New York, NY/US*, [2]*Monserrato/IT (corriasgmd@gmail.com)*

Purpose: Patients with pancreatic cancer frequently present to tertiary referral centers with imaging studies that have been performed and interpreted elsewhere. At our institution, these outside studies undergo formal second opinion reporting by a fellowship-trained oncologic radiologist with expertise in abdominal imaging. The purpose of this study was to determine the impact of this practice on cancer staging and patient management
Methods and Materials: Randomised original and second opinion reports for 65 consecutive cases of biopsy proven pancreatic adenocarcinomas in a 4 years period from 2009 to 2013 were considered. Discrepancy rates for recommended patient management, as recommended by two experienced abdominal surgeons, were calculated. For the 10,8% (7/65) of cases that subsequently went to surgery, the accuracies of the reports were determined relative to the pathologic staging gold standard. For all other patients, performed management, checked with clinical and imaging standard of reference at 6 months, was considered.
Results: Following oncologic radiologists second opinion review, the cancer stage changed in 13% (9/65) for surgeon 1 and in 18,4% (12/65) for surgeon 2. The recommended management changed in 38,4% (25/65) for surgeon 1 and in 20% (13/65) for surgeon 2. When compared to the pathologic staging gold standard, the second opinion was correct 85,7% (6/7) of the time for both surgeons' interpretation.
Conclusion: Specialist second opinion review of outside imaging studies resulted in an accurate change in cancer stage and this frequently led to a change in their management plan.

Prognostic impact of body composition in patients with metastasised malignant melanoma with checkpoint-inhibitor therapy

J. Nattenmüller, L. Eller, S. Lücke, A. Lonsdorf, H.-P. Schlemmer, H.-U. Kauczor, O.L. Sedlaczek; *Heidelberg/DE (johannawelzel@gmail.com)*

Purpose: Checkpoint-inhibitors (CI) are a major breakthrough in the treatment of a variety of human malignancies and led to significant improvements in response and survival rates in metastatic melanoma patients. However, prognostic markers to select for patients that will respond to CI-therapy remain vastly elusive. As a close link between body composition (esp. fat distribution) and immune competence has been suggested, the aim of this study is to evaluate the prognostic impact of body composition on therapy response.
Methods and Materials: 82 stage IV malignant melanoma patients (41 female, mean age 66ys, mean BMI 26.2kg/m^2) treated with CI (Ipilimumab, Nivolumab, Pembrolizumab) underwent staging-CT with densitometric quantification of total (TFA), visceral (VFA) and subcutaneous fat area (SFA) and skeletal muscle index (SMI) at the spinal level L3/4 to evaluate their impact on progression-free (PFS) and overall survival (OS).
Results: Median PFS and OS time were 293 and 913 days, respectively. On OS, a significant univariate negative impact of male gender (HR=2.88; p=0.018) and a beneficial multivariate impact of SFA (HR=0.64, p=0.044) was found. On PFS, a significant beneficial effect was found for SFA in univariate (HR=0.69, p=0.01) and multivariate (HR=0.49, p<0.001) analyses. These effects of SFA were independent of gender. No significant impact of BMI, VFA, TAT and SMI was detected.
Conclusion: SFA had a significant beneficial prognostic value on both PFS and OS in stage IV melanoma patients undergoing CI-therapy. Further studies are needed to validate body composition and SFA as candidate biomarkers of favorable efficacy in CI therapy.

B-0376 14:52

Influence of Trigger-PSA and molecularactive tumour volume evaluated with 68Ga-PSMA PET/CT on detection rate and localisation of recurrence in patients with prostate cancer

S.S. Medina-Ornelas, F. Garcia-Perez; *Mexico City/MX (dr.sevastian@outlook.com)*

Purpose: Investigate the association between molecular active tumour volume (MATV) evaluate with ^{68}Ga-PSMA-PET/CT and levels of Trigger-PSA for patients with Prostate cancer (PC).
Methods and Materials: Eighty-four patients who underwent to evaluation of PSA levels on the same week of the ^{68}Ga-PSMA-PET/CT (Trigger-PSA) were studied. were included. Sixty patients had received ADT at last 6 months before the examination. The median of the Trigger-PSA was 8.9 ng/mL (range 0.2-127 ng/ml).
Results: The median MATV of bone metastatic disease was significantly higher than that in metastatic lymph nodes (LN) and prostate bed (139.5 versus 17.7; p<0.05). Respect to Trigger-PSA values, the median Trigger-PSA levels of patients with tumours that were limited to the prostate bed (median Tigger-PSA 2.8ng/ml); loco-regional and/or distant lymph node disease (median Tigger-PSA 6.8ng/ml) and metastatic bone disease (median 46.8ng/ml (p<0.05). Positive patients had a mean Trigger-PSA of 4.3ng/mL vs 1.5ng/mL in negative patients (p <0.05). We established several threshold points for Trigger-PSA level and studied the detection rate for each one: Trigger-PSA ≤1ng/mL, detection rate 47.3%; Trigger-PSA 1-4ng/mL, 68.4%; Trigger-PSA ≥4ng/mL, 96.7%. When analyzing the best association between Trigger-PSA and MATV, we found that when Trigger-PSA was >4ng/mL, was greater for patients with a higher MATV (p<0.001).
Conclusion: The correlation of a low MATV evaluate with ^{68}Ga-PSMA-PET/CT has greater influence than the level of Trigger-PSA, which may have an impact on the timely change of the therapeutics used. A detection of the site of metastatic disease could lead to an appropriate therapeutic strategy.

B-0377 14:56

Improved detection of skeletal muscle metastases in iodine-density overlay maps and virtual monoenergetic reconstructions provided by spectral detector CT

S. Lennartz[1], M. Le Blanc[1], N. Abdullayev[1], N. Grosse Hokamp[1,2], D. Maintz[1], J. Borggrefe[1], T. Persigehl[1]; [1]*Cologne/DE*, [2]*Cleveland, OH/US (simon.lennartz@uk-koeln.de)*

Purpose: To investigate if iodine density overlay maps (IDM) and/or virtual monoenergetic images at 40 keV (VMI_{40keV}) acquired with dual layer spectral detector computed tomography (SDCT) can improve detection of skeletal muscle metastases (SMM) compared to conventional polyenergetic images (PI).
Methods and Materials: In total, 36 oncologic patients, 12 patients with confirmed SMM proven by prior or follow-up CT, FDG-PET or histopathology, and 24 patients without SMM who received SDCT staging examinations were included in this retrospective, IRB-approved study. Detection rate was determined in a blinded, randomised multi-reader analysis of PI, IDM and VMI_{40keV}. Quantitatively, iodine density and contrast-to-noise-ratio (CNR) were determined using the following ROIs: metastasis, adjacent skeletal muscle, subcutaneous fat, and air. Size and localisation of ROIs were kept constant between IDM, VMI_{40keV} and PI. Standard deviation within the fat was considered to be representative of image noise. Statistical analysis was performed using Wilcoxon test and ROC-analysis.
Results: Both, IDM (69.1%) and VMI_{40keV} (49.2%) yielded a significantly increased sensitivity for SMM compared to PI (24.2%). Specificity slightly dropped by 3.1% in IDM (78.0%) compared to PI (81.4%), while in $VMI_{40keV,}$ it decreased to 68.4%. Quantitative image analysis revealed a significant higher CNR (14.3±8,0) of SMM in VMI_{40keV} compared to PI (5.5±6,2, p≤0.0001). Iodine density in SMM was significantly enhanced compared to adjacent muscle tissue (1.83±1,1 mg/ml vs. 0.28±0,22 mg/ml, p≤0.0001).
Conclusion: Iodine density maps (IDM) provided by SDCT significantly improve detection rate of SMM in oncologic patients while maintaining an equivalent level of specificity.

B-0378 15:00

Comparison of biopsy and pathological Gleason score in patients with biopsy-proven prostate cancer

V. Romano[1], V. Doronzio[1], S. Pedalino[1], V. Giannini[1], S. Mazzetti[1], A. Giacobbe[2], G. Muto[2], F. Russo[1], D. Regge[1]; [1]*Candiolo/IT*, [2]*Milan/IT (vittorio.romano@ircc.it)*

Purpose: To compare biopsy Gleason Score (bGS) with pathological Gleason score (pGS) after prostatectomy in patients with positive MRI finding and biopsy-proven PCa.
Methods and Materials: Men with biopsy-proven PCa from either MR-targeted biopsy or saturation TRUS-guided biopsy were included in this study and

underwent radical prostatectomy within 3 months from diagnosis. Overall, 24 men with positive MR-targeted biopsy, and 30 subjects with positive saturation biopsy were considered. Whole-mount histological sections resected from radical prostatectomy were used as the reference standard, and biopsy/pathological Gleason score (GS) were compared, assessing the proportion of correctly classified PCa, upgrading and downgrading rates.
Results: After surgery, biopsy GS was correctly identified in 67% and 43% of cases, in MR-targeted biopsy and saturation biopsy, respectively (p=0.08). Biopsy GS was upgraded in 29% of MR-targeted and 30% of saturation biopsy , respectively (p=0.94). Downgrading was registered in 4% and 27% of cases in MR-targeted biopsy and saturation biopsy, respectively (p=0.03). Stratifying patients according to bGS, a higher number of 4+4 PCa were detected in the saturation than in the MR-targeted biposy (16% vs 2%, p=0.13), while considering the pGS, the two sampling techniques (MR-targeted or saturation) reported no statistical difference when men were stratified by pGS (p>0.27).
Conclusion: MR-targeted and saturation biopsy reported a similar rate of correctly classified bGS, while in-bore MR-targeted biopsy showed a significant lower rate of downgrading with respect to saturation biopsy.

B-0379 15:04

Efficacy of intravoxel incoherent motion MRI in discrimination of metastatic vs non-metastatic abdominal lymph nodes in hepatobiliary malignancies: a correlation study with PET-CT
S. Sabet, S. Server, I. Karalok, E.K. Namal, N. Inan, Y. Tokat; *Istanbul/TR (soheyl_61@yahoo.com)*

Purpose: The aim of this study was to evaluate the diagnostic performance of IVIM MR parametres in differentiating metastatic from non-metastatic abdominal lymph nodes in hepatobiliary malignancies.
Methods and Materials: MR images of 34 consecutive patients harbouring 83 upper abdominal lymph nodes with diagnosis of hepatobiliary malignant tumor were evaluated retrospectively. IVIM parameters were calculated for each lymph node form MR images obtained with 16 different b factors (0, 50, 100, 150, 200, 300, 400, 500, 600, 700, 800, 900, 1000, 1100, 1200, 1300 s/mm2) by a 1.5 Tesla MR scanner (Siemens, Magnetom Symphony, Erlangen, Germany). These parameters were compared with SUV max. values of target lesions in FDG PET-CT studies.
Results: The mean value of D was lower, and mean value of f was higher significantly for metastatic group than those of non-metastatic group (p<0,001), while D* and ADC did not show significant difference. D and f had largest area under curve in the ROC analysis (0,649 and 0,984 respectively) compared to other individual IVIM parameters leading to sensitivity and specifity of %96 and %86 for f in identification of metastatic lymph nodes.
Conclusion: IVIM parameters, specially D and f, reflect the metabolic activity of lymph nodes, providing a reliable diagnostic tool in distinguishing metastatic from non-metastatic lymph nodes with a lower price, shorter scan time and radiation free modality instead of PET-CT and may be applicable not just in cervical and thoracic tumors but also in abdominal lymphadenopathies caused by hepatobiliary malignancies.

B-0380 15:08

T2 hyperintense myometrial tumours: can MRI features differentiate leiomyomas from leiomyosarcomas?
G. Rio[1], M. Lima[2], R. Gil[2], M. Horta[2], T.M. Cunha[2]; [1]*Braga/PT*, [2]*Lisbon/PT (giselario_123@hotmail.com)*

Purpose: To establish MRI features that help differentiate atypical and degenerated leiomyomas that show hyperintensity on T2WI from leiomyosarcomas (LMS).
Methods and Materials: This retrospective study evaluated 51 women who performed MRI and had T2 hyperintense myometrial tumours, proved by histology as atypical or degenerated leiomyomas or leiomyosarcomas (21 leiomyomas; 20 leiomyosarcomas), before they underwent hysterectomy. The association between MRI features (contours; free pelvic fluid, intra-tumoural haemorrhagic areas, T2 heterogeneity; T2 dark areas; flow voids; signal intensity and heterogeneity after contrast administration; unenhanced areas, localization of unenhanced areas; necrosis; cystic areas) and the histology (leiomyoma vs leiomyosarcoma) were calculated using Fisher's exact test. For those features that showed a significant association, a multivariate linear regression was performed.
Results: Five MRI features demonstrated a significant correlation with malignant histology: lobulated borders (p= 0,002); T2 dark areas (p=0,02); necrosis (p=0,001); hyperintensity relative to the myometrium after contrast administration (p=0,007) and central unenhanced areas (p=0,016). Three of these features demonstrated a significant result predicting a malignant histology: lobulated contours, central unenhanced areas and necrosis (F (3;34)= 8,95; p < 0,001; R^2= 0,506).
Conclusion: The presence of lobulated borders, T2 dark areas, necrosis, hyperintensity relative to the myometrium after contrast administration and central unenhanced areas can help distinguish between leiomyoma and leiomyosarcoma. The association of lobulated borders, necrosis and central unenhanced areas can help predict a malignant histology.

B-0381 15:12

3D imaging biomarkers for the prediction of survival in patients with non-small cell lung cancer or melanoma brain metastases treated with stereotactic body radiation therapy
M. Della Seta, F. Collettini, D. Kaul; *Berlin/DE (marta.della-seta@charite.de)*

Purpose: To investigate the value of 3D-quantitative tissue enhancement as an early imaging biomarker for survival in patients with singular non-small cell lung cancer (NSCLC) and melanoma brain metastases (BM) treated with stereotactic body radiation therapy (SBRT).
Methods and Materials: 48 patients with a singular BM were treated with SBRT (27 NSCLC- and 21 melanoma patients). Baseline contrast-enhanced MRI (ceMRI) was used for image analysis using the qEASL tool (Philips Healthcare). A segmentation-based 3D-quantification was performed to measure the relative tumour enhancement. Survival was evaluated using univariable and multivariable cox regression models.
Results: Median overall survival (OS) of the cohort was 8.9 months. The stratification of the cohort according to a 65% cutoff for the relative enhancing tumour volume achieved statistical significance in univariable and multivariable analysis for OS (univariable regression: p=0.005, HR= 0.375 [95% CI, 0.168-0.744], multivariable regression: p=0.006, HR= 0.376 [95% CI, 0.186-0.757]). Patients with >65% enhancing lesion volume survived significantly longer than patients with less-enhancing tumour lesions (4.9 months vs 10.2 months). In subgroup analysis of NSCLC-patients adenocarcinoma showed significantly longer median OS than non-adenocarcinoma NSCLC patients in univariable and multivariable analysis (3.5 months vs 10.2 months).
Conclusion: Enhancement on baseline ceMRI in patients with singular NSCLC and melanoma BM is strongly associated with patient survival after SBRT. Specifically, patients with hyper-enhancing lesions demonstrated improved survival as compared to those with mainly hypo-enhancing lesions. Lesion enhancement may be a potential factor in future prognostic indices for the prediction of survival of patients with BM.

Radiomics of high-grade serous ovarian cancer: association between quantitative CT features and prognosis
F. De Piano, V. Buscarino, M. Femia, L. Tofanelli, S. Raimondi, D. Origgi, F. Botta, S. Rizzo; *Milan/IT (fran.depi@gmail.com)*

Purpose: To determine if radiomic features, alone or combined with clinical data, are associated with residual tumour (RT) at surgery, and predict the risk of disease progression within 12 months (PD12) in ovarian cancer (OC) patients.
Methods and Materials: This retrospective study enrolled 101 patients according to the following inclusion parameters: cytoreductive surgery performed at our Institution (05/09/2007-23/02/2016), assessment of BRCA mutational status, pre-operative CT available. Radiomic features of the ovarian masses were extracted from 3D structures drawn on CT images. A phantom experiment was performed to assess the reproducibility of radiomic features. The final radiomic features included in the analysis (516) were grouped into clusters using a hierarchical clustering procedure. The association of each radiomic feature with RT and PD12 was assessed by Chi-Square test. Multivariate analysis was performed using logistic regression models. P-values < 0.05 were considered significant.
Results: Patients with values of F2-Shape/Compactness1 below the median, values of F1- GrayLevelCooccurenceMatrix25/0-1InformationMeasureCorr2 below the median, and values of F1-GrayLevelCooccurenceMatrix25/-333-1InverseVariance above the median showed a higher risk of RT (36%, 36% and 35%, respectively, as opposed to 18%, 18% and 18%). Patients with values of F4-GrayLevelRunLengthMatrix25/-333RunPercentage above the median, values of F2 shape/Max3DDiameter below the median, and F1-GrayLevelCooccurenceMatrix25/45-1InverseVariance above the median showed a higher risk of PD12 (22%, 24% and 23%, respectively, as opposed

to 6%, 5% and 6%). At multivariate analysis F2-Shape/Max3DDiameter remained significant (HR (95%CI)=11.86 (1.41-99.88)).
Conclusion: This study demonstrated significant associations between radiomic features and prognostic factors such as RT and PD12.

B-0383 16:04

Prostate cancer detection rate in patients with negative multi parametric (mp) MRI or negative biopsy after 2 years of follow up

E. Appending[1], S. Pedalino[1], E. Tabone[1], V. Romano[1], S. Mazzetti[1], A. Giacobbe[2], G. Muto[2], F. Russo[1], D. Regge[1]; [1]*Candiolo-Turin/IT*, [2]*Milan/IT (elena.appendino@gmail.com)*

Purpose: To assess prostate cancer (PCa) detection rate among patients in follow-up after a negative mp-MRI or biopsy, and to assess the negative predictive value (NPV) of mpMRI in the detection of PCa.
Methods and Materials: 140 men with negative prostate mp-MRI (PI-RADS 1, 2 or 3 with lesion diameter <7 mm), and 10 men with positive mp-MRI (PI-RADS>3 or =3 with diameter >7 mm) but a negative biopsy (TRUS or RM-guided) were monitored periodically with PSA values and urological visit. In case of PSA doubling time < to 3 years or following urological indication, subjects underwent a second mpMRI (2nd-MRI).After 2-year follow-up, we defined as negative patients with: a) no increase of PSA, or b) patients with negative 2nd-MRI, or c) patients with negative biopsy after a 2nd-MRI.
Results: During follow-up 44/150 patients underwent a 2nd-MRI. In 10/44 patients a prostate lesion was found, triggering a biopsy. Presence of PCa was biopsy-confirmed in 8/10 patients (6 men with GS=3+4, 1 with GS=4+3 and 1 with GS=3+3). Among the 8 biopsy-proven PCa after the 2nd-MRI, 2 were already reported on the first MRI, although not confirmed by biopsy. No clinical or laboratory changes were observed in the remaining 106/150 patients (102 men with negative mpMRI and 4 men with negative biopsy) during the 2-year follow-up period (70,6%). Overall 142/150 patients were considered negative (NPV of 94,7%).
Conclusion: Biopsy can be safely avoided in subjects with a negative mp-MRI if follow-up is performed with clinical examination and PSA assessment.

B-0384 16:08

Which cancer-related factors are associated with prostate cancer missing when evaluating mpMRI with PI-RADS v2?

R. Girometti[1], F. Greco[1], L. Cereser[1], G. Como[1], V. Ficarra[2], G. Giannarini[1], A. Crestani[1], C. Zuiani[1]; [1]*Udine/IT*, [2]*Messina/IT (rgirometti@sirm.org)*

Purpose: To assess which prostate cancer (PCa)-related factors are associated with cancer missing (CM) on multiparametric magnetic resonance imaging when using prostate imaging reporting and data system version 2 (PI-RADS v2).
Methods and Materials: Between May 2016-February 2017 we prospectively enrolled patients with biopsy-proven prostate cancer who underwent staging 3.0T Multiparametric magnetic resonance imaging (mpMRI) before radical prostatectomy. Two readers with 6 and 8 years of experience, respectively, detected and scored mpMRI findings according to PI-RADS v2 criteria in a blinded fashion compared to final whole-mount pathology. Using PI-RADS ≥4 score as threshold, we calculated the per-lesion cancer detection rate (CDR) of each radiologist. We then performed multiple logistic regression to assess whether PCa-related factors (clinical significance according to Epstein criteria, Gleason score, prostate specific antigen (PSA) level, histological lesion size, extraprostatic extension and prostatic location) were predictors of CM.
Results: Included were forty-eight patients (median iPSA 7.2 ng/ml) with 71 cancers (median size 16 mm, median Gleason score 6, stage ≥T3 in 19/48 cases, 51/70 clinically significant cancers (csPCa)). CDR ranged 0.48-0.60 for all cancers and 0.61-0.72 for csPCa. On univariate analysis, the model of both readers showed significant association (p<0.01) between CM and non-csPCa, Gleason score <7, size <1.4-1.5 cm, and absence of extraprostatic extension. On multivariate analysis, lower lesion size was the only independent predictor of CM (p<0.01) for both radiologist 1 (OR 0.12) and 2 (OR 0.18).
Conclusion: Smaller cancer size is the most impacting factor in CM when assessing PCa with PI-RADS v2.

B-0385 16:12

Role of ureteric jet angle as measured by colour Doppler ultrasound in evaluating severity (grading) of VUR in patients presenting with urinary complaints

P. Maravi; *Bhopal/IN (maravipoornima@gmail.com)*

Purpose: To correlate ureteral jet angles (UJA), measured by colour Doppler USG with VUR grades on micturating cystourethrogram (MCU) and establish ureteral jet angle (UJA), as non-invasive screening tool for detecting high grade vesioureteral reflux (VUR).
Methods and Materials: Symptomatic children referred in Dept. of Imaging for MCU were examined by colour Doppler USG in order to get the bilateral ureteric jet angles (UJA). UJA was measured as angle between the direction of the ureteral jet and inter-ureteral ridge. Patients, who showed VUR in MCU, UJA were then correlated to grades of VUR using excel data tool.
Results: In total 34 children (8 mon- 12 yrs) including 20 males (M) and 14 females (F) were examined. Mean age was 4.96 yrs {4.60 yrs (M) and 5.47 yrs in (F)}. 21 patients, (10 (F) and 11 (M) showed VUR on MCU. 8 patients showed higher grade (grade 4 -5) including 7 M, 1 F. Range of UJA in VUR negative patients was 27-59° on right side (R) and 23-60° on left side (L). VUR positive patients showed angle range 42-84°(R) and 40-84° (L). Mean ureteric jet angle was 62.61°(R) and 61.80° (L). Grade IV/V VUR seen above >70°. Positive correlation {r=0.88 on R and 0.73 on L} was noted between UJA and VUR grading.
Conclusion: Colour Doppler USG measurement of UJA can be used as simple and non-invasive screening tool to detect the grade of VUR in symptomatic children therefore minimising the need for MCU, which is invasive and imposes risks related to radiation/contrast media administration.

B-0386 16:16

Accuracy of multiparametric MRI of prostate cancer recurrence after high-intensity focused ultrasound (HIFU): is dynamic contrast enhancement still needed?

R. Lotte, A. Lafourcade, M. Ezziane, P.-H. Jouve de Guibert, S. Tavolaro, P. Mozer, F. Boudghene, O. Lucidarme, R. Renard Penna; *Paris/FR (raissalotte@hotmail.com)*

Purpose: To assess the added value of dynamic contrast-enhanced (DCE) imaging to the combination T2-weighted imaging (T2w) + diffusion-weighted imaging (Dw) in detecting recurrence of prostate cancer (PCa) after HIFU using multiparametric magnetic resonance imaging (mpMRI).
Methods and Materials: We retrospectively selected 45 patients with clinical and biological suspicion of recurrence of PCa after focal HIFU. All patients underwent mpMRI at 1.5 and 3 Tesla (T2w, Dw and DCE) before biopsies. Two readers independently assigned a Likert score (from 1 to 5) of cancer likelihood for each prostatic sector (divided on 6 sextants) on T2w + Dw + DCE and T2w + Dw images. Prostatic biopsies were taken as the gold standard.
Results: Recurrent PCa was identified at biopsy in 37 (82%) of 45 patients. Area under the receiver operating curve of T2w + Dw and T2w + Dw + DCE imaging were not significantly different for both readers, at patient level and at lobe level. Using a Likert score ≥3 for PCa diagnosis threshold, sensitivity at lobe level for (a) senior and (b) junior reader for T2w +Dw +DCE was (a) 0.97 (b) 0.94 vs (a) 0.94 (b) 0.97 for T2w + Dw, specificity was (a) 0.27 (b) 0.09 vs (a) 0.27 (b) 0.27, respectively.
Conclusion: Accuracy of mpMRI was not significantly improved with added DCE to T2w + Dw imaging. Sensitivity was high for T2w + Dw + DCE and T2w + Dw with no significant difference, either for the junior or the senior reader.

B-0387 16:20

Development of preoperative prediction of high Fuhrman grade in the patient with clear cell renal cell carcinoma

J. Ding, J. Chen, J. Sun, W. Xing; *Changzhou/CN (dingjiule@163.com)*

Purpose: To develop and validate a nomogram for the preoperative prediction of high Fuhrman grade ccRCC (III-IV).
Methods and Materials: The prediction model was developed in a training cohort that consisted of 114 patients with ccRCC. The pseudocapsule, intratumoural artery, morphological feature and tumour size were assess by a radiologist. Radiomic features were extracted from the CT images of ccRCC at both arterial and portal venous phases. The least absolute shrinkage and selection operator was used for data dimension reduction and radiomics score calculation. A multivariate logistic regression model was used in training cohort to predict the high Fuhrman grade at nephrectomy. The predictors included pseudocapsule, intratumoural artery, morphological feature, tumour size and texture analysis of renal mass, and a nomogram was generated. The performance of the nomogram was assessed in an independent validation cohort contained 92 consecutive patients.
Results: The radiomics score, which consisted of 2 selected features, was significantly associated with Fuhrman grade (P < 0.05). Predictor contained in the individualized prediction nomogram included the features of radiomics score and morphological feature. The model showed the good discrimination with a concordance index of 0.859 (concordance index = 0.861 through the 80 samples in training cohort) and good calibration. Application of the nomogram in the validation cohort still gave good discrimination [concordance index = 0.782 (75%CI, 0.575 to 0.987)] and good calibration.
Conclusion: The nomogram that incorporated the radiomics and morphological features can be conveniently used to facilitate the preoperative individualized prediction of the high Fuhrman grade ccRCC.

B-0388 16:24

Prognostic value of diffusion-weighted imaging for clinical outcome prediction in uterine cervical cancer treated with radiotherapy

K. Gu, C.K. Kim, J. Lee; *Seoul/KR (kyowon.gu@gmail.com)*

Purpose: To investigate the prognostic value of diffusion-weighted imaging (DWI) in predicting clinical outcome in patients with cervical cancer after radiotherapy (RT).
Methods and Materials: Enrolled 124 patients with stage IB-IVB cervical cancer who received definitive RT with (n=117) or without (n=7) concurrent chemotherapy underwent MRI at 3T including DWI before and during (at 1 month) treatment. The mean apparent diffusion coefficient (ADC) value was measured on the tumour and the percentage change (ΔADC_{mean}) between 2 time points was calculated. Cox proportion hazard model was performed to evaluate the association of imaging and clinical variables with progression-free survival (PFS) and cancer-specific survival (CSS).
Results: During a median follow-up of 3.6 years, disease progression was found in 40 patients (32.2%) and 19 patients (15.3%) died of their disease. On multivariate analysis, ΔADC_{mean} (hazard ratio [HR]=0.98, P=0.015) and histologic type (HR= 2.66, P= 0.020) were significantly independent factors for PFS, and ΔADC_{mean} (HR=0.97, P=0.015) and parametrial invasion on MRI (HR=0.22, P=0.024) were significantly independent factors for CSS. Pretreatment ADC values were not associated with PFS and CSS (P>0.05). Using the optimal cutoff values of ΔADC_{mean}, the 3-year PFS was significantly lower for ΔADC_{mean} <38.7% than for ΔADC_{mean} ≥38.7% (P<0.001). The 3-year CSS was significantly lower for ΔADC_{mean} <15.7% than for ΔADC_{mean} ≥15.7% (P<0.001).
Conclusion: The percentage change of tumour ADC after RT may be a useful predictor of tumour progression and survival in patients with cervical cancer.

B-0389 16:28

Intravoxel incoherent motion and blood oxygen level-dependent of early iodinated contrast-induced acute kidney injury induced in a rabbit model

Y. Wang[1], K. Ren[1], L. Xie[2]; [1]*Shenyang/CN*, [2]*Beijing/CN*
(wangyongfang1219@163.com)

Purpose: To assess if parameters in intravoxel incoherent motion (IVIM) and Blood oxygen level-dependent (BOLD) can be used to evaluate early Iodinated Contrast-Induced Acute Kidney Injury (CIAKI) in a Rabbit model.
Methods and Materials: 21 zealand white rabbits weighing 2.5-3.0 kg were choosen and received iohexol at the dosage of 5.0gI/kg. IVIM and BOLD were performed longitudinally at 24 h prior to and 1 h,1 d, 2 d, 3 d and 4 d postinjection of iohexol. The parameters D, f, D* and ADC and R2* values were obtained.The expression of hypoxia inducible factor (HIF-1α) in renal tissue was detected by immunohistochemistry. Repeated measure One-way analysis of variance was used for data analyses.
Results: BOLD and IVIM demonstrated distinct signals in all of the four renal regions, and inner stripes of the renal outer medulla showed the most pronounced modifications. For the measurements, an increased R2* value and strong attenuation of D and ADC were observed at 1-2 d after iohexol injection (p<0.05). As perfusion measurement, a significant decrease was shown for D* and f in 1 h-2 d (p<0.05) and an increase in 3-4 d. Compared with baseline levels, distinct elevation of R2* value were observed in all the anatomical compartments at 1 hour (p<0.05), to the maximum levels at 1 d (p<0.05), this observed trends were consistent with the expression of hypoxia inducible factor HIF-1α.
Conclusion: The IVIM and BOLD techniques can be used as noninvasive tools to perform a time course study of the pathogenesis associated with CIAKI.

B-0390 16:32

Comparison of MRI and transvaginal ultrasonography in the diagnosis of retrocervical septum endometriosis

M. Wang, J. Lu, Y. Dai, Y. Xia; *Beijing/CN (wmd328@126.com)*

Purpose: To explore the clinical value of MRI and transvaginal ultrasonography (TVS) in the identification of retrocervical septum endometriosis.
Methods and Materials: Thirty-five patients with histologically confirmed endometriosis in retrocervical septum were retrospectively studied. All the patients underwent both MRI and TVS before laparoscopic surgery. Mapping of deep infiltrating endometriosis(DIE) in retrocervical septum was performed. MRI and TVS results were compared with surgical and pathological findings.
Results: The accuracy for MRI in the identification of endometriosis in retrocervical septum was 62.9% (22/35) and for TVS was 28.6% (10/35). Among 35 patients, the sensitivity, specificity and accuracy for MRI in the detection of posterior cul-de-sac obliteration and adhesion was 71.4% (10/14), 61.9% (13/21), 65.7% (23/35). The sensitivity, specificity and accuracy for MRI in the detection of DIE in uterosacral ligment was 47.6% (10/21), 87.8% (43/49), 75.7% (53/70).
Conclusion: MRI was superior to TVS for the diagnosis of DIE in retrocervical septum. MRI can demonstrate high sensitivity in the detection of cul-de-sac obliteration and adhesion, as well as evaluation the locations and extension of DIE. The information offered by MRI is helpful in determining surgical options and planning appropriate treatment.

B-0391 16:36

Clinical complications in percutaneous renal biopsy guided by ultrasound: 16 vs 18-gauge needles

P. Ramos Botelho Antunes[1], M.C. Barbosa Álvares[1],
F. Franco Monteiro Prado[1], F. Tinôco Alvim de Souza[1],
M. Álvares de Campos[1], E. Carvalho de Siqueira[1], R. Berindoague Neto[1],
B. Carvalho Silva Rabelo[2]; [1]*Belo Horizonte/BR*, [2]*Itauna/BR*
(brenorabelomed@gmail.com)

Purpose: Compare complications of percutaneous renal biopsy using two gauge(G) needles, 16G and 18G.
Methods and Materials: 238 individuals with renal biopsy(RB) indication were randomly separated into two groups according to the gauge of needle used. 134 patients(110 non-transplanted, and 24 renal transplanted) were biopsied with a 16G needle and 104(64 non-transplanted, and 40 renal transplanted) were biopsied with a 18G needle. Major and minor complications were analyzed immediately, and at 3 different times after procedure(4 hours, 12 hours and 7 days).
Results: The study presented a general index of 11.3% major complications. Patients who underwent RB with a 16G needle were more likely to complicate than 18G needle biopsies(17% vs. 3.8%; OR 5.1; 95% CI, 1,7-15.4; p=0.001). Although renal transplant patients submitted to 16G needle biopsies also presented higher complication rates when compared to patients submitted to 18G needle biopsies(OR 5.5; CI 95%, 0,5-56,9), there was no statistically significant association(p=0.14). On the other hand, non-transplanted renal patients had higher rates of complications in patients submitted to 16G needle biopsy in relation to patients submitted to 18G needle biopsy(OR 4.5; 95% CI, 1,3-15,8; p=0.01). The mean number of complete glomeruli harvested per biopsy for 16G and 18G needles was 22.1 and 17.5, respectively.
Conclusion: Our study findings suggest that there is a need to carefully weigh the potential risks for using a larger biopsy needle against the desire for more diagnostic tissue. Kidney biopsies taken by 18G needles resulted in lower frequency of complications compared to 16G.

B-0392 16:40

Developing a new PI-RADS v2-based nomogram for forecasting high-grade prostate cancer

X. Niu; *Chengdu/CN (niu19850519@163.com)*

Purpose: To establish a predictive nomogram for high-grade prostate cancer (HGPCa) in biopsy-naive patients based on the prostate imaging reporting and data system version 2, magnetic resonance imaging (MRI)-based prostate volume, MRI-based PV-adjusted prostate-specific antigen density, and other classical parameters.
Methods and Materials: Between August 2014 and August 2015, 158 men who were eligible for analysis were included as the training cohort. A prediction model for HGPCa was built using backward logistic regression and was presented on a nomogram. The prediction model was evaluated by a validation cohort between September 2015 and March 2016 (n=89). Histology of all lesions was obtained with MRI-directed transrectal ultrasound (TRUS)-guided targeted and sectoral biopsy.
Results: The multivariate analysis revealed that patient age, PI-RADS v2 score, and adjusted PSAD were independent predictors for HGPCa. The most discriminative cut-off value for the logistic regression model was 0.33; the sensitivity, specificity, positive predictive value, and negative predictive value were 83.3%, 87.4%, 88.4%, and 81.2%, respectively. The diagnostic performance measures retained similar values in the validation cohort (AUC=0.83).
Conclusion: The nomogram for forecasting HGPCa is effective and potentially reducing harm from unnecessary prostate biopsy and over-diagnosis.

B-0393 16:44

Diffusion-weighted MRI as a prognostic and response biomarker in patients with castration-resistant prostate cancer and bone metastases

R. Perez Lopez[1,2], N. Tunariu[1], D.-M. Koh[1], J.S. de Bono[1]; [1]*London/UK*,
[2]*Barcelona/ES (rperez@vhio.net)*

Purpose: To correlate diffusion-weighted imaging (DWI) MRI features of bone metastases from castration-resistant prostate cancer (CRPC) with pathology (1), and evaluate whole-body DWI as prognostic (2) and response biomarker (3) in CRPC.
Methods and Materials: 1. 43 consecutive bone metastasis biopsies (33 patients) with DWI performed <12 weeks before bone biopsy and a reference cohort of 10 patients with no bone metastases were reviewed. DWI differences in bone biopsy positive/negative for tumour cells (Mann-Whitney) and DWI

cellularity correlations (Spearman's correlation "r") were assessed. 2. Prognostic value was evaluated in 43 consecutive patients. Total volume of bone metastases by DWI (tDV) was correlated with survival (Kaplan-Meier) and prognostic factors (*r).* 3. Utility as response biomarker was assessed in a clinical trial of olaparib in CRPC (n=21), comparing whole-body DWI at baseline and after 12 weeks of treatment. Regression analysis between tDV and median apparent diffusion coefficient (mADC) changes and treatment response were pursued.
Results: 1. mADC in bone metastases and non-metastatic bone was $993x10^{-6}mm^2/s$ vs $601.8x10^{-6}mm^2/s$, median normalized (n) nDWI signal was 4AU vs 1.6AU; p<0.001. ADC and nDWI signal correlated with tumour cellularity; p<0.001. 2. tDV correlated with all evaluated prognostic factors (haemoglobin; prostate-specific antigen; lactate dehydrogenase; alkaline phosphate; all p<0.001) and CTC count (p=0.004). tDV associated with overall survival (hazard ratio: 1.74; p=0.035). 3. Change in tDV and mADC at 12 weeks associated with response to therapy (p<0.01, p=0.04, respectively).
Conclusion: DWI of bone metastases informs on prognosis and response to treatment in CRPC. DWI findings correlate with pathology. These data contribute towards DWI implementation in prostate cancer care.

B-0394 16:48

Tumour size at MRI association with lymph node metastasis and lymphovascular space invasion in resectable cervical cancer: a multicentre evaluation of surgical specimens
X.-l. Chen, P. Zhou, H. Li; *Chengdu/CN (penghyzhou@126.com)*

Purpose: To determine whether the gross tumour volume (GTV) and the maximum diameter of resectable cervical cancer at MRI could predict the presence of lymph node metastasis (LNM) and lymphovascular space invasion (LVSI).
Methods and Materials: 315 consecutive patients with cervical cancer who underwent surgery in 1 week after contrast-enhanced MRI were retrospectively identified from multiple hospitals. The tumour size including GTV and the maximum diameter of tumour were evaluated on MRI. Statistical analysis was performed to determine whether tumour size could predict LNM and LVSI. Cutoffs of GTV and the maximum diameter of tumour were first investigated in a cohort of 255 patients (group A) and then validated in an independent cohort of 60 patients (group B) using area under the receiver operating characteristic curve (AUC) analysis for predicting LNM and LVSI.
Results: Univariate analysis showed GTV and the maximum diameter of tumour could predict the presence of LNM and LVSI (all *P*<0.0001). Multivariate analyses indicated GTV as an independent risk factor of LNM and LVSI (all *P*<0.0001). In the group A, GTV and the maximum diameter of tumour could help identify the presence of LNM (AUC, 0.813 and 0.741, respectively) and LVSI (AUC, 0.806 and 0.751, respectively). In the group B, GTV and the maximum diameter of tumour could help identify the presence of LNM (AUC, 0.902 and 0.825, respectively) and LVSI (AUC, 0.771 and 0.748, respectively).
Conclusion: GTV and the maximum diameter of resectable cervical cancer at MRI demonstrated capability in predicting the presence of LNM and LVSI.

NSsaFe: observational study on the incidence of nephrogenic systemic fibrosis in patients with renal impairment following gadoteric acid administration
A. Gottschalk, B. Kress; *Frankfurt a. Main/DE (andreas.gottschalk@gmx.net)*

Purpose: To prospectively determine the incidence of nephrogenic systemic fibrosis (NSF) in patients with renal impairment after administration of gadoteric acid (Dotarem, Guerbet, France).
Methods and Materials: Worldwide post-marketing study including 540 patients with moderate, severe or end-stage renal impairment, scheduled to undergo a routine contrast-enhanced MRI with gadoteric acid. Medical history, MRI indication(s) and adverse events (AEs) were recorded for each patient. Patients were followed up over 2 years after gadoteric acid administration with three visits to detect any signs/symptoms suggestive of NSF.
Results: Included patients had a mean age of 69.6±12.7 years [range: 21-95], with a ratio male/female of 58.5%/41.5%. Renal impairment was graded as moderate for 69.3% of patients, severe for 16.1% and end-stage for 12.0%; 2.6% had undergone a kidney transplant. The mean (±SD) estimated glomerular filtration rate was 37.6 ± 15.7 ml/min/1.73 m2 [range: 4.0-74.2]. Central nervous system exploration was the main MRI indication (34.6%). The follow-up period was completed: 434 patients (80.4%) attended the first follow-up visit, 390 (72.2%) attended the second, and 354 (65.6%) attended the third. At the third follow-up visit, renal impairment was moderate for 40.1% of the patients, severe for 9.3% and end-stage for 14.4%. Overall, neither AEs related to the administration of gadoteric acid, nor signs of NSF were reported.
Conclusion: At the end of the 2-year follow-up period, the study shows no signs of NSF after gadoteric acid administration, confirming its good safety profile in this high-risk population.

B-0396 16:56

Staging of endometrial carcinoma with MRI: does the fusion T2-weighted and high b-value diffusion-weighted images improve diagnosis? An agreement study with histopathology
M. Correia[1], M.A. Serrado[2], M. Horta[1], T.M. Cunha[1], D. Virella[1]; [1]*Lisbon/PT*, [2]*Funchal/PT (marianatomecorreia@gmail.com)*

Purpose: To assess diagnostic accuracy of staging of endometrial carcinoma using MRI and evaluate the utility of fused T2-weighted (T2WI) and high b-value diffusion-weighted images (DWI).
Methods and Materials: This single-centre study includes 94 patients with endometrial carcinoma who underwent pretreatment MRI and subsequent surgery. One experienced radiologist assessed the grade of tumor invasion, according to FIGO system. The first evaluation was based on the T2WI, dynamic contrast enhance-MRI and DWI, afterwards the DWI and Fused T2-DWI images were considered for staging. These data were compared with the histopathologic findings as gold standard. The agreement was assessed by Cronbach Alpha test (kappa value) and interclass correlation coefficient (ICC).
Results: The diagnostic agreement of MRI without the fusion T2-DWI images was 85.7%, 50%, 22.2%, 30.8%, 50%, 40%, 28.6% and 25% for staging IA, IB, II, IIIA, IIIB, IIIC1, IIIC2 and IVB respectively (kappa=0.405±0.058; ICC=0.556, 95%CI 0.399-0.681). When fused T2-DWI images were considered, the agreement was instead 97.1%, 50%, 22.2%, 38.5%, 50%, 70%, 28.6% and 50% for IA, IB, II, IIIA, IIIB, IIIC1, IIIC2 and IVB respectively (kappa=0.537±0.057; ICC=0.695, 95%CI 0.574-0.786). The fused T2-DWI images improved the diagnostic agreement when evaluating tumor invasion of more than one-half of the myometrial thickness (kappa=0.787±0.063 vs. 0.617±0.063), the pelvic lymph node involvement (kappa=0.480±0.141 vs. 0.217±0.155) and the distant metastatic spread (kappa=0.569±0.166 vs. 0.378±0.192).
Conclusion: The use of fused T2-DWI images seems to improve the diagnostic performance for staging of endometrial carcinoma, particularly for assessing myometrial invasion, pelvic lymph node involvement and distant metastatic spread.

B-0397 17:00

Testicular microlithiasis: clinic-radiologic-pathologic correlation in 289 patients with germ cell tumour
M. De la Mora Malváez[1], A. Garza Gangemi[1], D.A. Sánchez Nava[1], M. Licano[2], O.C. Rico Rodríguez[1], C. Kauffman Ortega[1], R. Castillejos Molina[1]; [1]*Mexico City/MX*, [2]*Tlalpan/MX (mariannedlm27@gmail.com)*

Purpose: Testicular microlithiasis (TML) has been reported in 5.6% of asymptomatic patients in ultrasound examinations. Its association with primary testicular cancer (PTC) and extragonadal cell tumours (EGCT) is still controversial.
Methods and Materials: This is a retrospective observational study of prospectively collected data of 289 consecutive patients with germ cell tumours from a tertiary care centre between 2008 and 2017. Baseline characteristics (the presence of comorbidities, hypogonadism, primary tumour site, tumour histology, and clinical stage) and testicular ultrasonographic characteristics (testicular volume, tumour characteristics, and the presence of microlithiasis) were recorded for every patient. Imaging characteristics were analysed between groups according to primary tumour site and tumour histology.
Results: The median age at diagnosis was 27 ± 9 years and 12.7% of the patients had a history of cryptorchidia. Non-seminomatous tumours were more frequent (60.6%) than seminomas. Twenty two patients (7.6%) had EGCT and 267 had PTC. Unilateral TML was observed in 20.8% of the patients and bilateral microlithiasis was detected in 11.8% of the patients. Bilateral TML was more frequent in non-seminomatous tumours, 16.8% v.s. 6.5%, p = 0.04. Furthermore, the presence of bilateral TML was more common in patients with EGCT when compared with PCT patients 31.8% v.s. 10.1%, p = 0.01. Testicular atrophy (volume <12cc) was also associated with the presence of microlithiasis (p<0.01).
Conclusion: TML is more common in non seminomatous histology and it is associated with testicular atrophy. Bilateral testicular microlithiasis is more common in EGCT.

B-0399 17:04

Differentiation and diagnosis of benign and malignant testicular lesions using ^{18}F-FDG PET/CT
D. Shao; *Guangzhou/CN (312368517@qq.com)*

Purpose: The purpose of this study was to evaluate the differential diagnostic value of ^{18}F-fluorodeoxy glucose positron emission tomography/computed tomography (^{18}F-FDG PET/CT) for benign and malignant testicular lesions.
Methods and Materials: The PET/CT scans of 53 patients with testicular lesions confirmed by biopsy or surgical pathology were retrospectively analysed. There were 32 cases of malignant tumours and 21 cases of benign lesions. Differences in the maximum standardised uptake value (SUVmax)

measurements and the SUVmax lesion/background ratios between benign and malignant lesions were analysed. The diagnostic value of this PET/CT modality for the differential diagnosis of benign versus malignant testicular lesions was calculated.
Results: The differences in the SUVmax measurements and the SUVmax lesion/background ratios between benign and malignant lesions were statistically significant (SUVmax: Z=-4.295, *p*=0.000; SUVmax lesion/background ratio: Z=-5.219, *p*=0.000); specifically, both of these indicators were higher in malignant lesions compared to benign lesions. An SUVmax of 3.75 was the optimal cutoff value to differentiate between benign and malignant testicular lesions. The diagnostic sensitivity, specificity, accuracy, positive predictive value, and negative predictive value of this PET/CT modality in the differential diagnosis of benign versus malignant testicular lesions were 90.6%, 80.9%, 86.8%, 87.9%, and 85.0%, respectively.
Conclusion: ^{18}F-FDG PET/CT can accurately identify benign and malignant testicular lesions.

B-0400 17:08

Ectopic pregnancies in caesarean section scars: five-years' experience
H.S. Darwish[1], Y. Habash[1], M. Habsah[2]; [1]*Ismailia/EG*, [2]*Cairo/EG*
(darwish.hoda@yahoo.com)

Purpose: To evaluate our 5 years experience in diagnosis and treatment of ectopic pregnancy developing in a caesarean section scar.
Methods and Materials: The study included twenty one women who were diagnosed with a cesarean scar ectopic pregnancy (CSEP) in the first trimester, which was confirmed by ultrasound and treated in our hospital during 5 years between 2012 and 2016. The clinical presentations, imaging findings, and treatment outcomes of all these pregnancies were recorded.
Results: All our 21 cases underwent successful early first trimester diagnosis with trans-vaginal colour Doppler ultrasonography and termination by a systemic methotrexate administration, or with aspiration of the gestational sac. Fourteen of them underwent systemic methotrexate treatment; and seven patients underwent trans-cervical aspiration of the gestational sac. Intraoperative bleeding occur in all 7 cases that treated with aspiration of the gestational sac, one of them end with hysterectomy. Uterine rupture occurs in one patient and treated conservatively. No complications occur in cases treated with systemic methotrexate injection. The cesarean scar mass followed with trans-vaginal ultrasound and regressed from 2 months to about 1 year after treatment.
Conclusion: Early imaging recognition, diagnosis of CSEP and effective treatment is critically important to improve outcome, minimise the need for emergency extended surgery, minimise maternal complications, maintain treatment options, and potentially preserve future fertility.

B-0401 17:12

Role of ultrasound and MR imaging in evaluation of patients at high risk of morbidly adherent placenta
G. Khatri, N. Antil, R. Misra, S.K. Bajaj; *New Delhi/IN*
(garvit_khatri@hotmail.com)

Purpose: To study the spectrum of ultrasound Doppler and MR Imaging findings in patients at high risk for adherent placenta; to compare the efficacy of ultrasound Doppler and MR Imaging in diagnosis of adherent placenta.
Methods and Materials: A total of 50 high risk pregnant patients (at least one caesarean section and low lying placenta) were included in the study. Ultrasound and MR imaging was performed. Specific Ultrasound and MR Imging features were evaluated. All patients were followed up to delivery for confirmation of diagnosis.Categorical variables were presented in number and percentage (%) and continuous variables were presented as mean ± SD and median. Normality of data was tested by Kolmogorov-Smirnov test. If the normality was rejected then non parametric test was used. A p value of <0.05 was considered statistically significant.
Results: Diagnostic accuracy of MR imaging was 94 % compared to 78 % for ultrasound Doppler. Both the modalities have similar high sensitivity (92.3 %). However MR imaging has better specificity (97%) compared to ultrasound Doppler (82 %). Most sensitive MR imaging feature is dark intraplacental band on T2 images. Most sensitive ultrasound Doppler imaging feature is intraplacental lacunae with turbulent flow.
Conclusion: All pregnant patients with previous caesarean section should be screened for low lying placenta in the first trimester. Ultrasound Doppler should be the initial modality for choice to diagnose adherent placenta. In equivocal cases MR imaging should be used as supplementary modality.

Fully automated assessment of HRCT images for follow-up of IPF

R. Rubtsov, L. Kehler, A. Giannakis, M. Kreuter, M. Eichinger, O. Weinheimer, K. Maier-Hein, H.-U. Kauczor, C.P. Heussel; *Heidelberg/DE (roman.rubtsov.med@gmail.com)*

Purpose: To quantify CT data using computer-aided diagnostic tool compared to pulmonary functional tests (PFT) longitudinally in patients with idiopathic pulmonary fibrosis (IPF).
Methods and Materials: 112 patients (M:F; 92:20) with IPF diagnosed through interdisciplinary approach, with either stable disease (n=73) or acute exacerbation (n =39) underwent 2 consecutive HRCT (6 months interval)."In-house" software, Lung Fibrosis Quantification Tool (LUFIT), based on a 3D-metamodel algorithm was used for fully automated lung segmentation and histograms analysis. Percentiles of lung histogram analysis, reflecting the amount of end-stage fibrosis (80th) and “ground-glass” (40th), derived from baseline HRCT and follow-up, were correlated to PFT and analysed according to Mann-Whitney.
Results: The strongest correlation was found between TLC measured by LUFIT and with body plethysmography (R2=0.95). Moderate negative correlations were observed between 80th and VCIN (-0.696) and DLCO SB (-0.649) in the "exacerbation-group"at baseline. In the stable group no relevant change of PFT or histogram parameters was found. In the "exacerbation" group 80th/40th percentile rise by 42/14 HU (p=0.0008/0.0047).
Conclusion: LUFIT proved to be accurate in quantifying the lung volume. In patients with exacerbation it detects the acute end-stage changes, developing in the course of the disease. Fully automated assessment of fibrosis extent and can be helpful as an additional tool in quantitative analysis of CT data in patients suffering from IPF.

B-0403 08:34

Quantitative prediction of malignancy on newly developed 3D computer-aided volumetry (CADv) with pulmonary nodule component evaluation on thin-section CT

Y. Ohno[1], A. Yaguchi[2], K. Aoyagi[3], S. Kaminaga[3], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1]; [1]*Kobe/JP*, [2]*Kawasaki/JP*, [3]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To evaluate the quantitative capability of newly developed 3D computer-aided volumetry (CADv) with pulmonary nodule component assessment for predicting malignancy and postoperative recurrence on thin-section CT.
Methods and Materials: 59 consecutive patients with 101 pulmonary nodules underwent repeated thin-section CT, pathological examination, surgical resection and/or follow-up examination. Then, all nodules were divided into malignant (n=64) and benign (n=37) nodule groups. In this study, CADv automatically assessed solid, ground-glass opacity, cavity and total nodule volumes from two serial CT data. Then, total volume change per day (TV/day), solid to total volume change ratio per day (S/T ratio/day) and doubling time (DT) were determined. Student’s t test was performed to compare all indexes between malignant and benign groups. Then, ROC analyses were performed to compare differentiation capabilities of indexes as having significant differences between malignant and benign groups. Finally, each diagnostic performance was compared by McNemar’s test.
Results: TV/day and DT had significant differences between malignant and benign nodule groups (p<0.05), although TV/day and S/T ratio/day had significant difference between recurrence and non-recurrence groups (p<0.05). On distinguishing malignant from benign groups, area under the curves (Azs) of TV/day (Az=0.94) was significantly larger than that of DT (Az=0.62, p<0.001). In addition, specificity (SP) and accuracy (AC) of TV/day were significantly higher than those of DT (p<0.001).
Conclusion: Newly developed 3D CADv system has quantitative capability for prediction of malignancy and postoperative recurrence on thin-section CT.

B-0404 08:38

Logistic regression analysis and a risk prediction model of tumour spread through air spaces (STAS) in patients with stage I lung adenocarcinoma

X. Wang; *Beijing/CN (oliverwxy_zz@sina.com)*

Purpose: Tumour spread through air spaces (STAS) is an important pattern of invasion and impacts the frequency and location of recurrence. The objective was to assess the correlation between STAS and metabolic tumour burden measured by PET/CT, and to establish a risk prediction model of STAS in patients with stage I lung adenocarcinoma.
Methods and Materials: We reviewed 121 consecutive patients. The standardised uptake value (SUV_{max}, SUV_{mean} and SUV_{peak}), metabolic tumour volume (MTV), total lesion glycolysis (TLG), diameter and computed tomography volume (CTV) were measured. All risk factors were analysed by multivariate logistic regression analysis; regression coefficients and odds ratios were calculated for independent risk factors. A STAS risk prediction model was created using the regression coefficients to determine the predictive probability (PP).
Results: There was significant difference of STAS distribution among different nodule types (P = 0.001). In the correlation analysis of STAS with the metabolic tumour burden parameters, SUVmax (P=0.020), SUVmean (P=0.002), SUVpeak (P=0.002) and TLG (P=0.004) were significantly correlated with STAS. MTV (P=0.721), diameter (P=0.480) and CTV (P=0.651) showed no significant correlation with STAS. The predictive probability of STAS and the incidence of STAS were analysed using the ROC curve (AUC = 0.749, P = 0.000). The sensitivity, specificity, and accuracy of the predictive model for STAS were 67.3%, 70.8% and 69.4%, respectively.
Conclusion: The predictive model developed was accurate in predicting the incidence of STAS. SUV and TLG were valuable predictive indices in the prediction of STAS.

B-0405 08:42

Quantitative MRI assessment of interstitial lung disease

M.T.A. Buzan[1], A. Wetscherek[2], C. Heussel[2], M. Kreuter[2], J. Dinkel[3]; [1]*Cambridge/UK*, [2]*Heidelberg/DE*, [3]*Munich/DE*

Purpose: To evaluate the contribution of advanced quantitative magnetic resonance imaging (MRI) in the assessment of interstitial lung disease (ILD).
Methods and Materials: We prospectively included 34 patients (mean age: 68 years; M:F, 1:1) with pathologically proven usual interstitial pneumonia (UIP) and nonspecific interstitial pneumonia (NSIP). All patients underwent thin-section multislice computed tomography (CT) and MRI of the lung at 1.5T. The MRI protocol included entire lung T2 mapping based on ECG-gated multi-echo single shot turbo spin-echo sequence (TE: 20, 40, 79, 140, 179 ms), and a contrast-enhanced radial-VIBE sequence with golden-angle spacing acquired during 5 minutes of free-breathing, followed by 5D reconstructions of the data. For this study, we used the end-expiratory phase. The CT images were used to assess the patterns and severity of lung fibrosis.
Results: The T2 relaxation of normal lung showed significant difference to pathological areas (p<0.001). The T2 relaxation time increased with the increase in fibrotic tissue density. UIP and NSIP regional patterns could not be differentiated by T2 relaxation times. T2 relaxation showed a significant statistical difference between active-inflammatory and stable-fibrotic NSIP. Both in severe and non-severe disease, there is later peak enhancement in idiopathic pulmonary fibrosis (IPF) compared to non-IPF, p<0.01. In non-IPF, the more severe lesions had longer time to peak and slower washout rate as compared to non-severe lesions, p<0.05.
Conclusion: MRI is a non-invasive, non-irradiating method that allows advanced, quantitative tissue characterization in ILD both in chronic and active states.

Primary and metastatic lung tumours treated with stereotactic body radiation therapy (SBRT): own experience

N. Martynova, N. Vorobyov, A. Mikhailov, J. Gutsalo, E. Smirnova, A. Kalesnik, G. Andreev, A. Kubasov, A. Lyubinskij; *St. Petersburg/RU (natlmartynova@gmail.com)*

Purpose: Assessing SBRT efficiency and toxicity for primary lung cancer and lung metastases.
Methods and Materials: In a period from 12.2011 to 02.2017, 71 patients with primary and metastatic lung tumours were treated. SBRT was applied to 103 tumours: 33 primary tumours and 70 metastases of different tumour sites. Two linear accelerators with different respiratory motion tracking systems (RMTS) were used: CyberKnife (CK) with Synchrony RMTS and TrueBeam STx (TB) with gating.
Results: Clinical observation group includes 52 patients with 81 lung tumours. Average tumour volume was 44.7 cc (0.2-496.5 cc). Observation median was 7 months. Local control (LC) was achieved in all cases, median of LC was 6

months. For 19 (23.5%) tumours complete response was achieved, median was 5 months. There was a local relapse in 17 (21%) cases, 15 of which were squamous cell relapse. There was discovered a negative linear dependence of local relapse probability from BED_{10} for squamous cell tumours. Disease progression was observed among 29 patients, 93% of them had a local control preserved during the whole observation period. TB demonstrated higher early toxicity rate than CK (19% vs 8%, p=0.01), grade 1-2 for most patients; 5 patients had grade 3 early toxicity. None of the patients had grade 4 early toxicity. Late toxicity did not exceed grade 2 for all the patients.
Conclusion: SBRT appears to be safe and effective treatment option for patients with lung lesions, including huge and central tumours. Potentially, higher radiation doses are needed to achieve better LC for squamous cell tumours.

B-0407 08:50

Diagnostic value of radiologic signs of pulmonary hypertension: pulmonary artery aortic ratio, pulmonary artery vertebral ratio and contrast regurgitation in hepatic veins

G. Zanirato Rambaldi, F. Niro, N. Galiè, M. Zompatori; *Bologna/IT (giuseppe.zanirato@gmail.com)*

Purpose: To assess the diagnostic value of pulmonary artery (PA) aortic ratio (PAr), PA vertebral ratio (VR) and regurgitation of intravenous contrast medium (CM) into hepatic veins (HVR) as predictors of pulmonary hypertension (PH).
Methods and Materials: We retrospectively reviewed clinical characteristics, CT scans, echocardiograms, and right-sided heart catheterization of patients with suspected PH undergoing angio-CT scan of PA between 2005 and 2013. The PA, aortic and anteroposterior vertebral diameter from the same CT image were measured. HVR was evaluated based on reflux of CM into hepatic veins. Linear and logistic regression were used to examine the relationships between CT studied parameters and PA systolic (PASP), diastolic (PADP), mean pressure (mPAP) and PA resistances (PAR) by invasive haemodynamics.
Results: 359 patients (96 with primary PH, 77 and 98 with, respectively, connective tissue diseases and congenital heart diseases: Eisenmenger syndrome associated PH and 88 without PH) were enrolled. PAr and VR correlated linearly with PASP, PADP, mPAP and PAR ($p<0.0001$). PAr > 1 is 63.3% sensitive and 85.4% specific (area under the ROC curve (AUC)=0.83) for PH. VR > 1.33 is 71.53% sensitive and 80.9% specific (AUC=0.84) for PH. In younger subjects (<58 years), AUC for PAr and VR was 0.91 (respectively, p=0.0020 and p=0.0004). HVR was 89.6% specific for tricuspid regurgitation and correlated with increased PAP and PAR.
Conclusion: PAr, VR and HVR correlate with haemodynamic dysfunctions in PH, PAr > 1.07 and VR > 1.33 are valid predictors of possible PH, especially in subjects < 58 years old.

B-0408 08:54

Application of high-pitch scanning mode in low-dose lung-computed tomography screening for patients with chronic obstructive pulmonary disease: a pilot study

C. Li, M. Li, L. Jin; *Shanghai/CN (licheng3456@sohu.com)*

Purpose: This study was performed to evaluate the performance of high-pitch scanning mode in computed tomography (CT) examination of chronic obstructive pulmonary disease (COPD).
Methods and Materials: Chest CT scans were performed in 300 patients clinically diagnosed with COPD before which the subjects were divided into 3 experimental groups and 2 control groups; Siemens sensation 16 was employed to perform spiral CT scanning for experimental group 1, a GE lightspeed VCT was used for experimental group 2, a Siemens definition flash was used for experimental group 3, with the parameters of 100kV and automatic mAs and different pitch.
Results: The average of lung parenchyma CT in experimental group 3 was -918.18±6.57, which was significantly different from the other 4 groups ($P<0.001$). There was no significant difference between control groups 1, 2 and experimental groups 1, 2 ($P>0.05$), but the experimental group 3 was significantly different from those of the remaining groups ($P<0.001$).
Conclusion: The application of a high-pitch scanning mode for patients with COPD can effectively reduce their breath holding time, prevent complications, and reduce motion artefacts. As such, the approach has great scanning performance and is promising for clinical applications.

B-0409 08:58

Morphological study of blood vessels near lung tumour by the 3D quantitative CT technique

Y. Li, Y.-l. Dai, Y.-m. Guo; *Xi'an/CN (yuyanyan_zi@126.com)*

Purpose: The effect of non-enhanced CT on the changes of vascular morphology in lung cancer is investigated. A 3D quantitative CT measurement method based on differential geometry algorithm was found to be suitable for the morphological study of blood vessels adjacent to lung tumour.
Methods and Materials: Lung cancer ipsilateral and contralateral pulmonary vascular changes were assessed by the routine visual examination and FACT-digital lung TM quantitative CT measurement software. This study included 162 patients with lung cancer and 178 healthy subjects. All cases of lung cancer were confirmed by pathology. The number of blood vessels and area of blood vessels normal to cross sections of 5/6-generation bronchioles were selected as pulmonary vascular morphological parameters.
Results: The visual method has revealed the ratio of ipsilateral pulmonary vascular abnormalities in lung cancer (151/162) to be less than that of quantitative CT (162/162). The visualization time required to determine pulmonary vascular abnormalities (3.2 ± 1.5 min) exceeded that of quantitative CT measurements (2.5 ± 1.3 min) for $P<0.05$. According to quantitative CT measurements, the number and area of pulmonary blood vessels in the ipsilateral lung cancer exceeded those in the contralateral side and in the control group (P = 0.00, 0.00).
Conclusion: A fully automated quantitative CT measurement method was successfully applied to the identification of pulmonary blood vessels and quantitative measurements of morphological changes of blood vessels near lung tumour.

B-0410 09:02

IPF: diagnosis and follow-up using CT fibrosis score, correlation with clinical and functional data in a cohort of patients in therapy with pirfenidone or nintedanib

S. Riva, G. Guzzardi, M. Barini, M. Valenti, A. Carriero, M. Pelle; *Novara/IT (silviariva.riva@gmail.com)*

Purpose: The aim of this study was to evaluate the utility of a VISUAL CT-FIBROSIS SCORE in evaluation of extension of usual interstitial pneumonia (UIP) and in the 12-month follow-up after the start of antifibrotic therapy with pirfenidone or nintedanib.
Methods and Materials: Since 2015, in our institute 15 patients have received IPF diagnosis on the basis of clinical and radiological data. The inclusion criteria was only the radiological diagnosis of UIP DEFINITE. For each patient a CT-FIBROSIS SCORE (as suggested by previous experiences in the literature as those of Ichikado, Ley and Sverzellati) was calculated and the value of diffusing capacity of the lungs for carbon monoxide (DLCO) was collected, which correlates with the progression of the disease, at diagnosis and follow-up. We used McNemar's test for the correlation between CT-FIBROSIS SCORE and DLCO.
Results: The assigned FIBROSIS SCORE score was measured in absolute terms within the sample a minimum value of 123.3 and a maximum of 238.3. The mean DLCO value at diagnosis was 46.24 and at the follow-up of 40.75. McNemar's test showed a statistically significant difference between evolution over time of the FIBROSIS SCORE parameter and the clinical-instrumental parameter of the DLCO. The value of p, returned by the application of this test, was in fact above 0.05, resulting in 0.7.
Conclusion: The interpretation of the statistical result allows us to assert that there is a correlation between the score of fibrosis and the performance of the DLCO.

B-0411 09:06

Pulmonary embolism-induced perfusion defects on iodine maps: quantitative comparison of dual-energy CT and subtraction CT

D. Grob[1], L.J. Oostveen[1], M.M. Prokop[1], C. Schaefer-Prokop[2], I. Sechopoulos[1], M. Brink[1]; [1]*Nijmegen/NL*, [2]*Amersfoort/NL (Dagmar.Grob@radboudumc.nl)*

Purpose: To compare signal-to-noise ratios for pulmonary embolism-induced perfusion defects on iodine maps derived from dual-energy CT (DECT) and subtraction CT (SCT).
Methods and Materials: We recruited 27 consecutive patients diagnosed with acute PE from a prospective trial for comparison of DECT and SCT, in which 100 kV unenhanced scans and 140/100 kV DECT pulmonary angiography had been performed in patients with suspected PE. We included all perfusion defects seen on DECT in which there was an acute segmental PE with ≥75% vascular obstruction but no emphysema or consolidation present. Noise was measured on the iodine maps as the standard deviation in normal parenchyma. Signal was defined as the enhancement difference between the perfusion defect and the surrounding normal parenchyma in a triangular region of interest. Signal-to-noise ratios (SNRs) were compared for iodine maps derived from DECT and SCT using a Wilcoxon signed test.
Results: Median dose-length product was 154 mGy·cm for SCT and 162 mGy·cm for DECT. Noise was not significantly different between the two (p=0.86). Seventy perfusion defects in 45 lungs were included. The average SNR was 18.5 for SCT and 16.9 for DECT (p=0.09). Significant differences in SNR were only found in perfusion defects in the upper lobes, with an average SNR of 22.0 for SCT and 18.1 for DECT ($p<0.05$).
Conclusion: At similar radiation dose, perfusion defects on subtraction CT show similar or higher SNR than those on dual-energy CT. This implies that SCT is a viable alternative to DECT for depicting perfusion defects.

Advantages of spectral CT in staging of patients with non-small cell lung cancer (NSCLC)

U. Fehrenbach[1], K. Merz[1], G. Böning[1], J. Kahn[1], F. Feldhaus[1], M.H. Maurer[2], D. Renz[3], B. Hamm[1], F. Streitparth[1]; [1]*Berlin/DE*, [2]*Berne/CH*, [3]*Jena/DE (uli.fehrenbach@charite.de)*

Purpose: Imaging of NSCLC is based on morphological criteria in contrast-enhanced CT studies. Spectral CT(SCT) offers additional information by specific SCT values. We evaluated the SCT values' usefulness in staging of lung cancer patients.
Methods and Materials: 116 patients with confirmed NSCLC were included in a prospective cohort study. All patients received a single-phase contrast-enhanced SCT (80kV/140kV). SCT values (iodine content(IC), spectral slope pitch(k) and quantitative HU increase) of tumor tissue (primaries and metastases) and lymph nodes(LN) were acquired. Adrenal masses(AM) were evaluated in virtual native series(VNS). Additional lung structure changes were analyzed as secondary findings.
Results: 52 non-treated NSCLC primary tumors were sufficiently measurable. Adenocarcinoma showed significantly higher normalized IC than squamous cell carcinoma (18,8vs12,0;p=0,035). 126 LN were analyzed and metastases showed significantly lower IC and k than benign LN (20,8vs25,8;p=0,023;1,6vs2,5;p=0,000). Tumors in local control after radiochemotherapy showed significant lower IC in hot spot analysis than tumors in progressive disease (4,27vs2,06;p=0,000). In 34 AM, VNS identified adenomas with high sensitivity and specificity (96%,100%). Pulmonary metastases showed no significant differences to benign lung nodules (p=0,18-0,76). Secondary findings of atelectasis, pneumonia, scar tissue and pleural effusion showed heterogeneous IC. In 2 patients a perfusion defect through pulmonary embolism could be visualized.
Conclusion: SCT and its specific values may support the differentiation between histological NSCLC subtypes and may improve the identification of LN metastases. It can also improve evaluation of tumor response after radiochemotherapy. With VNS, adrenal adenomas can be differentiated to metastases. Pulmonary perfusion defects can be visualized in iodine maps.

B-0413 09:14

Longitudinal airway remodeling in active and past smokers in a lung cancer screening population

T.D. Buschulte, M.O. Wielpütz, B.J. Jobst, M. Trauth, J. Tremper, O. Weinheimer, S. Delorme, N. Becker, H.-U. Kauczor; *Heidelberg/DE (T.Buschulte@gmx.de)*

Purpose: Little is known on the longitudinal changes of airways on computed tomography (CT) depending on smoking status. Thus, we assessed CT-based airway metrics by quantitative post-processing repeatedly over a period of 4y in a group of heavy smokers.
Methods and Materials: CT scans in a lung cancer screening program were performed for 4y at 12mon intervals in 284 long-term ex-smokers (ES), 405 continuously active smokers (CS), and 31 subjects who quitted smoking during 2y after baseline CT (recent quitters, RQ). CT were evaluated by airway analysis software, computing the total diameter (TD), luminal area (LA) and wall percentage (WP) from 5th-8th airway generation.
Results: At all time points, TD and LA were significantly higher in ES compared to CS, for example at baseline with 6.24mm vs. 5.93mm ($p<0.001$) and 15.23mm² vs. 13.51mm² ($p<0.001$), respectively. RQ also showed a tendency towards higher TD (6.15mm vs. 5.93mm, n.s.) and significantly higher LA (14.77mm² vs. 13.51mm², $p<0.001$) than CS after 3y, and also after 4y. Smoking status independently predicted TD, LA, and WP at baseline as well as at 3y and 4y follow-up ($p<0.01$-0.001) in a multivariate analyses, with a stronger impact than pack years.
Conclusion: Bronchial narrowing and wall thickening depend on the smoking status. Smoking-induced airway wall inflammation may partially be reversible after smoking cessation even in heavy smokers at risk of COPD. Therefore quantitative CT-based airway metrics within clinical trials should consider the current smoking status instead of pack years only.

B-0414 09:18

Bronchial wall changes after thermoplasty in the treatment of severe asthma: CT scan assessment at 3 months

Y.W. Kim[1], M.P. Debray[2], C. Fetita[3], O. Fouque[1], M. Aubier[2], P.-Y. Brillet[1]; [1]*Bobigny/FR*, [2]*Paris/FR*, [3]*Evry/FR (wouk1805@gmail.com)*

Purpose: Our goal is to assess by CT scan bronchial wall changes induced by thermoplasty, an endoscopic technique aiming at reducing airway smooth muscle mass.
Methods and Materials: This prospective study included 24 patients with severe asthma. For each bronchus, airway lumen area (LA), wall area (WA) and WA as a percentage of total bronchial area (WA%) were automatically generated from CT acquisitions by the software BronCare, before (M0) and after (M3) treatment. The measures were confronted to functional data and asthma control.
Results: After treatment, LA remained unchanged. By contrast, WA and WA% increased at M3 (M0/M3: 16.7/19.0 mm² for WA and 63.7/66.7% for WA%; $p<0.0001$). These variations were correlated to pre-thermoplasty values, with a negative linear correlation ($r>0.7$, $p<0.0001$). The less thick bronchi tended to thicken more. The importance of this effect differed between patients ($p=0.0004$ for WA%). Thereby, the patients could be split into two clusters in relation to WA and WA% pre-thermoplasty values, their modifications after treatment and patient's height ($p<0.0046$). The clusters did not differ according to other initial clinical data or follow-up events.
Conclusion: Bronchial thermoplasty results in bronchial structural changes, reflecting a residual inflammation and might be adjusted to patient's morphotype.

B-0415 09:22

Optimisation of a chest CT protocol for the detection of ground glass opacity nodules: feasibility study with a computer-assisted detection system and a lung cancer screening phantom

S. Kang, T.H. Kim, I.K. Park, C.H. Park; *Seoul/KR (smkang13@gmail.com)*

Purpose: To optimise computed tomography (CT) parameters for the detection of ground glass opacity nodules (GGNs) using a computer-assisted detection (CAD) system and a lung cancer screening phantom.
Methods and Materials: A phantom containing GGNs (–600 HU) was examined with a 256-row multi-detector CT scanner. Three tube voltages (120, 100, 80kVp) were used in combination with five tube currents (400, 200, 100, 50, 25mA); three slice thickness (0.625, 1.25, 2.5mm); and four different reconstruction algorithms (ASIR-V) of 0, 30, 60, 90. For each protocol, the accuracy of the CAD system was evaluated for the 6 target GGNs that were 8, 10, or 12mm in size.
Results: Among the 180 combinations of CT parameters, 80kVp, 200mA, and 1.25mm had the best performance with 6 true positives (TP) and no false positives (FP). For 80kVp, 400mA, 1.25mm, there were 5TP, 1FP; and 100kVp, 100mA, 1.25mm had 4TP and 1FP; while 100kVp, 50mA, 1.25mm had 4TP and 1FP; and 120kVp, 25mA, 1.25mm had 4TP and 3FP. (All above combinations were with ASIR-V of 90.) Other combinations had fewer than 3TP and especially any combinations with a 0.625mm had 0TP and at least 1FP result.
Conclusion: Chest CT at low voltage with thin slice thickness and high iterative reconstruction algorithm might improve the detection rate of a CAD system for small GGNs in lung cancer screening.

B-0416 09:26

Diagnostic ability of the primary lung cancer by radiologists with chest x-ray

R. Nishino[1], H. Numasaki[2], N. Minamoto[1], S. Nakai[1], T. Uchigashima[1], A. Takahashi[1], S. Ehara[1], M. Sakai[1], S. Takashima[1]; [1]*Suita/JP*, [2]*Osaka/JP (u686321c@ecs.osaka-u.ac.jp)*

Purpose: The purpose of this study was to determine the factors that influence the diagnostic ability of pulmonary nodules with chest x-ray (CXR) and to assess the factors that influence the confidence on the diagnosis of the nodules that were correctly detected.
Methods and Materials: Five chest radiologists interpreted chest radiographs (non-nodule images: 200 and nodule images; 200 (subsolid nodule: 95 and solid nodule; 105)), and diagnostic ability was assessed using localized receiver operating characteristics (LROC) analysis. For nodule group, we studied statistical differences between the correctly diagnosed group and incorrectly diagnosed group in 9 factors, and assessed the factors that influence the diagnostic ability using logistic regression analysis. For the correctly diagnosed group, we performed statistical tests in 9 factors, and assessed the factors that influence the confidence on the diagnosis using multiple regression analysis.
Results: The mean area under the LROC curves was 0.73 ± 0.015 (accuracy: 70.3%, sensitivity: 48.7% and specificity: 91.9%). On logistic modeling, CT value of the nodule, diameter of the nodule and the overlap with other

structures were common significant factors for 5 radiologists. On multiple regression analysis, the overlap with other structures was common significant factor for 5 radiologists.
Conclusion: The significant factors that influence the diagnostic ability of CXR for primary lung cancer were CT value of the nodule, diameter of the nodule and the overlap with other structures. The significant factor that influences the confidence on the diagnosis of the nodules that were correctly detected was the overlap with other structures.

B-0417 09:30

Salivary gland tumours in the central airway: the comparison of CT features between adenoid cystic carcinoma and mucoepidermoid carcinoma

Y. Deng, Q. Zeng, X. Wu, X. Li, W. Luo; *Guangzhou/CN (hotden_1@hotmail.com)*

Purpose: To compare the CT features between adenoid cystic carcinoma (ACC) and mucoepidermoid carcinoma (MEC) in the central airways.
Methods and Materials: This retrospectively study complying with HIPAA was approved by Institutional Review Board. A total of 10 patients with ACC (7 females, 3 males; median age, 33 years; age range, 21 to 59 years) and 9 patients with MEC (7 females, 2 males; median age, 21 years; age range, 15 to 37 years), who underwent contrast-enhanced CT before surgery or biopsy, were identified and included. The CT features of the tumour including location, maximum diameter, growth pattern, and enhancement were evaluated . The difference of tumour location and growth pattern between ACC and MEC was compared using Chi-squared test. The difference of maximum tumour diameter, enhancement between ACC and MEC were compared using Mann-Whitney U test.
Results: 8 of 10 ACC (80%) origin from trachea, while 2 of 9 MEC (22%) origin from trachea (p=0.04). 9 of 10 ACC (90%) and 3 of 9 MEC (33%) exhibited infiltrative growth pattern, while 1 of 10 ACC (10%) and 6 of MEC (67%) exhibited expansile growth pattern (p=0.04). There was no difference of maximum tumour diameter between two subtypes (p=0.762). The MEC showed significant greater enhancement than ACC (MEC: median, 62 HU; 25^{th}-75^{th} percentile, 55-67 HU; ACC: median, 30 HU; 25^{th}-75^{th} percentile, 26-37 HU; p=0.002).
Conclusion: ACC and MEC in the central airways has distinct CT features including the location, growth pattern and enhancement.

B-0418 09:34

Early residual tumour differentiation from benign periablational thermal injury after radiofrequency ablation by spectral analysis with dual-energy computed tomography

L. Yuekao; *Shi Jiazhuang/CN (64502240@qq.com)*

Purpose: To investigate the applicative value of dual-energy computed tomography (DECT) spectral analysis on the quantitative assessment of residual tumour after radiofrequency ablation.
Methods and Materials: With CT-guided percutaneous tumour tissue inoculation, we established rabbit VX2 tumour model and incomplete tumour ablation model. Triple-phase contrast-enhanced DECT data on 24 rabbits with VX2 carcinoma then were assessed at day 3 (n=6), 1 week (n=6), 2 weeks (n=6) and 3 weeks (n=6) after incomplete RFA independently by two readers. Under different KeV values, we determined the average CT value of the area of interest and the plot of spectra and compared the differences between the residual tumour and inflammation. The pathologic specimens were sectioned in the same plane as DECT imaging.
Results: With CT-guided percutaneous tumour tissue inoculation, we established a rabbit VX2 tumour model and an incomplete tumour ablation model. Triple-phase contrast-enhanced DECT data on 24 rabbits with VX2 carcinoma then were assessed at day 3 (n=6), 1 week (n=6), 2 weeks (n=6) and 3 weeks (n=6) after incomplete RFA independently by two readers. Under different KeV values, we determined the average CT value of the area of interest and the plot of spectra and compared the differences between the residual tumour and inflammation. The pathologic specimens were sectioned in the same plane as DECT imaging.
Conclusion: Spectral curve with DECT might help in differentiating benign periablational reactive tissue from residual tumour in VX2 carcinoma in rabbits after RF ablation.

B-0420 09:38

Assessment of survival in patients with idiopathic pulmonary fibrosis using Kurtosis and mean lung density HRCT indexes

A.G. Torcitto[1], D. Falsaperla[1], S.E. Torrisi[1], L.A. Mauro[1], M. Pavone[1], G. Russo[2], A. Stefano[2], C. Vancheri[1], S. Palmucci[1]; [1]*Catania/IT*, [2]*Cefalù/IT (alfre.84@katamail.com)*

Purpose: To investigate the diagnostic accuracy of Kurtosis and Mean Lung Density (MLD) in the assessment of survival in a cohort of patients with Idiopathic Pulmonary Fibrosis (IPF).
Methods and Materials: 42 patients with IPF diagnosis and a minimum follow-up time of 3 years were retrospectively collected; HRCT and pulmonary function tests (FVC and DLCO) performed at diagnosis time were analysed; the extent of fibrotic disease was quantified on HRCT using Kurtosis, MLD, percentage of HAA and Fibrotic areas. Patients were divided into 3 groups according to Kurtosis value (kurtosis index <3, 3-4 and >4) and according to MLD (MLD <-800, between -800 and -750, >-750). Survival analysis was performed according to these variables. Correlations between kurtosis and MLD indices and pulmonary function tests were also performed using Spearman's Rank correlation.
Results: Significant survival differences were found according to the kurtosis values (p=0.002) and MLD value (p=0.003) obtained from HRCT quantitative evaluation at the diagnosis time. Spearman's Rank correlation analysis showed also a positive correlation between kurtosis value and FVC (r=0.57, p=0.0001); a positive correlation between kurtosis value and DLCO (r=0.52, p=0.0004); a negative correlation between MLD value and FVC (r=-0.53, p=0.0003); a negative correlation between MLD value and DLCO (r=-0.41, p=0.0069).
Conclusion: Kurtosis index and MLD value may provide an accurate estimation of survival in a population of IPF patients from the time of diagnosis. These HRCT-derived indices demonstrate also a correlation with common pulmonary function values (FVC and DLCO) pointing out their possible use in clinical practice.

B-0421 09:42

Volumetric analysis of intravoxel incoherent motion diffusion-weighted MRI in predicting the invasiveness of non-small cell lung cancer

J. Jiang[1], L. Cui[2], Y. Fu[1], G. Xu[1]; [1]*Yancheng/CN*, [2]*Nantong/CN (1021809719@qq.com)*

Purpose: To investigate the value of intravoxel incoherent motion (IVIM) parameters D, D*, f and apparent diffusion coefficient (ADC) in preoperative prediction of tumour grade, lymph node metastasis and pleural invasion in non-small cell lung cancer (NSCLC) patients.
Methods and Materials: 39 surgically-diagnosed NSCLC patients (39 lesions) were enrolled in this study and underwent free-breathing DWI and IVIM (10 b-values, 0-1000 s/mm^2) scans one week before the operation on a Siemens 3T MRI. ADC_{mean}, ADC_{min}, D, D* and f values were independently calculated by volumetric region of interest (ROI) by 2 observers. Inter-observer reproducibility was assessed. Differences of these parameters in tumors with different differentiation degree, with or without lymph node metastasis, and with or without pleural invasion were compared. Receiver operating characteristic (ROC) curves were generated to determine the diagnostic performance.
Results: Good inter-observer reproducibility was seen in all parameters except D*. D and ADC_{min} were significantly lower in poorly differentiated lung cancer (P<0.001 and 0.001, respectively) and so was D in patients with lymph node metastasis (P=0.010). While in patients with pleural invasion, D was significantly lower and f was significantly higher (P=0.017 and 0.005, respectively). According to ROC curve analysis, highest values of area under the curve (AUC) appeared when predicting tumor grade and lymph node metastasis with D (0.858, 0.761) and predicting pleural invasion with f (0.766).
Conclusion: IVIM diffusion parameter D can better predict tumor grade and lymph node metastasis whereas IVIM perfusion fraction f can better predict pleural invasion before operation in NSCLC patients.

Potential ketamine-related cholangitis in severely ill burn patients: liver imaging features

M. Hajji, C. De Tymowski, P. Bourrier, V. Mallet, A.M. Zagdanski, M. Legrand, E. De Kerviller; *Paris/FR (hajjimaha1989@gmail.com)*

Purpose: The French national drug agency (ASM) has recently issued a warning regarding potential ketamine-related liver toxicity in burn patients, with cases of severe liver cholestasis. Our aim was to describe the radiological pattern of biliary tract abnormalities in this setting.
Methods and Materials: We included patients admitted in the St-Louis burn unit between 2012 and 2017 with liver cholestasis (Alkaline phosphatase and Gamma-glutamyltransferase more than 1.5N) and treated with intravenous ketamine. Liver imaging was analyzed for potential signs of bile duct abnormalities. Among 154 patients with liver imaging,116 had scanner, 45 had US, and 10 had liver MRI.
Results: Liver imaging was most of times found normal except for hepatomegaly (n=15). Seven patients had cholangitis images with diffuse enlargement of intra and extra-hepatic bile ducts and abnormal heterogeneous intra-luminal material in bile ducts (fig). . In 3 cases, small satellite abscesses were noticed. They received cumulative high doses of ketamine (mean 122 g [min 62-max 221g] during their hospitalization. They had a severe biological cholestatsis = 5time N . Liver biopsies showed an aspect of cholangitis with overloaded bile without ischemic lesions in one patient and portal-lobular fibro-inflammatory lesions in another.
Conclusion: In severely ill burn patients receiving very high doses of ketamine, we observed bile duct images featuring cholangitis together with intra-luminal heterogeneous abnormal material. Imputability and mechanisms of liver toxicity of ketamine still requires further exploration. In the meantime, radiologist should specifically search for such features in patients exposed to high doses of ketamine.

B-0423 10:38

Gd-BOPTA excretion MRI analysis in patients with compromised and non-compromised bile ducts

M. Shorikov, M. Lapteva, P. Polyakov, D. Frantsev, O.N. Sergeeva, B. Dolgushin; *Moscow/RU (mglapteva@inbox.ru)*

Purpose: Magnetic resonance contrast agent (MRCA) Gd-BOPTA demonstrated dual excretion either by liver or kidneys. As it was previously shown in obstructive jaundice models, a bile duct ligation in the rodents significantly reduced the liver-to-kidneys excretion ratio compared to that in the animals after sham procedure. MRI assessment of the hepatic function based on Gd-BOPTA excretion shift is attempted in the study.
Methods and Materials: 25 patients that had MRI-examination with Gd-BOPTA in period 2015-2016 showing normal total serum bilirubin level were included in the study: 15 patients with cholestatic liver diseases (14-Klatskin tumour,1-primary sclerosing cholangitis) after biliary decompression (group 1) and 10 patients without cholestasis(10-metastatic neuroendocrine tumours, group 2). They were studied on 1.5T MRI system. MRCP was also done in all the cases. T1VIBE-images were acquired before/after (arterial, portal, venous, delayed (1, 20, 40 minutes) phases) 10ml Gd-BOPTA i.v.injection. One patient from group 1 had an additional study with 7.5ml of Gd-DTPA a month later; T2WI, DWI+ADC-maps were also evaluated in this patient for liver fibrosis detection.
Results: Endobiliary Gd-BOPTA was registered in 3/10 patients in group 1 and in all group 2. Maximal diameter of bile duct correlated to SI (liver) at 20, 40min (r^2=0.9, p<0.002). SI(liver)/SI(kidney) was significantly lower in group 1 compared to group 2 (p<0.02) at 20, 40min phase. Additionally in patient who had two studies with different MRCAs: 1)Gd-BOPTA: SI(liver)/SI(kidney) for segment with signs of liver fibrosis was lower than SI(liver)/SI(kidney) for segment without fibrosis (p<0.05); 2) Gd-DRPA: the ratio for segments was not significantly different (p>0.05) and higher than in case of the Gd-BOPTA injection (p<0.05).
Conclusion: Patients with cholestatic liver diseases demonstrated Gd-BOPTA excretion shift even after biliary decompression and serum bilirubin normalisation.

B-0424 10:46

Spectral CT and cholesterol content in gallbladder stone

E. Danse[1], N. Joudiou[1], G. Muccioli[1], N. Michoux[1], J. Collart[1], C. Hubert[1], A. Vlassenbroeck[2], B. Gallez[1], E. Coche[1]; [1]*Brussels/BE*, [2]*Eindhoven/NL (etienne.danse@uclouvain.be)*

Purpose: To assess whether dual energy CT measurements can predict the percentage of cholesterol in gallstones taking spectro-MR as reference.
Methods and Materials: In 18 patients operated for symptomatic gallbladder stone, the removed stones were evaluated in vitro using a spectral MDCT (IQon, Philips Healthcare, Cleveland, OH). These specimens were evaluated in the Biomedical MRI research lab with a Spectro-MR system, to assess the presence and the amount of cholesterol and Calcium respectively. Correlation between spectro-MR measurements and CT data was assessed using Spearman rank correlation coefficient. Relationship between CT attenuation (HU) and MR measurements was investigated for different voltages (40kVp, 70kVp, 80kVp and 200kVp) using linear regression. The correlation between effective atomic number (Zeff) and MR measurements was also investigated.
Results: The proportion of the variation in the dependent variable ($\%^{cholesterol}$) explained by the regression model was found to be high at 40kVp (Equation: $\%^{cholesterol} = 56.4 - 0.15*HU$, $p^{intercept} < 0.0001$, $p^{slope} = 0.0001$, coefficient of determination $R^2_{40kVp} = 0.76$). A linear model was found to describe well the relationship between Z_{eff} and the cholesterol content determined by RMN (Equation: $\%^{cholesterol} = 192 - 21.0*Z_{eff}$, $p^{intercept} < 0.0001$, $p^{slope} < 0.0001$, coefficient of determination $R^2 = 0.73$).
Conclusion: At 40kVp, a linear model explains the relationship between the density of the stones measured in Hounsfield unit and the % of cholesterol in the stones measured in MR. Additionally, the Z number allows predicting the content in cholesterol within the stones.

Is cross-sectional imaging predictive of difficult hepatectomy in patients undergoing liver transplantation?

R. Girometti, D. Iorenzin, L. Montaldo, G. Como, A. Risaliti, C. Zuiani; *Udine/IT (rgirometti@sirm.org)*

Purpose: Dissecting the inferior vena cava (IVC) from the dorsal sector (DS) of the recipient's liver is a major cause of difficult hepatectomy (DH) in orthotopic liver transplantation (OLT). We investigated whether DS morphology is associated with DH (primary end point) or early postoperative complications (EPOC).
Methods and Materials: We retrospectively included 67 patients who underwent preoperative 64-raw multidetector (CT) (n=57) or 1.5T magnetic resonance imaging (MRI) (n=10) before OLT. Two radiologists in consensus calculated the volume of the liver dorsal sector (V-LDS, including Couinaud segments I and IX), volume of caudate lobe (V-CL), degree of IVC encirclement (E-IVC), length of IVC-DS contact (L-IVC-DS), and caudate lobe-to-right lobe ratio (CL/RL). Imaging findings, clinical and operative features (including sex, age, aetiology of cirrhosis, model end-stage liver disease (MELD), IVC-related operative times, packed red blood cells and fresh frozen plasma) were entered into a logistic regression model to identify predictors of the study end points.
Results: DH and EPOC occurred in 19/67 (28.4%) and 15/67 patients (19.7%), respectively. On multivariate analysis, no imaging, clinical or operative features were predictors of DH (p>0.05), while a V-LDS <33.6 cm^3, V-CL <15.0 cm^3, and CL/RL <0.75 were found to be significant (p<0.05) protectors from EPOC (OR 0.08, 0.03 and 0.13, respectively). On receiving operating characteristic (ROC) analysis, the sensitivity/specificity for DH and POC of V-DLS, V-CL and CL/RL were 0.65/0.63, 0.70/0.51 and 0.70/0.4 for DH, and 0.46/0.71, 0.73/0.56 and 0.86/0.57 for EPOC.
Conclusion: While having no role in predicting DH, liver DS morphology can help in the preoperative stratification of the risk of EPOC.

B-0426 11:02

Improved visualisation of hepatic metastases in gadoxetate disodium-enhanced MRI: potential of contrast-optimised (phase-sensitive) inversion recovery imaging

U.L. Fahlenkamp, L.C. Adams, S.M. Böker, G. Engel, M. Huynh Anh, M. Wagner, B. Hamm, M.R. Makowski; *Berlin/DE (ute.fahlenkamp@charite.de)*

Purpose: To investigate the potential of a contrast-optimised (phase-sensitive) inversion recovery (IR) MR imaging technique in gadoxetate disodium-enhanced scans for detection of hepatic metastases.
Methods and Materials: The institutional review board approved this prospective study. After written informed consent, 31 patients (16 male, 15 female) with suspected or known hepatic metastases were examined on a 1.5 T MR system 20 minutes after administration of 10 ml gadoxetate disodium. A single-breath-hold T1-weighted gradient-echo volumetric-interpolated-breath-

hold (VIBE) sequence was acquired as part of the standard clinical imaging protocol. In addition, a contrast-optimised (phase-sensitive) IR sequence was acquired with an inversion time (TI) adjusted for optimal suppression of signal from metastases compared to surrounding liver parenchyma. In both sequences, number of metastases and lesion-to-liver contrast (LLC) was assessed.
Results: Overall, 302 liver metastases were identified in the investigated patient collective (n=31). A significantly ($p \leq 0.05$) higher LLC was measured on contrast-optimised (phase-sensitive) IR sequences (0.79 ± 0.13) compared to VIBE sequences (0.40 ± 0.17). Detection rate for metastases ≤ 0.5 cm was significantly higher ($p \leq 0.05$) based on (phase-sensitive) IR (n=106/117) compared to standard VIBE sequence (n=88/117). Detection rate for metastases > 0.5 cm was comparable ($p > 0.05$) between both sequences. Size measurement revealed a slightly larger lesion size (1.14 ± 0.80, $p \leq 0.05$) of the metastases on (phase-sensitive) IR images compared to T1 VIBE.
Conclusion: Contrast-optimised (phase-sensitive) IR MR imaging improves the detection of small hepatic metastases in gadoxetate disodium-enhanced scans compared to a conventional T1 gradient-echo VIBE sequence.

B-0427 11:10

CT-based liver surface nodularity quantification for the detection of clinically significant portal hypertension in cirrhotic patients
R. Sartoris[1], V. Vilgrain[2], P.-E. Rautou[2], M. Ronot[2]; [1]*Genoa/IT*, [2]*Clichy/FR (riccardo.sartoris@hotmail.it)*

Purpose: To evaluate the diagnostic performance of non-invasive liver surface nodularity (LSN) quantification derived from CT images for the diagnosis of clinically significant portal hypertension (CSPH), with respect to hepatic venous pressure gradient (HVPG) and to compare it with other non-invasive measures and derived scores.
Methods and Materials: 203 cirrhotic patients [(mean 58±10 years, women: 119); 102 of them with CSPH] with valid HVPG measurement and abdominal CT within 60 days were selected. Transient elastography (fibroscan) was performed in 91 patients. LSN was measured by drawing a ROI over the liver edge and the software calculated the margin irregularity. LSN and derived scores (LSN x spleen diameter and LSN/platelet count) were compared with other common non-invasive measures including liver-to-spleen volume, platelet count/spleen diameter, liver stiffness, PH-risk score and LSPS score.
Results: LSN valid measures were obtained in 189 patients (93.1%). LSN was significantly correlated with HVPG ($r=0.75$; $p< 0.001$). Patients with CSPH had a significantly higher LSN score (3.22±0.59 vs 2.44±0.34; $p<0.001$), with AUROC of 0.884±0.03. Cut-off value of 2.76 allowed identifying CSPH with sensitivity, specificity, PPV and NPV of 80%, 87%, 88% and 79%. AUROC of LSN was significantly higher than that of all other non-invasive tests (all $p<0.001$).
Conclusion: CT-based non-invasive LSN quantification is effective for the detection of patients with CSPH, with higher diagnostic performance than other non-invasive measurements and could improve the detection of CSPH.

B-0428 11:18

Improvement of diagnostic image quality of abdominal CT using a deep learning-based reconstruction: initial clinical trial targeting hepatic metastases
Y. Nakamura[1], T. Higaki[1], F. Tatsugami[1], J. Zhou[2], Z. Yu[2], N. Akino[3], Y. Ito[3], M. Iida[1], K. Awai[1]; [1]*Hiroshima/JP*, [2]*Vernon Hills, IL/US*, [3]*Ōtawara/JP*

Purpose: We developed a new reconstruction method which could generate better image quality CT image using a deep learning-based reconstruction (DLR) trained by teaching dataset of higher dose CT image reconstructed with model-based iterative reconstruction. The purpose of this study was to confirm clinical feasibility of our method compared with conventional hepatic CT images targeting hepatic metastases.
Methods and Materials: We evaluated 51 hepatic metastases from colorectal cancer in 17 patients. A radiologist measured standard deviation of the attenuation measured in the paraspinal muscle as image noise, and calculated contrast-to-noise ratio (CNR) = $(ROI_L\text{-}ROI_T)/N$, where ROI_L is the mean attenuation of the liver parenchyma, ROI_T is the mean attenuation of the tumour, and N is noise. Each liver lesion was reviewed independently by other two radiologists and graded on a 5-point confidence scale ranging from 1 = cannot identify to 5 = can detect lesion without diagnostic compromise. The difference between conventional CT processed with hybrid iterative reconstruction (hybrid-IR) and CT processed with our new method using DLR was determined.
Results: Image noise was significantly lower on images with DLR compared to hybrid-IR (p<0.01). In addition, CNR on images with DLR was significantly higher than those with hybrid-IR (p<0.01). Confidence score for liver lesions was significantly higher with images with DLR compared to those with hybrid-IR (p<0.01 for both radiologists).
Conclusion: DLR improved quantitatively and qualitatively image quality of abdominal CT for evaluation of hepatic metastases.

Up to seven criteria for liver transplantation: a single-centre experience
K. Koryukova, M. Bezzi, M. Di Martino, S.G. Ginanni Corradini, M. Rossi, C. Catalano; *Rome/IT (micdimartino@hotmail.it)*

Purpose: To test "up to seven" criteria for HCC in liver transplant candidates, with emphasis on imaging role and patients outcome.
Methods and Materials: The study was approved by the Institutional Review Boards. In this prospective study were analysed patients who underwent liver transplantation (LT) between January 2012 and December 2015. Of 79 transplant procedures 31 patients reported HCC nodules (69 lesions of which 43 were treated before). Diagnosis of HCC was taken by two expert radiologists in liver imaging according to LI-RADS classification in MR or CT examinations. Radiological staging correlated with histological result (Pearson). One-year survival was also take into account.
Results: Of 31 patients with HCC, 10 exceed Milan criteria for imaging analysis but were considered within "up-to-seven". On a patient-per-patient analysis, imaging reported a sensitivity of 60% (in explanted liver four patients were out of "up to seven" criteria). One-year after liver transplantation, four patients developed recurrence of HCC, of these 2 patients were out of Milan criteria.
Conclusion: "Up-to-seven" criteria for LT should replace Milan criteria and allow more patients with HCC to be candidates of this treatment.

B-0430 11:34

A deep-learning approach to the significant liver fibrosis binary classification problem using gender, morphologic and haemodynamic measurements derived from B-mode ultrasound images
A. Angelakis, I. Gatos, A. Soultatos, A. Kanavaki, E. Panteleakou, I. Theotokas, I. Vafiadis, E. Manesis, P. Zoumpoulis; *Athens/GR (ath.angelakis@gmail.com)*

Purpose: Traditional methods such as haematologic tests, e.g. FIBROMETER®, strain, shear wave elastographic (SWE) stiffness cut-off values, e.g. FIBROSCAN™, SuperSonic Imagine SWE, and parameters derived from image analysis, e.g. color clustering of SWE, are used for the significant liver fibrosis binary classification (SLFBC) problem. The AUC of the above methods is: 0.82, 0.82, 0.84 and 0.87 accordingly. The purpose of this study was to design and tune a deep neural network (DNN) to automate classification of a patient's liver fibrosis stage (F≤F1, F≥F2) with high accuracy, sensitivity, specificity and AUC.
Methods and Materials: Our data set consisted of 103 liver biopsy validated patients with chronic liver disease from which 62 were F≤F1 and 41 were F≥F2. Input parameters for our model were: {patient gender}, four B-mode morphologic longitudinal diameter (LD) measurements: {right lobe, caudate lobe, left lobe, spleen} and one haemodynamic parameter {portal vein LD}. We normalized the values of these features and designed a DNN with two hidden layers. A 10-fold cross validation (CV) technique was used to overcome underfitting, overfitting, bias and variance issues.
Results: 10-fold CV provided the following results: accuracy: 0.9364 +/- 0.0582, F1: 0.9136, sensitivity: 0.9024, specificity: 0.9365, AUC: 0.927 with 95% CI [0.817 - 1.000].
Conclusion: In this study, we proposed a different approach to solve SLFBC problem using deep learning. Our preliminary results demonstrate improved accuracy, sensitivity, specificity, and AUC (all > 0.90) compared to traditional diagnostic methods. Larger data sets are required to further validate our algorithm.

Three-dimensional texture analysis technology in computed tomography: a new radiological marker in the pathology of liver cancer
H. Xu, Y. Gao; *Chengdu/CN (xuhuisophia@163.com)*

Purpose: Texture analysis is a new technology with many advantages such as non-invasive, quantized and economical. This research is performed to explored the relationship with the parameters of TA(texture analysis) and the pathological grade of liver cancer.
Methods and Materials: Patients were involved in the retrospective research from march of 2011 to November of 2014 who have primary liver cancer. According to the radiology and pathology, 47 patients who have contrast-enhanced CT imaging were involved in the study. Analysis software is CT Kinetics APP, in which includes GLH, grey-level histogram, GLCM, grey-level co-occurrence matrix and GLRLM, grey-level run-length matrix. CT imaging

(Siemens 128 multislice spiral CT,slice thickness=1mm;scan protocol:plain scan,arterial phase and venous phase). Region of interest(ROI) was drawn by 2 radiologists with at least 2 years of experience. ROI was drawn in three phases and merge to 3d imaging for texture analysis.
Results: All parameters were divided into 2 groups by high differentiation and poor differentiation in pathology, which calculated by Mann-Whitney U test from SPSS23.0. The area under curve (AUC) of inverse difference moment (arterial phase) in GLCM is 0.762(cutoff=0.60097) , which is tested by receiver operating characteristic. The AUC of correlation (arterial phase) in GLCM is 0.755(cut off=0.3021). The AUC of energy and skewness in GLCM are 0.731 (cutoff=0.0679) and 0.672 (cutoff=-0.2186) respectively.
Conclusion: Texture analysis could predict the pathological grade of liver cancer from pre-treatment CT imaging. As a non-invasive and post-processing computer-aided diagnosis, TA could provide more information for clinic.

B-0432 11:50

Analysis of the relationship between imaging patterns of calcification and response to chemotherapy in patients with colorectal metastases
J. Zhang, B. Wu, Y. Zhou; *Chengdu/CN (396297113@qq.com)*

Purpose: The purpose of our study was to determine the relationship between the CT features (morphology ,distribution and density) of colorectal cancer metastases calcification and response to chemotherapy(cetuximab combined).
Methods and Materials: A retrospective review of CT of 111 patients who were treated with cetuximab-combined chemotherapy between 2011 and 2016 revealed 27 cases of tumor calcifications .The Response evaluation was performed according to the standard of Response Evaluation Criteria in Solid Tumors1.1(RECIST1.1). And the patients with metastases calcification was divided into two groups according to the response to the therapy. Analysis included the survival time between the two groups; the morphology and distribution of calcifications; and changes in number, density,morphology.
Results: The common site of metastatic calcification is the liver (70.4%), followed by lymph nodes (29.6%). The overall prognosis of patients with metastases calcification is better than those without calcification,279 ± 37 VS 186± 18 days(P=0.022)respectively. In all patients with metastases calcification, the overall outcome of the effective group was better than that in the ineffective group, 385 ± 17 VS244 ±38 days(P =0.042)respectively. The density increases with time, the effective group compare to the ineffective group slope are 11.9±4.0 VS 7.9±1.6, P =0.025. The calcification number changes between the two groups is significantly different. But the differences of morphology and distribution between the two groups are not significantly.
Conclusion: Metastasis of colorectal cancer with calcification predicts a favorable prognosis. Calcification density growth rate and increased calcification number, which correlated with the response to the chemotherapy.

Role of iliac crest tangent sign in correct numbering of lumbosacral transitional vertebrae
N. Gunduz, G. Durukan, M.B. Eser, A. Aslan, A. Kabaalioglu; *Istanbul/TR (gulcin_dr_kan@hotmail.com)*

Purpose: Iliac crest tangent (ICT) sign has recently emerged as a reliable landmark to correctly number the lumbosacral transitional vertebrae (LSTV) in patients with degenerated intervertebral disc disease. We retrospectively evaluated the usefulness of ICT in subjects without disc degeneration.
Methods and Materials: Fifty-eight patients with LSTV [19 (32.8%) female, 42±18 years] and 55 control subjects without LSTV [23 (41.8%) female, 42±19 years] who had undergone vertebral computed tomography in the emergency service for evaluation of suspected trauma were included. The ICT was drawn on the coronal images, with the cursor in the sagittal view set to the posterior one third of the vertebral body located one level above the LSTV. The last lumbar vertebra was used instead of LSTV in control group. When more than 1.25 vertebral body was counted below the ICT, the LSTV was considered as S1, otherwise as L5. The gold standard numbering was determined by counting the vertebrae craniocaudally. Two readers blinded to the correct LSTV numbers analysed the images. Interobserver agreement and accuracy of ICT sign were assessed.
Results: The interobserver agreement was good for determining ICT level (Cohen's kappa=0.78, p<0.001). The rate of correct numbering by ICT sign in LSTV group was significantly lesser than controls (43.1% vs 96.4%, respectively, p<0.001). Moreover, patients with sacralisation had significantly less rate of correct numbering than those with lumbarisation (33.3% vs 63.2%, respectively, p=0.03).
Conclusion: The ICT does not seem as a reliable landmark for correct numbering of LSTV in patients with no intervertebral disc degeneration.

B-0434 10:47

The termination level of dural sac relevant to caudal epidural block in lumbosacral transitional vertebrae: comparison between sacralisation and lumbarisation groups
J.Y. Jeon; *Incheon/KR (mdjeonjy@gmail.com)*

Purpose: Back and buttock pain can be associated with lumbosacral transitional vertebrae (LSTV). Appreciation of anatomical variations due to LSTV may impact safe performance of caudal epidural block (CEB). We investigated the termination level of the dural sac (DS) and anatomical features of lumbosacral region in patients with LSTV, and compared these findings between sacralisation and lumbarisation groups.
Methods and Materials: 494 LSTV were included and categorised into sacralisation (n=201) or lumbarisation groups (n=293). MRI of the all LSTV patients were reviewed to determine the termination level of DS, the presence and the caudal level of sacral perineural cyst. MRI findings in the both groups were compared and analysed.
Results: The distribution frequency of termination levels of DS demonstrated significant difference between the two groups. The mean caudal DS level in the lumbarisation group was significantly lower than the sacralisation group (lower third of S2 [131 {44.7%} of 293 patients] vs. lower third of S1 [78 {38.8%} of 201 patients]). The DS terminated at S3 in more than 19% of lumbarisation group, whereas in only one case of sacralisation group. The incidence of perineural cyst was not significantly different between two groups.
Conclusion: When planning CEB for patients with LSTV, especially in the lumbarisation cases, pre-procedural MR imaging to check the termination level of DS, presence of perineural cysts would be of great use for lowering the risk of unexpected dural puncture during the procedure.

B-0435 10:55

Modic changes: the association with low back pain and activity limitation - a systematic literature review and meta-analysis
C. Herlin[1], P. Kjaer[1], A. Espeland[2], J. Skouen[2], C. Leboeuf-Yde[1], J. Karppinen[3], J. Niinimaki[3], J.S. Sørensen[4], T.S. Jensen[5]; [1]*Odense/DK*, [2]*Bergen/NO*, [3]*Oulu/FI*, [4]*Svendborg/DK*, [5]*Silkeborg/DK (tuejen@rm.dk)*

Purpose: To investigate if Modic Changes (MC) are associated with non-specific low back pain (LBP) and/or activity limitation and if such an association is modified by other factors.
Methods and Materials: The MEDLINE, CINAHL and EMBASE databases were searched for relevant cross-sectional and case-control studies including people of all ages from general, working or clinical study populations were eligible for inclusion. Data extraction for risk of bias assessment, associations and potential modifiers were completed independently by pairs of reviewers. Data were used to calculate odds ratio (OR) with for dichotomous outcomes or to perform t-tests for continuous outcomes. Meta-analysis was performed for homogeneous studies.
Results: In all, 5210 citations were identified and 31 studies were included. One study had low risk of bias. Fifteen studies (48%) reported statistically significant positive associations between MC and LBP. Meta-analysis resulted in an OR of 4.01 (1.52-10.61). Both pooled and individual study data showed no difference in the strength of association of MC1 and MC2 with LBP. One of seven studies reported a statistically significant positive association between activity limitation and MC. Lumbar disc level and disc degeneration were found to reduce the estimates of association between MC and LBP.
Conclusion: The results from this comprehensive systematic review indicate that the associations between MC and LBP related outcomes are inconsistent. This finding should call for caution when using "Modic changes" as a specific diagnosis, explanation for LBP, and indication for specific treatment in patients with non-specific LBP.

B-0436 11:03

Weight-bearing MRI evaluation of Modic changes: uncovering the "biomechanical stress" and "active discopathy" therories in low back pain

F. Bruno, C. Marsecano, M. Micelli, A. Splendiani, C. Masciocchi; *L'Aquila/IT (federico.bruno.1988@gmail.com)*

Purpose: To evaluate the MRI modifications of Modic 1 endplate changes under loading and the possible clinical correlation in patients with low back pain

Methods and Materials: We evaluated 38 patients (20 females, 16 males, mean age 48.3 years) with low back pain and MRI evidence of Modic 1 vertebral changes. Patients were examined on a low field MR scanner in standard supine and upright position. Patients with history of trauma, malformations, infectious-inflammatory diseases, spine tumours were excluded. For each patient, in each scan, two observers evaluated the endplate involvement by Modic changes (as percentage of vertebral body extension) , the intervertebral disc height at the level of the endplate changes and the degree of intervertebral disc hydration (according to Pfirmann). Pain evaluation in both supine and upright position was assessed by means of VAS score.

Results: In upright position Modic 1 changes increased in 24 patients (63.1%, p<0.001). A reduction of disc height (89.5% of patients) and disc hydration (68.4%), respectively with negative (r=-0.12) and positive (r=0.46, p<0.005) correlation with Modic 1 changes was observed. 30 patients (78.9%) reported increase of pain in the upright position, and positive correlation with Modic 1 increase

Conclusion: Our imaging results suggest an instrumental evidence of the biomechanical stress theory for the development of Modic 1 changes. Moreover, upright scans under physiological loading represent an added value to standard sequences, being able to provide diagnostic information for answering clinical questions, such as pain due to "active discopathy" in patients with Modic 1 changes

B-0437 11:11

Oblique sagittal images prevent underestimation of neuroforaminal stenosis grade caused by disc herniation in cervical spine MRI

L. Kintzelé[1], C. Rehnitz[1], H.-U. Kauczor[1], M.-A. Weber[2,1]; [1]*Heidelberg/DE*, [2]*Rostock/DE (laurent.kintzele@med.uni-heidelberg.de)*

Purpose: Identify whether sagittal MRI images (SMI) result in underestimation of neuroforaminal stenosis grade (NSG) compared to oblique sagittal MRI images (OSMI) in patients with cervical spine disc herniation.

Methods and Materials: 74 patients with 104 cervical disc herniations compromising the corresponding nerve root were evaluated. NSGs were evaluated in SMI and OSMI by one senior and one resident radiologist. OSMI were angled 30° towards the standard sagittal plane. NSGs were classified from 0 (no stenosis) to 3 (high-grade stenosis).

Results: Average NSG of both readers was significantly lower in SMI compared to OSMI (2.41 ± 0.65 and 2.92 ± 0.27). For 49 of 104 disc herniations (47,1%), one or both readers found a NSG which was at least 1 grade lower in SMI compared to OSMI. Significant difference maintained looking at patients who had neurological symptoms (2.50 ± 0.55 and 2.88 ± 0.32) or underwent cervical spine surgery subsequently (2.58 ± 0.49 and 2.90 ± 0.31). Based on location a significant difference between SMI and OSMI was found for foraminal herniations (2.36 ± 0.67 and 2.91 ± 0.27). In contrast, no significant difference was observed for recessal herniations (2.68 ± 0.46 and 2.91 ± 0.30) or herniations which caused myelopathy (2.74 ± 0.45 and 2.91 ± 0.29). Kappa values showed a very good interreader reliability for SMI (0,88) and OSMI (0,94).

Conclusion: SMI tends to underestimate NSG compared to OSMI for disc herniations in cervical spine MRI. OSMI should, therefore, be considered as a valuable option for selected patients.

B-0438 11:19

Disc and vertebral changes after spinal fusion at serial CT imaging: correlation with discstability

N. Amini, E. Fomekong, C. Raftopoulos, B. Vande Berg; *Brussels/BE (nadia.amini@uclouvain.be)*

Purpose: To assess disc and vertebral changes after translaminar interbody fusion (TLIF) of lumbar discs by comparing MDCT examinations of the lumbar spine obtained immediately after surgery and 6 months later with comparison between stable and unstable discs.

Methods and Materials: Two radiologists independently analyzed 36 discs after TLIF (Peek cage and bone grafting) by comparing CT examinations obtained immediately after surgery and 6 months later. They assessed changes in disc height and they scored bone formation and graft resorption (0 : no bone formation/graft resorption, 1 : bone formation without bridging bone/ partial graft resorption, 2 : bridging bone/complete graft resorption). Disc stability was determined by consensus reading on follow-up CT (unstable disc: intradiscal vacuum or bone resorption around the pedicle screws).

Results: There were 19 stable and 17 unstable discs at 6 months follow-up. For both readers, the frequency of complete bony fusion was statistically significantly higher in stable than in unstable discs (p=0.003/0.02 for reader 1/2). The frequency of trabecular bone thickening was statistically significantly higher in stable than in unstable discs (p=0.005 for reader 1 only). For both readers, the frequency of bone graft resorption, of trabecular bone atrophy and of disc space narrowing was not statistically significantly different between stable and unstable discs.

Conclusion: Appearance of bridging bone and of trabecular bone thickening near the cages are associated with disc stability. Disc space narrowing, vertebral bone resorption and bone graft resorption are seen in similar frequency in stable and unstable disc.

B-0439 11:27

Evaluation of colour-coded virtual non-calcium images reconstructed from dual-energy CT for detection of lumbar disc herniation in comparison to MRI: initial results

C. Booz, J. Noeske, S.S. Martin, L. Lenga, D. Leithner, T. Gruber-Rouh, K. Eichler, T.J. Vogl, J.L. Wichmann; *Frankfurt a. Main/DE (boozchristian@gmail.com)*

Purpose: Detection of lumbar disc herniation in standard grey-scale computed tomography (CT) is challenging. The aim of this feasibility study was to evaluate the diagnostic accuracy of two dual-energy computed tomography (DECT)-based colour-coded virtual non-calcium (VNCa) image reconstruction algorithms for detection of lumbar disc herniation in comparison to magnetic resonance imaging (MRI) as standard of reference.

Methods and Materials: In this retrospective study, thirty-seven patients underwent clinically indicated third-generation dual-source DECT and MRI of the lumbar spine. Conventional linear-blended CT scans were obtained and two different corresponding colour-coded VNCa reconstructions were generated. First, three radiologists independently evaluated standard VNCa images for presence and degree of lumbar disc herniation and spinal nerve root affection. After 4 weeks, VNCa images optimized for analysis of intervertebral discs were examined by the same observers. Findings were compared with MRI evaluated by two separate observers serving as reference standard.

Results: A total of 222 intervertebral discs were analysed. VNCa images optimized for analysis of intervertebral discs showed a higher overall sensitivity (94.7% vs 78.0%), specificity (97.0% vs 92.3%), positive predictive value (96.3% vs 89.3%) and negative predictive value (95.7% vs 83.5%) for detection of lumbar disc herniation compared with standard VNCa images (*P*<0.001). Receiver-operating characteristic analysis revealed areas under the curve of 0.958 (optimized VNCa) and 0.851 (standard VNCa).

Conclusion: Initial results showed that a novel DECT-based colour-coded VNCa image algorithm specifically optimized for analysis of intervertebral discs can substantially improve diagnostic accuracy for detection of lumbar disc herniation. Inexperienced observers showed the most benefit.

The effect of radiographically detected vertebral osteoarthrosis (VO) on bone mineral density (BMD) and trabecular bone score (TBS)

A. Corazza[1], D. Albano[2], S. Rapisarda[1], V. Chianca[3], C. Messina[1], L.M. Sconfienza[1]; [1]*Milan/IT*, [2]*Palermo/IT*, [3]*Naples/IT (angelcoraz@libero.it)*

Purpose: TBS is a recently developed textural score that provides an indirect index of vertebral trabecular microarchitecture from lumbar spine (LS) dual energy x-ray absorptiometry (DXA) scan. Our aim was to evaluate the effect of radiographically detected VO on BMD and TBS.

Methods and Materials: We retrospectively identified all patients who performed a LS DXA during the first six months of 2015, together with a LS x-ray (maximum interval between x-ray and DXA=4 months). Among them, we only included patients with VO visible on DXA and confirmed on LS x-ray (maximum two vertebrae involved). We calculate: 1. BMD/TBS difference between the vertebrae affected by VO and the adjacent vertebrae (AV) with the greater BMD/TBS value; 2. BMD/TBS difference between the vertebrae affected by VO and the average L1-L4 BMD/TBS (average value included the vertebrae with VO).

Results: Out of 542, we included 42 females (mean age=75±10y) with VO. Mean BMD (g/cm^2): vertebrae with VO=1.120±0.160; AV=0.976±0.152; L1-L4=0.988±0.127. Mean TBS: vertebrae with VO/VF=1.379±0.138; AV=1.298±0.144; L1-L4=1.310±0.104. BMD difference between VO and VA=+14,8%; between VO and L1-L4=+13,4%. TBS difference between VO and VA= +6,2%; between VO and L1-L4=+5,3%. All differences were significant (p<0.05). We found a positive correlation between BMD and TBS for vertebrae with VO (R=0.6194, p<0.05).

Conclusion: Compared to adjacent-vertebrae and L1-L4, VO significantly impacts both on BMD and TBS, despite the variation in terms of TBS was lower was lower compared to BMD. BMD and TBS values are positively correlated.

B-0441 11:43

Vertebral bone marrow composition: assessment of age and gender dependency using chemical shift encoding-based water-fat MRI

A. Rohrmeier, J. Syväri, M. Diefenbach, D. Franz, S. Ruschke, M. Dieckmeyer, J.S. Kirschke, D. Karampinos, T. Baum; *Munich/DE (Alexander.Rohrmeier@t-online.de)*

Purpose: Assessment of vertebral bone marrow composition has been recently proposed as an advanced imaging biomarker for osteoporosis-associated fracture risk prediction. We investigated the age and gender dependency of vertebral proton density fat fraction (PDFF) using chemical shift encoding-based water-fat MRI.
Methods and Materials: 156 subjects with no history of pathological bone changes were recruited (age range 20-29 years:12/30 males/females; 30-39:15/9; 40-49:4/14; 50-59:9/27; 60-69:5/19; 70-79:4/8). All subjects underwent 3T MRI with a sagittal spoiled gradient echo sequence for chemical shift encoding-based water-fat separation at the lumbar spine (pixel spacing: 0.98x0.98 mm²; slice thickness:4 mm). Vertebral bodies of L1-4 were manually segmented in the PDFF maps to extract PDFF values at each vertebral level.
Results: PDFF increased from L1 to L4 in all subjects (L1: 35.9±11.7%; L2: 36.2±10.9%; L3: 37.2±10.7%; L4: 39.5±11.2%; p<0.05). Mean PDFF was significantly (p<0.05) greater in males than females in their twenties (32.0±8.0% vs 27.2±6.0%) and thirties (35.3±6.7% vs 27.3±6.2%). With increasing age, females showed an accelerated fatty conversion of the bone marrow compared to men with no significant (p>0.05) PDFF differences in their forties (males: 32.4±8.4%; females: 34.5±6.8%) and fifties (males: 42.0±6.1%; women: 40.5±9.7%). The accelerated conversion process continued resulting in greater PDFF values in females than males in their sixties (males: 40.2±6.9%; females: 48.8±7.7%; p=0.033) and seventies (males: 43.9±7.6%; females: 50.5±8.2%; p=0.208).
Conclusion: Vertebral bone marrow composition is dependent on age and gender. An accelerated fatty conversion of the bone marrow was observed in females with increasing age. The results allow insights into physiological changes of the vertebral bone marrow and may serve as reference data.

B-0442 11:51

A preliminary study of dual-energy CT spectral curve equation for the diagnosis of osteoporosis

L. Wang, S. Gong; *Nantong/CN (wanglin_nt@126.com)*

Purpose: To investigate the diagnostic value of dual-energy CT (DECT) spectral curve equation for osteoporosis (OP).
Methods and Materials: The prospective study was approved by the institutional ethics committee. Informed consent was obtained from all patients. Sixty-seven patients with lumbago underwent both DECT and dual-energy x-ray absorptiometry (DXA) examinations. DECT images were reconstructed using iterative algorithm (ADMIRE) with strength level 3. Spectral curves were generated through measuring CT values from photon energy 40 keV to 190 keV with commercially available software (virtual monoenergetic plus, Syngo Via, version VB10A, Siemens Healthcare). Curve estimation was implemented for analysing correlations between photon energies and CT values under functions of linear, quadratic, cubic, inverse and power. In addition, degree of fittings was recorded to determine the optimal curve equation. Bone mineral density (BMD) and T-score of patient measured by DXA were set as the reference standard. Diagnostic value of curve equation was assessed by ROC analysis.
Results: 16 patients were diagnosed as OP and 51 patients were diagnosed as non-osteoporosis (NOP) under DXA. R^2 of cubic and inverse curve equation was significantly higher than linear, quadratic, and power (all $P < 0.01$). The average coefficients of inverse curve equation ($a_{i\text{-}average}$) were correlated with BMD and T-score (r were 0.56 and 0.55, respectively. All $P < 0.01$). The sensitivity and specificity of $a_{i\text{-}average}$ for diagnosing OP were 93.75% and 83.39% with a cut-off value of 10760.97.
Conclusion: The DECT spectral curve equation is clinically applicable for quantitative assessment of osteoporosis.

CT-guided transgluteal drainage of deep pelvic abscess

S.F. Murphy, C.J. Sullivan, P. McCormick, B.J. Mehigan, D. Kevans, I.M. Brennan, M.J. Guiney, N. Sheehy, J.F.M. Meaney; *Dublin/IE (stephenmurphy@rcsi.ie)*

Purpose: Deep pelvic abscesses can be challenging to drain percutaneously. Transabdominal drainage, the simplest approach, may be precluded by overlying structures including bowel loops, bladder and iliac vessels. The greater sciatic foramen, an oval space in the posterolateral aspect of the pelvis lying inferior to the sacroiliac articulation, offers an effective alternative access route, but requires detailed anatomical knowledge of the region to avoid vessel and nerve injury. We describe a consecutive case series of CT-guided transgluteal drainages from our institution.
Methods and Materials: We retrospectively reviewed all cases from January 2007 to August 2017 identified on our RISPACS database. Data collected included patient demographics, cause/size of abscess, catheter size, microbiology, inflammatory markers, follow-up scans and complications.
Results: 100 patients (65 female, 35 male) underwent CT-guided transgluteal drainage. The mean age was 57.4 (range 20-89) years. Causes included post-operative anastomotic leak, perforated malignancy, inflammatory bowel disease, diverticulitis and appendicitis. The mean collection diameter was 7.6 cm (range 1.2-16). 78 patients had complete resolution following single (71) or 2 drainages (7), 9 failed to resolve and required surgical intervention and the remainder (13) had a partial resolution that was managed conservatively.
Conclusion: CT-guided transgluteal drainage is a safe and effective technique and is the procedure of choice for deep pelvic abscesses when a transabdominal approach is not possible.

B-0444 10:38

Virtual guidance of percutaneous transthoracic needle biopsy with c-arm cone-beam CT: diagnostic accuracy, risk factors and effective radiation dose

D. Fior[1], D. Leni[1], F. Vacirca[1], D. Ippolito[1], S. Sironi[2], R. Corso[1]; [1]*Monza/IT*, [2]*Bergamo/IT (davidefior85@gmail.com)*

Purpose: C-arm cone-beam computed tomography (CT)-guided transthoracic lung core-needle biopsy (CNB) is a safe and accurate procedure for the evaluation of patients with pulmonary nodules. The purpose of our study was to retrospectively evaluate the diagnostic performance, complication rates and effective radiation dose of C-arm cone-beam CT-guided core-needle biopsy in a large monocentric XperCT-guided lung CNB series.
Methods and Materials: We retrospectively collected data regarding 514 C-arm cone-beam CT-guided CNBs from January 2010 to June 2017. Diagnostic performance, complication rate and effective radiation dose were investigated. Variables influencing diagnostic performance and complications were assessed using univariate logistic regression analyses.
Results: The sensitivity, specificity, positive and negative predictive value and accuracy for patients subjected to CNBs were, respectively, of 96.8%, 100%, 100%, 100% and 97.2%. Considering risk factors for pneumothorax, no significant differences were found regarding patient and lesion characteristics. Perilesional haemorrhage occurred more frequently in older patients (P=.046) and in smaller lesions (P=.001). Haemoptysis was more frequent in patients with perilesional haemorrhage, with a statistically significant P value (P=.01). Mean effective dose through CBCT-guided biopsies and CT-guided biopsies was 7.12 ± 8.78 mSv and 20.91 ± 8.12 mSv, respectively, with a statistically significant difference (p=0.024).
Conclusion: Our results demonstrate that C-arm cone beam CT biopsy combined with Xper-CT virtual guidance is a reliable and accurate technique that allows exact localisation of pulmonary lesions, effective preprocedural planning and real-time fluoroscopy altogether, potentially improving the accuracy of lung biopsies while reducing the effective radiation dose to the patient.

B-0446 10:46

Real-time 3D-guidance based on C-arm-acquired cone-beam CT (CBCT) in transjugular intrahepatic portosystemic stent shunt (TIPSS) placement

G. Böning[1], W. Lüdemann[1], J. Chapiro[2], M. Jonczyk[1], B. Gebauer[1], R.W. Günther[1], F. Streitparth[1]; [1]*Berlin/DE*, [2]*New Haven, CT/US*

Purpose: Placement of TIPSS is a technically challenging intervention. The aim of this study was to evaluate the feasibility of CBCT-based real-time 3-D guidance and its potential benefits compared to standard guiding methods.
Methods and Materials: 21 patients were prospectively included. We used real-time, 3-D guidance based on a C-arm-acquired CBCT. Feasibility, technical success, procedure/puncture time, applied dose of the intervention and the relative dose share of CBCT were determined. As control groups, we prospectively analyzed 15 TIPSS interventions with ultrasound (US) guidance, retrospectively 23 cases with US guidance and 23 cases with puncture utilizing anatomical landmarks.
Results: CBCT guidance was feasible in all patients. Additional US guidance was necessary in 7 cases, and in 2 of these cases TIPSS implantation was not successful (9,5%). TIPSS placement failure in the prospective US-guided group was 20% and 13% in both retrospective control groups. All failures were excluded from analysis. In the CBCT only group a median of 2 attempts and a mean of 11±14 minutes were needed for portal vein puncture. The mean procedure time in this group was 91±38 minutes with an applied dose of 426±208 Gy*cm and 4% mean dose share of CBCT in the intervention. Regarding to our results CBCT guidance is not significantly inferior to current standard guiding techniques.
Conclusion: CBCT-based guidance for TIPSS placement was feasible and comparable to standard guidance procedures regarding to puncture attempts, time and dose. The relative dose of CBCT is low compared to total dose of intervention.

B-0447 10:54

Impact of personality and experience of interventional radiologists in outcome of CT-guided percutaneous lung biopsies

M.-L. Kromrey[1], S. Schäfer[1], T. Ittermann[1], B. Mensel[1], J.-P. Kühn[1,2]; [1]*Greifswald/DE*, [2]*Dresden/DE (marie-luise.kromrey@uni-greifswald.de)*

Purpose: To investigate the influence of personality and experience of interventional radiologist itself on technical success and rate of complication in computer tomography-guided percutaneous transthoracic needle biopsies (PTNB) of suspicious pulmonary nodules.
Methods and Materials: Between 2006-2014, 38 interventional radiologists performed 1,056 PTNB. Technical success, rate of complications and interventional-related predictors of PTNB were determined. PTNB of radiologists with less than 20 interventions, lack of consent, and PTNB with missing variables were excluded, leaving 445 interventions performed by 14 radiologists. Interventionalists underwent a Big-Five personality trait and State-Trait Anxiety Inventory to quantitatively assess personality and psyche. Adjusted for predictors, factors to describe personality such as openness to experience, conscientiousness, extroversion, agreeableness, neuroticism (range 0-20), and anxiety (range 20-80) as well as experiences of interventional radiologists were compared to outcome of PTNB for each interventionalist.
Results: There was no significant difference in technical success of interventional radiologists, which ranged between 75.8-95.7%, P=0.428. Rate of complications ranged between 56.1-85.7%, P=0.12 (major complications: 15.0-24.1%, P=0.57; minor complications: 31.6-67.5%, P<0.05). Personality traits of interventionalists did not differ in technical success and rate of complications. Experience of interventional radiologists had no significant impact on technical success (P=0.132) or rate of complications (P=0.459).
Conclusion: Using a standard operation procedure for CT-guided lung biopsies, technical success and rate of complications are unaffected by the interventional radiologists itself, as well as their years of experience and personality traits such as openness to experience, conscientiousness, extroversion, agreeableness, neuroticism and anxiety.

B-0448 11:02

MR-guided transrectal prostate biopsy with robotic assistance: initial experience

F. Cornud[1], A. Lefevre[1], P. Camparo[2], P. Soyer[1]; [1]*Paris/FR*, [2]*Amiens/FR (francois.cornud@imagerietourville.com)*

Purpose: To show our preliminary results of MR-guided transrectal biopsies (MRGB) with a robotic assistance (Soteria, the Netherlands) for the diagnosis of prostate cancer.
Methods and Materials: 33 patients (67±33y/o, PSA level: 10±6ng/ml), with a single PI-RADS lesion score equal to or greater than 2, underwent MRGB. In 18 patients, MRGB was a repeat biopsy session following one to three series of systematic biopsies (15 patients) or three targeted biopsies (3 patients) with a software-based image fusion system, all showing no cancer or a microCa, Gleason score 3+3. The remaining 15 patients had no prior biopsy. The success rate to sample the lesion, the cancer-detection-rate (CDR) and the occupation time of the MR-room were evaluated.
Results: The PI-RADS score was 2, 3, 4 and 5 in 3, 8, 13 and 9 cases, respectively. Sixteen lesions originated in the peripheral zone and 17 in the transition zone (one in the anterior stroma). Software-based adjustments of the robot allowed to align the needle guide with the target in all lesions. Two cores were obtained in 31 patients and 3 cores in 2 patients. The MR-room occupation time dropped from approximately 45-50mn to 20-30mn after 20 cases. The overall CDR was 64.7% and, according to the PI-RADS score, 0, 50, 64 and 100% for PI-RADS score 2, 3, 4 and 5 lesions, respectively. No complication was observed.
Conclusion: Robotic-assisted MRGB can be performed with a short MR-room occupation time. Sampling is possible whatever the lesion location, with two cores in the vast majority of cases.

B-0449 11:10

Volumetric magnetic resonance-guided high-intensity focused ultrasound ablation of adenomyosis: the influence of T1 perfusion in predicting treatment outcome

N.M. Duc[1], B. Keserci[1], H.Q. Huy[1], P.N. Hoa[1], P.M. Thong[2]; [1]*Ho Chi Minh/VN*, [2]*Ha Noi/VN (bsnguyenminhduc@pnt.edu.vn)*

Purpose: We investigated the role of magnetic resonance (MR) T1 perfusion-based time-signal intensity (SI) curves of adenomyosis tissue compared to the myometrium in predicting the treatment outcome of MR-guided high-intensity focused ultrasound (HIFU) ablation of adenomyosis.
Methods and Materials: 30 adenomyosis patients (39.2 ± 5.1 years with a range of 30-56 years) who underwent MR-guided HIFU ablation were divided into 2 groups based on dynamic contrast-enhanced (DCE) MR images at screening: group A (n = 15) if the time-intensity curves of adenomyosis are lower than that of myometrium and group B (n = 15) if the time-intensity curves of adenomyosis are equal or higher than that of myometrium. The immediate post-HIFU non-perfused volume (NPV) ratio and adenomyosis volume reduction ratio at 6-month follow-up were assessed.
Results: The volume of adenomyosis was 101.2 ml ± 59.0 (32-189.0 ml) for group A and 98.3 ml ± 53.5 (27.0-186.0 ml) for group B. Immediate post-HIFU NPV ratio of adenomyosis was 84.5± 6.9 (80-100%) for group A and 42.7% ± 17.2 (11.3-59.6%) for group B (p<0.001). Adenomyosis volume reduction ratio at 6-month follow-up was 26.8% ± 15.2 (21.2-42.6%) for group A and 7.5% ± 8.2 (-8.9-21.6%) for group B (p<0.001).
Conclusion: Our findings suggest that T1 perfusion-based classification could be served as the MRI classification parameter before MR-guided HIFU ablation for predicting the treatment outcome of HIFU ablation.

B-0450 11:18

Transjugularrenal biopsy in patients with impaired coagulation status

P. Heil, B. Tyczynski, M. Reinboldt, Y. Li, J. Theysohn, S. Suntharalingam, J. Grüneisen, A. Kribben, A. Wetter; *Essen/DE (axel.wetter@uk-essen.de)*

Purpose: To evaluate transjugular renal biopsy (TJRB) in patients with acute nephritic or nephrotic syndrome and impaired coagulation status.
Methods and Materials: 99 TJRB were performed in 42 patients (median age 58y, range 18-83y; 31 male/11 female) from August 2008 to September 2017. After ultrasound-guided puncture of the right jugular vein, a 9F-sheath was inserted in Seldinger technique and the lower branch of the right kidney vein was probed with a 5f multipurpose-catheter. Biopsies were performed under fluoroscopic control with a curved 9F-renal biopsy set and a 19G-Tru-Cut needle. The obtained samples were visually checked by an experienced nephrologist.
Results: Tissue of the renal cortex was extracted in 97 of 99 biopsies. The mean number of glomeruli obtained was eight per procedure. Two specimens contained renal medulla without glomeruli, however, one of those specimens was sufficient for histopathological diagnosis. Main diagnoses were IgA nephritis and glomerulosclerosis. We observed two complications: One patient developed haematuria and urinary bladder tamponade. Another patient suffered from a retroperitoneal haematoma.
Conclusion: In our large unicenter experience, TJRB enabled histopathological diagnosis in 41 of 42 Patients (98%). TJRB proofs to be an effective procedure in patients at risk for bleeding complications.

B-0451 11:26

Development of a new image display system for angiography based on detection of electroencephalogram signals from operator's brain

M. Sato[1], T. OGURA[1], S. Yamanouchi[1], N. Hayashi[1], H. Watanabe[1], K. Doi[2]; [1]*Maebashi/JP*, [2]*Willowbrook, IL/US (mitubati.mitu.mitu@gmail.com)*

Purpose: Various radiographic images obtained during interventional radiology are commonly used. Although radiographic images may be displayed by physicians, they could not use the console of the image display system to

avoid their unsanitary hands. Therefore, we developed an image display system with use of an electroencephalogram (EEG) without use of hands.
Methods and Materials: We used Mindwave MOBILE (Neurosky Ltd., CA, US) as an EEG sensor. We programmed proper algorithms to provide suitable commands such as paging and zooming by use of EEG signal obtained. For observer study, we investigated the average response time required for paging due to observer' s eye blink and the correct detection rate. We also investigated the average response time required for zooming due to the observer's concentration and the correct detection rate.
Results: The average response time required for paging which can be controlled by operator's eye blink was 0.43±0.02 s. The correct detection rate of 100% was achieved by 28 observers, whereas three observers provided 80%. The average response time required for zooming which can be controlled by operator's concentration on his/her mind was 5.85±0.56 s. The correct zooming rate of 100% was achieved by 27 observers, whereas three observers provided 90%, and one observer provided 80%. The correct detection rate of 100% was achieved by approximately 90% observers. The results seem to indicate that the image display system could be utilized for physicians properly.
Conclusion: Radiographic images can be displayed by use of EEG signals without use of physician's hands for angiography.

B-0452 11:34

Contrast enhancement improves PET-US fusion navigation for tumour ablation targeting
N. Gennaro[1], G. Mauri[1], S. de Beni[2], T. Ierace[1], D. Poretti[1], V. Pedicini[1], A. Chiti[1], L. Solbiati[1]; [1]*Milan/IT*, [2]*Genoa/IT (nicolo.gennaro@humanitas.it)*

Purpose: To assess if tumour targeting improves when US/^{18}FDG-PET/CT image fusion-guided percutaneous ablations of liver metastases inconspicuously seen or undetectable with US are performed using contrast enhanced PET-CT (PET-CECT) vs conventional unenhanced PET-CT.
Methods and Materials: Fifty-eight metastases mostly from colorectal cancer (38/58, 65.5%) in 23 patients (13 males/10 females, mean age 62.8±9 years) underwent percutaneous microwave ablation (MWA) guided by US/^{18}FDG-PET/CT image fusion, either with PET-CECT (28/58, 48.3%) (group 1) or with unenhanced PET-CT (30/58, 51.7%) (group 2). Lesion size (1.0-4.0 cm, mean 2.0 in group 1 and 0.6-4.5 cm, mean 1.9 in group 2) was comparable in the two groups. Time needed for co-registration and rates of technical success and complete ablation were evaluated in both groups.
Results: Time needed for co-registration was significantly shorter in group 1 (mean 4.5 vs 6.0-14.0 min, mean 10.9 in group 2). All lesions were targeted in group 1, while 5/30 were missed in group 2 (technical success 100% vs 83.3%)(p= 0.0237). Complete ablation was achieved in one session for 23/28 (82.1%) metastases of group 1 and for 17/30 (56.7%) of group 2 (p=0.03).
Conclusion: Percutaneous ablation of liver metastases inconspicuously visible of totally undetectable with US, guided by US/^{18}FDG-PET/CT image fusion is feasible and effective. If PET-CECT is performed and used for co-registration with US, time needed for co-registration, technical success and completeness of ablation are significantly improved, since the visualisation of hepatic vascularity on CECT allows to achieve more accurate spatial registration and therefore more precise lesion targeting.

B-0453 11:42

Prospective comparison US vs. CEUS guided percutaneousbiopsy in the diagnosis of large intra-and retroperitoneal tumors
Z. Spirchez, P. Radu, N. Al Hajjar, G. Kacso, T. Mocan; *Cluj-Napoca/RO (zsparchez@yahoo.co.uk)*

Purpose: Due to the presence of necrosis the accuracy of echoguided percutaneous biopsy (US-PB) in the diagnosis of large retro (RPT) and intra peritoneal tumors (IPT) is around 70-80%. CEUS is able to deliniate necrotic from well perfused areas inside the tumors. The aim of this prospective study is to compare the sensitivity of US and CEUS guided PB in the diagnosis of these tumors.
Methods and Materials: 60 patients with 24 IPT and 36 RPT (mean diameter 7.5 cm, range 4-22 cm) were referred for PB. In 32 patients (11 IPT, 21 RPT) PB was performed using US guidance. 28 patients (13 IPT, RPT) were biopsied using real time CEUS guidance The lesions in the CEUS -PB group were larger than those in US-PB group (mean diameter 8.1 cm vs. 6.8 cm) (P>0.05). PB was performed with an 18G Bard needle coupled on Biopty Gun.
Results: Real time CEUS-PB was technically successful in all procedures (100% technical success rate). The sensitivity of PB was significantly higher in CEUS -PB group than in conventional US -PB group for all lesions (96.4% vs. 78.1%, p< 0.05) and RPT (100% vs. 78.9%, p<0.05). For IPT the sensitivity was also higher for CEUS-PB (90.9% vs. 76.9%) but without statistical significance (p=0.36). No major complication occurred in both groups.
Conclusion: Percutaneous CEUS guided PB in intra and retroperitoneal tumors is a feasible and safe technique. It significantly improves the overall sensitivity of the procedure in patients with large lesions.

Oligaemia of tumour-involved lung displayed by Z-effect of dual-detector spectral CT
Y. Yue, X. Lu, Q. Guo; *Shenyang/CN (ghostaa2000@aliyun.com)*

Purpose: Tumour destruction of pulmonary vessels may result in reduced blood flow of distal or proximal lung tissue. Our purpose is to display blood flow change by Z-effect of dual-layer detector CT. Z-effect is an image in which the pixel values represent the effective atomic number of the displayed tissue.
Methods and Materials: We reviewed 29 cases with enhanced dual-detector spectral CT scan. In them, 23 were proved to have malignancy, with 5 cases of squamous cell carcinoma, 16 cases of adenocarcinoma and 2 cases of small cell carcinoma. Ten of these cases are central type tumour while other 19 cases are solid solitary nodules (SPN) or mass, including all 6 inflammatory cases. Conventional unenhanced lung window, virtual monoenergetic at 70keV and 40keV, Z-effect slices were saved for evaluation. Abnormal attenuation at distal or proximal part of the tumour in artery or delay phase were identified as positive for oligaemia.
Results: According to morphological type, all ten central type cases are positive for oligaemia in Z-effect images in both artery and delay phase. While 4 positive in monoenergetic slice. In the 13 malignant SPN or mass cases, 8 (72.7%) show oligaemia in artery phase and 4 in delay phase in Z-effect images. Two (33.3%) in the 6 inflammatory cases show oligaemia in Z-effect images in artery and delay phase.
Conclusion: Z-effect image is sensitive in detecting blood flow changes of lung caused by tumour invasion. These changes take places in most central type and peripheral type carcinomas but less likely to appear in inflammatory cases.

B-0455 10:38

Application value of dual-detector spectral CT in evaluation of metastatic lymph nodes in lung cancer
L. Gao, Y. Hou, Y. Ma, X. Lu, Z. Jia; *Shenyang/CN*

Purpose: To investigate the application value of dual-detector spectral CT in the evaluation of metastatic lymph nodes in lung cancer.
Methods and Materials: 24 patients with lung cancer undergoing dual-phase enhanced scan with dual-detector spectral CT were selected. Short diameter of lymph nodes, spectral curve, and iodine uptake were measured. According to pathological findings, lymph nodes were divided into metastatic group and non-metastatic group. The slope of the spectral Hounsfield unit curve (λHu), arterial enhancement fraction (AEF) and short diameter were calculated (AEF = iodine uptake in arterial phase/iodine uptake in venous phase × 100%) and compared. Additionally, receiver operating characteristic (ROC) curves were drawn to confirm the optimum threshold and diagnostic efficiency.
Results: A total of 50 lymph nodes were included, with 24 metastatic lymph nodes and 26 non-metastatic lymph nodes. Short diameter of lymph nodes, λHu and AEF in the 2 groups all showed significant differences (1.49 ± 0.69 vs 0.87 ± 0.22, 2.77 ± 0.24 vs 2.40 ± 0.17, 98.54 ± 15.83 vs 70.14 ± 16.38, respectively; $P < 0.05$). The optimum diagnostic efficiency of AEF was the largest (AUC_{AEF} = 0.928, $AUC_{\text{short diameter}}$ = 0.809 and $AUC_{\lambda Hu}$ = 0.889), and its threshold was 76.84%. The sensitivity, specificity, negative predictive value and positive predictive value were 88.00%, 76.00%, 90.48% and 75.00%, respectively.
Conclusion: Multiple quantitative parameters of dual-detector spectral CT provide an effective noninvasive method for accurate evaluation of metastatic lymph nodes in lung cancer, especially, AEF has the higher diagnostic efficacy in differentiating metastatic and non-metastatic lymph nodes.

B-0456 10:46

Evaluation of diagnostic value of iodine base material of dual-detector spectral CT for pulmonary aspergillosis invasion by ROC
B. Yuan, W. Zhang, X. Lu, Z. Jia; *Shenyang/CN (zhw65321@sina.com)*

Purpose: To explore the diagnostic value of iodine base material of dual-detector spectral CT for pulmonary aspergillosis invasion by receiver operating characteristic curve (ROC curve).

Methods and Materials: The patients who underwent chest contrast-enhanced scanning by dual-detector CT and confirmed with pathology results were enrolled (20 cases with pulmonary aspergillosis invasion and 30 cases with lung neoplasm). The normalised iodine concentrations (NIC-ROI iodine concentration/thoracic aorta iodine concentration) of all lesions on both arterial and venous phases were measured and calculated and the results were compared between the two groups. ROC curve was used to determine the best cut- off points of NIC on arterial and venous phases for pulmonary aspergillosis invasion group. Pathological diagnosis as gold standard, the diagnostic values of NIC on arterial and venous phases for pulmonary aspergillosis invasion were analysed.
Results: The differences of NICs on arterial and venous phases between the two groups were statistically significant (both P <0.01). The areas under ROC of NICs on arterial and venous phases were 0.901 and 0.900, respectively, and the best cut-off points of NIC on arterial and venous phases obtained via analysis of the ROC were 0.90 and 0.85, respectively. Their sensitivities for the diagnosis of NPC were 88% and 86%, while the specificities were 85% and 83%, respectively.
Conclusion: With high values in the diagnosis of pulmonary aspergillosis invasion, the NICs on arterial and venous phases can be used as effective indicators for diagnosis of pulmonary aspergillosis invasion by dual-detector spectral CT.

B-0457 10:54

Are there suboptimal CTPE studies in the DECT era: low mono-energetic images for pulmonary artery assessment

N. Lev Cohain, I. Leichter, J. Sosna; *Jerusalem/IL (NAAMAL@HADASSAH.ORG.IL)*

Purpose: Low mono-energetic images (MEI) of dual-energy CT (DECT) enable greater contrast density. We hypothesized that low-energy MEI could salvage suboptimal pulmonary emboli CT (CTPE) studies. Hence, the contrast enhancement of the pulmonary arteries (PA) on conventional CTPE and low MEI was compared.
Methods and Materials: 49 patients who underwent CTPE using DECT at 120kV and 90mAS (IQon, Philips Healthcare, Eindhoven, Netherlands) between 1 and 4/2017 were retrospectively reviewed. Early arterial enhanced series were evaluated using conventional images and MEI at 50-keV. Regions of interest (ROI) were marked in four locations: the main, left, right and right lower lobe PA. Any HU value below 220 was considered suboptimal. Paired t test determined the significance of difference in contrast density.
Results: Of the conventional images, 32.1% (63/196 ROIs) had HU values lower than 220, and considered limited for the evaluation of an emboli. 24.5% (12/49) were suboptimal in the main PA, 34.7% (17/49) in the left PA, 32.7% (16/49) in the right PA and 36.7% (18/49) in the right lower lobe PA. No low HU values were found on the MEI at 50-keV. The mean HU value on the 50-keV images was significantly higher (p<0.001) compared to the conventional image (536.4 HU vs 257.5HU, respectively). The mean enhancement factor of the contrast density on the 50-keV images was 2.08.
Conclusion: Low mono-energetic DECT images significantly enhance the contrast density in the pulmonary vessels. The diagnostic yield of CTPE studies can be increased, by salvaging suboptimal studies and turning them into diagnostic studies.

B-0458 11:02

Transient interruption of contrast (TIC) in CT pulmonary angiography: frequency and impact on the diagnostic value of CT examinations using a dual-source CT system

J. Hennicaux, A. Hutt, M. Kyheng, J.-B. Faivre, J. Remy, M. Rémy-Jardin; *Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To evaluate the incidence of transient interruption of contrast (TIC) during dual-source chest CT angiographic (CTA) examinations and its impact on the diagnostic value of examinations.
Methods and Materials: Retrospective review of 449 consecutive chest CTA examinations obtained on a 3rd generation DSCT system was undertaken to search for TIC on single- (SE) (n=276; 61.5%) and dual-energy (DE) (n=173; 38.5%) CT examinations. This physiological artifact was recognized on the basis of (a) decrease in opacification within pulmonary arteries (PAs); (b) concurrent depiction of unopacified blood from the inferior vena cava entering the right heart; and (c) adequate opacification of pulmonary veins and left cardiac cavities.
Results: TIC was identified on 19 examinations (19/449; 4%), more frequently seen on DE (14/19; 74%) than SE (5/19; 26%) examinations. Four types of TIC were depicted: (1) decreased opacification only within central PAs, observed in 4 patients (Group 1; 4/19; 21%); (2) decreased opacification within central and peripheral PAs in the remaining 15 patients (Group 2; 15/19; 79%) with TIC depicted in the middle third of the chest (12/15), the initial (1/15) or late (1/15) part of the acquisition, or over the entire thorax (1/15). In both groups, the mean level of attenuation within PAs of the TIC zone was 228.7± 69.1 HU in central and 223.9 ± 54.8 HU in peripheral PAs, enabling confident analysis of PAs down to the segmental (2/19) or subsegmental (15/19) level.
Conclusion: TIC was identified in 4% of the study population, never responsible for indeterminate CTA examinations.

M. Rémy-Jardin: Research/Grant Support; Siemens Healthcare.

B-0459 11:10

Incidence of transient interruption of contrast (TIC): a retrospective single-centre analysis in 225 consecutive CT pulmonary angiography studies

S. Sudarski[1], T. Henzler[1], H. Haubenreisser[1], S.O. Schönberg[1], A. Gutzeit[2]; [1]*Mannheim/DE*, [2]*Zurich/CH (sonja.sudarski@medma.uni-heidelberg.de)*

Purpose: To assess occurrence of transient interruption of contrast (TIC) phenomenon in pulmonary CT angiography (CTPA) studies performed to rule out pulmonary embolism.
Methods and Materials: In this retrospectively designed single-centre study, CTPA exams of 225 consecutive patients scanned between 9/1/2016 and 12/31/2016 on a 16-slice single-source CT scanner system were analysed. Exams were screened a priori to measurements and exams with non-adequate pulmonary artery contrast due to incorrect bolus tracking or failure of i.v. contrast administration were excluded from the analysis. HU values in the thoracic aorta and in the pulmonary trunk were assessed in duplicate measurements and the aorto-pulmonary ratio was calculated. An aorto-pulmonary ratio > 1 was defined as presence of TIC.
Results: 3 patients had to be excluded due to incorrect bolus tracking. Final analysis in 222 patients (mean age 65 ± 19 years, range 18 to 99 years) were analysed. Mean density in the pulmonary trunk was 275 ± 17 HU, in the aorta 208 ± 15 HU. Mean aorto-pulmonary ratio was 0.81± 0.29. 48 patients (21.6%) had an aorto-pulmonary ratio >1.
Conclusion: TIC is a common phenomenon in CTPA studies with an incidence of 22% in our retrospective cohort.

B-0460 11:18

Assessment of optimal window settings for display of traditional and noise-optimised virtual monoenergetic imaging in dual-energy CTPA

J.L. Wichmann[1], A.M. Bucher[1], L. Lenga[1], C. Arendt[1], D. Caruso[2], T. D'Angelo[3], A. Blandino[3], G. Ascenti[3], T.J. Vogl[1]; [1]*Frankfurt a. Main/DE*, [2]*Rome/IT*, [3]*Messina/IT (docwichmann@gmail.com)*

Purpose: To define optimal window settings for display of virtual monoenergetic images (VMI) of dual-energy CT pulmonary angiography (DE-CTPA) and assess impact on image quality in comparison to standard reconstruction and settings.
Methods and Materials: Data from 45 patients who underwent DE-CTPA were retrospectively evaluated. Three image dataset were assessed: standard linearly-blended (M_0.6), 70-keV traditional VMI (M70), and 40-keV noise-optimised VMI (M40+) reconstructions. For M70 and M40+, the subjectively best window setting (width and level, B-W/L) was initially assessed independently by two blinded observers and subsequently related with pulmonary artery attenuation to obtain calculated optimised values (O-W/L) using linear regression. Subjective evaluation of image quality between different W/L settings were assessed by two additional blinded readers.
Results: Best (B-W/L) settings for M70 and M40+ were 880/280HU and 1410/450HU, respectively. Regression analysis resulted in an O-W/L of 850/270HU for M70 and 1350/430HU for M40+. Significant differences for W/L were found between B-W/L and O-W/L for M40+, and between M70 and M40+ for both B-W/L and O-W/L (all p<0.001). Subjective image quality was significantly increased for M70 and M40+ after application of O-W/L (all p<0.001). Highest subjective scores were observed for M40+ regarding vascular contrast, embolism demarcation, and overall image quality (all p<0.001).
Conclusion: Application of O-W/L settings is mandatory to optimise subjective image quality of VMI reconstructions of DE-CTPA. M40+ showed better subjective image quality than M70. A width slightly less than two times the pulmonary trunk attenuation and a level approximately of overall pulmonary vessel attenuation are recommended.

B-0461 11:26

Optimalmonochromatic energy levels in spectral CT pulmonary angiogram for thedetection of pulmonary thromboembolism: using detector-based spectral CT

M. Ha, K.Y. Lee, C. Kim, S.-K. Kim, S.-J. Park, B.-K. Je, S.H. Lee, Y. Lee, J. Cha, A. Jeong-Cheon; *Ansan/KR (bearksk@gmail.com)*

Purpose: The aim of this study was to investigate the optimal monochromatic level, in spectral CT pulmonary angiography, for the detection of pulmonary thromboembolism, using detector-based spectral CT.
Methods and Materials: 103 patients were referred to undergo pulmonary CTPA with spectral CT mode in the arterial phase. Images of both conventional (120 kVp) and multiple monochromatic energy level (VME) images from 40 keV to 100 keV at intervals of 10 keV were generated using Spectral CT viewer. Image noise, clot diameter and clot to artery contrast-to noise ratio (CNR), signal-to-noise ratio (SNR) at selected monochromatic levels were measured and compared. Subjective image quality was also assessed by two radiologists and compared. We analyzed data using Kruskal-Wallis test and correlation analyses.
Results: The lowest noise was obtained at VME level of 100 keV. There was no difference in the mean noise between the VME images of 50, 60, 70, 80, 90 and 100 keV. The CNR and SNR values were achieved at the 40 keV level and increased as energy decreased. The highest diagnostic confidence for the detection of pulmonary thromboembolism was at VME level of 70 keV, because two reader's agreement at this level had the highest kappa coefficient (k=0.68). The clot diameter decreased with decreasing energy level.
Conclusion: Virtual monochromatic images at 100 keV yielded the lowest image noise. The highest CNR and SNR were obtained at 40 keV VME image. An optimal analysis of pulmonary thromboembolism can be achieved on virtual monochromatic spectral images at 70 keV.

B-0462 11:34

Right heart thrombi and acute pulmonary embolism: analysability of right cardiac cavities in the conditions of routine dual-source chest CT angiographic examinations

C. Fantini, J. Hennicaux, J.-B. Faivre, P. Felloni, J. Remy, M. Remy-Jardin; *Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To evaluate the analysability of right cardiac cavities on dual-source chest CT angiographic (CTA) examinations positive for acute pulmonary embolism (PE) in the conditions of routine clinical practice.
Methods and Materials: Among 449 patients referred for suspicion of acute PE, chest CTA was found positive in 59 patients (13%). The analysability of the right atrium (RA) and right ventricle (RV) was based on the evaluation of (a) the homogeneity of contrast attenuation; (b) the presence & severity of beam-hardening artifacts. A second acquisition during the CT session was at the radiologist's discretion.
Results: The RA was deemed interpretable in 44 patients (44/59; 74.6%) (Group 1a: 31/39; 79%) (Group 2a: 13/20; 65%) with homogeneous or slightly heterogeneous opacification and no beam-hardening artifacts (mean attenuation: 340.5 ±140.6 HU) while it was rated as not confidently interpretable in 15 patients (15/59; 25.4%) (Group 1b: 8/15; Group 2b: 7/15). The RV was always interpretable. In Group 1b, the RA became analysable on the delayed acquisition, obtained in all but one patient. In group 2b, the use of monochromatic images at 90 and 100 keV provided interpretable images (absence of beam-hardening artifacts; sufficient level of attenuation to depict intracardiac thrombi) in all but 2 patients, leading to a total of analysable cavities in 90% of Group 2 patients (18/20). Right intracardiac thrombi were depicted in two patients (2/59; 3%).
Conclusion: Right cardiac cavities were interpretable on a single acquisition in 79% and 90% of patients scanned with SE and DE, respectively.

Automatic spectral chest CT assist protocol: can the improvement of the noise index setting further decrease the radiation dose and optimise the image quality?

R. Wang, J. Gao, Y. Zhou; *Zhengzhou/CN (wr807115125@163.com)*

Purpose: To investigate the effect of automatic spectral imaging assist (ASIA) on radiation dose and image quality of enhanced chest CT examinations with low-dose contrast agent for patients with different body mass index (BMI).
Methods and Materials: 120 patients with dual-phase enhanced chest CT were randomly divided into experimental group (A) and control group (B). In each group, patients in three different BMI intervals were scanned at the noise index of 13, 18 and 22 respectively. By using 300 mgI/kg contrast agent ,the group A used the ASIA combined with 50% adaptive statistical iterative reconstruction (ASIR) technique to obtain the spectral monochromatic images (40~70 keV). The conventional 120 kVp CT with 450 mgI/kg contrast agent was adopt in the group B, and the filtered back-projection (FBP) algorithm was used to reconstruct images. Then, the index of radiation dose and image quality were calculated and evaluated.
Results: The images of the group A show better performance in reducing and maintaining image noise than that of group B ($p < 0.05$), especially for patients with BMI < 18.5kg/m^2 and BMI > 24.9 kg/m^2. There are no statistical differences of CTDIvol, DLP and ED between two groups at all BMI levels with noise index of 13($p>0.05$). However, the NI of 18 and 22 in group A were higher than that of group B.
Conclusion: The quality of images obtained by using ASIA combined with ASIR technique can meet the requirements of clinical diagnosis. However, its ability to reduce radiation doses is not satisfactory.

B-0464 11:50

Segmental and sub-segmental pulmonary embolism displayed by dual-detector spectral CT

Y. Yue, X. Lu, W. Zhang, Q. Guo; *Shenyang/CN (ghostaa2000@aliyun.com)*

Purpose: Pulmonary embolism involving segmental or sub-segmental artery is difficult to diagnosis in enhanced CT. Dual-detector spectral CT can promote detecting ability by display low perfusion area and small thrombi. We reviewed cases of segmental or sub-segmental embolism and correlate with there clinical background.
Methods and Materials: Enhanced dual-detector CT scans of lung were performed in 1200 cases. Lung and mediastinum slices along with iodine density and Z-effect map were reviewed (Z-effect is an image in which the pixel values represent the effective atomic number of the displayed tissue). Pulmonary embolism was described as artery thrombi with or without low perfusion in corresponding area in iodine density or Z-effect maps. Embolism involving pulmonary artery trunk or lobar branches is not included in this study. Clinical information including patient history, serum D-dimer level and revised Geneva score was recorded for analysis.
Results: Twenty-three cases were confirmed to have single or multiple segmental or sub-segmental embolisms. In them, 16 cases have a history of malignancy, including 5 cases of cervical cancer, 4 cases of esophageal cancer, 3 cases of lung cancer, 2 cases of liver cancer, 1case of lymphoma and 1case of pancreas cancer. In benign cases, 3 patients have brain stroke and 4 patients have no special history. Serum D-dimer level varied from 674 to 5440 (1520±1313) mmol/l and revised Geneva score varied from 4-7 (5.28±0.83).
Conclusion: Segmental or sub-segmental embolism is more likely to involve patients with malignancy and with mild symptoms or D-dimer levels.

Myometrial infiltration by deep pelvic endometriosis: MRI assessment

M. Francavilla[1], D. Resta[1], F. Lorusso[2], G. Angelelli[1], C. Tartaglia[1], P. Pignataro[1], M. Scioscia[3], A.A. Stabile Ianora[1], A. Scardapane[1]; [1]*Bari/IT*, [2]*Castellana Grotte/IT*, [3]*Negrar, Verona/IT (marianto_fra@hotmail.it)*

Purpose: Myometrial infiltration from peritoneal implants is often associated with endometriotic lesions in bowel, bladder, and with adenomyosis. Evaluation of the correlation between myometrial invasion and severity of deep pelvic endometriosis was made.
Methods and Materials: A retrospective survey of 198 women with previous laparoscopic surgery for pelvic endometriosis was carried out. A pelvic MRI was performed in all patients: it consisted in T2w-TSE sequences in axial, sagittal, and coronal planes and T1w and THRIVE sequences in the axial plane.The presence of endometriomas and endometriotic nodules in Douglas pouch, rectovaginal septum, torus uterinus and uterosacral ligaments was reported. Similarly, intestinal infiltrative nodules, vesical and ureteral implants and pelvic adherences were recorded. Results were analysed with $\chi 2$ test.
Results: Uterine infiltration was found in 26/198 (13%) patients, adenomyosis in 76/198 (38%) of cases, and their coexistence in 19/198 (9%) of women. Uterine invasion was detected in 19% of patients with Douglas pouch obliteration (vs 3% of women without Douglas involvement), in 24% of patients with rectovaginal septum lesions (vs 3% of women without RVS foci), in 28% and 38% of patients with bowel nodules and major intestinal resection

respectively (vs 2,5% of women that did not show these two findings). All the results demonstrated to be statistically significant, with p<0.05.
Conclusion: Myometrial infiltration is associated with severe features of deep pelvic endometriosis, in particular with colorectal involvement and consequent bowel resection.

B-0466 10:38

Diffusion tensor imaging (DTI) for evaluation of sacral plexus abnormalities in patients with pelvic deep infiltrating pelvic endometriosis with pelvic pain: a pilot study

A.M. Kalovidouri, M.I. Vargas, B. Delattre, N. Pluchino, X. Montet, D. Botsikas; *Geneva/CH (Anastasie-Marie.Kalovidouri@hcuge.ch)*

Purpose: To prospectively investigate if fractional anisotropy(FA) or apparent diffusion coefficient(ADC) of the lumbosacral plexus roots, correlate with intensity of pelvic pain in patients with pelvic deep infiltrating endometriosis(DIE). A secondary aim was to compare FA and ADC values in patients with DPE documented on MRI with those with negative morphologic MRI.
Methods and Materials: A DTI sequence was performed in all patients(mean age 33.5±8.9y)referred for pelvic MRI with clinical suspicion or known DIE from June 2016 to July 2017.The patients filled in a questionnaire with self-evaluation of pelvic pain in a scale from 0-10. A radiologist tracked all roots of lumbosacral plexus, from L5 to S3. Mean FA and ADC for all roots were calculated. Correlation coefficient r between pain scale and FA and ADC was calculated. FA and ADC values between patients with MRI documented DIE and those without DIE lesions on MRI were compared.
Results: 149 patients(74 with endometriosis detected on MRI and 75 without)were included in the study. There was a statistically significant negative correlation between overall pain and ADCmean(r=-0.1967, p=0.0181) and a weak positive correlation of FA mean and pain, with a statistical trend(p=0.0541). There was no statistically significant difference between ADC and FA values for patients with and without DPE detected on morphological MRI(p>0.05).
Conclusion: This study showed a negative correlation between ADC and positive correlation between FA of the lumbosacral plexus and pain. This could be explained by a intramyelinic oedema or microarchitectural abnormalities of the neural roots providing innervation to DIE lesions.

B-0467 10:46

Ovaries in patients with Mayer-Rokitansky-Küster-Hauser syndrome vs normal females: a retrospective cohort study with magnetic resonance imaging

Y. Wang, J. Lu, L. Zhu, R. Chen, B. Jiang, Z. Jin; Beijing/CN *(wang_yue111@126.com)*

Purpose: To explore the MRI appearances of ovaries in patients with Mayer-Rokitansky-Küster-Hauser (MRKH) syndrome as compared with a control group.
Methods and Materials: Pelvic MRI of 83 MRKH patients and 60 age-matched normal females were retrospectively reviewed by two experienced gynaecological radiologists in consensus. Characteristics including location of ovary, ovarian volume, and follicle counts were assessed. Ectopic ovary was established when it was located out of the pelvis, anterolaterally just behind the anterior pelvic wall, or far laterally in the paracolic gutter or near the lateral pelvic wall. Ovarian volume was calculated using the formula for the volume of an ellipsoid. Average numbers of follicle counts determined by two radiologists were recorded. The incidence of ectopic ovary was compared between MRKH patients and controls. The ovarian volume and follicle counts were compared among three groups: ectopic ovaries in MRKH patients, eutopic ovaries in MRKH patients, and normal controls.
Results: In total, 166 ovaries in 83 MRKH patients and 120 ovaries in 60 control females were evaluated. Thirty-seven ovaries in 23 MRKH patients (28%, 23/83) and 3 ovaries in three control females (5%, 3/60) were abnormally located (P<0.001). The mean volume was 9.2±6.3ml of the ectopic ovaries in MRKH patients, 7.8±4.0ml of the eutopic ovaries in MRKH patients, and 8.9±4.8ml in control females (P>0.05). No obvious difference was observed with regard to follicle counts.
Conclusion: MRKH patients associated with increased incidence of ectopic ovaries. Ovarian volumes and follicle counts were not differed statistically between MRKH patients and normal controls.

B-0468 10:54

Invasive placenta: MRI prognosticators for patients' clinical outcome

C. Bourgioti, K. Zafeiropoulou, E. Panourgias, K. Chatoupis, A. Antoniou, M. Nikolaidou, L.A. Moulopoulos; *Athens/GR (charisbourgioti@yahoo.com)*

Purpose: To investigate any possible association between MRI features and maternal peripartum outcome in patients with abnormal placentation.
Methods and Materials: Between March 2016 and June 2017, 49 gravid patients (mean age: 35.7years, mean gestational age: 32.5weeks) with sonographically confirmed placenta previa were referred for dedicated prenatal MRI. All MRIs were reviewed prospectively by two radiologists experienced in genitourinary imaging. All patients underwent C-section within 6 weeks from MRI; perioperative or/and pathological findings were used as standard of reference. Logistic regression models were used to investigate which MRI features were predictive of adverse peripartum events including increased blood loss, prolonged duration of delivery or hysterectomy performance.
Results: Thirty-eight (77.6%) patients had invasive placenta (percreta, n=26, accreta/increta, n=12) on surgery; 22/38 patients had bladder involvement, while 11/38 patients had parametrial invasion. Stepwise linear regression analysis showed that evidence of bladder invasion on MRI and T2 dark intraplacental bands were independently associated with prolonged duration of delivery (> 60 min). Additionally, bladder invasion on MRI, serosal hypervascularity and T2 dark bands were independently associated with massive blood transfusion (> 10 units packed red blood cells) during surgery. Serosal hypervascularity (OR=18.34, 95% CI: 1.53-219.0, p=0.021) and T2 dark bands (OR=11.32, 95% CI: 2.09-61.38, p=0.005) were significantly associated with hysterectomy performance.
Conclusion: MRI evidence of bladder invasion, serosal hypervascularity or T2 dark intraplacental bands were independently associated with poor maternal outcome in patients with abnormal placentation.

Colour Doppler unhappy surprise in transvaginal ultrasound evaluation of post-abortive vaginal bleeding: uterine arteriovenous malformations

S.A.H. Hassanein; *Shebin el-kom/EG (shaimaahamid@hotmail.com)*

Purpose: To assess the prevalence of uterine arteriovenous malformations and emphasize its presence as a cause of post-abortive bleeding.
Methods and Materials: A retrospective study was conducted reviewing the data acquired from transvaginal ultrasound combined with Doppler examination to patients presented by post-abortive bleeding at our institute during the last two years. The studied group included 548 patients presented clinically by post-abortive bleeding. All of them were examined by transvaginal ultrasound. Both grey-scale and Doppler examination were conducted in all cases.
Results: Reviewing the transvaginal ultrasound data revealed retained products of conception in 412 patients, normal scan in 118 patients and 18 cases of suspected uterine arteriovenous malformations which constitute the study population. Reviewing the patients' clinical data revealed post-abortive bleeding with duration ranging from 3 days to 3 weeks post-abortion. The mean age was 28.7 years. History of previous curettage was present in 16 cases. Doppler study showed the intense myometrial hypervascularisation with turbulent flow in 18/18 cases of AVM. The size of the intra-myometrial component exceeded 5 cm in 12/18 cases (66.7%). The largest vessel diameter ranged from 8 to 28 mm with a mean of 16.2 mm. The mean velocity detected was 22 cm/sec.
Conclusion: Uterine arteriovenous malformations are a serious cause for post-abortive bleeding and although their incidence is rare, it is very important to be identified using transvaginal ultrasound whether grey-scale or Doppler to avoid serious life-threatening bleeding.

B-0470 11:10

Ovarian ischaemia vs haemorrhagic infarction: differentiation by MRI in cases of adnexal torsion

Y. Ragab[1], H. Kheir[1], H. Hamza[2], S. Maher[1]; [1]*Cairo/EG*, [2]*London/UK (yragab61@hotmail.com)*

Purpose: To demonstrate the role of magnetic resonance (MR) imaging findings, in differentiating between ovarian infarction and ischaemia and consequently the rate of ovarian salvage in cases of adnexal torsion.
Methods and Materials: 25 patients with surgically proven ovarian torsion were evaluated by two radiologists regarding the following MR findings: pelvic fluid collection, uterine deviation, ovarian enlargement, ovarian parenchymal hypointensity on T2-weighted images (WI), hyperintensity on T1 (WI) with fat saturation, recognition of twisted pedicle, diffusion restriction and ovarian parenchymal enhancement. These MR findings were statistically correlated with the operative findings and histopathological results (for cases of ovarian infarction).
Results: Pathologically, ovarian haemorrhagic infarction was confirmed in 6 out of 25 cases. Ovarian hyposignal on T2 WI was seen in all cases with

infarction 6/6. Ovarian hyperintensity (compared to the contralateral sides) was observed in 4/6 and 5/6 cases with infarction on T1WI and DWI, respectively. Ovarian enlargement, fluid collections, uterine deviation and twisted pedicle were detected in most cases with or without haemorrhagic infarction. Poor parenchymal contrast enhancement was observed in all cases without or with necrosis.
Conclusion: Detection of ovarian infarction is of prognostic importance in cases of torsion to assess salvageability, and thus may affect the surgical decision. Swollen hypointense ovarian parenchyma on T2 WI with lack of contrast uptake are the most reliable MRI signs, followed by hypersignal on T1 WI fat sat and DWI.

B-0471 11:18

MRI predictive factors for vaginal stenosis in patients with cervical cancer after ChemoRadiation Therapy (CRT)

M. Sbarra, M. Miccò, B. Gui, E. Rodolfino, A.L. Valentini, R. Manfredi; *Rome/IT (sba.martina@gmail.com)*

Purpose: Vaginal Stenosis (VS) is a toxicity after radiotherapy. Our purpose was to describe radiotherapy induced changes in the vagina after CRT for cervical cancer and to find any Magnetic Resonance Imaging (MRI) predictive factors for the development of stenosis.
Methods and Materials: This retrospective study included 43 patients (mean age 49,5 y) with FIGO IB2-IIIB cervical cancer treated with CRT administered with external beam radiation therapy. They underwent 1.5 T pelvic diffusion weighted DW-MRI before (baseline), at 2 weeks from the start (early) and at the end of the treatment (late). On all MRIs, tumor volume (TV), the lenght and the thickness of the vagina were measured. DWI were analysed qualitatively at each time point. VS was clinically graded at each follow-up using Common Terminology Criteria for Adverse Effect v.4.03. The statistical analysis were made with Mann-Whitney test. ROC curves were generated for statistically significant DW-MRI parameters.
Results: According to CTCAE: Grade1 had 15 pts and Grade≥2 had 28 pts. TV was higher in Grade1 (p= 0,013). The mean vaginal length and thickness decreased between baseline and final MRI from 82,0 to 71,6 mm and from 3,3 to 2,6 mm respectively. DWI had a lower signal intensity at the final MRI in Grade≥2 (p<0,0001). According to ROC analyses the AUC was 0,917 (p< 0,0001) for DWI and 0,731 (p= 0,013) for TV.
Conclusion: This is the first study that demonstrates the utility of DW-MRI to find predictive factors for VS in cervical cancer after CRT.

B-0472 11:26

Female Skene's gland diseases: CT and MR imaging evaluation

H. Wang, J. Guan, Y. Guo; *Guangzhou/CN (usefulkey0077@hotmail.com)*

Purpose: To analyse the imaging characteristics of Skene's gland (periurethral gland) diseases on CT and MRI, further to improve the understanding and imaging diagnosis.
Methods and Materials: 15 female cases with Skene's gland disease confirmed by pathology were retrospectively analysed. Imaging features of Skene's gland disease were summarized.
Results: Skene's gland cysts (n=3) located in the distal and posterolateral urethra or close proximity to the urethra, presenting as cystic lesions with teardrop shape on sagittal images, appeared as hypo-attenuation on CT, and hypo-intensity on T1WI, hyper-intensity on T2WI, and without enhancement. One with infection presented as hyper-intensity on T1WI and gaseous intensity inside, and thickened cystic wall. Urethral diverticulums (n=10) located in the middle or distal and posterolateral urethra, and presented as a horseshoe-shaped cystic lesion partially surrounding the urethral (n=3) or spoke wheel-like cystic lesion with multiple septum completely surrounding the urethra (n=7). They appeared as fluid attenuation/intensity on CT and MRI without enhancement. Heterogenous signal or attenuation and enhanced septum or cystic wall were found in 6 cases with infection. Malignant tumour of Skene's gland (n=2, adenocarcinoma and neuroendocrine carcinoma) presented as cystic-solid mass surrounding the urethral, showing heterogeneous low attenuation on CT and iso- to hyper-intensity on T2WI and hypo- to iso-intensity on T1WI with enhancement. A “prostate” sign was specific for determining the lesion origin of the Skene's gland.
Conclusion: According to the lesion location and imaging features, we can make an accurate diagnosis and distinguish different types of female Skene's gland diseases.

B-0473 11:34

Diagnostic value of MR perfusion in characterisation of complex adnexal masses

H.A.S. Sabet, R.M. El Kady, N.N. Omar, A.M. Abbas; *Assiut/EG (bobaez1989@gmail.com)*

Purpose: To assess the role of MR perfusion weighted imaging (MR PWI) in characterisation of complex adnexal masses.
Methods and Materials: Twenty-seven patients underwent MR PWI using rapid dynamic contrast-enhanced T1-weighted gradient echo. Regions of interest (ROIs) were drawn in the solid part of the adnexal lesion and the outer myometrium. PWI was analysed using descriptive, time signal intensity curves and semiquantitative parameters (relative enhancement (RELENH), maximum enhancement (MAXENH), maximum relative enhancement (MAXRELENH), time to peak (TTP), and wash-in rate (WASHIN) and wash-out rate (WASHOUT). Time intensity curve and semiquantitative parameter results were correlated to the histopathological results.
Results: Curve type 1 was found to be 100% specific for benign ovarian tumours (p=0.017). Type III curve showed (76%) sensitivity and (60%) specificity for malignant tumours. MAXENH showed accuracy of 73.2%, sensitivity of 76.5% and specificity of 70% for malignant tumours. WIR showed the highest sensitivity (88.2%) while WOR with a cut-off value of 6.03 showed the highest specificity (90%).
Conclusion: PWI is useful in characterisation of adnexal masses. We can depend upon WIR in depicting malignant masses and applying the cut-off of WOR to exclude the false-positive cases and avoid radical surgery in unnecessary patients especially in women aiming at preserving fertility.

B-0474 11:42

MRI in endometriosis: a new platform

W.R.A. Abdel Hamid; *Cairo/EG (w.gforever@yahoo.com)*

Purpose: The aim of this study is to validate the ability of MRI as an accurate tool in verifying the endometriotic load in patients with clinically suspected endometriosis. Our aim was also to verify the results of non-contrast MRI compared to contrast enhanced MRI through laparoscopic correlation.
Methods and Materials: 60 female patients within an age range of 27 and 44 years were included in the study. A thin slice high resolution MR study was performed for all patients with a protocol including Axial & sagittal T2W, T1W (with and without fat suppression), DWI images together with delayed post contrast T1W fat suppressed images in the three orthogonal planes. Findings were compared to results of laparoscopy.
Results: Based on our results, IV contrast didn’t add much. The data acquired from T1W images with fat suppression and DWI's were sufficient and showed high sensitivity and specificity values when compared to laparoscopic findings. Each key finding was validated separately including endometriomas, adenomyosis, solid endometriotic implants, giving high sensitivity (94.59%, 100% & 95.35%), specificity (96.15%, 95.65% & 100%), PPV (97.22%, 88.89% & 100%) and NPV (92.59%, 100% & 90.48%) respectively.
Conclusion: Non- contrast MRI can be considered a highly accurate tool in screening for endometriotic load. It can be used as a roadmap prior to laparoscopic intervention to help guide gynecologists so as not to miss lesions.

B-0475 11:50

Utility of histogram analysis of apparent diffusion coefficient maps obtained using 3.0T MRI for distinguishing uterine endometrial carcinoma from endometrial polyps

W. Wang, J. Cheng, Y. Zhang; *Zhengzhou/CN (weijianwang520@163.com)*

Purpose: We explored the role of histogram analysis of apparent diffusion coefficient (ADC) maps for discriminating uterine endometrial carcinoma and endometrial polyps.
Methods and Materials: We retrospectively evaluated findings in 40 patients with uterine endometrial polyps and 50 patients with endometrial carcinoma who underwent diffusion-weighted imaging (b = 0,800 s/mm(2)) at 3T with acquisition of corresponding ADC maps. We derived histogram data from regions of interest drawn on all slices of the ADC maps in which tumour was visualised, including areas of necrosis and haemorrhage in the tumour. We used the Mann-Whitney test to evaluate the capacity of histogram parameters (mean, skewness, kurtosis,50th,90th percentiles) to discriminate uterine endometrial carcinoma from endometrial polyps and analysed the receiver operating characteristic (ROC) curve to determine the optimum threshold value for each parameter and its corresponding sensitivity and specificity.
Results: Uterine endometrial carcinoma demonstrated significantly higher mean vales of ADC, skewness, kurtosis, 50th, 90th percentiles than endometrial polyps (P < 0.05). ROC curve analysis of the 90th percentile yielded the best area under the ROC curve (AUC; 0.92), sensitivity of 90%, and specificity of 95%, with a cutoff value of 198.
Conclusion: Histogram analysis of ADC maps might be helpful for discriminating uterine endometrial carcinoma from endometrial polyps

Radiomics of metastatic clear-cell renal carcinoma: reproducibility and correlation for feature reduction

A. Bouchouicha, J. Deidier, K. Benac, D. Balvay, S. Oudard, R. Pirracchio, L.S. Fournier, B. Rance; *Paris/FR (afef.bouchouicha@aphp.fr)*

Purpose: To evaluate the robustness and redundancy of radiomics features extracted from CT images.
Methods and Materials: 28 metastatic clear-cell renal carcinoma patients were enrolled, before therapy initiation. Tumour was manually delineated by three expert physicians. Three categories of features were extracted: shape descriptors, intensity histogram statistics and textural features. Impact of filters and grey-level scales on features was studied. Concordance correlation coefficients (CCC) and inter-class correlation coefficients (ICC) were calculated to assess the reproducibility. Spearman correlations were performed to assess feature redundancy.
Results: 1564 radiomics features were extracted from each image. Different filters had little effect and grey levels no significant effect on extracted radiomics feature values. 231/1564 features showed high reproducibility for ICC (ICC≥0.8), and 198/1564 for CCC (CCC≥0.9). Features with an ICC≥0.8 and CCC≥0.9 were considered the most robust. This step reduced the number of relevant features to 158. Among these, highly correlated features with correlation ≥ 0.9 were removed. This procedure yielded 23 features both robust and independent.
Conclusion: This study allows understanding feature stability and redundancy, and impact of pre-processing filters and grey-scales levels. These steps are mandatory to subsequently use radiomics features for prediction of therapy response and outcome in oncology.

B-0477 10:38

Application of radiomics and artificial intelligence in survival prediction of lung cancer patients

I. Shiri, P. Geramifar, H. Abdollahi, S. Shayesteh, G. Hajianfar, H. Pouraliakbar, A. Mohammadzadeh, A. Bitarafan-Rajabi; *Tehran/IR (Isaac.sh92@gmail.com)*

Purpose: Before initiation of therapy, accurate prediction of tumor's response to treatment enhance clinical care management. The aim of current study was to develop a predictive model based on lung cancer survival using artificial neural network (ANN) algorithm on image biomarkers.
Methods and Materials: Lung lesions from archived DICOM images (TCIA) of four hundred and sixty cancer patients were segmented using automatic region growing algorithm. Image preprocessing steps were performed by wavelet decompositions. Following image preprocessing and decompositions, eight images based on the wavelet, 632 quantitative 3D textures based on the GLRLM, GLCM and GLSZM, and 15 Shape features and 19 first order features were extracted from the 3D-tumor volumes segmentation. Supervised back-propagation ANN classifier was used to predict survival and dead status in lung cancer patients using radiomics features. Sixty-six percent of data was recruited as test and remained was used as training set.
Results: ANN was found as an effective method in prediction of survival in lung cancer patients. Our results showed this model with 73.4%, sensitivity, 79.1% specificity and 78.7% area under the curve (AUC) has a strong predictive power.
Conclusion: We discovered a novel prognostic model based on radiomics and artificial intelligent which can effectively predict survival in lung cancer patients. This study demonstrates that radiomics and artificial intelligent can provide valuable clinical information for advance personalized treatment in patients with lung cancer.

B-0478 10:46

Multimodality radiomics signature analysis improves prediction power against Stand-Alone analysis of PET, CT and MRI images

I. Shiri, P. Geramifar, H. Abdollahi, A. Bitarafan-Rajabi, A. Mohammadzadeh, H. Pouraliakbar; *Tehran/IR (Isaac.sh92@gmail.com)*

Purpose: Radiomics is a high-throughput computing process convert medical tomographic images to high dimensional data sets. These data is subsequently mined and can effectively contribute for improving decision support system. Although radiomics signature was performed on different image modality systems, in this study, we assessed the possible improvement of prediction power of multi-modality analysis against stand-alone imaging systems.
Methods and Materials: Forty two soft tissue sarcoma (STS) patient from the Cancer imaging archive with MRI, CT, PET scans and information about lung metastases were subjected to current study. Image were preprocessed by different methods including image resampling, Laplacian of Gaussian (LOG) filtration with different sigma value, and wavelet. Following preprocessing and segmentation of GTV, 3D radiomics features based on shape, SUV (for PET) and intensity histogram, texture features including NGTDM, GLSZM, GLRLM, TFC were extracted. After feature selection and reduction, different supervised machine learning methods were used to predict lung metastases from stand alone and multimodality systems.
Results: Improvement in radiomics signature was observed in multimodality imaging system. The results of the prediction model using stand-alone analysis of CT, MRI and PET shows area under the curve (AUC) values of 0.731, 0.89, and 0.95 respectively. The corresponding value is 0.978 in multi-modality imaging systems analysis.
Conclusion: The results of this study indicate that multimodality radiomics signature analysis improves prediction power against stand-alone analysis of PET, CT and MRI images which lead to better predicting model of lung cancer in patients with STS.

B-0479 10:54

A new radiomics approach to predict the evolution of PI-RADS score 3/5 prostate areas in multiparametric MR

N.C. D'Amico, E. Grossi, G. Valbusa, A. Malasevschi, G. Cardone, S. Papa; *Milan/IT (damiconatascha@gmail.com)*

Purpose: To characterize, through a radiomic approach, the nature of areas classified PI-RADS 3/5, recognized in multiparametric prostate magnetic resonance with T2-weighted (T2w), diffusion and perfusion sequences with paramagnetic contrast.
Methods and Materials: 24 cases undergoing multiparametric prostate MR and biopsy were admitted to this pilot study. The clinical outcome of the PI-RADS 3/5 was found through biopsy, which found eight malignant tumours. The analysed images were acquired with a Philips achieva 1.5T machine with a CE-T2-weighted sequence in the axial plane. Semi-automatic tumour segmentation was carried out on MR images using 3DSlicer image analysis software. 45 shape-based, intensity-based and texture-based features were extracted and represented the input for pre-processing. An evolutionary algorithm (a TWIST system based on KNN algorithm) was used to subdivide the dataset into training and testing set and select features yielding the maximal amount of information. After this pre-processing 20 input variables were selected and different machine learning systems were used to develop a predictive model based on a training testing crossover procedure.
Results: The best machine learning system (three-layer feed-forward neural network) obtained a global accuracy of 90% (80 % sensitivity and 100% specificity) with an ROC of 0.82.
Conclusion: Machine Learning systems coupled with radiomics show a promising potential in distinguishing benign from malignant tumours in PI-RADS 3/5 areas.

B-0480 11:02

Quantitative CT-based radiomics as predictor of local resectability of pancreatic ductal adenocarcinoma

J. Van der Putten[1], S. Zinger[1], P.H.N. De With[1], M.M. Prokop[2], J.J. Hermans[2]; [1]*Eindhoven/NL*, [2]*Nijmegen/NL (jjhermans@gmail.com)*

Purpose: To compare the performance of an expert radiologist to that of quantitative radiomics for prediction of local resectability of pancreatic ductal adenocarcinoma on routine abdominal CT.
Methods and Materials: We included 66 patients (m:f=32:34; range 35-82 yrs) with histologically proven pancreatic ductal adenocarcinoma who were operated within 4 weeks of an initial routine portal-venous phase multidetector-row CT examination. An expert abdominal radiologists scored CT data for tumor resectability. Another expert abdominal radiologist drew tumor contours to obtain a volume of interest, from which we computed 90 intensity, shape and texture features. During training the feature vector was reduced with a feature selection algorithm and combined with several classifiers to predict local respectability using radiomics.
Results: There were 43 hypo- and 23 iso-attenuating tumors, of which 29 were resectable and 37 non-resectable. The best classification result was obtained with a logistic regression classifier with the feature vector reduced by regularized discriminative feature selection. Accuracy for predicting resectability was 67% for the radiologist, and 83% for radiomics. Sensitivity, specificity, positive and negative predictive value for resectability were 90%, 49%, 58% and 86%, respectively, for the radiologist and 79%, 86%, 84%, and 82%, respectively, for radiomics.

Conclusion: Quantitative CT-based radiomics for prediction of resectability of pancreatic adenocarcinoma on routine CT may outperform expert radiologists with respect to accuracy and positive predictive value but at a lower sensitivity.

B-0481 11:10

Radiomics: prediction of acoustic neuroma response to the CyberKnife treatment

N.C. D'Amico, I. Castiglioni, E. Grossi, G. Valbusa, G. D'Anna, F. Rigiroli, I. Bossi Zanetti, G. Scotti, S. Papa; *Milan/IT (nataschaclaudia.d'Amico@cdi.it)*

Purpose: The objective of the study is to analyse MR images acquired before CyberKnife treatment, to predict the response and avoid unnecessary radiosurgery for patient.
Methods and Materials: T1-weighted MR images of 38 patients presenting an acoustic neuroma treated with CyberKnife® at the CDI (52.6% responders with volume reduction) were selected and analysed. Analysed images were acquired on 1.5T machines with contrast-enhanced T1-weighted sequences in the axial plane. Semi-automatic tumour segmentation was carried out on MR images using the 3DSlicer image analysis software. Shape-based, intensity-based and texture-based features were extracted. An evolutionary algorithm (a TWIST system based on KNN algorithm) was used to subdivide the dataset into training and test set and select features yielding the maximal amount of information. After this pre-processing, a predictive model based on a training-testing crossover procedure was developed. The best neural network obtained was a 3-layer feed forward back propagation algorithm with 8 input variables containing the maximal amount of information.
Results: The neural network was used twice inverting the training/testing set. In the first analysis, the sensitivity was 100%, while the specificity, was 77.78%. These two results gave a global accuracy of 88.89%. In the second analysis the sensitivity was 61.54% and the specificity 100%, with a global accuracy of 80.77%. The mean value of the global accuracy was 84.83%.
Conclusion: The obtained results show that machine learning coupled with radiomics has a great potential in distinguishing responders with volume reduction from responders without volume reduction to radiosurgery, before the treatment.

B-0482 11:18

Automated translation of radiologic reports with deep learning-powered translation engines: a feasibility study

T. Weikert[1], R. Wyttenbach[2], G. Nicolas[1], R. Hendel[3], C. Glessgen[1], J. Bremerich[1], E.M. Merkle[1]; [1]*Basle/CH*, [2]*Bellinzona/CH*, [3]*Würzburg/DE (thomasjohannes.weikert@usb.ch)*

Purpose: The quick, accurate and inexpensive translation of medical reports is a task of increasing importance in a globalised world with many patients crossing language borders during their treatment. Recently, deep learning-powered translation engines showed impressive results translating prose texts. The purpose of our study was to assess the utility of such engines in a radiological context.
Methods and Materials: 20 German radiology reports of oncologic follow-up examinations generated between March and September 2017 were randomly selected. The impression section was translated into English, French and Italian by two deep learning-powered translation engines (DeepL and Google Translate). The translations were then evaluated by three bilingual radiologists in the respective language (RH: English; NG: French; RW: Italian). Three error categories were labeled (stylistic error, content error without significance, potentially dangerous error).
Results: Overall, 79% of all words were translated correctly. However, only nine out of 120 translations were free of potentially dangerous errors and altogether 806 mistranslations were identified. Overall, the two translation engines showed a comparable performance. Of note, the quality of the translations into English was noticeably superior with 89% of all words correctly translated and 43% less potentially dangerous errors.
Conclusion: Deep learning-powered translation engines in their current version are not suitable for automated translation of complex oncologic radiology reports. However, considering the fact that the performance of neuronal networks depends heavily on the data they were trained on, training on medical texts holds an enormous potential for better results in the near future.

B-0483 11:26

Automated detection and localisation of skull fractures from CT scans using deep learning

R. Ghosh[1], S. Chilamkurthy[1], P. Rao[1], M. Biviji[2]; [1]*Mumbai/IN*, [2]*Nagpur/IN (rohit.ghosh@qure.ai)*

Purpose: To develop and validate deep learning-based algorithm pipeline for fast detection and localisation of skull fractures from non-contrast CT scans. All kinds of skull fractures: undisplaced, depressed, comminuted, etc. were included as part of study.
Methods and Materials: Anonymized and annotated dataset of 350 scans (11750 slices) with skull fractures were used for generating candidate proposals for fractures. Stacked network pipeline was used for candidate generation - a fully convolutional network for ROI generation and another deep convolutional network for ROI classification. Final ROI classification model (ResNet18) yielded fracture probabilities for candidates generated through the fully convolutional (UNet) network. Separate deep learning model was trained to detect haemorrhages on scan level which was used as proxy for clinical information. Fracture candidate features like size, probabilities, depth for top 5 most probable fracture candidates along with haemorrhage model confidence ($p_{haemorrhage}$) were combined to train random forest classifier to detect fracture on scan level. In case of predicted fracture, most probable candidate(s) were used for localization.
Results: Separate set of 2971 scans, uniformly sampled from database with no exclusion criterion, was used for testing scan-level decisions with 108 scans reported as skull fracture cases. To evaluate scan-level decisions for fractures, area under receiver operating curve (AUC-ROC) was calculated as 0.83 with $p_{haemorrhage}$ as feature and 0.72 without. Free receiver operating curve yielded 0.9 sensitivity at 2.85 false-positives-per-scan. Predictions on each patient takes <30s.
Conclusion: Deep learning-based pipeline can accurately detect and localize skull fractures. Pipeline can be used for triaging patients for presence of skull fractures.

Fast estimation of kidney volumes and time courses in DCE-MRI using convolutional neural networks

A.S. Lundervold[1], K. Sprawka[2], A. Lundervold[1]; [1]*Bergen/NO*, [2]*Lodz/PL (allu@hvl.no)*

Purpose: We create a novel method for fast and accurate estimation of kidney volumes and signal intensity time courses in DCE-MRI, aiming at extracting both structural and functional quantitative information from the moving kidney.
Methods and Materials: Two repeated SPGR-DCE-MRI datasets were acquired from 20 healthy volunteers, resulting in 40 examinations, each consisting of 74 volumes recorded over ~6 min. We trained a 3D convolutional neural network (using a single standard NVIDIA GeForce 1080Ti GPU) for segmentation of left and right kidneys. The network has a dual-pathway architecture, incorporating both local and global information in the volumes. To create training data, we manually delineated 10 individual volumes from 10 different time-series, and extended the delineations to 740 volumes using image registration.
Results: Our implementation is able to segment all 74 volumes in a previously unseen, unregistered recording in less than 7 minutes. Mean segmentation accuracy (Dice) was 0.843 (SD=0.010). Mean (SD) left and right kidney volumes [ml] (incl. renal hilum) in one of the subjects (FF03) examined seven days apart (MR1 and MR2) was: MR1 L: 301.6 (15.9), R: 389.8 (16.9); MR2 L: 307.4 (17.8) R: 395.3 (23.6).
Conclusion: A CNN is able to quickly and accurately segment the moving kidneys in DCE-MRI, providing estimates of kidney volumes and mean signal intensity time courses. We are currently working to achieve sub-segmentation of the kidney (cortex, medulla, pelvis) and segmentation of the aorta (for AIF), enabling automated and fast estimation of GFR directly from the DCE-MRI.

B-0485 11:42

Automatic detection of intracranial calcifications in non-contrast CT

G. Bortsova, G. van Tulder, F. Dubost, A. van der Lugt, D. Bos, M. De Bruijne; *Rotterdam/NL (gerdabortsova@gmail.com)*

Purpose: Intracranial carotid artery calcification (ICAC) is a major risk factor for stroke, and might contribute to dementia and cognitive decline. Further research into the relationship between ICAC and neurological diseases is much demanded, but hampered by the time-consuming manual annotation of ICAC lesions. Therefore, we introduce the first fully automatic ICAC lesion detection method.
Methods and Materials: Non-contrast-enhanced CT scans were performed in 1882 participants of the Rotterdam Study, a population-based cohort study (mean age 69.6(6.8), 51.7% female). Two trained observers annotated the scans by indicating regions of interest on the intracranial carotid artery track (from the horizontal petrous segment to the circle of Willis) where calcifications were visible. ICAC lesion segmentations were obtained from these annotations by thresholding at 130 HU. We developed a deep learning based algorithm to automatically delineate ICAC lesions in CT scans. The algorithm was trained on scans of 882 subjects and validated on 1,000 scans of other subjects.
Results: The intraclass correlation between ICAC volumes computed from manual and automatic ICAC segmentations was 97.7%. This is close to the interrater agreement of 99%. The Bland-Altman bias (95% CI) was 197(-384, 778). (Mean ICAC volume is 1151±1624.)

Conclusion: Our algorithm can be used to automate the time-consuming manual annotation of ICAC in large epidemiological studies, whilst maintaining a comparable level of accuracy. This can facilitate research into causes and consequences of ICAC, which might result in development of new treatments and establishment of ICAC volume as a stroke risk estimator in clinical practice.

B-0486 11:50

Automatic liver metastases detection on CT using multi-class patch based convolutional neural networks

E. Klang[1], M. Frid[2], I. Diamant[2], A. Ben Cohen[2], M. Di Segni[3], E. Konen[1], H. Greenspan[2], M.M. Amitai[1]; [1]*Ramat Gan/IL*, [2]*Tel Aviv/IL*, [3]*Rome/IT*

Purpose: To evaluate a patch based deep learning approach for liver metastases detection that models the variability between liver metastases, normal liver parenchyma and normal liver boundary.
Methods and Materials: This research was supported by the ISRAEL SCIENCE FOUNDATION (grant No. 1918/16). In this study we evaluate a patch based Convolutional Neural Networks (CNN) approach for liver metastases detection on portal phase CT studies. Patches (~32X32 pixels/patch) are extracted from each liver and then fed into a multi-class CNN, which classifies the patches into three categories: (1) liver metastases, (2) normal liver parenchyma, (3) normal liver boundaries. The networks decisions between the three categories are then fused to reach a binary lesion versus non-lesion decision. Data augmentation was applied to enrich the number of patches (flipping, rotation). A senior radiologist segmented all liver and metastases boundaries. True positive rate (TPR) and false positive per case (FPC) were compared to a binary patch based CNN classifier (metastases vs. liver).
Results: The entire dataset included CT images of 132 livers with 498 2D segmented liver metastases. The CNN was trained using ~140,000 patches for each class. Evaluation was performed on the 132 livers with 2-fold cross validation. TPR and FPC were 85.9% and 1.9 for the multi-class CNN and 80.0% and 2.8 for the binary CNN.
Conclusion: The multi-class deep learning algorithm shows promising results in liver metastases detection task. Using prior knowledge of medical data, such as differences between interior and boundaries, may enhance CNN results.

In vivo evaluation of optic nerve and periorbital structures' biomechanical properties using shear-wave elastography in patients with glaucoma

M. Guazzaroni, S. Marsico, V. Girardi, T. Campagnuolo, S. Altobelli, R. Floris; *Rome/IT (salvatore.marsico@hotmail.it)*

Purpose: Glaucoma is an eye disease characterised by a slow and progressive damage of the optic nerve, retinal ganglion cell and visual field. The purpose of this study was to investigate shear-wave elastosonography use in the evaluation of the optic nerve and periorbital structures (orbital fat, lateral rectus and complex retinal-choroid).
Methods and Materials: An observational retrospective study, including 20 patients with glaucoma and 20 volunteers of the control group, was carried out. All of the participants had comprehensive ophthalmological exams (tonometry, OCT). In vivo evaluations of the biomechanical properties of the optic nerve and periorbital structures were performed with shear-wave elastosonography using a linear multifrequency probe (10-2 Mhz) in all participants. Differences of parameter stiffness of patients with and without glaucoma were evaluated using Student's t test.
Results: The mean stiffness of the optic nerve and periorbital structures (fat tissue, complex retinal-choroid) was significantly higher in glaucoma patients for each measured region ($P<0.05$). Statistical significance of these results increased by the evaluation of the "Strain Ratio", which is the relationship between the optic nerve and periorbital structure. Indeed, the "Strain Ratio", optic nerve/fat tissue, was significantly higher in patients with glaucoma.
Conclusion: Shear-wave elastosonography allows to identify stiffness variations of the optic nerve and periorbital structures in glaucomatous eyes.

B-0488 10:47

Ultrasound elastography of solid thyroid nodules: how far could we get?

N.F. El Ameen, M.F. Amin; *El Minia/EG (nadia.elameen@yahoo.com)*

Purpose: To evaluate the diagnostic accuracy of elastography in differentiation between benign and malignant solid thyroid nodules.
Methods and Materials: A prospective study, included 100 patients having 120 solid thyroid nodules. All patients were referred from surgery department between June 2016 and June 2017. All patient cohorts undergo routine ultrasonography and then elastography (USE). All radiological results were correlated with surgery and histopathology results.
Results: Using routine ultrasonography only showed sensitivity and specificity of 91% and 94%, respectively. Adding elastography to routine ultrasonography examination increases the sensitivity and specificity to 95% and 97.3%, respectively. Elastography confirmed that scores 4 and 5 were diagnostic for malignant nodules in examination of 40/48 nodules and scores 1 and 2 were diagnostic for benign nodules in the examination of 59/72 nodules.
Conclusion: Elastography is a promising technique if added to routine ultrasonography examination. It will improve the diagnostic accuracy of ultrasonography in differentiation between malignant and benign solid thyroid nodules. It will reduce the need for unnecessary biopsy and surgery.

B-0489 10:55

Complementary diagnostic role of shear wave elastography (SWE) in assessment of thyroid nodules during ultrasound examination

M. Schiavone; *Monza/IT*

Purpose: To evaluate the feasibility of the application of shear wave elastography (SWE) in the routine management of thyroid nodules, as a possible additional tool to the standard ultrasonography (US) triage.
Methods and Materials: A total of consecutive 214 patients, scheduled for US-guided thyroid fine-needle aspiration (FNA), were included in the study group. The presence of a pure colloid lesion was an exclusion criteria. The patients underwent conventional US examination and software 2D-SWE measurements. Absolute SWE stiffness measurements on color-coded elastograms, expressed in kPa and m/s, were correlated with radiological and pathological features and their discriminatory performances have been assessed and statistically analysed.
Results: The SWE values in thyroid nodules were significantly higher than normal thyroid tissue ($p=0.0001$), proving the different elastic properties of the pathological tissues. The SWE elasticity was not influenced by the characteristics of the bioptic smears, being unrelated to content and haematic composition of FNA. Regarding the radiological characteristics of the nodules, SWE highest values were associated with largest lesions ($p=0.0105$) but independent from ecographic and Doppler findings. The final correlation between the SWE results and the pathological diagnoses showed a trend in stiffness from tender tumours (follicular adenoma) to papillary thyroid carcinoma ($p= =0.0160$).
Conclusion: SWE represents a quick, feasible, reproducible and helpful complementary diagnostic tool in routinely clinical practice in identifying the presence of thyroid nodules within normal parenchyma.

Comparison of shear-wave elastography (SWE) and real-time elastography in the same thyroid nodules: which is more accurate?

Y. Fu; *Beijing/CN (13699216067@163.com)*

Purpose: Virtual touch tissue imaging (VTi), conventional US elasticity imaging (EI), virtual touch tissue imaging quantification (VTIQ), acoustic radiation force impulse (ARFI) are four elastographic forms available in one ultrasound machine. The purpose of this research is to establish the diagnostic accuracy of VTi, VTIQ, ARFI, EI in differentiating benign from malignant thyroid nodules.
Methods and Materials: All solid nodules identified on grey-scale imaging were subjected to elastography in 2016. Diagnostic performance was compared with histological findings as the gold standard. Receiver operating characteristics curves were applied to look for any significant differences. Univariate and multivariate analyses with potential variables were examined to identify independent variables for malignancy prediction.
Results: There were 85 patients (mean age, 42 years) with 90 pathologically proven thyroid nodules included in our research. There were 32 benign nodules and 58 malignant nodules. Forty nodules could not be assessed using ARFI for the lesion velocity was x.xx m/s. So, ARFI was not included for statistics. Four potential factors were found with significant effects on malignancy prediction and they were echogenicity, echogenic foci, VTI, VTIQ. After multivariate analysis, VTi was the only independent variable for

malignancy prediction (P=0.001). Area under the ROC curve for VTi was higher than that with other significant independent variables, and VTi of at least grade III was the best cutoff values for malignant thyroid nodules.
Conclusion: VTi is a useful tool for the differential diagnosis of thyroid nodules with higher diagnostic performance than shear-wave elastography and traditional EI.

B-0491 11:11

Comparison between the US vs MRI features of papillary thyroid carcinoma

S. Hu; *Zhenjiang/CN (hsd2001054@163.com)*

Purpose: This study aimed to evaluate the magnetic resonance imaging (MRI) and ultrasound (US) features of papillary thyroid carcinoma (PTC) and to compare the US and MRI features of PTCs.
Methods and Materials: Between January 2015 and April 2016, 86 consecutive patients underwent surgery for pathologically confirmed PTCs. All patients underwent neck US and MRI examination before thyroid surgery. For each case, the US and MRI features emphasised included the echogenic/signal, margin, shape, anteroposterior to transverse diameter ratio (A/T), microcalcifications and lymph node metastasis. Statistical analysis was performed using the χ^2 test.
Results: In the comparison of US and MRI features, A/T≥1 (41.9% in US and 62.8% in MRI) and lymph node metastasis (88.0% in MRI; 56.0% in US) demonstrated a statistically significant difference (P=0.009, P =0.025) and there was no significant difference in the margin and shape (P=0.724, P=0.316).
Conclusion: The study results demonstrated that the MRI features of PTCs including A/T and lymph node metastasis were inferior to US.

B-0492 11:19

Role of ultrasound in management of indeterminate thyroid nodules (Bethesda III and IV)

E. Horvath, C. De la Barra, G. Aguilera, C. Silva, J. Slater, V. Skoknic, S. Majlis, M. Garcia, P. Gonzalez; *Santiago/CL (camidlb@gmail.com)*

Purpose: To evaluate the role of US in predicting benignity or malignancy of lesions Bethesda III and IV, to support medical decisions (follow-up, re-puncture or surgery).
Methods and Materials: IRB approved retrospective descriptive study. Thyroid fine needle aspirations (FNA) with clot technique, performed between 2010 and 2015 were reviewed. Nodules classified as Bethesda III (atypia of undetermined significance = AUS; follicular lesion of undetermined significance = FLUS) and IV (follicular neoplasm = FN and suspicion of follicular neoplasia = SFN) were selected. Only patients who underwent thyroidectomy were included for this analysis. Nodules were considered low risk on US when presenting as TIRADS score 2, 3, 4A and intermediate-high risk with TIRADS 4, 4B, 5. US risk was compared with the presence of malignancy in the surgical specimen.
Results: In total 3.738 FNAs were performed in the period studied; 269 (7.2%) were Bethesda III and 46 (1.2%) Bethesda IV. Ninety patients (65 FLUS, 11 AUS and 14 FN/SFN) underwent surgery. In TIRADS 4, 4B and 5 nodules malignancy was 12.2% (6/49) in FLUS, 100% (10/10) in AUS and 50% (6/12) in FN/SFN. Meanwhile, in TIRADS 2, 3 and 4A nodules, no malignancy was identified (0/19).
Conclusion: The high presence of AUS malignancy is highlighted. No malignancy was detected for Bethesda III-IV nodules presenting with low risk US TIRADS patterns. This information could assist the clinician in making therapeutic decisions.

B-0493 11:27

Prospective assessment of TIRADS US assessment and strain and Shear wave elastography to discriminate benign from malignant thyroid lesions

V. De Soccio, G. Alagna, V. Forte, M. Di Segni, V. Cantisani, E. Tassone, C. Catalano, F. D'Ambrosio; *Rome/IT*

Purpose: To determine the diagnostic performance of strain ratio elastography (SR) and shear wave elastography (SWE) associated with TIRADS based US classification, in order to differentiate benign from malignant thyroid nodules.
Methods and Materials: 210 consecutive, histopathologically proven nodules in 200 patients (55 males, 145 females; mean age: 42.2 years; range: 18-83 years) and were evaluated through B-mode US with Color-Doppler assessment, SR and SWE. Each lesion was classified according to the TIRADS lexicon - as proposed by Kwak et al. and evaluated for US features (size, B-mode and Color-Doppler features), SR semi-quantitative and SWE quantitative data. Imaging and histopathological findings were compared. Diagnostic performances of B-mode ultrasound, SR, SWE, and their combination were estimated using ROC analysis and 2x2 contingency tables.
Results: Histological examination identified 136 benign and 74 malignant thyroid lesions. US according to TIRADS, SR and SWE showed a sensitivity (Se) of 59.6%, 82.7% and 51.9% and a specificity (Spe) of 83.8%, 92.7%, 85.3%, respectively. SR with B-mode US increased the diagnostic performance (Se: 90.4%, Spe: 93%, AUC: 0.9 p<0.004); SWE with B-mode US did not improve overall accuracy (Se: 58.3%, Spe: 84.2%), though representing a valid tool in selected cases
Conclusion: SWE and SR are useful additional US techniques. SE was, in general, more accurate than SWE - which proved useful only in selected cases. The combination of SR with B-mode US increased the diagnostic accuracy between benign and malignant nodules.

Ultrasonographic diagnosis of salivary gland atrophy after radio-iodine treatment for papillary thyroid cancer

E. Horvath, V.S. Skoknic, C. Silva, H. Tala, N. Sánchez, C. Whittle, J.P. Niedmann, S. Majlis, C. Schweinitz; *Santiago/CL (velimirskoknic@gmail.com)*

Purpose: To describe ultrasonographic (US) findings of mayor salivary glands (MSG) atrophy in patients who received radio-iodine (RAI) treatment for papillary thyroid cancer (PTC). Determine MSG damage prevalence and associated risk factors.
Methods and Materials: IRB approved, prospective non-concurrent cohort study. Patients that had CPT surgery with subsequent RAI between 2005-2015, were included. All had a preoperative US and at least one follow-up US 12months after RAI administration. Patients with prior MSG altered findings were excluded. Uni and multivariate analysis with logistic regression was performed using US gland damage as dependent variable and RAI dose, gender and age as independent variables. Statistical significance was defined as p<0.05.
Results: In total 328 patients [average age: 42.47(IQR 34-53), female: 263 (80.2%)] met inclusion criteria, receiving a median dose of 105mCi (IQR 100-150). Follow-up period: 12-107months. In 103 patients (31.4%) US detected salivary gland atrophy (size reduction, wavy contours, hypoechogenicity and heterogenous structure) in at least one MSG. Univariate analysis indicated that total RAI dose received was significantly associated with atrophy (p<0.01). No actinic injury was present in patients treated with a total dose lower than 100mCi. Multivariate logistic regression revealed total radiation dose OR of 2.35 (IC95% 1.80 to 3.06) and women OR of 2.17 (IC 95% 1.07 to 4.42) for MSG atrophy.
Conclusion: Actinic sialoadenitis is common, affecting approximately one-third of patients. Cumulative dose is the main factor related to this damage. For the first time, US was used to prospectively and systematically evaluate the MSG of patients with RAI treatment.

B-0495 11:43

Sonographic evaluation of abdominal wall fat index, intima-media thickness and plaque score in obstructive sleep apnoea syndrome

N. Cetin, I. Gunes Tatar, O. Ergun, M. Yüceege; *Ankara/TR (mdnurcan@hotmail.com)*

Purpose: Visceral obesity is prevalant in obstructive sleep apnoea syndrome (OSAS) and it is an independent risk factor for cardiovascular diseases. The aim of this study was to investigate whether patients with OSAS have an increase in abdominal wall fat index (AFI), a new indicator of visceral fat deposition, intima-media thickness (IMT) and plaque score (PS), two indicators of cardiovascular risk.
Methods and Materials: 104 patients (73 females, 31 males) between ages 23-73 years without known atherosclerotic or metabolic disease were evaluated by ultrasonography to calculate AWFI, to measure İMTs and to determine plaque scores, who underwent polysomnography with suspect of OSAS. Maximum thickness of preperitoneal fat (P_{max}) and minimum thickness of subcutaneous fat (S_{min}) were measured to calculate AFI ($AFI=P_{max}/S_{min}$), IMTs were measured and carotid arteries were evaluated for the presence of atherosclerotic plaques to determine PS. Patients were grouped as no OSAS (<5), mild OSAS (5-15), moderate OSAS (15-30) and severe OSAS (>30) according to AHI.
Results: While AHI correlated with AFI (p=0.019), it was not with IMT_{mean} (p=0.158) and PS (p=0.345). There was no significant difference between four OSAS groups in terms of AFI (P=0.179).
Conclusion: This study suggests that AFI may reflect and be used in the follow-up of OSAS. AFI was correlated with AHI but not with OSAS groups. It was thought to be due to low numbers of patients in each group. AHI was also not correlated with IMT_{mean} and PS. This could be due to majority of newly diagnosed patients.

B-0496 11:51

Transverse and sigmoid sinus stenosis and pressure gradient in patients with pulsatile tinnitus

T. Su, L. Jin, Y. Han; *Beijing/CN*

Purpose: To investigate angiographic features in patients with pulsatile tinnitus (PT) and assess intravenous pressure gradient in venous sinus stenosis associated with PT.
Methods and Materials: This study retrospectively analyzed cerebral angiography in a group of patients with diagnosed PT. Besides conventional arterial images, all angiography included indirect 2D and 3D venography focusing on related venous sinus. A subgroup of venous stenosis in transverse and sigmoid sinus detected by venography was noted. Subsequent direct venography and intravenous pressure gradient in venous sinus stenosis was acquired.
Results: Our study included consecutive 37 PT patients with angiography. Except for four cases with dural arteriovenous fistula, all had normal arterial appearances. There were only two cases showing complete normal arterial and venous patterns. Among other 31 PT patients, there were nine with sigmoid sinus diverticulum (SSD) and ipsilateral upstream sinus stenosis (SS) and ipsilateral dominant venous sinus (DVS), nine with transverse and sigmoid SS and ipsilateral DVS, three with SSD and ipsilateral upstream SS, four with transverse and sigmoid SS, three with SSD, three with DVS, respectively. Besides 15 cases with SSD (48.4%) known as one of the causes for PT, 25 cases with transverse and sigmoid SS (80.6%) were found, and average intravenous pressure gradient in venous sinus stenosis was 906 Pa (130-2170 Pa). In addition, DVS in PT diseased side (67.7%) may have some relation with PT.
Conclusion: High rates of transverse and sigmoid Sinus abnormalities were observed in PT. Related sinus stenosis with pressure gradient may have connection with PT.

Histogram analysis of apparent diffusion coefficients for monitoring early response in patients with breast cancer undergoing concurrent chemotherapy

W. Wang, J. Cheng, Y. Zhang; *Zhengzhou/CN (weijianwang520@163.com)*

Purpose: To explore the role of histogram analysis of apparent diffusion coefficient (ADC) related parameters in early assessment of treatment response during the concurrent chemotherapy(CCT) course of breast cancer.
Methods and Materials: We retrospectively evaluated findings in 42 patients with breast cancer who underwent diffusion-weighted imaging (b = 0,800 s/mm^2) at 3T with acquisition of corresponding ADC maps before CCT, at the end of 2nd and 4th week during chemotherapy. Whole lesion ADC histogram analysis generated several histogram related parameters including skewness, kurtosis, mean, variance and percent. The ADC histograms of 42 patients were generated to visually observe dynamic changes of the histogram parameters following CCT.
Results: All parameters except mean and variance showed significant changes during CCT (all $P < 0.05$). Skewness and kurtosis both showed high early decline rate (25%, 32 %) at the end of 2nd week of CCT. The percent of ADC histogram also changed obviously following CCT.
Conclusion: ADC histogram analysis held the potential in monitoring early tumor response in patients with breast cancer undergoing CCT.

B-0498 10:38

Imaging of the hypoxic microenvironment in breast cancer using PET/MR

J.C. Carmona-Bozo, T. Torheim, R. Woitek, A.J. Patterson, O. Abeyakoon, C. Carraco, E. Provenzano, M.J. Graves, F.J. Gilbert; *Cambridge/UK (jcc83@cam.ac.uk)*

Purpose: To investigate relationships between hypoxia (^{18}F-FMISO-PET), tumour perfusion (DCE-MRI) and pathology in breast cancer.
Methods and Materials: Imaging was performed using a GE Signa PET/MR scanner on 13 patients with pathologically confirmed breast cancer. A 60-min simultaneous PET/MR scan was performed following injection of 300 MBq ^{18}F-FMISO and a 2-hour uptake period. Hypoxic status was assessed using the influx rate constant K_i determined through Patlak-plot analysis. Tumour hypoxic fractions were estimated as the percentage of voxels with K_i values >2SD of the mean in normoxic muscle. Perfusion was derived from DCE-MRI data using the extended Tofts model (K^{trans}). Pathological correlates included tumour type, grade, size, percentage of tumour-infiltrating lymphocytes, necrosis, nodal and receptor status.
Results: A total of 26 lesions were assessed (ER+: n=25; ER-: n=1). Linear mixed effects analysis indicated that tumour grade and necrosis were significant predictors of K_i (p=0.014 and 0.027, respectively). Hypoxia was identified in 46% of the lesions, with hypoxic fractions ranging between 0-36%. Higher median hypoxic fractions were observed in lobular (6.7%) vs ductal (3.0%), HER2- (8.4%) vs HER2+ (3.6%), and positive (6.0%) vs negative (2.6%) nodal status, although these differences were not significant. A negative significant correlation was observed between tumour-infiltrating lymphocytes and hypoxic fraction (ρ=-0.45; p=0.023). An inverse, heterogeneous relationship was observed between K_i and K^{trans} (ρ=-0.1; p>0.05).
Conclusion: Necrosis, tumour grade and lymphocyte infiltration were strong predictors of hypoxic status. Hypoxia had a negative, heterogeneous relationship with perfusion and may also be influenced by tumour type, HER2 and nodal status.

B-0499 10:46

What is the diagnostic performance of 18-FDG-PET/MR and PET/CT in the initial staging of breast cancer?

D. Botsikas, I. Bagetakos, M. Picarra, S. Boudabbous, X. Montet, G.T. Lam, I. Mainta, A.M. Kalovidouri, M. Becker; *Geneva/CH (diomidis.botsikas@hcuge.ch)*

Purpose: To compare the diagnostic performance of 18-FDG-PET/MR and PET/CT for the initial staging of breast cancer.
Methods and Materials: Two independent readers blinded to clinical/follow-up data retrospectively reviewed PET/MR and PET/CT examinations performed for initial breast cancer staging in 80 consecutive patients (mean age =55.3+/-7.7 years). The diagnostic confidence for lesions in the contralateral breast, axillary and internal mammary regions, bones and other distant sites were recorded. Sensitivity, specificity, positive predictive (PPV) and negative predictive values (NPV) were calculated and results were compared with the gold standard (pathology and/or follow-up>24months).
Results: 9/80 patients had bone metastases, 13/80 had other distant metastases, 46/80 had axillary, 9/80 had internal mammary metastases and 3/80 had contralateral breast tumours. Inter-reader agreement for lesions was excellent (weighted kappa=0.833 for PET/CT and 0.823 for PET/MR) with similar results regarding reader confidence between the two tests (ICC=0.875). In the patient-per-patient analysis, sensitivity and specificity of PET/MRI and PET/CT were similar (p>0.05). In the lesion-per-lesion analysis, the sensitivity of PET/MR and PET/CT for bone metastases, other metastases, axillary and internal mammary lymph nodes, and contralateral tumours was 0.924 and 0.6923 (p=0.034), 0.923 and 0.923 (p=1), 0.854 and 0.812 (p=0.157), 0.9 and 0.9 (p=1), 1 and 0.25 (p=0.083), respectively. The corresponding specificity was 0.953 and 1 (p=0.081), 1 and 1(p=1), 0.893 and 0.92 (p=0.257), 1 and 1 (p=-1) and 0.987 and 097 (p=1), respectively.
Conclusion: Diagnostic confidence with both examinations was similar. Although PET/MR had a superior sensitivity for bone metastases than PET/CT in the lesion-by-lesion assessment, the diagnostic performance in the patient-per-patient analysis was similar.

B-0500 10:54

A proposal diagnostic algorithm for F-18FDG PET/CT-detected breast incidental lesion based on BI-RADS and SUVmax criteria

M. Bakhshayeshkaram, S. Zahirifard, F. Aghahosseini, R. Hashemi Beni; *Tehran/IR (kfaghahosseini@gmail.com)*

Purpose: To propose a diagnostic algorithm for PET-detected breast incidental lesion by applying BI-RADS and SUVmax criteria.
Methods and Materials: A total of 58 breast incidental lesions from 51 patients contemporaneously investigated by BI-RADS within 1 month from PET study constituted the study cohort and verified by histopathologic results or a 2-year clinical formal follow up (malignant=10, benign=48). The performance characteristics were then calculated for SUVmax≥2, SUVmax≥3.7 and BI-RADS≥4, separately and conjunctively.
Results: Diagnostic performance of SUVmax≥2, SUVMAX≥3.7 and BI-RADS≥t4 were calculated to be 70%, 60% and 80% for sensitivity, 73.2%, 82.9% and 92.7% for specificity and 72.54%, 88.23% and 90.19% for accuracy, respectively. Combined criteria using either SUVmax≥2 or SUVmax≥3.7 had 100% sensitivity, 73.2% and 87.8% specificity and 78.43% and 90.19% accuracy, respectively. The distribution of combined criteria in benign and malignant groups were found to be as the following: Benign group: double positive: 2 (4.87%), 1 (2.44%), PET-only positive: 9 (21.95%),1 (2.44%), BI-RADS-only positive: 1 (2.44%), 2 (4.87%), double negative: 28 (68.29%), 37 (90.24%), respectively, Malignant group: double positive: 7 (70%), 4 (40%), PET-only positive: 2 (20%), 2 (20%), BI-RADS-only positive: 1 (10%), 4 (40%), double negative: 0, respectively.

Conclusion:
Malignancy can be confidently excluded in double negative lesions. Lesion with BI-RADS<4 and SUVmax≥3.7 and those with BI-RADS ≥4 and SUVmax <2 should prompt into histopathologic confirmation. BI-RADS negative lesions with 2<SUVmax<3.7 may benefit from a short term imaging follow up.

B-0501 11:02

Breast MRI and dedicated breast PET (dbPET): friends and foes

M. Herranz[1], S. Argibay-Vazquez[1], I. Dominguez-Prado[1], P. Ling Ling[2], L. Graña[3], M. Vázquez Caruncho[3], A. Ruibal[1]; [1]*Santiago de Compostela/ES*, [2]*Shanghai/CN*, [3]*Lugo/ES (michel.herranz.carnero@sergas.es)*

Purpose: Breast MRI shows high sensitivity with non-ionizing radiation; however, significant disadvantages including its moderate specificity are also reported. Recently, dedicated breast PET (dbPET) system has emerged as an additional imaging tool for breast cancer diagnosis and follow-up. To compare FDG-dbPET with MRI on breast lesion characterization, we analysed sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).
Methods and Materials: Two hundred women with known or suspected breast carcinoma were enrolled in this study. Both a dbPET scan and breast MRI scans were performed. Sensitivity and specificity of MRI and dbPET scans were calculated on the basis of pathology reports.
Results: A total of 252 lesions were assessed. Lesion size range was 0.18 to 7.6 cm. In lesion-by-lesion analysis, specificity and sensitivity of MRI alone were 93% and 81%, respectively; meanwhile, the lesion-based sensitivity of dbPET was 96% and the breast-based specificity was 98%. The positive predictive value and the negative predictive value for MRI alone were 80% and 89%, respectively; however, for dbPET were 98% and 96%, respectively. In a significant number of cases, dbPET helped to disprove positive findings by resonance, and in 4% helped to define new positives that had gone unnoticed at resonance.
Conclusion: Dedicated breast PET scans increase the specificity of MRI. False positives are reduced. The results of the current study showed that FDG-dbPET is much more effective than MRI in detecting early breast cancer positives.

B-0502 11:10

Value of quantitative magnetic resonance imaging T1-relaxation time in predicting contrast-enhancement in breast cancer

X. Zhang, M. Li, L. Mao, C. Wang, S. He, M. Liu; *Guangzhou/CN (764673239@qq.com)*

Purpose: To evaluate the feasibility of T1 mapping in assessing the tissue properties equivalent to contrast-enhancement without the need for contrast agent.
Methods and Materials: Patients with newly-diagnosed breast cancer were selected for this study. The subtraction of T1 maps pre and post-conrast enhancement lt; ΔT1 mapsgt: was used to determine areas of contrast-enhancement. With the contrast-enhancement on ΔT1 maps as reference, ROC analysis served to detect an optimal T1 cut-off on T1 maps prior contrast agent injection to distinguish between contrast-enhancing tissue and its surroundings.
Results: 15 patients were included. A T1 value >2081ms predicted contrast-enhancing tumor tissue with a sensitivity of 83% and specificity of 71% lt;AUC, 0.89; p<0.0001gt;. Interestingly, T1 prolongation >2081 ms that did not overlap with contrast-enhancing area transformed into contrast-enhancement later on.
Conclusion: T1- relaxation time may be a useful technique to assess tissue properties in breast disease equivalent to contrast-enhancement without the need for contrast agent. It may also provide information on sites with future tumour progression.

B-0503 11:18

MRI of invasive mass breast cancer: correlation of global vascularity and ADC with pathological features

A. Milani, R.M. Trimboli, L.A. Carbonaro, M. Codari, G. Di Leo, F. Sardanelli; *Milan/IT (angelomilani9296@gmail.com)*

Purpose: To investigate the association between breast global vascularity (GV), apparent diffusion coefficient (ADC) and pathological prognostic factors in invasive mass lesions.
Methods and Materials: Thirty invasive mass breast cancers were included: 27 (89%) ductal, 2 (8%) lobular and 1 (3%) mucinous. Vessels with ≥ 2mm diameter and ≥ 30mm length were identified on maximum intensity projections from contrast-enhanced subtracted MRI, then lengths of all selected vessels were summed and considered as GV, for each of the two breasts. ADC was obtained for each lesion placing a region of interest encompassing the mass. Grade, Ki67, human epidermal growth factor receptor 2 (HER2), estrogen and progesterone receptors, pT and pN were obtained from pathology reports. Spearman, Mann-Whitney U, Kruskal-Wallis and Jonckheere-Terpstra statistics were used.
Results: Women were aged 57.9±10.6 (mean ± standard deviation); median lesion size was 19.8 mm (interquartile range [IQR] 13-27 mm). A significant difference in GV was observed between cancerous and healthy breasts (p<0.001). A trend for correlation of GV and ADC was observed (r=0.337, p=0.08). A higher GV was associated with HER2 positive tumors (p=0.027) and lower ADC values were associated with a higher proliferation of Ki67 (p=0.017).
Conclusion: In invasive mass breast cancers, GV is associated with HER2 overexpression, showing an interplay between receptor status and vascularization. The association of ADC with Ki67 proliferation subtends an increased cellularity of aggressive cancers. Multiparametric MRI, including GV, has a potential for defining the hallmarks of breast cancers.

Utility of diffusion in evaluating chest wall invasion of breast tumours

N. Samreen, C. Lee, K. Adler, A. Bhatt, T. Hieken, S. Zingula, K.N. Glazebrook; *Rochester, MN/US (samreen.naziya@mayo.edu)*

Purpose: To investigate the sensitivity and specificity of diffusion-weighted imaging (DWI) in determining chest wall invasion of breast malignancies.
Methods and Materials: A retrospective search was performed on keywords including “chest wall invasion” in breast MRI reports at our institution over the last 12 years. The presence of chest wall invasion based on T2-weighted, DWI, and post-contrast acquisitions was evaluated through consensus readings by two board-certified breast imagers. Correlations with histopathology and neoadjuvant chemotherapy were made.
Results: Search results yielded 58 patients; 30 had no DWI and were excluded. The remaining 28 patients each showed loss of fat plane on T2-weighted and post-contrast acquisitions. 23/28 (82%) additionally showed enhancement within the chest wall, and 20/28 (71%) qualitatively showed restricted diffusion within the chest wall. The mean ADC values (automatically calculated by CAD software) in the chest wall (-0.4±1.2 mm^2/s, [-1.8, 1.5]) were similar to those in the breast tumour (-0.2±1.3 mm^2/s, [-1.5, 1.4]). Review of clinical notes showed 5/28 patients with unavailable follow-up, so 23 patients were used in subsequent data analysis. Sensitivity, specificity, and negative predictive value (NPV) were 100%, 33%, and 100% for DWI and 100%, 27%, and 100% for post-contrast MRI, respectively, in the assessment of chest wall invasion.
Conclusion: DWI when used in conjunction with post-contrast MRI suggests a high NPV for assessing chest wall invasion of breast cancers which can increase confidence for surgical planning.

B-0505 11:34

MR evaluation of fibroglandular tissue (FGT) and background parenchymal enhancement (BPE) in breast cancer and its association with receptor status

S.B. Grover[1], P. Jain[1], S.K. Jain[1], A.K. Mandal[1], H. Grover[2]; [1]*New Delhi/IN*, [2]*Bridgeport, CT/US (shabnamgrover@yahoo.com)*

Purpose: Breast cancer encompasses a spectrum of several molecular subtypes with distinct epidemiological and pathophysiological profiles, leading to significant variations in treatment response. Fibroglandular tissue (FGT) proportion and background parenchymal enhancement (BPE) on breast MR have been proposed as predictors of tumour molecular subtypes, thereby affecting treatment protocol. The aim of our study was to evaluate the biomarker role of FGT and BPE in breast cancer, by correlating with oestrogen receptor (ER), progesterone receptor (PR) and HER2 receptor status.
Methods and Materials: 36 patients with newly diagnosed, biopsy-proven breast cancer underwent breast MR on 1.5T, in this IRB-approved study. FGT proportion and BPE were recorded and classified based on previously described criteria. Pathological analysis for receptor status was done. Association between the considered variables was evaluated using Pearson’s chi-square, continuity correction chi-square, and Fisher's exact test. A p<0.05 was considered statistically significant.
Results: Patients with increased FGT proportion were found to have ER- and PR-positive tumours (p<0.01 for both). Higher extent of BPE was associated with ER positivity (p=0.002); however, no significant association was found with PR status (p=0.310). Both FGT and BPE showed no relation with HER2 status (p=0.536 and p=0.226, respectively).
Conclusion: Higher FGT proportions in breast cancer show association with both ER and PR positivity, whereas BPE showed association only with ER. Our work further substantiates research on the biomarker role of MR-assessed FGT and BPE in breast cancer, in predicting molecular subtypes and their individual treatment regimes.

B-0506 11:42

Implementation of imaging biomarkers of healthy breast tissue with multiparametric [18F]FDG-PET/MRI may aid breast cancer diagnosis

D. Leithner[1,2], G.J. Wengert[2], M. Weber[2], T.H. Helbich[2], P. Kapetas[2], P.A.T. Baltzer[2], E.A. Morris[1], G. Karanikas[2], K. Pinker[1,2]; [1]*New York, NY/US*, [2]*Vienna/AT (doris.leithner@googlemail.com)*

Purpose: To assess imaging biomarkers of breast tumors and contralateral healthy breast parenchyma with 3T multiparametric (mp) PET/MRI and to investigate which can be used for breast cancer diagnosis.
Methods and Materials: In this IRB-approved prospective study 125 women, who underwent fused 3T mpPET/MRI with dynamic contrast-enhanced MRI (DCE-MRI), diffusion-weighted imaging (DWI) and [18F]FDG-PET for a BI-RADS 0,4/5 lesion and histopathological verification were included. BI-RADS descriptors with DCE, ADC with DWI, and SUVmax with [18F]FDG-PET of the lesion were recorded. SUVmax, ADCmean, BPE (background parenchymal enhancement), and FGT (amount of fibroglandular tissue) for the contralateral healthy breast were noted. A stepwise logistic regression with forward selection to identify the combination of biomarkers for the differentiation of benign and malignant tumors and to assess diagnostic parameters was performed.
Results: There were 98 malignant lesions (81 IDC, 8 ILC, 5 DCIS, 4 other; 90 masses) and 27 benign lesions (16 masses). The biomarkers that were different between benign and malignant lesions and included in the equation were BI-RADS descriptor DCE margins (P<0.001), and tumor ADCmean (P=0.008). Other biomarkers of tumor and normal breast tissue did not reach significance. Based on the combination of these two imaging biomarkers, diagnostic accuracy was 96.2%, sensitivity was 98.9%, and specificity was 81.3% for separation of benign and malignant lesions.
Conclusion: The combination of qualitative and quantitative MRI imaging biomarkers (DCE margins, ADCmean tumor) show promise to improve differentiation of benign and malignant breast lesions. In this study, other mpPET/MRI imaging biomarkers did not add diagnostic accuracy.

B-0507 11:50

Are there differences in multiparametric breast [18F]FDG-PET/MR imaging biomarkers of contralateral healthy tissue in patients with and without breast cancer?

D. Leithner[1,2], T.H. Helbich[2], B. Bernard-Davila[1], G.J. Wengert[2], P. Kapetas[2], P.A.T. Baltzer[2], A. Haug[2], E.A. Morris[1], K. Pinker[1,2]; [1]*New York, NY/US*, [2]*Vienna/AT (doris.leithner@googlemail.com)*

Purpose: To evaluate whether there are differences in multiparametric (mp) [18F]FDG-PET/MR imaging biomarkers of contralateral healthy breast tissue in patients with benign and malignant breast tumours.
Methods and Materials: In this IRB-approved prospective study, 141 women underwent 3T mpPET/MRI with contrast-enhanced MRI, diffusion-weighted imaging (DWI), and [18F]FDG-PET for the assessment an abnormality (BI-RADS 0,4/5). The following imaging biomarkers were recorded for the contralateral tumour-free breast: background parenchymal uptake (BPU) with [18F]FDG-PET; apparent diffusion coefficients (ADCmean) with DWI; BPE (background parenchymal enhancement); and amount of fibroglandular tissue (FGT). Appropriate statistical tests were used to assess differences in imaging biomarkers between benign and malignant lesions.
Results: There were 100 malignant and 41 benign lesions. BPE was minimal in 61, mild in 56, moderate in 19, and marked in 5 patients. BPE differed significantly (P<0.001) between patients with benign and malignant lesions, with patients with cancer demonstrating decreased BPE in the contralateral breast. A borderline statistically significant difference was observed for FGT (P=0.055). BPU for patients with mild BPE was 1.5, for mild BPE 1.9, for moderate BPE 2.2, and for marked BPE 1.9. BPU differed significantly between patients with benign (mean, 1.9) and malignant lesions (mean, 1.8) (P<.001), whereas ADCmean did not differ between groups (P=0.19).
Conclusion: Differences in mpPET/MR imaging biomarkers, obtained from contralateral healthy breast tissue, exist between patients with benign, and patients with malignant breast tumours. Contralateral BPE, BPU, and FGT are decreased in patients with cancer, and may potentially serve as imaging biomarkers for the presence of cancer.

Mechanical thrombectomy of M1 and M2 segment occlusions: a single-center experience with 546 patients

F. Seker, J. Pfaff, U. Neuberger, S. Nagel, P.A. Ringleb, M. Bendszus, M.A. Möhlenbruch; *Heidelberg/DE*

Purpose: Considering recent randomized controlled trials on mechanical thrombectomy (MT) in ischemic stroke, the American Heart Association guidelines state that MT in M2 occlusions may be reasonable, but with uncertain benefit. We, therefore, compared safety, angiographic and clinical results of M1 and M2 segment occlusions after MT in a retrospective study.
Methods and Materials: Between 2009 and 2016, patients with an acute occlusion of the M1 or M2 segment of the middle cerebral artery were retrospectively analyzed. Good outcome was defined as modified Rankin Scale score of 0-2 at 90 days. Successful recanalization was defined as a Thrombolysis in cerebral infarction score of 2b-3.
Results: In total, 546 consecutive patients with M1 (n=457) or M2 (n=89) occlusion were included. Compared to M1 occlusions, M2 occlusion presented with a significant lower baseline NIHSS score (15 vs. 17, p=0.010) and higher ASPECTS [9 (IQR 8-10) vs. 9 (IQR 7-9), p=0.004]. Endovascular treatment of M2 occlusions had a non-significant lower rate of symptomatic intracranial hemorrhages (2.2% vs. 8.1%, p=0.068). Furthermore, M2 occlusions showed a trend to higher recanalization rates (82.0% vs. 72.6%, p=0.065) and a significantly higher rate of good clinical outcome (49.4% vs. 34.8%, p=0.026).
Conclusion: This retrospective analysis adds evidence that MT in M2 occlusions is safe and achieves slightly better recanalization rates and significantly better clinical outcome compared to M1 occlusions with a lower rate of symptomatic intracranial hemorrhages after MT.

B-0509 10:38

Impaired cerebrovascular reactivity is at high risk of stroke in patients with intracranial stenosis

J. Papassin, A. Krainik, O. Heck, E. Condamine, J. Pietras, F. Tahon, O. Detante; *Grenoble/FR (akrainik@chu-grenoble.fr)*

Purpose: Impaired cerebrovascular reserve is suggested to explain haemodynamic stroke in symptomatic patients with intracranial atherosclerotic stenosis (IAS) in spite of intensive medical management. We studied relationships between baseline characteristics of patients with unilateral symptomatic IAS, recurrence of ischaemic events, basal perfusion, and cerebrovascular reactivity assessed by BOLD fMRI (CVR BOLD fMRI).
Methods and Materials: Twenty patients with symptomatic unilateral IAS of middle cerebral artery (MCA) or internal carotid artery were selected (61.0±11.5yo). We measured basal perfusion using DSC, and CVR elicited by hypercapnic challenge (8%CO_2) using BOLD contrast (3T AchievaTX, Philips, voxel=4x4x4mm, TR/TE/α=3000/35ms/90°, 240 dynamics in 12min during a block-design hypercapnia). Individual end-tidal CO_2 pressure was used as physiological regressor to conduct linear regression analysis. Post-processing was performed using AMIGOv0.9, an in-house software (Python3.6, Matlab8.6, SPM12), giving whole-brain and regional basal CBF, CBV, MTT and CVR. We calculated statistical relationships between individual clinical and biological baseline characteristics, recurrent ischaemic events, basal perfusion, and CVR BOLD fMRI in MCA territories (CVR_{MCA}) reported by laterality indices (LI).
Results: Nine patients (45%) had an abnormal LI CVR_{MCA} ($|LI|$ CVR_{MCA}≥0.08). During follow-up (m=3.0years), recurrent ischaemic events occurred within the first year. They were more frequent in impaired CVR_{MCA} group (n=7/9) than in normal CVR_{MCA} group (n=1/11), with different survival curves (log rank, p=0.001). Baseline characteristics were similar in both groups.
Conclusion: Impaired CVR assessed by BOLD hypercapnic fMRI is associated with increased risk of stroke in patients with symptomatic IAS. CVR mapping should be proposed to select high-risk patients to discuss additional treatment.

B-0510 10:46

Dual-energy computed tomography for optimised visualisation of early cerebral infarctions after endovascular stroke therapy

A.E. Grams, T. Djurdjevic, T. Schiestl, M. Knoflach, F. Dazinger, E.R. Gizewski, B. Glodny; *Innsbruck/AT (astrid.grams@i-med.ac.at)*

Purpose: The aim of this study was to investigate if dual-energy computed tomography (DECT) series, optimised for edema visualisation, allows an advantageous identification of early infarctions after endovascular stroke therapy (EST). Therefore, a modified virtual non-contrast (VNC) series, named "edema map" (EM), was generated.
Methods and Materials: Forty-six patients (21 women and 25 men) with a mean age of 63 years (24-89 years) were included. Brain window (BW), VNC and EM series were evaluated. Density differences between infarctions and contralateral areas (CID), final infarct volume predictability, infarction identifiability and image noise were assessed with region of interest measurements. Follow-up imaging served as standard for comparison. For the statistical evaluation, Kruskal-Wallis, Dunn's multiple comparison tests and receiver operating curve analyses were performed.
Results: Highest CIDs were found in the EM (73.3+/-49.3), compared to the BW (-1.72+/-13.29) and the VNC (8.30+/-4.74) series ($p < 0.0001$). The EM revealed highest infarction identification rates (area under the curve: 0.97, vs. 0.54 and 0.90, $p < 0.0001$) with a cut-off value of < 50.7 HU, despite slightly more pronounced image noise. A prediction of the future infarction size succeeded best with the EM series (area under the curve: 0.67, vs. 0.50 and 0.59, cut-off 16.74 HU).
Conclusion: With the EM series a higher contrast and better early infarct identifiability can be achieved than with VNC or BW series. This technique could feature the opportunity to modify early therapy decisions.

B-0511 10:54

Mechanical thrombectomy in basilar artery occlusion: the presence of bilateral posterior communicating arteries is a predictor of favorable clinical outcome.

V. Maus[1], A. Kalkan[1], C. Kabbasch[1], N. Abdullayev[1], U.B. Barnikol[1], T. Liebig[2], C. Dohmen[1], G.R. Fink[1], A. Mpotsaris[3]; [1]*Cologne/DE*, [2]*Berlin/DE*, [3]*Aachen/DE (volker-maus@gmx.de)*

Purpose: Mechanical thrombectomy (MT) in basilar artery occlusion (BAO) is a subject of debate. We investigated clinical outcome of MT in BAO and predictors of a favorable outcome.
Methods and Materials: 104 MTs in BAO (carried out between 2010 and 2016) were analyzed. Favorable outcome (modified Rankin Scale (mRS) ≤2) at 90 days was the primary endpoint; influence of following variables on outcome was investigated: number of detectable posterior communicating arteries (PcoAs), patency of basilar tip, completeness of BAO, and posterior circulation Alberta Stroke Program Early CT Score (PC-ASPECTS). Secondary endpoints were technical periprocedural parameters including symptomatic intracranial hemorrhage (sICH).
Results: Favorable clinical outcome at 90 days was 25% and mortality was 43%. Rate of successful reperfusion (modified Thrombolysis In Cerebral Infarction (mTICI) ≥2b) was 82%. Presence of bilateral PcoAs (AUC: 0.81, $p<0.0001$), low National Institute of Health Stroke Scale (NIHSS) on admission (AUC: 0.74, $p<0.01$), PC-ASPECTS ≥9 (AUC: 0.72, $p<0.01$), incomplete BAO (AUC: 0.66, $p<0.001$), and basilar tip patency (AUC: 0.66, $p<0.01$) were associated with favorable outcome. Stepwise logistic regression analysis revealed that the strongest predictors of favorable outcome at 90 days were bilateral PcoAs, low NIHSS on admission, and incomplete BAO (AUC: 0.923, $p<0.0001$).
Conclusion: MT in BAO is safe with high rates of successful reperfusion. Aside from baseline NIHSS and incomplete vessel occlusion, both known predictors of favorable outcome in anterior circulation events, we found collateral flow based on the presence or absence of PcoAs had a decisive prognostic impact.

Intracranial carotid artery calcification and endovascular treatment effect in acute stroke patients due to large vessel occlusion

K. Compagne[1], P. Clephas[1], C.B. Majoie[2], W. Van Zwam[3], A. van Es[1], D.W. Dippel[1], A. Van der Lugt[1], D. Bos[1]; [1]*Rotterdam/NL*, [2]*Amsterdam/NL*, [3]*Maastricht/NL (c.compagne@erasmusmc.nl)*

Purpose: Intracranial carotid artery calcification (ICAC) may interfere with the safety and efficacy of endovascular treatment (EVT). We assessed the influence of ICAC volume and pattern on the effect of EVT in patients with acute ischemic stroke.
Methods and Materials: All 500 patients included in the MRCLEAN trial on the effectiveness of EVT were analyzed. The volume (mm^3) and pattern (located in tunica intima or tunica media) of ICAC were determined on baseline CT. Functional outcome at 90 days was assessed with the modified Ranking Scale. Next, we investigated the association of ICAC volume and pattern with functional outcome using adjusted ordinal logistic regression models with an interaction term between treatment allocation and ICAC.
Results: We found no association of ICAC volume with functional outcome (acOR per unit increase ICAC volume 0.94 (95%CI 0.84-1.06). Moreover, we found no evidence for effect modification by ICAC volume (p=0.56). Predominantly medial ICAC pattern was nearly significant associated with poorer functional outcome (acOR 1.63; 95%CI 0.99-2.66). Yet, we found evidence for treatment effect modification by ICAC pattern (p=0.02): a better functional outcome after EVT in patients with predominantly medial calcification (acOR 2.55; 95%CI 1.38-4.72) and no effect of EVT in patients with predominantly intimal calcifications (acOR 0.76; 95%CI 0.39-1.50).
Conclusion: Predominantly medial calcification pattern of ICAC relates to poorer functional outcome in ischemic stroke patients, but the benefit of EVT in ischemic stroke patients with a medial calcification pattern is larger compared to the treatment effect in patients with a intimal calcification pattern.

Ipsilateral thalamic diaschisis in acute ischaemic stroke: occurrence, perfusion characteristics, and association with morphologic and clinical outcome

P. Reidler, K. Thierfelder, M.P. Fabritius, F. Schuler, W.H. Sommer, W.G. Kunz; *Munich/DE (Paul.Reidler@med.uni-muenchen.de)*

Purpose: Ipsilateral thalamic diaschisis (ITD) describes the reduction of thalamic function, metabolism and perfusion resulting from a distant lesion to the ipsilateral hemisphere. Our aim was to evaluate its perfusion characteristics and clinical impact in acute ischemic stroke.
Methods and Materials: Subjects were selected from a cohort of 1,644 patients who underwent multiparametric CT including CT-perfusion (CTP) for suspected stroke. Inclusion criteria were: acute middle cerebral artery (MCA) territory ischemia, follow-up-confirmed infarction and absence of posterior circulation ischemia. Perfusion-deficit regions were delineated according to the Alberta Stroke Program Early CT Score (ASPECTS) regions. ITD was defined as reduced perfusion of the ipsilesional thalamus present on ≥2 CTP maps. Morphologic outcome and subacute complications were assessed on follow-up. Functional outcome was quantified using the modified Rankin Scale (mRS). Statistical analysis contained univariate linear and binary logistic regression.
Results: We included 154 patients. ITD was present in 32 subjects (20.8%, ITD+). Perfusion deficit regions in ITD+ subjects revealed a more frequent involvement of caudate, internal capsule and lentiform nucleus (each with $p<0.001$). We observed larger perfusion-deficit volumes and smaller perfusion-mismatch ($p<0.001$) in the ITD+ group. There was no significant independent association of ITD with final infarction volume (beta=-0.110, p=0.135) or functional outcome (mRS≤2) after 90 days (OR=1.109, p=0.987). No differences in baseline characteristics or subacute complications were present ($p>0.05$).
Conclusion: ITD is frequently observed in acute MCA stroke associated with a marked involvement of subcortical areas. This finding should neither be misdiagnosed as posterior circulation ischemia nor considered unfavorable in clinical management.

B-0514 11:18

Improved assessment and evaluation of arterial occlusion in acute ischaemic stroke with contrast-enhanced MR angiography

S. Dhundass, A. Collin, L. Duron, S. Escalard, M. Obadia, R. Blanc, J.-C. Sadik, J. Savatovsky, A. Lecler; *Paris/FR (sdhundass@gmail.com)*

Purpose: To compare in acute ischaemic stroke (AIS) patients, the accuracy of two techniques of MR angiography: contrast-enhanced magnetic resonance angiography (CEMRA) and Time Of Flight MRA (TOF MRA) for the detection of the clot and their value in predicting clot location and length.
Methods and Materials: 131 consecutive adult patients admitted to our center for confirmed acute ischaemic stroke from august 2014 to july 2016 were assessed. Clot visibility, location and length on CEMRA were compared to those on TOF MRA and SWI. It was compared to Digital subtraction angiography (DSA) for the subgroup that underwent thrombectomy. Clot burden score (CBS) was evaluated on TOF MRA and CEMRA in case of anterior arterial occlusion.
Results: 52 patients showed an occlusion on CEMRA and 63 on TOF MRA. CEMRA showed higher correlation to SWI regarding detection of the clot (k=0.68 (0.55-0.81)) its length (ICC=0.72 (0.61-0.79)) and location (k= 0.69(0.57-0.79)), than TOF MRA (k=0.48(0.33-0.61) ;ICC=0.18 (-0.03-0.38);k=0.5 (0.36-0.62)). CBS was significantly higher on CEMRA (p=7e-06). In the thrombectomy sub group (N=28), occlusion was detected on both

techniques for all patients, CEMRA had a higher correlation with DSA (k= 0.73 (0.47-0.91) vs k= 0.62(0.35-0.85)) for determining clot's location.
Conclusion: Our results showed that CEMRA enabled a more accurate detection of arterial occlusion in patients with AIS in comparison with TOF MRA, as well as the evaluation of clot characteristics such as its length and location, adding valuable information to stratify patient's risk and management.

B-0515 11:26

Combined measurements of clot density in unenhanced and enhanced CT of acute ischaemic stroke in complete vessel occlusions of the medial cerebral artery predict 90 day patient outcome

J. Kottlors[1], C. Kabbasch[1], V. Maus[1], A. Mpotsaris[2], J. Borggrefe[1];
[1]*Cologne/DE*, [2]*Aachen/DE (Jan.Borggrefe@uk-koeln.de)*

Purpose: Ex-vivo CT-studies of blood thrombi (BT) showed, that contrast-enhancement (CE) is determined by fibrin-content while unenhanced density is associated with the fraction of red blood cells. This study investigates if CE BT measurements in CT of acute ischemic stroke (AIS) can enhance prediction of patient outcome.
Methods and Materials: This study includes 137 AIS patients treated with mechanical thrombectomy between 2010-2016, including M1 middle cerebral artery occlusions only. Outcome was determined with modified Rankin-Scale (mRS90). Differentiation of complete and incomplete large vessel occlusion (CLVO/ILVO) based on CT and angiography. Two blinded readers classified BT based on native CT (NECT); a) hypo-, b) iso-, and c) hyperdense as well as in CT angiography (CECT); d) not-enhancing, e) intermediate and f) enhancing.
Results: Twenty-three ILVO patients (16.8%) differed significantly from CLVO patients in mRS at admission (median: 4 vs. 5) and after 90 days (median: 1 vs. 4) (p<.05). Excluding ILVO, classification according NECT did not show statistical differences between hypo-, iso- and hyperdense CLVOs. Classification of CLVOs according CECT shows significant distinctions between the intermediate (median: 3) and enhancing BT-group (median: 4), also between the enhancing- and the not-enhancing BT-group (median: 3) (both p < .05). This is consistent with a correlation of .291 between CE and mRS after 90 days (p<.001).
Conclusion: As described in literature, NECT BT density is associated with good patient outcome. Increased contrast enhancement of the BT in CECT, shows a further significant association with unfavorable outcome. ILVO is a significant bias of thrombus characterization.

B-0516 11:34

The influence of CT perfusion on the selection of stroke patients for endovascular therapy

J.M. Ospel, G. Karwacki, K. Blackham; *Basle/CH*
(johannamaria.ospel@usb.ch)

Purpose: Determine whether CT perfusion changes patient selection for interventional therapy in acute stroke patients compared to combined native CT and CT angiography data.
Methods and Materials: 100 consecutive acute stroke CT examinations (non-contrast CT, CTA, CTP) from patients who received intravenous lysis at our hospital were retrospectively evaluated in a blinded fashion. An experienced neurointerventionalist reviewed the cases first without and, after a month delay, with the CTP data (Syngo.via, Siemens Healthineers). Clinical information such as NIHSS, age and side of neurologic deficit was provided to the reader. A questionnaire was used, including ASPECTS score, location of vessel occlusion and whether or not endovascular intervention was indicated. Differences in detection rate of vessel occlusion and interventional decision were compared. Criteria for intervention on CTP included <100 ml core infarct volume and > 1.2 mismatch ratio.
Results: ASPECTS score was >= 7 in all cases. Detection rates of proximal vessel occlusion (n=33) and the decision to intervene differed between the two interpretive sessions in only one case; in this group the average NIHSS was 16. Within the remaining group (distal or no vessel occlusion), there was discordance in 12 patients; average NIHSS was 8.
Conclusion: In selected acute stroke patients (NIHSS>=10 and ASPECTS>=7) presenting within the 4.5 hour intravenous lysis window, CTP is unnecessary for the detection rate of proximal vessel occlusion or the decision to proceed with endovascular intervention. CTP may be helpful in patients with NIHSS<10 where distal occlusions are more common.

B-0517 11:42

Classification of CT perfusion infarct core in acute ischaemic stroke using automated measurements of tissue density on non-contrast CT

P. Reidler, K. Thierfelder, M.P. Fabritius, W.H. Sommer, W.G. Kunz;
Munich/DE (Paul.Reidler@med.uni-muenchen.de)

Purpose: To determine the diagnostic value of automated quantification of tissue density on non-contrast CT (NCCT) to classify CT perfusion (CTP) infarct core in acute ischaemic stroke.
Methods and Materials: Out of 1,644 consecutive cases of suspected ischaemic stroke, we selected patients with follow-up-confirmed middle cerebral artery infarction, admission NCCT and CTP, and absence of prior stroke. NCCT density in Alberta Stroke Program Early CT Score (ASPECTS) regions were quantified as average Hounsfield Unit (HU) values using automated segmentation and calculation of HU ratios (rHU) between ischaemic and non-ischaemic hemispheres (ASPECTS-Tool.v1.2, Siemens, Germany). CTP-deficit was rated separately on cerebral blood flow (CBF) and volume (CBV) maps per region. Infarct core was defined as coexisting CBF- and CBV-deficit. Receiver operating characteristic curves (ROC) with Youden's index and associated rHU cut-off values with highest discriminative power were calculated per region.
Results: A total of 129 patients were included. ROC analysis demonstrated that density measurements enabled a significant discrimination of infarct core in the regions Capsula interna (C) (AUC=0.797, p<0.001), Insula (I) (AUC=0.663, p=0.002), Lentiform nucleus (L) (AUC=0.726, p<0.001), and M1 cortex (AUC=0.615, p=0.025). Youden's Index calculations indicating the power to discriminate infarct core resulted in cut-off values of rHU=0.963 for C (sensitivity/specificity=0.767/0.727), rHU=0.960 for I (sensitivity/specificity=0.506/0.886) rHU=0.957 for L (sensitivity/specificity=0.706/0.674), and rHU=0.949 for M1 cortex (sensitivity/specificity=0.343/0.903).
Conclusion: Automated NCCT density measurements can identify ASPECTS regions with CTP infarct core in C, I, L and M1 cortex. This technique has the potential to improve decision support in case CTP is not available.

B-0518 11:50

Haemorrhagic transformation and aspirin therapy after thrombectomy: an inter- and intra-rater agreement study

A. Guenego[1,2], A. Leclerc[1], K. Premat[1], C. Ducroux[1], M. Roques[2], R. Blanc[1], M. Piotin[1], R. Fahed[1]; [1]*Paris/FR*, [2]*Toulouse/FR (adrienguenego@gmail.com)*

Purpose: We aimed to systematically review the literature and assess the reliability of haemorrhagic transformation (HT) diagnosis and classification on brain computed tomography performed 22-36 hours after mechanical thrombectomy in acute ischaemic stroke (AIS) patients with anterior circulation large vessel occlusion.
Methods and Materials: Studies assessing the reliability of HT diagnosis and/or ECASS classification were reviewed. Eighteen raters independently assessed twice 30 brain CT scans realized 22 to 36 hours after mechanical thrombectomy in patients included in a multicentric randomized trial. Agreement was measured with Fleiss' and Cohen's unweighted kappa statistics.
Results: The review yielded 4 studies reporting 19 measures of agreement. Populations, methods, analyses, and results were heterogeneous (moderate to excellent agreement), precluding a meta-analysis. In our study, interrater agreement for HT diagnosis was moderate for all raters (κ=0.55, 95%CI [0.41-0.68]) and each subspecialty. The interrater agreement for ECASS classification was fair for all raters (κ=0.37 [0.27-0.50]), but improved to a moderate level after dichotomization. Dichotomization of the ECASS classification also improved the number of raters to reach a substantial (or higher) intrarater agreement (from 7/18 [38.9%] to 14/18 [77.8%]). The interrater agreement for aspirin therapy decision was moderate for all raters (κ=0.52 [0.40-0.66]), and substantial among the vascular neurologists (κ=0.70 [0.57-0.84]).
Conclusion: The diagnosis and classification of HT according to ECASS criteria on brain CT scans performed 22 hours to 36 hours after thrombectomy might not be reliable among untrained physicians. Despite the lack of reliability, the interrater agreement for aspirin therapy decision among vascular neurologists was substantial.

Impact of radiologist experience on detection of colorectal neoplasms at CT colonography screening
L. Pusceddu[1], V. Vani[1], G. Giannetto[1], L. Morra[2], L. Correale[2], S. Delsanto[2], C. Senore[2], D. Regge[1,2]; [1]*Candiolo/IT*, [2]*Turin/IT (laura.pscd@gmail.com)*

Purpose: To assess the relationship between radiologist experience and adenoma detection rate at CT colonography (CTC) screening.
Methods and Materials: Post-hoc analysis of a large RCT was performed, including 2593 CTCs read by 7 radiologists. Radiologist experience was classified according to the total number of CTC performed before the trial (i.e. <200, 200-1,000, >1,000). Multilevel logistic regression was used to model the influence of reading volumes on the probability to detect adenomas. Analyses were performed separately for each of the following lesions: all adenomas (ADR), distal adenomas (DADR), proximal adenomas (PADR), advanced histology (i.e. ≥10-mm, villous histology or high grade dysplasia). A 6-mm cut-off was used for post-CTC referral to colonoscopy.
Results: 1337 (51.5%), 584 (22.5%), and 672 (26.0%) CTCs were read by radiologists with reading volumes<200, 200-1000, and >1000, respectively. The average ADR, DADR and PADR were 8.0% (95% CI: 7.0-9.1%; range, 5.8-8.7%), 5.0% (95% CI: 4.3-5.9%; range, 2.1-8.4%), and 5.1% (95% CI: 4.2-6.3; range, 4.4-5.4%), respectively. Radiologist experience appeared to be related with DADR (OR, >1000 vs ≤1000: 1.49; 95% CI: 1.04-2.13), but not with PADR (OR, >1000 vs ≤1000: 0.91; 95% CI: 0.64-1.29). The association of radiologist experience with distal location appeared to be statistically significant also for advanced adenomas (OR, >1000 vs ≤1000: 1.73; 95% CI: 1.08-2.88).
Conclusion: High reading volumes, greater than 1000 CTCs, may be required to achieve high adenoma detection rates in the distal colon. Reading volume may be considered as a new quality indicator for CTC screening.

B-0520 10:47

Patients' experience with, and factors for participation in flexible sigmoidoscopy and CT colonography screening insight from the Proteus Colon Trial
V. Vani, G. Giannetto, L. Pusceddu, L. Morra, L. Correale, S. Del Santo, C. Senore, D. Regge; *Turin/IT (vanina.vani87@gmail.com)*

Purpose: To compare the acceptability of CTC and FS screening and the factors predicting CTC screening participation, targeting participants in the Proteus *Trial.*
Methods and Materials: 1984 eligible individuals, were randomly assigned to be invited to FS or CTC screening. All attendees and a 50% sample of CTC non-attendees were contacted 3-6 months after invitation for a phone interview, investigating screening experience and factors affecting participation. Odds ratios (OR) were computed by multivariable logistic regression.
Results: 239/264 (90.6%) FS attendees, 237/298 (79.5%) CTC attendees and 182/299 (60.9%) CTC non-attendees answered the interview. Attendees who would recommend the test to friends or relatives were 99.1% among FS and 93.3% among CTC attendees. Discomfort associated with bowel preparation was higher among CTC than FS attendees (OR: 2.77; 95% CI: 1.47-5.24). CTC non-attendees were less likely to be men (OR: 0.36; 95% CI: 0.18-0.71), retired (OR: 0.31; 95% CI: 0.13-0.75), to report regular physical activity (OR: 0.37; 95% CI: 0.20-0.70), or having read the information leaflet (OR: 0.18; 95% CI: 0.08-0.41); they were more likely to mention screening-related anxiety (mild - OR: 6.30; 95% CI: 2.48-15.97; moderate/ severe - OR:3.63; 95%CI:1.87-7.04), erroneous beliefs about screening (OR: 32.15; 95% CI: 6.26-165.19), or a recent FOBT (OR: 13.69; 95% CI: 3.66-51.29).
Conclusion: CTC and FS screening are well accepted. Further reducing the discomfort from bowel preparation may increase CTC screening acceptability. Negative attitudes, erroneous beliefs about screening and organizational barriers are limiting screening uptake. All these factors are modifiable and therefore potentially susceptible to interventions.

B-0521 10:55

Patient experience of screening CT colonography with reduced and full bowel preparation in a randomised trial
L. Sali[1], L. Ventura[1], A. Borgheresi[1], S. Delsanto[2], P. Mantellini[1], M. Mascalchi[1], M. Zappa[1], G. Grazzini[1]; [1]*Florence/IT*, [2]*Turin/IT (lapo.sali@unifi.it)*

Purpose: To assess patient experience of bowel preparation and procedure for screening CT colonography with reduced (r-CTC) and full preparation (f-CTC) in a randomised trial (SAVE study).
Methods and Materials: 4825 eligible subjects were randomly invited to screening r-CTC or f-CTC. Participants to r-CTC (n=674) and to f-CTC (n=612) were asked to complete a pre- and post-procedure questionnaire. Items were analysed separately and pooled with chi-square ant t test.
Results: Pre-procedure questionnaire was returned by 531 (79%) subjects in the r-CTC group and by 465 (76%) in the f-CTC group, and post-procedure questionnaire by 525 (78%) in the r-CTC group and by 453 (74%) in the f-CTC group. In pre-procedure questionnaire 88% of subjects in the r-CTC group reported no preparation related disorders compared to 70% of those in the f-CTC group (p<0.001). In post-procedure questionnaire average scores for discomfort of the procedure were not significantly different between r-CTC (3.53±0.04) and f-CTC (3.59±0.04) groups (p=0.84).
Conclusion: Reduced bowel preparation is reported to be more tolerable than full preparation for screening CT colonography. Procedure related discomfort is not influenced by bowel preparation.

Neoplasia yield with FIT two years after CTC screening
G. Giannetto[1], L. Pusceddu[1], V. Vani[1], L. Morra[2], L. Correale[2], C. Senore[2], S. Del Santo[2], D. Regge[1,2]; [1]*Candiolo/IT*, [2]*Turin/IT (ggiannetto27@gmail.com)*

Purpose: We have conducted a trial (Proteus trial) comparing neoplasia yield of CTC and sigmoidoscopy in a population based screening setting among subjects aged 58-60. Screenees detected with polyps ≧ 6 mm at CTC were referred for colonoscopy (TC) . We aim to assess the role of FIT screening among subject without polyps or with polyps< 6 mm at CTC screening.
Methods and Materials: According to the FIT screening protocol eligible screenees enrolled in the Proteus trial, were invited to undergo FIT screening (single sample, with a positivity cut-off at 20 µg/gr. faeces) two years after the screening CTC. The outcomes of interest were: participation rate (proportion of invitees examined), positivity rate (PR), positive predictive value of TC referral and detection rate (DR) of advanced adenomas or CRC (AN).
Results: Participation was 70.4% (1541/2331); the PR was 4.1% and 89.7% (57/64) of those referred for TC actually had the test. The PPV for AN was 17.5% (10/57, including 1 CRC) and the AN DR was 6.1% .
Conclusion: Participation in FIT screening among subjects having performed a CTC was lower than among subjects who had previous FIT tests. FIT is still detecting AN among subjects with diminutive polyps or negative CTC, although PR and PPV are lower as compared to subjects with previous negative FIT result.

B-0523 11:11

Focal colorectal uptake in ^{18}FDG-PET/ CT: maximum standard uptake value as a trigger in a semi-automated screening setting
W. Luboldt; *Munich/DE (luboldt@screening.org)*

Purpose: Focal colorectal uptake in ^{18}FDG-PET/CT may be associated with a malignancy and can be quantified. This provides the basis for an automatic trigger threshold above which cases are flagged for colonoscopic evaluation and below which for individual assessment. The purpose is to determine the lowest maximum standard uptake (SUV_{max}) in colorectal cancer that could be used as a threshold to trigger endoscopic evaluation and to evaluate whether the SUV_{max} needs to be further normalised to a priori known extrinsic factors.
Methods and Materials: The SUV_{max} was measured in 54 colorectal carcinomas and correlated with gender, age, blood glucose level, injected activity, body mass index and time to scan using t test or correlation coefficients (Pearson or Spearman, according to distribution).
Results: There was no correlation between SUV_{max} and any of the extrinsic factors mentioned above. The lowest SUV_{max} value was 5 [mean ± SD (range): 11.1 ± 4.8 (5.0-24.6)].
Conclusion: In contrast to most other screening techniques, semi-automation in colorectal screening seems possible with PET/CT. This opens the door for further study into the feasibility of automated screening. Independent from extrinsic factors, an SUV_{max} ≥5.0 in a focal colorectal uptake in ^{18}FDG-PET/CT should automatically trigger for endoscopic evaluation, if not contraindicated. Cases with SUV_{max} <5 should be assessed individually before referral for endoscopy. Thus, more interpretation time could be spent on those cases with a lower uptake and more ambiguous diagnosis.

B-0524 11:19

MRI T2WI and fat-suppressed-T2WI image fusion technology in improving image quality for the evaluation of anal fistulas

Z. Dong, S.-T. Feng, M. Huang, Y. Jia, H. Cai, Z.-P. Li, B. Shen;
Guangzhou/CN (asrachel@126.com)

Purpose: We aimed to develop a novel magnetic resonance (MR) image fusion technology (combined T2-weighted imaging [T2WI] and fat-suppressed T2WI [T2WI-FS]) to improve image quality for better display of both anal fistulas and the anatomical structure of the anus.
Methods and Materials: A total of 32 patients with proven anal fistula were retrospectively studied. All of the patients underwent anal MR imaging, including axial fast spin echo (FSE) T2WI and FSE T2WI-FS. T2WI and T2WI-FS were used to form the fusion image (T2WI-fusion) based on the addition of the gray values obtained from each pixel via a MR post-processing workstation. The signal intensities of the fistula, the peri-fistula sphincter and perianal fat in T2WI, T2WI-FS and T2WI-fusion were measured with the algorithm Fisher score=(μt-μm)/sqrt($σt^2$-$σm^2$), where μ and σ are the mean and standard deviation (SD), respectively, of the tissue signal intensity. The difference in Fisher scores between T2WI, T2WI-FS and T2WI-fusion were compared.
Results: The mean Fisher scores of the fistula vs sphincters from T2WI-fusion ($FS_{Fusion\text{-}fistula}$=6.56) were significantly higher than those from T2WI ($FS_{T2WI\text{-}fistula}$=3.35) (P=0.001). The mean Fisher scores of sphincter vs fat from T2WI-fusion ($FS_{Fusion\text{-}sphincter}$=10.84) were also significantly higher than those from T2WI-FS ($FS_{fat\ suppression\text{-}sphincter}$=2.57) (P=0.001).
Conclusion: The T2WI and T2WI-FS fusion technology integrates the advantages of both T2WI and T2WI-FS. The combination has the ability to improve image quality and facilitate accurate evaluation of anal fistulas and sphincters.

B-0525 11:27

Preoperative assessment of simple and complex anorectal fistulas: tridimensional endoanal ultrasound? Magnetic resonance or both?

F. Iacobellis, L. Roberto, L. De Pascale, R. Rella, R. Natella, A. Reginelli, R. Grassi; *Naples/IT (iacobellisf@gmail.com)*

Purpose: The purpose of this study was to evaluate the diagnostic value of 3D-EAUS and MR in the preoperative assessment of both simple and complex anorectal fistulas.
Methods and Materials: From Jan-2015 to Jan-2017, 124 patients with perianal fistulas underwent anamnestic evaluation, clinical examination, unnhanced and H2O2 enhanced 3D-EAUS and MRI. The results of imaging evaluation were compared with surgical findings, considered as reference standard.
Results: Perfect agreement between 3D-EAUS and surgery in the anal fistulas severity grading was found (K= 1). The fistulas were classified as simple in 68/126 (53.9%) and complex in 58/126 (46.03%) cases. In both simple and complex anal fistulas, 3D-EAUS showed a not significantly higher accuracy in the evaluation of internal openings, if compared with MRI (p= 0.47; McNemar Chi-Square Test). In the complex anal fistulas, MRI showed a significantly higher accuracy in the evaluation of secondary extensions if compared with 3D-EAUS (p= 0.041; McNemar Chi-Square Test) whereas, in the simple anal fistulas, not significantly difference was found.
Conclusion: In the preoperative work-up of patients with anorectal fistulas, 3D-EAUS may represent the first-line diagnostic tool. In the cases of fistulas classified as complex by 3D-EAUS, the MR may be indicated as adjunctive diagnostic imaging examination, to more carefully describe the fistulas complete anatomy.

B-0526 11:35

Identification of internal opening in perianal fistula: comparison of 3D cube vs 2D at 3.0 Tesla

V. Nyapathi; *Rajahmundry/IN (drvinaynyapathy@gmail.com)*

Purpose: The hypothesis was that 3D T2FSE cube in comparison to 2D T2FSE sequence would be more accurate in detection of internal opening with perianal fistula.
Methods and Materials: A total of 100 (age 20-60yrs) patients with clinically suspected fistula-in-ano (72 men and 28 women) underwent pelvic MR examinations on a GE Signa HDxt 3.0 Tesla. All the patients had T2-weighted MR imaging at 3T with both 1-mm-thick 3D T2FSE cube and 5-mm-thick axial, coronal and sagittal 2D T2FSE sequences. The internal opening, side tracts and abscesses were evaluated on both sequences. Statistical analysis of detection rate was performed to compare 3D T2FSE with 2D T2FSE images using Fisher exact test and Chi-square test.
Results: Accuracy in detection of internal opening is higher on 3D cube than 2D images. A p value of 0.0004 in Fisher exact test and p value of 0.00023 in Chi-square test are considered to indicate a significant difference.
Conclusion: The advantage of 3D T2 FSE cube sequence is its accuracy in the identification of internal opening in a perianal fistula and secondary lesions with multiplane reconstruction in comparison with 2D T2 FSE sequence.

B-0527 11:43

Can we reliably identify the appendix on unenhanced ultra-low-dose CT in the era of iterative reconstruction?

D. Ordu, L.-P. Rollandi, K. Rippel, C. Scheurig-Muenkler, T. Kröncke, F. Schwarz; *Augsburg/DE (deniz.ordu@klinikum-augsburg.de)*

Purpose: To determine factors influencing the accuracy in the identification of the appendix on ultra-low-dose CT by residents with on-call experience.
Methods and Materials: We included 163 patients presenting to the ED over a 5-month period who were referred for an unenhanced ultra-low-dose CT of the abdomen for urolithiasis. A model-based iterative algorithm was used for image reconstruction. As reference standard, two faculty radiologists evaluated all datasets and information from the electronic health records. Two residents blinded towards this reference standard independently analysed all datasets for the presence of the appendix and digitally marked it if identified.
Results: 35 patients were excluded due to uncertain AE status. Of the remaining 128 patients (80 men, median age 47, median DLP 46mGy*cm), 56 had had prior appendectomy. Interobserver agreement was high (88%, κ=0.75). Readers had a sensitivity, specificity and accuracy of 91%, 88%, 90% and 92%, 91%, 91%, respectively. The subgroup of patients with incorrect identification of the appendix had lower BMI (23.5±4 vs 28±7kg/m², p=0.02) and tendencies towards lower CTDI (0.91±0.3 vs 1.21±0.6mGy, p=0.1) and lower DLP (43±13 vs 53±25mGy*cm, p=0.16) but there was no difference in image noise (15.9±3.8 vs 15.9±3.6HU, p=1.0). BMI had high predictive value for an incorrect identification of the appendix (AUC=0.73, p<0.01), while image noise lacked any measurable effect (AUC=0.52, p=0.84).
Conclusion: The normal appendix or its absence can be correctly identified on unenhanced ultra-low-dose CT scans in the vast majority of cases by residents with on-call experience. Low BMI is a strong predictor for misclassification, while image noise lacked any measurable effect.

B-0528 11:51

Use of conventional defecography or dynamic MRI defecography in patients with symptomatic pelvic floor dysfunction: a retrospective intraindividual trial

M.C. Langenbach, M. Kaup, M. Beeres, J.-E. Scholz, C. Park, C. Frellesen, T.J. Vogl, T. Gruber-Rouh; *Frankfurt a. Main/DE (marcel.langenbach@me.com)*

Purpose: Conventional defecography [CD] is a standard method in diagnostic of pelvic floor dysfunction. Since dynamic magnetic resonance imaging [MRI] has become more common, examinations are possible without X-ray and iodinated contrast media. Differences of both methods will be compared in this retrospective intraindividual trial.
Methods and Materials: 50 patients (44 females, 6 males; mean age: 57 years) were evaluated with CD and dynamic MRI defecography [MRD]. Iodinated contrast media was used for CD, ultrasound gel for MRD. Two radiologist with more than 5 years' experience evaluated the presence of rectal prolapse, rectocele, enterocele, sigma deverticula and Cul de sac [CdS] phenomenon/syndrome.
Results: In CD, rectal prolapse was observed in 45 patients, in MRD only in 8 patients (p<0.001). CD showed a rectocele in 37, MRD in 41 patients (p=0.337). No significant differences were documented for retention of rectoceles (p=0.188), but significant for the size (MRD: 2.40cm; CD: 1.91cm; p=0.016). For occurrence of enterocele and sigma diverticula (p=0.604; p=0.149), no significant differences were found. Identification of elongated sigma is more sensitive in CD than MRD (p=0.008). CdS phenomenon and syndrome were seen in CD in 8 and 9 cases, in MRD only in one patient, respectively (p=0.015; p=0.008).
Conclusion: MRD instead of CD is a strong alternative option for diagnosis of pelvic floor dysfunctions. Additionally, lack of radiation and possibility for direct evaluation of anterior and middle compartment puts MRI into a stronger role. Despite various advantages of MRD, the choice of the method is depending on the clinical question.

Three-material decomposition with dual-layer spectral detector CT compared to MRI for the detection of bone marrow oedema in patients with acute vertebral fractures

B.J. Schwaiger, A. Gersing, J. Hammel, K. Mei, F.K. Kopp, E.J. Rummeny, K. Wörtler, T. Baum, P.B. Noel; *Munich/DE*

Purpose: To assess whether bone marrow oedema in patients with acute vertebral fractures can be accurately diagnosed based on three-material decomposition with dual-layer spectral detector CT (SDCT).
Methods and Materials: Acute (n=41) and chronic (n=19) osteoporotic thoracolumbar vertebral fractures in 28 subjects (70±14 years, 18 women) as diagnosed by MRI (hyperintense signal in STIR sequences) were assessed on a SDCT (Philips IQon). Data were processed using an in-house developed algorithm to decompose spectral data into calcium, oedema-equivalent and fat-equivalent density maps. Two radiologists, blinded to clinical and MR findings, assessed the images independently, using a Likert scale (1=no oedema; 2=likely no oedema; 3=likely oedema; 4=oedema). Accuracy, sensitivity and specificity for identifying acute fractures (Likert scale, 3 and 4) were analysed using MRI as standard of reference.
Results: For the identification of acute fractures, conventional CT images showed a sensitivity of 63% and specificity of 84%, whereas the sensitivity (95%) and specificity (90%) of decomposed SDCT images were substantially higher. Accuracy increased from 70% for conventional images to 93% using SDCT. Readers considered MRI necessary for fracture age determination in 60% (based on conventional images) and 28% (based on SDCT images), respectively. Interreader agreement was high for the classification of acute fractures in conventional (ICC, 0.79 [95% confidence interval, 0.68-0.87]) and SDCT images (ICC, 0.95 [0.92-0.97]).
Conclusion: Material decomposition of SDCT data substantially improved accuracy for the diagnosis of acute vertebral fractures, with a high interreader agreement. This may spare patients' additional examinations and facilitate the diagnosis of vertebral fractures.

B-0530 10:38

Single-source dual-energy computed tomography for the assessment of bone marrow oedema in vertebral compression fractures: a prospective diagnostic accuracy study

T. Diekhoff[1], N. Engelhard[1], M. Fuchs[1], M. Pumberger[1], M. Putzier[1], J. Mews[2], B. Hamm[1], K.-G. Hermann[1]; [1]*Berlin/DE*, [2]*Neuss/DE*
(torsten.diekhoff@charite.de)

Purpose: The aim of this study was to evaluate the diagnostic accuracy of single-source dual-energy computed tomography (DECT) in patients with vertebral compression fractures.
Methods and Materials: Patients aged 50 or more years were prospectively included and underwent both DECT on a single-source machine (80/135 kVp sequential volume acquisition) and 1.5 Tesla MRI including T1 and STIR sequence that severed as standard of reference. Virtual non-calcium images (VNCa) were reconstructed using a three-material decomposition algorithm. Only vertebras with loss of height in CT were included in the analysis. Images were independently scored for bone marrow oedema by three blinded readers using a 0-3 rating scale. A contingency table analysis, test for inter-reader reliability using Cohen's kappa and measurements of signal-to-noise (SNR) and contrast-to-noise ratios (CNR) were performed.
Results: 70 patients and 192 vertebras were included. DECT showed a reader-dependent sensitivity of 72% (62 to 80%) and a specificity of 70% (46 to 71%) for BME. Sensitivity increased with the oedema score in MRI (81% for grade 2 and 89% for grade 3). Cohen's kappa was inferior for DECT (0.32 to 0.48) compared to MRI (0.56 to 0.62). T1 provided a significantly better signal- and contrast-to-noise ratio compared to STIR, CT and VNCa ($p < 0.0001$); however, there were no differences between STIR and VNCa.
Conclusion: DECT is able to detect BME with substantial diagnostic accuracy and can be performed utilizing a single-source system. It provides sufficient image quality; however, trained readers are needed for image interpretation.

Contribution of ultra-low dose CT in lumbar spine trauma

F. Snene, A. Hamard, J. Greffier, P. Viala, J. Beregi, A. Larbi; *Nîmes/FR (snenefehmi@gmail.com)*

Purpose: To evaluate the diagnostic power of ultra-low-dose CT (ULD-CT) of the lumbar spine compared to the X-ray in emergency room.
Methods and Materials: A preliminary study on anthropomorphic phantom made it possible to determine the level of reference dose and the iterative level for the ULD-CT. Then an ULD acquisition without contrast medium injection as well as an X-ray of the lumbar spine were performed in 28 patients consulting the emergency department of our institution from March to August 2017.Raw data were reconstructed with *Sinogram-Affirmed-Iterative-Reconstruction* (SAFIRE, Siemens) with bone (I70f) and soft tissue (I30f) reconstructions kernel.
The subjective analysis (image quality, diagnostic quality, characterization of the lesions with confidence level) was performed by double blind reading (1 senior and 1 junior radiologist).The diagnostic performance of the ULD-CT and X-ray were compared.
Results: Effective dose for ULD-CT were lower than the national X-ray Diagnostic Reference Level (DRL). Kappa Cohen test agreement among the two observers for the evaluation of traumatic lesions was substantial, ranging from 0.9 to 1. The analysis of data showed the absence of inferiority of the ULD-CT in the detection of traumatic lesions comparatively to the X-ray. The ULD-CT showed its superiority in the detection of disc disease ($p<0.05$)Readers recorded a significantly high score of diagnostic confidence level for ULD-CT compared to X-ray ($p<0.05$)
Conclusion: ULD-CT with iterative reconstructions allowed a reliable study of spine trauma patients with a lower irradiation dose than spine radiography. Reproducibility is independent of the level of experience of the readers.

B-0532 10:54

Evaluations of outcomes for drop in pain and analgesic use for kyphoplasty in the treatment of 249 patients with vertebral compression fractures: a single centre results

R. Marcello, G. Assegnati, A. Di Blasi, F. Cortese, S. Vitale; *Rome/IT (robermarcello@gmail.com)*

Purpose: Vertebral compression fractures (CF) resulting from osteoporosis, cancer and trauma are common and painful. QoL is at high risk and morbidity and mortality rates increase following a compression fracture (CF). Kyphoplasty is a minimally invasive procedure to stabilise a CF. The effectiveness and reliability to reduce pain and drop in pain killers use were considered.
Methods and Materials: 249 patients suffering from CF due to osteoporosis, trauma and malignancy receiving percutaneous trans-pedicle fluoro-guided balloon kyphoplasty were evaluated. The primary objective was to show significant improvement in two end points such as back pain relief (VAS score) and analgesic use at one week and three months after treatment. Pre-procedural workup was carried out on spinal unenhanced multiplanar MRI or CT.
Results: Back pain significantly decreased after treatment: the mean VAS pain score before treatment was 16.33 +/- 2.45 (range 13-20) versus 9.25 +/- 4.90 (range 2-18) one week after treatment and was 7.00+/- 5.25 (range 1-14) three months after treatment. Analgesic use dropped after treatment. Device- and procedure-related complications were asymptomatic balloon rupture in three patients, asymptomatic to the skin cement leakage through monolateral pedicle access successfully removed with a clamp in one patient and possibly cement-related new CF within four weeks post-procedure in five patients.
Conclusion: Our large single centre evaluation shows that balloon kyphoplasty is a very effective and reliable procedure for the treatment of vertebral CF due to osteoporosis, trauma and malignancy.

B-0533 11:02

Vertebral body insufficiency fractures: detection of vertebrae at risk on clinical CT images using texture analysis and machine learning

U. Mühlematter, M. Mannil, T. Finkenstaedt, A.S. Becker, G. Osterhoff, R. Guggenberger, M. Fischer; *Zurich/CH (urs.muehlematter@gmail.com)*

Purpose: Osteoporotic insufficiency fractures of the spine are frequent complications in elderly patients. We introduce an alternative for bone quality measurements based on texture analysis (TA) with machine learning (ML) of CT scans of the trunk to identify vertebrae at risk for fracture.
Methods and Materials: Consecutive standard CT scans of 57 patients with insufficiency fractures of the spine were analyzed. Intact vertebrae in the first scan that either fractured ('instable') or remained intact ('reference') in the consecutive scan were manually segmented on mid-sagittal reconstructions. If available, a third scan was assessed to validate the reference vertebra over a longer period. Texture features for all vertebrae were extracted using open source software (MaZda). Multiple ML approaches, e.g. random forest and

support vector machines were used to classify instable and reference vertebrae as well as cases (instable and reference) and matched (gender, age and fracture level) controls from a prior study.
Results: 60 vertebrae were included. Mean time difference between the first and second scan was 237 days (SD ±117.5), between latter and third 548 days (SD ± 386). ML based classification of cases vs. controls showed sensitivity, specificity and AUC of 0.91, 0.86 and 0.93 and of 0.63, 0.43 and 0.45 for instable vs. reference vertebrae, respectively.
Conclusion: TA combined with ML allows to distinguish healthy and diseased bone with a high accuracy. However, within the diseased spine the prediction of single vertebrae that will fracture at a future point in time remains challenging.

B-0534 11:10

Comparing trabecular bone score and serum bone biomarker in predicting vertebral fracture for diabetes

Y.-C. Lin[1], A.Y. Cheung[2], S.-F. Kuo[1], K.-H. Wu[1], C.-M. Sung[1], C.-M. Fan[1], F.-P. Chen[1]; [1]*Keelung/TW*, [2]*Taoyuan/TW (yuching1221@gmail.com)*

Purpose: Type 2 diabetes patients (T2D) have poor bone quality with increased vertebral fracture (VF) risk. There are two available methods for predicting fracture risk, trabecular bone score (TBS) and serum bone turnover biomarkers. This study compares the diagnostic performance and also studies the association between these two methods.
Methods and Materials: Postmenopausal T2D female patients were prospectively enrolled. All received image studies of bone densitometry for TBS calculation and lateral lumbar spine radiographs for VF assessment. Laboratory studies of vitamin D, intact parathyroid hormone (iPTH), bone-specific alkaline phosphatase (sBALP, bone resorption biomarker) and beta-C-terminal telopeptides (sCTX, bone formation biomarker) for bone turnover assessment. We compared the performance of each parameters with vertebral fracture using Student's *t* test, age-adjusted odds ratio (OR) and receiver operating characteristic (ROC) curve. Lastly, Pearson for correlation of different parameters was calculated.
Results: A total of 285 T2D patients were analysed with mean age of 61.1 years and total of 32 patients with VF (11.23%). Significantly lower TBS and higher sBALP ($p<0.001$; $p=0.030$) were shown in group with VF with OR of <0.001 and 1.080 ($p<0.001$; $p=0.029$) and area under curve (0.820 and 0.746). Vitamin D, iPTH and CTx is not significantly associated with VF. TBS only significantly correlated to sBALP (-0.276, $p<0.001$) but not to sCTX (-0.096, $p=0.107$).
Conclusion: TBS has a better diagnostic performance than serum bone turnover biomarkers in predicting VF in T2D and lower the TBS are predisposed to unbalanced rate of bone turnover and resulted in bone fragility.

B-0535 11:18

Haemarthrosis of the knee and knee fracture: evaluation with high-resolution ultrasound

S.P. Ivanoski[1], V. Vasilevska Nikodinovska[2]; [1]*Ohrid/MK*, [2]*Skopje/MK (slavcoivanoski@gmail.com)*

Purpose: To evaluate the presence of knee fracture in patients with sonographic signs of knee haemarthrosis.
Methods and Materials: 31 patients with acute knee trauma and ultrasound signs of knee haemorrhagic effusion were evaluated for presence of bone fractures. High-resolution transducer was used for detecting haemorrhagic knee effusion within the suprapatellar and parapetellar knee recesses. Emergency radiography or CT was performed for establishing diagnosis of bone fracture. Control group consisted of 31 patients with acute knee trauma and anechoic, non-haemorrhagic knee effusion on ultrasound. Sensitivity, specificity, positive and negative predictive value of the method were evaluated.
Results: Radiography and CT findings were positive for bone fracture in 26 of 31 patients with knee haemarthrosis on ultrasound. In 12 cases patellar osteochondral fracture in acute dislocation were found, followed by fracture of femoral condyle (6 patients), platotibial fracture (5 cases), and tibial eminence fracture (2 patients). Avulsion fracture of the tibial tuberosity was present in 1 patient. In control group 4 avulsion fractures were detected (2 Pelegrini-Stieda, and 2 segond fractures), without any intraarticular fracture. Sensitivity of the method for detection of intraarticular fractures was 83.9%. Specificity was 87.1%, positive and negative predictive value were 86.7% and 84.4%.
Conclusion: High resolution ultrasound is a good method for detecting even a small amounts of fluid within the knee recesses. Sonographic diagnosis of knee haemarthrosis can be a good predictor of intraarticular knee fracture. Further investigations should be performed for detecting small knee fracture in all cases of haemarthrosis detected by ultrasound.

B-0537 11:26

Anatomy-based MR classification of the iliopsoas muscle complex after pertrochanteric femur fracture

M. Kaniewska[1], M. Schenkel[1], K. Eid[1], T. Bühler[1], R. Kubik-Huch[1], S. Anderson[1,2]; [1]*Baden/CH*, [2]*Sydney/AU*

Purpose: Petrochanteric femur fracture (PFF) with a dislocation of the lesser trochanter may lead to deterioration of quality of the iliopsoas muscle complex (IMC). In this prospective study, an anatomy-based evaluation of the IMC after PFF using MRI is proposed. Additionally, the inter-reader reliability of 2 classifications of fatty muscle degeneration (FMD) was determined.
Methods and Materials: Adult patients after surgery of PFF with a displaced lesser trochanter were included. Muscle quality was evaluated by means of MRI using Goutallier and Slabaugh classifications at 3 anatomic levels (L4/L5, L5/S1, spina iliaca anterior inferior). Two radiologists independently reviewed the images. Force measurement was performed on both hips. Linear mixed-effect models were used to determine the effect of fracture on muscle quality and strength. Cohen's kappa statistic was used to assess the inter-reader agreement.
Results: 18 patients were included. The IMC showed higher grades of FMD (grade 3 and 4 in Goutallier and grade 3 in the Slabaugh classification, respectively) on the fractured side (FS) than on the non-fractured side (NFS). The mean difference between muscle strength on FS and NFS was -12N (p value>0.05). Inter-reader agreement for the Goutallier and Slabaugh classifications was good and very good, respectively (weighted K = 0.78 and 0.85).
Conclusion: Anatomy-based MR evaluation of the IMC provides a valuable tool for the assessment of muscle quality after PFF. FMD of the IMC is evident and results in a minimal reduction of muscle strength. In terms of inter-reader agreement, the Slabaugh classification is superior to the Goutallier classification.

Are fractures of the anterior calcaneal process indicative of a more advanced Chopart joint injury?

A. Hirschmann[1,2], W.R. Walter[2], E.F. Alaia[2], E. Garwood[2], Z.S. Rosenberg[2]; [1]*Basle/CH*, [2]*New York, NY/US (anna.hirschmann@usb.ch)*

Purpose: To assess the co-existence of anterior calcaneal process (ACP) fractures with talonavicular joint injury, indicating advanced Chopart joint injury, and to correlate our findings with radiologic and clinicians' diagnosis.
Methods and Materials: Retrospective radiological data search ("avulsion fracture"; "anterior calcaneal process fracture") was performed. Inclusion criteria were imaging evidence of injury to ACP on radiographs and MRI within 8 weeks of ankle injury. Injuries at ACP and talonavicular component of Chopart joint, using radiographs and MRI, were assessed by three musculoskeletal radiologists. The prospective radiologic and clinical diagnosis were documented. McNemar and kappa statistics were used ($P<0.005$).
Results: Final cohort had 21 patients. On radiographs, avulsion fractures of the ACP and at talonavicular joint were evident in 48% (10/21) and 38% (8/21), respectively. Concomitant fractures of both joints, indicating advanced Chopart joint injury, were evident in 14% (3/21). On MRI, avulsion fractures of the ACP and at the talonavicular joint were evident in 100% (21/21) and 76% (16/21), respectively. Thus, concomitant fractures at both joints were present in 76% of the cases. Differences between imaging modalities were significant ($p<.008$). Interrater agreement was 0.144-0.538 and 0.976-1 for ACP and 0.488-0.637 and 0.286-0.364 for talonavicular injuries on radiographs and MRI, respectively. 60% of ACP fractures were prospectively missed on radiographs (none on MRI), while 38% and 25% of talonavicular findings were prospectively missed on radiographs and MRI, respectively. 60% of Chopart joint injuries were clinically misdiagnosed as ankle sprains.
Conclusion: Radiological evidence of injury at either component of Chopart joint should draw attention to a more severe Chopart joint sprain.

Comparing dGEMRIC and clinical outcome 6 years after FAI surgery with versus without microfracturing: a controlled pilot study

F. Schmaranzer[1], P. Haefeli[1], M. Hanke[1], T. Lerch[1], K. Siebenrock[1], S. Werlen[1], M. Tannast[1], L. Büchler[2]; [1]*Bern/CH*, [2]*Biel/CH*

Purpose: To compare (1) T1 indices and (2) clinical outcome in patients with a minimum 6-year follow-up who had undergone FAI surgery with versus without microfracturing.
Methods and Materials: After IRB approval patients with a minimum 6-year follow-up who had undergone surgical hip dislocation with or without microfracturing for treatment of FAI and of extensive chondral flaps and defects were searched. A total of 46 patients were identified, 17 in the `Mfx group' and 29 in the `no Mfx group'. All eligible patients underwent indirect MR arthrography (Gd-DTPA 2-0.2 mmol/kg) with a dual-flip angle GRE-technique for acquisition of 3D T1 maps at latest follow-up. (1) T1 indices of acetabular cartilage were assessed on radially reformatted images. Regions of interest were manually placed. (2) Patient-reported outcome was evaluated at latest follow-up using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and Harris Hip Score (HOOS). Unpaired Student's t tests and Mann-Whitney U tests were used ($p<0.05$).
Results: There was no significant difference ($p>0.05$) in the overall (438 ± 150ms versus 434 ± 136ms) and regional (superior [11-1 o'clock], anterior [2-4 o'clock], posterior [8-10 o'clock]) T1 indices between the two groups. WOMAC (52 ± 65 versus 39 ± 46) and HHS (71 ± 27 versus 87 ± 12) did not differ significantly ($p>0.05$) between the two groups.
Conclusion: The results suggest that treatment of cartilage lesions with microfracturing during FAI surgery does not positively or negatively affect clinical or radiographic mid-term results compared to patients with no treatment of cartilage lesions.

Impact of software parameter settings on image quality of Virtual Grid processed radiography images: a contrast-detail study

T. Gossye, M. Peleman, P. Smeets, E. Achten, K. Bacher; *Ghent/BE (tim.gossye@ugent.be)*

Purpose: The use of an anti-scatter grid is uncommon in bedside radiography. Dedicated software to compensate scatter in the images became recently available. The aim was to evaluate the influence of software parameter settings on the image quality using a contrast-detail study.
Methods and Materials: 2400 images of a CDRAD (Artinis) test object were acquired with a digital D-EVO II GOS detector accompanied with Virtual Grid (VG) post-processing software (Fujifilm Medical Systems). The test object was placed between PMMA to mimic patient scatter (total thickness range: 12-26 cm). For each phantom thickness images were acquired with a kVp range 81-125. 12 different VG software parameters combinations were investigated (2 grid ratios, 3 linepairs/cm, 2 types of interstitial material). The acquired images were analysed with the CDRAD Analyser software 2.1 and the relative Image Quality Figure inverse (IQFinv) was calculated. A linear mixed model statistical design was performed for data analysis (IBM SPSS 23).
Results: VG software significantly ($P<0.001$) improved the digital images. Compared to non-VG images, mean relative IQFinv values significantly increased from 26% to 32% for grid ratio 6 and 10 respectively ($P<0.001$). For the other two parameters no statistically significant differences are observed ($P>0.05$). Small but significant interactions are noticed for: ratio*linepairs/cm and ratio*PMMA thickness*kV.
Conclusion: VG software is able to improve bedside radiography imaging significantly. The most important factor influencing the image quality improvement is the VG grid ratio setting. The other software parameter settings did not significantly affect the relative IQ_{inv}.

B-0541 10:38

X-ray dark-field and phase-contrast images facilitate the detection of wooden and glass foreign bodies on radiographs

K. Hellbach[1], E. Beller[1], A. Schindler[1], F. Schoeppe[1], N. Hesse[1], A.B. Baumann[1], R. Schinner[1], C. Hauke[2], F. Meinel[1]; [1]*Munich/DE*, [2]*Forchheim/DE*

Purpose: The purpose of this study was to assess the value of dark-field and phase-contrast radiography for the detection of foreign bodies (FB) compared to transmission radiographs.
Methods and Materials: Ex vivo pig paws were prepared with metallic, wooden and glass FB (n=10 each). Paws without FB served as controls (n=30). Images were acquired with a prototype, preclinical grating-based large object radiography system (not commercially available). To investigate the diagnostic value of adding dark-field and/or phase-contrast images to transmission images a reader study was performed, asking five blinded readers to independently assess the images for the presence or absence of any FB.
Results: Sensitivity for the detection of metal FB was 100% for all readers. The sensitivity for the detection of wooden FB increased from 2% for transmission images to 78% for dark-field images ($p<0.0001$), and to 16% when phase-contrast images were added ($p=0.0264$). For the detection of glass FB, the sensitivity slightly increased from 84% for transmission images to 96% when adding phase-contrast images ($p=0.041$). The sensitivity for the detection of any foreign bodies was highest when transmission, dark-field and phase-contrast images were assessed simultaneously: 91%, compared to 62% for the sole analysis of transmission images ($p<0.0001$).
Conclusion: Detection of glass FB was significantly improved when phase-contrast images were analysed. Assessment of dark-field images resulted in a substantially improved detection of wooden FB compared to the sole analysis of transmission images.

High-fidelity vessel visualisation in diagnostic CT: low-dose dynamic CTA via singular value decomposition-guided filter (SVGF)

F. Pisana[1], T. Henzler[2], H. Haubenreisser[2], E. Klotz[3], B. Schmidt[3], M. Kachelrieß[1]; [1]*Heidelberg/DE*, [2]*Mannheim/DE*, [3]*Forchheim/DE*

Purpose: To provide high-fidelity images of vessels in low-dose dynamic CT angiography (CTA).
Methods and Materials: Dynamic CTA provides additional unique information compared to conventional CTA. Low-dose acquisitions, however, typically result in noise and artefacts and small vessels may be hard to be visualised, particularly in the temporal MIP volume. We developed a non-linear filter to significantly improve image quality. After subtracting the baseline, the temporal redundancy of the dataset is enforced via singular value thresholding, which has the effect of reducing the temporal noise while preserving the temporal signal. The temporal MIP of the such-filtered volume is used to guide a spatial bilateral filter. Additionally, to preserve temporal coherence, we introduced a weight depending on the similarity of the smoothed temporal profiles. The SVGF was retrospectively tested on several low-dose dynamic CTA cases, acquired at 70 kV, with a Somatom Force CT scanner (Siemens, Forchheim, Germany).
Results: The CNR of small vessels was evaluated on the temporal MIP of both the unfiltered and filtered cases. The SVGF improved the CNR by 80% on average, resulting in a potential dose reduction of a factor of 3. Also, each temporal phase was significantly improved, allowing for higher details in the dynamic MPR, MIP and VRT visualisations.
Conclusion: Dynamic CTA could potentially replace conventional CTA given the significance of the additional information provided. Our new SVGF approach could allow for dynamic CTA at very low doses, roughly 1.5 mSv instead of 4.5 mSv, and restore detailed dynamic visualisation of the vessels.

Potential of spectral photon-counting CT for the differentiation between blood and iodine in a bovine brain

I. Riederer[1], D. Bar-Ness[2], F. Pfeiffer[3], P. Douek[2], S.A. Si-mohamed[2], A.A. Fingerle[1,3], E.J. Rummeny[1], P.B. Noel[1,3], D. Muenzel[1,3]; [1]*Munich/DE*, [2]*Bron/FR*, [3]*Garching/DE (isabelle.riederer@tum.de)*

Purpose: To evaluate the potential of Spectral Photon-Counting CT (SPCCT) for the differentiation between blood and iodine in a bovine brain.
Methods and Materials: Tubes with blood and a concentration series of iodine-based contrast agents were scanned with a preclinical SPCCT system (both in-vitro and in an ex-vivo bovine brain tissue sample) to obtain spectral

and conventional data. Iodine density maps and virtual non-contrast images were generated using the multibin spectral information to perform material decomposition. Region-of-interest (ROI) analyses were performed within the tubes to quantitatively determine the absolute content of iodine.
Results: In conventional CT images, ROI analysis showed similar HU density values for the tubes with blood and iodine (59.9 +/- 1.8 versus 59.2 +/- 1.5). Iodine density maps enabled clear differentation between blood and iodine in-vitro, as well as in the bovine brain. Quantitative measurements of the different iodine concentrations matched well with those of actual prepared mixtures (measured: 0.57 +/- 0.09 mg/cm³, actual: 0.5 mg/cm³; measured: 0.77 +/- 0.16 mg/cm³, actual: 0.75 mg/cm³; measured: 0.93 +/- 0.15 mg/cm³, actual: 1 mg/cm³; measured: 2.11 +/- 0.21 mg/cm³, actual: 2mg/cm³; measured: 5.06 +/- 0.06 mg/cm³, actual: 5 gm/cm³; measured: 10.33 +/- 0.18 mg/cm³, actual: 10 mg/cm³; measured: 16.08 +/- 0.13 mg/cm³, actual: 15 mg/cm³).
Conclusion: Spectral Photon-Counting CT allows for multi-material decomposition and differentiation between blood and iodine in-vitro and within a bovine brain, providing reliable quantification of the iodine concentration.

An automated alignment correction algorithm for CT imaging: evaluation based on a CT image quality phantom and application to sediment cores from cold-water coral mounds
S. Skornitzke[1], G. Pahn[1], A. Bahr[1], J. Raddatz[2], H.-U. Kauczor[1], W. Stiller[1]; [1]*Heidelberg/DE*, [2]*Frankfurt a. Main/DE*
(Stephan.Skornitzke@med.uni-heidelberg.de)

Purpose: Alignment of objects during computed tomography (CT) acquisition can be crucial for evaluation, e.g. for image quality assurance. An algorithm for automated alignment correction of scanned objects was developed, evaluated in a phantom, and applied to acquisitions of sediment cores, enabling extraction of geological samples.
Methods and Materials: A phantom (ConeBeam Phantom; QRM, Germany) was scanned at 120kV$_p$/150mAs (SOMATOM Definition Flash; Siemens Healthineers, Germany). Image series were randomly rotated (up to ±2.86°) and translated (up to ±15mm) 1000 times and alignment was automatically corrected using the developed algorithm. Alignment parameters determined by the algorithm were compared to randomised parameters, and four regions of interest (ROIs) were placed in the low-contrast phantom segment, comparing mean values before and after correction. After validation, CT series of six sediment cores from cold-water coral mounds acquired at 140kV$_p$/570mAs were corrected for alignment.
Results: Average absolute differences between detected and randomized parameters were 0.15±0.07° around x-axis, 0.02±0.02° around y-axis, 0.01±0.06mm in x, and 0.11±0.08mm in y. Mean values for ROI measurements averaged for corrected datasets were -148.54±1.40HU, -76.78±0.90HU, -48.16±0.86HU and -16.64±0.48HU, compared to original measurements of -149.76HU, -77.54HU, -48.61HU and -17.00HU. Alignment could be corrected for all six CT series of sediment cores. Average absolute rotation was 0.37±0.33° around x-axis, 0.21±0.22° around y-axis, and average absolute translation was 3.93±2.89mm in x and 7.21±2.37mm in y.
Conclusion: The algorithm allows to automatically correct alignment of imaged objects, e.g. in CT series of standard quality assurance phantoms as well as general cylindrical objects, enabling further evaluation.

Correcting for acoustic and optical inaccuracies in photoacoustic imaging using multimodal priors
S. Mandal, D. Komljenovic; *Heidelberg/DE (s.mandal@dkfz.de)*

Purpose: Photoacoustic (PA) imaging depends on the principle of optical generation and acoustic detection of signals from tissue sample. However, biological tissue suffer from significant depth dependent optical fluence losses and acoustic attenuations. We aim to correct for these inaccuracies aided by extrinsic imaging priors obtained through concurrent high-frequency ultrasound (US) imaging of tissue samples.
Methods and Materials: A hybrid PA-US system (Vevo LAZR-X, VisualSonics) was employed for acquisition of fused multimodal data in real time. The temperature was monitored continuously using built-in temperature sensor, it was used as an initial estimate for speed-of-sound (SoS) calibration. We corrected for the small variations in SoS by incorporating multiple SoS in tissue and coupling medium, which was modelled using skin-line detection from the US image. The optical fluence correction was achieved through Monte Carlo modeling of light transport in multi-layered tissues (MCLM). The information regarding the different tissue layers were obtained through multi-label segmentation of US images. Finally, anisotropic diffusion was used for noise reduction in the images without loss of edge information.
Results: The corrected beamformed PA image showed an improvement of PSNR (43.289) and MSE (3.049). Further, fluence correction offers improved resolution at greater depths in the PA images. Results were verified using phantom studies and *in vivo* kidney images of small animal (rat) models.
Conclusion: These experimental results demonstrate that mutual information from US and PA can significantly improve the imaging performance of the beamformed PA image, and reduce errors introduced by optical and acoustic attenuations.

Improved contrast-enhanced time-resolved MR angiography on a small bore 3T MRI system
S. Riederer, E. Stinson, M. Bernstein, N. Campeau, J. Huston, J. Trzasko; *Rochester, MN/US (riederer@mayo.edu)*

Purpose: To describe the implementation of an improved time-resolved contrast-enhanced MR angiography sequence on a compact 3T MRI scanner.
Methods and Materials: Recently a 37-cm bore "compact" 3T MRI system has been developed, specifically targeted to imaging the head and extremities, with smaller bore size enabling improved-performance gradient hardware. Compared to typical gradient amplitude and slew rates (50 mT/m, 200 T/m/sec) of a 70 cm whole body MRI, the compact 3T system has specifications (80 mT/m, 700 T/m/sec). The smaller gradient diameter reduces peripheral nerve stimulation at higher switching limits than conventional diameter gradients. For this work, a reference time-resolved CE-MRA sequence was adapted to benefit from the compact 3T scanner's increased gradient performance. This enabled reduction of the TR/TE of the SPGR T1-weighted sequence from 4.2/1.9 msec to 2.9/1.3 msec. This technique was evaluated in five human volunteers under an IRB-approved protocol.
Results: Acceleration techniques enabled 1 mm isotropic resolution with 2.5 sec update time on the compact 3T. The improved CE-MRA technique was able to resolve multiple phases of the arterial-venous passage of blood through brain vasculature of the volunteers. Benefits of shorter TE imaging include increased SNR and fewer flow-related artefacts. None of the volunteers experienced peripheral nerve stimulation.
Conclusion: The enhanced gradient performance of the compact 3T MRI scanner permits 30% reduction in TR and TE parameters for contrast-enhanced MRA, affording increased SNR and improved spatial/temporal resolution compared to that achievable using a whole body MRI scanner.

B-0547 11:26

Fast field-cycling MRI for medical applications
L.M. Broche, J. Ross, G.R. Davies, D.J. Lurie; *Aberdeen/UK*
(l.broche@abdn.ac.uk)

Purpose: The relationship between T_1-relaxation time and field strength in MRI is known to be very informative on molecular dynamics but is not accessible by conventional MRI systems. Here we introduce a new technology that measures T_1 as a function of field strength, accessing that rich source of information to provide novel contrast.
Methods and Materials: Our prototype human-scale Fast Field-Cycling (FFC) measures T_1-dispersion by rapidly switching the main magnetic field (B_0) during the pulse sequence to reach any field strength between 25 uT and 0.2 T within 20 ms. Its resistive magnet is driven by power amplifiers giving full control of B_0 with a 15 ms stabilisation time. Additional coils outside the main magnet provide local cancellation of the Earth's field.
Results: The system has been fully commissioned and is capable of in vivo imaging using its full field range. Images of the head and knees were obtained from normal volunteers and patients within 40 minutes for a resolution of 4x4x8 mm over 250 mm field of view. T_1-dispersion images were obtained that agreed with measurements on excised tissues from a benchtop FFC instrument.
Conclusion: FFC-MRI allows us to explore and take advantage of the unique T_1-dispersion contrast. The use of a purely resistive magnet allows us to access ultra-low magnetic fields, providing information on slow molecular dynamics. Our work currently concentrates on demonstrating how this newly accessible region of the T_1 dispersion curve can be exploited for clinical diagnosis in stroke, osteoarthritis and Alzheimer's disease.

Radiopaque 3D printing of patient individual phantoms for computed tomography and radiation therapy
P. Jahnke, F.B. Schwarz, M. Ziegert, B. Hamm, M. Scheel; *Berlin/DE*
(paul.jahnke@charite.de)

Purpose: To develop a method for 3D printing realistic anthropomorphic phantoms of individual patients.
Methods and Materials: Conventional inkjet technology is used together with radiopaque ink to print CT images of individual patients on standard paper. Stacking of the printed sheets results in 3D objects that are examined in the CT scanner. Calibration of the printer and a gray scale correction procedure of

the CT images are necessary to achieve realistic Hounsfield units. Processing of the printed stack with a paper based 3D printer creates stable phantoms with the attenuation properties and the shape of the original patient.
Results: Radiopaque 3D printing allows transfer of patient anatomy and pathology into a detailed individual phantom. Gray scale analysis with ink containing potassium iodide solutions (0.6 g/mL) on a HP Deskjet 6940 inkjet printer (Hewlett Packard, Palo Alto, Calif) yields an exponential correlation between template gray scales and printer deposition. Correction of the print template allows to achieve a linear correlation (r = 0.9946; 95% CI: 0.9916, 0.9966). Application of the gray scale correction procedure to the CT image data set results in linear correlation of phantom and patient Hounsfield units (r = 0.9925; 95% CI: 0.9635, 0.9985).
Conclusion: Radiopaque 3D printing realizes detailed anthropomorphic phantoms of individual patients. Applications are in training, device and protocol optimization, quality assurance and dosimetric investigations.

Gallium Arsenide hybrid photon counting x-ray detectors: towards large area single-shot spectral mammography
S. Gkoumas, M. Habl, V. Radicci, M. Rissi, T. Thuering, S. Traut, P. Trueb, P. Zambon, C. Broennimann; *Baden-Daettwil/CH*
(spyridon.gkoumas@dectris.com)

Purpose: This study presents the latest developments of two dimensional GaAs hybrid photon counting (HPC) detectors with respect to breast imaging applications. We discuss why direct conversion GaAs sensors combined with HPC technology is an optimum choice for fast exposure, single-shot and large area spectral mammography.
Methods and Materials: The two prototype HPC X-ray imaging detectors used for this study are based on the DECTRIS SANTIS 0804 HR design using IBEX technology. They employ GaAs and CdTe as direct conversion sensor materials. Each detector has an active area of 8 x 4 cm^2, a pixel size of 75 μm^2 and two fully calibrated and independently adjustable energy selective thresholds. The detectors' performance is assessed using mammography phantoms such as the ACR 156 and also imaging performance characteristics such as quantum efficiency (QE), modulation transfer function (MTF) and the newly introduced spectral efficiency (SE).
Results: Both GaAs and CdTe show an excellent 5/4/5 score when imaging the ACR 156 phantom. For the relevant energy range of screening and diagnostic mammography, or digital breast tomosynthesis, GaAs exhibits QE higher than 80%. Moreover, GaAs shows higher QE than CdTe for the 30-50 keV energy range which is significant in terms of dose efficiency for spectral mammography. Spectral efficiency in combination with preliminary material decomposition results are discussed.
Conclusion: GaAs HPC X-ray imaging detectors present very attractive characteristics optimally suited for large area, low dose single-shot spectral mammography. They exhibit excellent image quality and optimum QE for the energy range of breast imaging applications.

Development of algorithms to degrade the image quality of mammograms for lesion detectability studies
J. Boita[1,1], A. Mackenzie[2], R. Van Engen[1], M.J. Broeders[1,1], I. Sechopoulos[1,1]; [1]*Nijmegen/NL*, [2]*Guildford/UK (joana.dossantosboita@radboudumc.nl)*

Purpose: To develop algorithms to degrade mammographic image quality for future studies of how varying image quality affects lesion detectability.
Methods and Materials: Algorithms were developed to reduce the contrast in specific image areas, decrease spatial resolution, and add correlated noise in digital mammograms: problems sometimes observed in processed images of several systems. First, an algorithm was developed to segment dark and bright areas on mammograms, reducing their contrast using a sigmoid function. To decrease resolution, images were multiplied by the difference between the standard and the desired, lower modulation transfer function (MTF). Correlated noise was created by enhancing the high spatial frequencies content in the image. The low contrast algorithm was tested by comparing mammograms to low-quality mammograms. Validation of resolution reduction was performed comparing the image of a 3D printed breast phantom placed on the support table corrupted by the MTF obtained 7 cm above the table, to an image of the phantom when placed there, using the Universal Quality Index (UQI). Addition of correlated noise was tested with breast phantom images using the Normalized Noise Power Spectrum (NNPS).
Results: Changes in contrast appeared realistic comparing to real low-quality mammograms. Comparison of phantom images and the simulated reduced resolution images resulted, as expected, in a UQI of 1. Breast phantom images with added correlated noise showed, as expected, a higher NNPS.
Conclusion: The three algorithms appear to result in realistic images with degraded quality, allowing for flexible paired comparisons with high-quality mammograms when evaluating image quality and detectability.

MRI of children aged 4-9 without anaesthesia using communication at the children's cognitive level
S. Scheffmann Olloni, N. Villadsen; *Odense/DK*
(signe_scheffmann@hotmail.com)

Purpose: The primary purpose was to assess if MRI can be performed without anaesthesia on children aged 4-9 using communication at their cognitive level. The secondary purpose was to evaluate the parents' perception of the children's confidence using an app to inform about the scan.
Methods and Materials: During a 3-month period, we asked 52 children aged 4-9 to show up 30 minutes before their MRI scan. 11 of the children were scheduled for MRI under general anaesthesia (GA). We welcomed each child in the waiting room and established a good relation with the child to provide the necessary information before the MRI scan. We used an app called 'HC And' with animated characters showing how MRI and other examinations are performed. Furthermore, we asked the parents to answer a questionnaire to assess if they thought their children were better informed and more confident after using the app.
Results: All children scheduled for GA completed the scan without GA. All parents rated the app either overall good or very good. All parents felt their child got more information about the scan using the app. All parents felt that their child was more confident before and during the scan using the app.
Conclusion: Using communication at the children's cognitive level, more children can complete MRI scan without GA. At the same time, the use of the app markedly improves the parents' perception of the children's confidence.

B-0552 10:38

Development of an fMRI linguistic paradigm to monitor PPA patients: a pilot study
C. Ferreira[1], I. Cadório[2], A. Barbosa[2], A. Freixo[2], B. Silva[2], D. Figueiredo[2], M. Lousada[2], M. Castelo-Branco[1], P.M. Martins[2]; [1]*Coimbra/PT*, [2]*Aveiro/PT*
(pmartins@ua.pt)

Purpose: Functional magnetic resonance Imaging (fMRI) is an emerging technique used to report therapy induced changes in primary progressive aphasia (PPA). However, there are no well-defined protocols and most studies only use picture naming tasks. This study aimed to develop and test an adequate fMRI paradigm for future use in PPA patients.
Methods and Materials: Five right-handed healthy volunteers were enrolled in this study. Three lists of stimuli were visually presented, one for each task. The naming task consisted of 40 black and white line drawings. Semantic task included 15 related word-pairs and 15 unrelated word-pairs. A total of 36 non-word pairs were specifically tailored to the phonological task, considering European-Portuguese syllabic structure. Image acquisition was carried out in a 3T scanner and general linear model analysis was performed using BrainVoyagerQx. Statistical findings were thresholded at the voxelwise level $p<.05$ and corrected for multiple comparisons.
Results: The naming task induced a left-sided activation of frontotemporal cortices accompanied by a bilateral activation of occipital regions. In the semantic task, participants recruited semantic processing areas located in the left frontotemporal and parietal lobes, as well as occipital lobe bilaterally. The phonological task revealed cortical activity in the left frontal lobe, right cerebellar areas, and bilateral occipital lobe. In general, cerebral activation patterns found in this study are supported by the literature.
Conclusion: This protocol can be used in future studies targeting PPA population. Diagnosis and treatment monitoring can be facilitated by comparing the activated areas of PPA individuals with a matched-control group.

B-0553 10:46

1.5T vs 7T in determining changes of white matter in multiple sclerosis: preliminary studies

A. Pankowska, K. Kochalska, K. Dyndor, A. Łazorczyk, R. Pietura; *Lublin/PL (zubianna@gmail.com)*

Purpose: Multiple sclerosis is a chronic, progressive neurological disease which causes disablement and cognitive impairment. The aim of this work is to reveal main advantages of examinations performed in the ultra-high magnetic field. More precise and detailed imaging may help in better understanding of mechanisms responsible for origination and progression of this disease.
Methods and Materials: MRI examinations were performed on 1.5 T Optima MR GE using 8-channel NV Head Array Coil and Discovery 950 GE 7T scanner with Nova Head 32-channel head coil. At 1,5 T we performed a 3D CUBE T2 FLAIR and 3D T1 SPGR sequence with inversion time of 1000ms. At 7 T we acquired 3D CUBE T2, 3D T1 BRAVO sequence with an inversion time of 1000ms and SWAN. All ten patients with a demyelinating disease with age in a range of 22 to 58 and EDSS scale in the range of 1 to 6 were imaged on the both MRI systems. Images of all patients group were analyzed by two radiologists working in consensus.
Results: Studies performed in 7T showed higher sensitivity and specificity in detecting the presence of demyelinating plaques in the subcortical white matter and changes in the cerebral cortex. SWAN sequence presented the characteristic course of the blood vessels through a demyelination plaque.
Conclusion: Ultra-high 7T field MR imaging contributes to the better detection and characterisation of MS lesions due to an increased signal to noise ratio (SNR) and improved contrast what allows clinician for better visualisation of white matter lesions.

B-0554 10:54

A multi-centre study: qualitative and quantitative comparison of liver MR image quality

S. Al Dahery, L.A. Rainford, A. McGee; *Dublin/IE (shrooq_talal@hotmail.com)*

Purpose: Quality evaluation of axial liver MR images acquired at 1.5T using two-dimensional (2D) breath-hold T2-weighted (T2W) fast spin-echo (FSE) and three-dimensional (3D) T1-weighted (T1W) gradient echo sequences, focusing on the clarity of visualisation of normal liver anatomy.
Methods and Materials: Axial 2D T2W FSE and T1W 3D GRE pre-contrast liver MR images from (n=96 cases) acquired at Irish (n=10) and Kingdom of Saudi Arabia (n=9) hospitals were analysed. SNR and CNR values were calculated for normal liver parenchyma, spleen and background noise. Images were evaluated qualitatively for the presence of motion artefacts, visualisation of liver parenchyma and vascular pattern and spleen parenchyma. Optimal sequence parameters were independently agreed by expert readers (n=8) and applied to 10 volunteers. Radiologists (n=3) and radiographers (n=2) qualitatively evaluated optimised liver MR images and indicated their preferred sequence (original/optimised).
Results: Differences in motion artefact within original T2W FSE images was noted between countries. Differences in 3D T1W GRE image quality criteria scores for spleen parenchyma visualisation, SNR and spatial resolution from protocol 1 using a slice thickness ≤3 mm compared to protocol 2 using slice thickness of ≥4 mm were noted ($p < 0.05$). SNR and CNR findings elicited significant differences following optimisation compared the original protocols ($p = 0.004$). Qualitative descriptive statistics were higher for the optimised protocols compared to the original protocols for all sequences.
Conclusion: Radiographers require appropriate knowledge of MR physics to fully optimise MR image quality. Quantitative and qualitative evaluation of MR images can usefully guide sequence parameter optimisation.

B-0555 11:02

Performance of single-use syringe versus multi-use MR contrast injectors: a prospective comparative study

F. Struik, J.J. Futterer, M. van der Graaf, M.M. Prokop; *Nijmegen/NL (femkestruik@gmail.com)*

Purpose: To compare performance parameters of a single-use syringe and a multi-use MR contrast injector.
Methods and Materials: We compared preparation time, cost for disposables and volumes of contrast material used for a single-use syringe (A; Mallinckrodt Optistar LE, Liebel-Flarsheim, USA) and a multi-use MR contrast injector (B; Max 3, ulrich medical, Germany) in a prospective cross-over trial. All consecutive patients eligible for dynamic MRI on two MR systems were included during a period of 20 working days. After 10 days, the injector was switched. Technician satisfaction was evaluated using a questionnaire.
Results: We could include 111 and 95 patients for systems A and B, respectively. Average preparation time was 4:55 min for A and 2:24 min for B ($p < 0.05$). Total injected volume was 752 ml for A and 695 ml for B (N.S.). Contrast waste for A was 10.7% using 7.5-ml syringes. Contrast waste for B was 4.5% for 7.5-ml containers. Costs for disposables were lower for B if more than 5 patients per days were injected. Technicians satisfaction was higher for B (4.7 versus 2.8 on a 5-point scale; $p < 0.05$).
Conclusion: The multi-use MR contrast injector led to higher technician satisfaction, shorter preparation time, and lower cost if more than 5 patients were injected per day. In addition, cheaper contrast containers of 15 or 30 ml could be used for the first patients if more than 2 or more than 4 injections are performed per day.

Ambient experience in MRI

P. Pedersen[1], L. Fremmelevholm[1], S.H. Jørgensen[2], S. Moerup[1]; [1]*Odense/DK*, [2]*Svendborg/DK (curly64@gmail.com)*

Purpose: To investigate if radiographers can contribute to reduced anxiety during MRI scans for adults with the use of new developed Ambient Experience system.
Methods and Materials: In total, 102 patients were included in this study and randomized into two groups, 61 patients (61.8%) were scanned with the Ambient Experience system turned on and 41 (40.1%) were scanned with white light. Two validated questionnaires "*The Magnetic Resonance Imaging-Anxiety Questionnaire*" and "*The Claustrophobia Questionnaire"* were used to illustrate whether Ambient Experience (Philips Healthcare, Amsterdam) could reduce anxiety for adults during an MRI scan. Patients included in this study were all scanned with head first to get the perfect effect of the Ambient Experience system.
Results: Results showed that 83 of the 102 patients had a degree of claustrophobia. 29 patients had a mild degree, 33% of these patients scanned with Ambient Experience were more relaxed during the MRI scan, than patients scanned without the system (9%). Furthermore, six patients scanned with Ambient Experience described that previous scans were horrible or uncomfortable, but the use of Ambient Experience made it a better experience with reduced anxiety.
Conclusion: The questionnaire indicated that patients preferred to be scanned with Ambient Experience. It is difficult to conclude that Ambient Experience alone can reduce anxiety. Communication, time and previous experiences can also affect the patient; however, all 61 patients scanned with Ambient Experience had a better experience during the scan and felt less anxious than those who have been scanned with white light.

B-0557 11:18

Evaluation of occupational exposure from electromagnetic field radiation on mobile magnetic resonance imaging units

A.F.C. Sousa, J. Santos, A. Ferreira; *Coimbra/PT (a.filipa.c.sousa@gmail.com)*

Purpose: The health staff exposure to electromagnetic fields in Magnetic Resonance Imaging (MRI) has been increasing and no evidence is found regarding the mobile MRI units and their exposure measurement. This study intends to measure the staff exposure to static magnetic fields on these units to assess compliance with exposure limits.
Methods and Materials: This investigation was performed in the United Kingdom, in 5 mobile MRI units, Siemens Symphony 1.5T and was divided in three phases: analyses of the examinations frequency; Measurement of the first operator exposure using a TAOMA TS/001/UB combined with a TS/002/BLF probe during routine protocols (n=98); Quantification of the exposure variation in different locations using a homogenous phantom.
Results: The lumbar spine, knee and brain are the three most common anatomic regions examined. On the second phase, no significant differences were found between the anatomic region selected and the amplitude or frequency ($p>0.05$). However, significant differences were found ($p=0.001$) between the anatomic regions and the maximum value detected on the lumbar spine. On the third phase, the amplitude values shown significant differences between the amplitude value and the probe's position ($p=0.015$).
Conclusion: The obtained results are in compliance with the Electromagnetic Field Directive. However, it would be interesting to promote training for MRI mobile workers, in order to present methods for their exposure reduction during patients attending. Further research on this subject would be helpful and interesting, not just on the mobile units but also at other facilities.

B-0558 11:26

Detection of colorectal cancer liver metastases with MRI: is diffusion-weighted imaging (DWI) solely as good as DWI + dynamic T1-weighted sequences after extracellular Gd?

M.N. Tettero; *Alkmaar/NL (mereltettero@gmail.com)*

Purpose: To compare the diagnostic performance of unenhanced liver magnetic resonance imaging (MRI) with diffusion-weighted MR (DWI) and Gd-

based enhanced liver MRI with DWI in patients with colorectal liver metastases (CRLM) on per-patient basis.
Methods and Materials: A query of our image database was performed between 2014 and 2016, identifying patients with histologically proven colorectal cancer, who were submitted to MRI for suspicion of CRLM. 24 patients were found with CRLM, and 24 patients without liver metastases were found to form the control group. All patients underwent dedicated liver MR protocol among others with DWI and T1-weighted GRE sequences after extracellular Gd. Comparison was performed between the entire dataset (extended protocol) and reduced dataset in which the post-contrast T1 GRE had been removed (reduced protocol). Three abdominal radiologists evaluated both datasets independently of each other, with a minimum time between the reading of 2 weeks. Images were correlated with the reference standard (consisting of histopathology/comparison imaging/follow-up).
Results: The diagnostic performance for the detection of CRLM, on per-patient basis is as follows. Reduced protocol: sensitivity 92% (CI 80.6-100), specificity 100%. Extended protocol: sensitivity 100%, specificity 100%.
Conclusion: DW-MRI is an excellent imaging tool for screening and surveillance of patients at risk of CRLM (sensitivity 92%, specificity 100%) with a short scan time of 10-15 minutes. The combination of DWI with enhanced T1-weighted MRI is the best screening modality for CRLM with 100% sensitivity and 100% specificity, however, with long scan times, 40-45 minutes and with the administration of intravenous contrast agent.

B-0559 11:34

A data mining approach to the SAR values over large MR image repositories

A.C.C. Murraças[1], P.M. Martins[1], C. Ferreira[2], T.M. Godinho[1], M. Castelo-Branco[2], A. Silva[1]; [1]*Aveiro/PT*, [2]*Coimbra/PT (accm@ua.pt)*

Purpose: In magnetic resonance imaging, the radiofrequency energy absorption arises as one of the main safety concerns, being mainly related with increased body temperature. Monitoring radiofrequency absorption is achieved by the estimation of specific absorption rate (SAR), whose implementation lies on equipment manufacturers, which in turn are not totally enlightening about its calculus. This work presents an exploratory approach of whole-body SAR values stored in DICOM metadata aiming to find correlation with body weight, body mass index (BMI), gender and pulse sequences for abdominal/pelvic (17.812 series) and head (29.907 series) studies.
Methods and Materials: All studies were acquired in a 3 Tesla scanner with high-performance gradients. Data were extracted using Dicoogle, a DICOM metadata mining tool. Several DICOM tags were analysed (e.g. patient weight, height, gender, sequence name). For each study type, specifically weighted pulse sequences were related with weight, BMI and gender through boxplot diagrams, statistical and effect size analysis.
Results: SAR limits were never exceeded. Generally, SAR values tended to decrease with increasing body weight and BMI values for abdominal/pelvic studies. On the other hand, head studies showed different trends regarding distinct pulse sequences. SAR values tend to be higher in male individuals ($p<0,05$). As expected, turbo spin echo sequences present the highest SAR values. The values found for echo gradient spoiled sequence (FLASH) were also high.
Conclusion: It is confirmed that SAR estimates are related with the analysed variables. An individual examination of pulse sequences is recommended to observe trends regarding weight, BMI or gender.

Optimisation of the Blade technique in the cervical spine MRI

R.M. Lopes[1], D. Carvalho[2]; [1]*Vila Nova de Gaia/PT*, [2]*Coimbra/PT (rogeriolopes87@gmail.com)*

Purpose: The Blade technique for MRI imaging of the cervical spine has proven to be a reliable tool for reducing artifacts typically for this anatomic region. The objective of the study is to evaluate the image quality, the contrast and diagnostic acuity between T2 TSE conventional and T2 Blade in the axial and sagittal planes.
Methods and Materials: The sample is composed of 14 patients in the sagittal plane and 12 patients in the axial, being acquired with similar acquisition parameters and evaluated by two neuroradiologist. Statistical evaluations were achieved using the X^2 test.
Results: The neuroradiologist A considered the images of the sagittal Blade excellent in 42.9% of the cases and only 14.3% in the TSE that relates the characterization of bone lesions. The neuroradiologist B considered the sagittal Blade technique excellent in 78.6% of the cases and only 35.7% in the TSE in the representation of herniated disc. In the axial plane, in the representation of bone lesions, the neuroradiologist A, considers the Blade technique excellent in 41.7% of the cases and only 25% in the TSE. The neuroradiologist A, select the Sagittal Blade technique in 42.86% and the TSE in 7.14% of the cases. The neuroradiologist B, in the axial plane prefers the Blade in 41.67% and only 8.33% in the TSE.
Conclusion: The quality of the images belonging to the T2 Blade sequences on the sagittal and axial plans were considered superior to the T2 TSE conventional.

B-0561 11:50

Comparing the detection rate of melanoma metastases on gadolinium-based contrast-enhanced MRI brain scan compared to a non-enhanced scan.

K. Thakor, V. Major, S. Patel, H.R. Bergman, W. McGuire, A. Lakhani; *Northwood/UK (kirti_tailor@yahoo.co.uk)*

Purpose: Malignant melanoma is the 3rd most common malignancy to metastasise to the brain. At our institution, patients with high-risk melanoma undergo surveillance with regular MRI brain scans with intravenous gadolinium-based contrast agents (GBCA). Research has recently shown that recurrent administration of GBCA can result in gadolinium deposition within the brain although the effects of this is yet unknown. The purpose of this study was to identify if intracranial metastatic melanoma deposits can be visualised on the pre-contrast scans to evaluate if these patients can undergo surveillance with unenhanced brain MRI scans.
Methods and Materials: A retrospective study was conducted. Consecutive patients attending for MRI brain scans with intravenous GBCA for metastatic melanoma were reviewed for the period of January 2016 to December 2016. The pre-contrast T1 coronal sequence was compared to the post-contrast 3D sequence.
Results: 195 patients were evaluated. An intracranial metastatic deposit was reported in 13.9% of the scans, out of which only 25.9% of the scans showed identifiable metastasis on the pre-contrast scan.
Conclusion: The results demonstrate that the use of GBCA is essential in brain scans for metastasis detection in patients with melanoma as the majority of lesions are not identifiable without contrast enhancement. However, at our institution the pre- and post-contrast sequences are not identical, this difference could account for some of the number of lesions detected. Using the same sequence for pre- and post-contrast scans for further investigation would help in a more accurate comparison.

Correlation of a new formula measuring carotid-femoral pulse wave velocity with cardiovascular risk factors, major adverse events and mortality

S. Chin, J. Weir-McCall, L. Brown, J. Summersgill, P. Talarczyk, M. Bonnici-Mallia, F. khan, A.D. Struthers, G. Houston; *Dundee/UK (sookcheng@doctors.org.uk)*

Purpose: Carotid femoral pulse wave velocity (PWV) is a strong predictor of cardiovascular mortality and methods using external distance measurements are not reliable as they are prone to confounding factors. A new formula for PWV calculation was derived from whole-body magnetic resonance angiograms (WB-MRA) and we aim to examine if this formula correlates better with cardiovascular risk factors, major cardiovascular adverse event (MACE) and mortality.
Methods and Materials: Arterial pathlengths were measured from WB-MRA from the TASCFORCE study group and backwards linear regression was applied to derive the formula: carotid femoral pathlength=100.36+(0.70 ×age[years])+(137.81×height[m])+(0.51×weight[kg])-(0.18×pulse)+(46.25 [if female],53.89 [if male]). This was then applied to two population study groups. From this, correlation between the new PWV calculations (PWV_{NEW}) versus external measurements (PWV_{CAER} and PWV_{SUM}) and cardiovascular risk factors were calculated using Pearson and Spearman correlation co-efficients. Significant difference was assumed when $p<0.05$.
Results: There were 1242 SUMMIT study participants and 825 Caerphilly study participants. There were no loss of correlation between PWV_{NEW} with age, blood pressure or creatinine levels ($p<0.01$). In both the SUMMIT and Caerphilly cohort, the PWV_{NEW} showed a loss correlation with obesity and waist circumference. The hazard ratio was 1.11 and 1.17, respectively, for cardiovascular mortality and MACE and is unchanged for all PWV measurements.

Conclusion: The new formula based on the patient's height, weight, sex and pulse measurements demonstrates less variability and is more accurate compared to measurements using external distances without losing its association with cardiovascular risk factors, MACE and mortality.

Acute adverse events in cardiac MR imaging with gadolinium-based contrast agents: results from the European Society of Cardiovascular Radiology (ESCR) MRCT registry in 72,839 patients

J. Uhlig[1], C. Lücke[2], R. Vliegenthart[3], C. Loewe[4], M. Grothoff[2], A. Jacquier[5], M. Francone[6], J. Lotz[1], M. Gutberlet[2]; [1]*Göttingen/DE*, [2]*Leipzig/DE*, [3]*Groningen/NL*, [4]*Vienna/AT*, [5]*Marseille/FR*, [6]*Rome/IT (cluecke@gmx.de)*

Purpose: To assess the incidence of acute adverse events (AAE) in gadolinium-enhanced cardiac magnetic resonance (CMR) imaging with statistical adjustment for potential confounders.
Methods and Materials: Gadolinium-based contrast agents (GBCA) enhanced CMR from the ESCR MR/CT registry were included. AAEs were classified according to the ACR manual on contrast media. Multivariable logistic regression was used to model the likelihood of AAEs in various GBCA, adjusting for pharmacological stressor, main indications, age and sex.
Results: In 72,839 CMR, 260 AAE occurred (0.36%), with a minority of severe adverse events (SAE) (n=24, 0.033%). Patients without pharmacological stress (PS) imaging had a lower AAE rate (n=120/54,285, 0.22%) than patients receiving PS (n=140/18,554, 0.75%). Highest AAE rates were reported for regadenoson (n=34/1,151, 2.95%), and dobutamine (n=7/482, 1.45%), mainly dyspnoea (n=24). Compared to the most frequently used gadobutrol [56%], AAE were more likely for gadoteridol [4%] (OR=3.16, 95% CI: 2.10-4.74, p<0.001), and less likely for gadoter acid [20%] (OR=0.64, 95% CI: 0.44-0.93, p=0.018). There was multiplicative interaction between GBCA and PS (p<0.01). Comparing adenosine to regadenoson, the AAE rate differed by the factor 9 for gadobutrol (0.52% vs 4.56%), while rates were comparable for gadoter acid (0.3% vs 0.47%), independent of PS. However, no significant difference in the frequency of AAEs depending on the molecular structure, ionicity or chelate stability of GBCAs was found.
Conclusion: GBCA-enhanced CMR is generally safe with event rates comparable to those of other body regions. The likelihood of AAE increases with stress imaging and depends on the pharmacological stressor and main indication.

B-0564 10:46

Prevalence and clinical relevance of extra-cardiac findings in CMR imaging

D. Mastrodicasa[1], C. Mantini[2], F. Bianco[2], F. Ricci[2], S. Gallina[2], G. Messalli[3], F. Cademartiri[4], A.R. Cotroneo[2]; [1]*Charleston, SC/US*, [2]*Chieti/IT*, [3]*Naples/IT*, [4]*Rotterdam/NL (domenico.mastrodicasa@gmail.com)*

Purpose: To estimate the prevalence of ECF detected from clinically indicated CMR scans, and to determine the associated downstream effect on clinical management and resource utilisation.
Methods and Materials: ECF were retrospectively evaluated in 500 consecutive patients undergoing CMR for different cardiovascular diseases. Two independent radiologists retrospectively reviewed transaxial bSSFP multi-slice images acquired with a field of view including thorax and upper abdomen. The ECF were classified as clinically non-significant (benign), clinically significant (potentially or absolutely considered to be of clinical significance, mandatory to be reported and monitored), and major (remarkable pathology, mandatory to be reported, further investigated and treated). A 15-month clinical follow-up was obtained from hospital records and referring physicians.
Results: Of 500 patients, 108 patients (21.6% of study population) had a total of 153 ECF, 59 (38.8%) non-significant, 76 (50%) significant and 18 (11.7%) major. Of 94 significant and major ECF, 46 (36 clinically significant and 10 major) were previously unknown and more common in older patients. The 10 newly diagnosed major ECF (2% of study population and 6.5% of all IEFs), including tumours in 5 patients (1% of study population), were confirmed by downstream evaluations and required specific treatment.Patients with major ECF were older than patients without. Significant and major newly diagnosed ECF both required additional diagnostic tests respectively in 44% and 100% of cases.
Conclusion: ECF are increasingly being spotted by radiologists and cardiologists on CMR scans. The detection of previously unknown major ECF has a strong impact on the course of patients' clinical history.

Results from the Italian Registry of Contrast Material use in Cardiac Computed Tomography (IRCM-CCT)

L. La Grutta[1], A. Clemente[2], E. Maffei[3], G. Privitera[4], M. Rengo[5], P. Toia[1], M. Francone[6], M. Midiri[1], F. Cademartiri[7,8]; [1]*Palermo/IT*, [2]*Massa (MS)/IT*, [3]*Urbino/IT*, [4]*Catania (CT)/IT*, [5]*Latina/IT*, [6]*Rome/IT*, [7]*Rotterdam/NL*, [8]*Naples/IT (ludovicolagrutta@hotmail.it)*

Purpose: The Italian Registry of Contrast Material use in Cardiac Computed Tomography (IRCM-CCT) is a retrospective, multicenter, multivendor, observational study on the use of contrast media (CM) in patients undergoing CCT. The aim of IRCM-CCT is to assess safety profile and influence on image quality of CM use.
Methods and Materials: IRCM-CCT enrolled 1894 consecutive patients (≥50 per site; CCT indicated for suspected coronary artery disease) at 20 cluster sites. Demographic characteristics, CT and CM protocols, clinical indications, safety markers, radiation dose reports, qualitative (i.e. poor vascular enhancement) and quantitative (i.e. HU attenuation values) image parameters were recorded. A core lab assessed all image parameters.
Results: The cohort includes 1117 men and 777 women (mean age 61±14 years, mean body mass index 26±4) studied with ≥64 detector rows CT scanners and several iodine contrast media protocols and molecules (iodixanol, iopamidol, iobitridol, iopromide, and iomeprol). The following adverse reactions to CM were recorded: 6 extravasations and 17 reactions (11 mild, 4 moderate, 2 severe). The core lab reading reported the following vascular attenuation: 537±160HU in the aorta, 472±160HU in the right coronary artery, 502±158HU in the left main, 475±156HU in the left anterior descending artery, and 458±158HU in the circumflex artery. In 4% of cases the image quality was not satisfactory due to poor enhancement.
Conclusion: In a multicenter registry on CM use during CCT the prevalence of CM-related adverse effects was very low. The appropriate use of CM is a major determinant of image quality.

B-0566 11:02

Frequency and spectrum of incidental findings in cardiovascular disease CT screening trial

M. Vonder[1], C.M. van der Aalst[2], R. Vliegenthart[1], M. Kaatee[1], J. Gratama[3], D. Kuijpers[4], H. de Koning[2], M. Oudkerk[1]; [1]*Groningen/NL*, [2]*Rotterdam/NL*, [3]*Apeldoorn/NL*, [4]*The Hague/NL (marleenvonder@gmail.com)*

Purpose: To determine the frequency, spectrum, and potential clinical relevance of incidental findings found on computed tomography coronary artery calcium scans (CT-CAC) of screenees.
Methods and Materials: Incidental findings on CT-CAC scans of screenees from the ROBINSCA trial were recorded from January 2015 through September 2017. Informed consent for the ROBINSCA trial was obtained from all participants. Incidental findings were described individually and grouped based on potential clinical relevance and organ level. Incidental findings with a high potential of being clinically relevant were reported to the screenee's general practitioner.
Results: In total, 10,129 screenees underwent a CT-CAC scan, mean age was 61.6 (SD: 7.3) years and 52.1% were male. One or more incidental findings were recorded on 603 (6.0%) CT-CAC scans, the mean of age of screenees with an incidental finding was 64.1 (SD: 6.5) year and 40.7% were male. Of the incidental findings found, 46.1% was hepatic, 24.5% cardiovascular, 13.5% pulmonary, 12.0% gastrointestinal, 3.0% lymphatic and 0.7% splenic. Of all incidental findings, 9.0% were potentially clinically relevant and were reported to the general practitioner.
Conclusion: In 1:16 screenees one or more incidental findings are found on CT-CAC scans for cardiovascular screening, and 1:200 is potentially clinically relevant and reported to the general practitioner.

B-0567 11:10

Correlation between haptoglobin phenotypes and myocardial reperfusion injury in consecutive ST-elevation myocardial infarction as detected by cardiac magnetic resonance

M. Guglielmo[1], C. Banfi[1], E. Giannazza[1], A. Guaricci[2], A. Baggiano[1], D. Andreini[1], S. Mushtaq[1], M. Pepi[1], G. Pontone[1]; [1]*Milan/IT*, [2]*Bari/IT (marco.guglielmo@ccfm.it)*

Purpose: Primary percutaneous coronary intervention (pPCI) has significantly reduced cardiovascular mortality of ST segment elevation myocardial infarction (STEMI) patients. Cardiac magnetic resonance (CMR) has emerged as the gold standard technique for the measurement of the myocardial salvage index (MSI) and microvascular obstruction (MVO). We sought to evaluate the correlation between variants of haptoglobin and myocardial reperfusion injury.
Methods and Materials: Consecutive STEMI patients reperfused by primary PCI were enrolled in this study with characterization of phenotypes of haptoglobin. A CMR was performed by 1 week after STEMI evaluating the following parameters: left ventricle ejection fraction (LVEF), MSI and

prevalence and amount of MVO. Primary endpoint of study was to evaluate the correlation between different phenotypes of haptoglobin and myocardial reperfusion injury as detected by CMR.
Results: 124 consecutive STEMI were enrolled.Three different phenotypes Hp 1-1, Hp 1-2, Hp 2-2 were observed in 10 (8%), 55(44%) and 59(48%) patients, respectively. CMR showed a LVEF and MSI of 49±10% and 0.38±0.9, respectively.The MVO was observed in 33 patients (27%) with a mean value of 2±4% of left ventricle myocardial mass. The patients with phenotype Hp 1-1 or Hp 1-2 showed no differences in terms of LVEF (p:0.18) and MSI (p:0.3) but higher prevalence(37% vs 17%, p<0.01) and amount (2.7±0.4% vs 1.3±0.4% of left ventricle mass, p<0.05) of MVO as compared to phenotype Hp 2-2. Hp 2-2 was an independent predictor of MVO [HR:1.28 (1.08-2.4), p:0.20].
Conclusion: Different variants of haptoglobin may play a crucial role in cardiac repair responses. Further studies might evaluate if different therapeutic strategies should be developed based on phenotypes of haptoglobin of patients.

B-0568 11:18

Basic haematological biomarkers are associated with coronary calcification

A.M. den Harder[1], J.M. Wolterink[1], P.A. de Jong[1], M.C.H. de Groot[1], R.P. Budde[2], I. Isgum[1], S. Haitjema[1], I.E. Höfer[1], T. Leiner[1]; [1]*Utrecht/NL*, [2]*Rotterdam/NL (t.leiner@umcutrecht.nl)*

Purpose: Improved understanding of potential associations between basic haematological biomarkers and the coronary artery calcification (CAC) score may help unravel the pathophysiology of CAC and subclinical coronary artery disease. Therefore we investigated the association between basic haematological biomarkers and the CAC score.
Methods and Materials: A retrospective cross-sectional study was performed within the Utrecht Patient Oriented Database. Patients with suspected/known coronary artery disease who underwent CT CAC scoring and standard haematology analysis that was part of routine clinical care (within 3 months of CT acquisition) were included. Complete haematology datasets were extracted from haematology analyzers. Linear regression adjusted for clinical confounders was used to assess if haematological biomarkers were related to the CAC score.
Results: In total, 1,507 patients were included of which 43% (n=648) had a CAC score of 0. Mean age (±SD) was 53±13 years, and 34% of patients were female. Red blood cell count (β=-0.16 [-0.25 - -0.04], p=0.011), red blood cell distribution width (RDW, β=0.24 [0.10 - 0.40], p=0.001), coefficient of variation of neutrophil lobularity (β=0.13 [0.01 - 0.26], p=0.028) and mean lymphocyte cell size (β=0.24 [0.11 - 0.38], p<0.001) were independently associated with the CAC score after adjustment.
Conclusion: RDW, coefficient of variation of neutrophil lobularity, and mean lymphocyte cell size are associated with a higher CAC score. While increased red blood cell count is associated with a lower CAC score. These biomarkers may further contribute to our understanding of the pathophysiology of CAC. Future studies should determine the pathophysiological significance of these associations.

Accuracy of an artificial intelligence deep learning algorithm for the detection of calcified plaques at coronary CT angiography

M. Eid[1], C.N. De Cecco[1], D. De Santis[2], A. Varga-Szemes[1], M.H. Albrecht[3], D. Mastrodicasa[1], P. von Knebel Doeberitz[1], P. Sahbee[4], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Rome/IT*, [3]*Frankfurt a. Main/DE*, [4]*Malvern, PA/US (eidmarwen.md@gmail.com)*

Purpose: Evaluate the accuracy of an artificial intelligence deep learning algorithm for the detection of coronary artery calcium in coronary CT angiography (CCTA) studies.
Methods and Materials: 194 patients who had undergone clinically indicated CCTA were retrospectively selected. Two readers independently evaluated the contrast-enhanced images noting the presence of calcified plaques in the right coronary artery (RCA), left anterior descending artery (LAD) and left circumflex coronary artery (LCx). In this analysis, the left main coronary artery (LM) was merged with the LAD. Evaluation discrepancies were solved by a third reader. For the automated analysis, the heart detection, coronary artery centreline detection, centreline labeling, and plaque detection was performed fully automatically. The presence of coronary calcified plaques was assessed by a recurrent neural network with long short-term memory, previously trained for coronary artery calcium detection. Per-vessel and overall sensitivity, specificity and diagnostic accuracy of the algorithm were calculated.
Results: A total of 194 patients were analysed for a total of 565 vessels. No patient was excluded. On a per-vessel analysis, the algorithm achieved a sensitivity (Se), specificity (Sp), and diagnostic accuracy (DA) of 92.96% (CI 84.33%-96.67%), 82.76% (CI 74.64%-89.14%), and 86.63%, respectively, for the RCA, 93.07% (CI 86.24%-97.17%), 95.45% (CI 88.77%-98.75%), and 94.17%, respectively, for the LM/LAD, 89.86% (CI 80.21%-95.82%), 90.00% (CI 83.18%-94.73%), and 89.95%, respectively, for the LCx. The overall Se, Sp and DA were 92.12 (CI92.12%-95.19%), 88.89% (CI 84.95%-92.10%), and 90.26%, respectively.
Conclusion: The proposed deep learning algorithm performs with high diagnostic accuracy for the automated detection of calcified plaques at CCTA.

Computer-aided detection of coronary plaques in cardiac CTA

L. Liu, J. Yang; *Beijing/CN (tjdxdxxy@qq.com)*

Purpose: Computed Tomography Angiography (CTA) is a widely used non-invasive imaging modality to diagnose and treat Cardiovascular diseases (CVD). Detection of coronary plaques(CP), especially non-calcified plaques with lower intensity values, from CTA data is a time-consuming and challenge task. In this work, we proposed and evaluated an automated segmentation system for plaques detection in CTA imagery.
Methods and Materials: We developed a machine-learning framework for plaque detection using 3D convolutional neural network (3D CNN). The system combined both a priori knowledge of CPs and data-driven learning method. CP candidates were generated using intensity, geometric features. The CP candidates in the form of 3D cubes are fed into a 3D CNN to classify plaque and non-plaque inputs. Due to the limited amount of CTA data, transfer learning was utilized to obtain highly discriminative features. The performance of the system on 52 CTA volumes with manually labeled plaques was investigated.
Results: The total detection accuracy was 90.4% with respect to the manual expert. Specifically, 86.3% of non-calcified and 92.4 of calcified plaques were achieved. The mean accuracy of plaque localization was 91.2% in term of the Dice similarity coefficient.
Conclusion: Using a priori knowledge in our computer-aided framework improved the accuracy of coronary detection. The overall performance of the proposed computer-aided frameworks demonstrates a good agreement with manual expert annotations.

Comparison of coronary calcium distribution in large population-based screening trials: Dutch (ROBINSCA) vs multi-ethnic (MESA) population

M. Vonder[1], C.M. van der Aalst[2], R. Vliegenthart[1], M. Kaatee[1], J. Gratama[3], D. Kuijpers[4], H. de Koning[2], M. Oudkerk[1]; [1]*Groningen/NL*, [2]*Rotterdam/NL*, [3]*Apeldoorn/NL*, [4]*The Hague/NL (marleenvonder@gmail.com)*

Purpose: To compare coronary artery calcium (CAC) distribution of the Dutch ROBINSCA trial and with the multi-ethnic MESA trial.
Methods and Materials: ROBINSCA participants screened with CAC computed tomography (CT) were included in this study, and informed consent was obtained from all participants. The Agatston score was determined and CAC distribution based on the number of affected coronary arteries and diffusivity index was calculated. Diffusivity index (%) was defined as: 1-(CAC in most affected vessel/total CAC). Agatston score-based risk categorization (1-100, 101-300, >300) was performed, and CAC distribution was analysed per risk category. The CAC score and distribution were compared for the Dutch ROBINSCA trial and multi-ethnic MESA trial as published by Blaha et al. (JACC Cardiovascular Imaging 2016).
Results: In total 59.8% of the 7,516 ROBINSCA participants (mean age 62.9 (SD 7.1)) had a positive Agatston score, being higher than in MESA (49.9%). The number of affected arteries increased for increasing age, calcium score and diffusivity index (p<0.001). The CAC distribution tended to be less diffuse for a similar number of affected arteries (2, 3, 4 arteries with CAC) in ROBINSCA (19.7%, 33.1%, 44.1%) compared to MESA (24.3%, 38.2%, 46.0%). On the contrary, a comparable distribution pattern for number of affected arteries over the risk groups was found for the two populations.
Conclusion: The amount of CAC tends to be less diffuse for similar number of affected arteries, while the distribution of the number of affected arteries over the risk categories is comparable for ROBINSCA compared to the multi-ethnic MESA population.

Mitral annular plane systolic excursion assessed by cardiovascular magnetic resonance is an independent predictor of major adverse cardiac events after STEMI

M. Pamminger, T. Nalbach, M. Reindl, G. Klug, S.J. Reinstadler, W. Jaschke, B. Metzler, A. Mayr; *Innsbruck/AT (Mathias.Pamminger@tirol-kliniken.at)*

Purpose: We aimed to assess whether mitral annular plane systolic excursion (MAPSE) as assessed by cardiac magnetic resonance (CMR) imaging is a predictor of major adverse cardiac events (MACE) after ST-elevation myocardial infarction (STEMI).
Methods and Materials: CMR was performed in 322 consecutive patients within 3 days (IQR 2-4 days) after reperfused first acute STEMI. MAPSE was determined in a 4-chamber CINE view by measuring the distance of mitral annulus position between the end diastole and the aortic valve closure. Patients were followed for major adverse cardiac events (MACE) - death, non-fatal myocardial re-infarction, stroke and congestive heart failure. Cox proportional hazards regression modelling was used to identify factors independently associated with MACE.
Results: Thirty-eight MACE (12%) occurred during a median follow-up of 18 months [IQR 12-19 months]. In ROC analysis, the AUC of MAPSE for the prediction of MACE was 0.72 (95%CI 0.64 - 0.80, p<0.0001) with an optimal cut-off value of 8.6 mm. Univariate Cox regression analysis revealed a hazard ratio (HR) for reduced MAPSE of 4.45 (95%CI 2.21 - 9.15, p<0.0001). After adjustment for age, left ventricular (LV) ejection fraction and infarct size the association between reduced MAPSE and MACE remained significant (HR: 3.74, 95%CI 1.51 - 9.22, p=0.004). By Kaplan-Meier analysis, patients with MAPSE < 8.6 mm experienced significantly higher incidence of MACE than patients with a MAPSE ≥ 8.6 mm (p <0.0001).
Conclusion: CMR assessed MAPSE represents an easily determinable parameter and is an independent predictor of MACE after acute STEMI.

Magnetic resonance enterography (MRE) surveillance of asymptomatic paediatric Crohn's disease patients

K. Wu, M. Gee, J. Kaplan; *Boston, MA/US (kwu4@partners.org)*

Purpose: Magnetic resonance enterography (MRE) has become the primary modality for the evaluation of symptomatic paediatric Crohn's disease (CD) patients. The role of MRE for surveillance in asymptomatic patients is not clear. We seek to analyse MRE studies performed on asymptomatic CD patients and to identify imaging features associated with clinical recurrence.
Methods and Materials: Retrospective search was performed to identify patients <18 years of age with known CD and MRE performed while asymptomatic on therapy. Studies were reviewed by an experienced paediatric radiologist blinded to clinical data for the presence or absence of four imaging features: wall thickening, T2 hyperintensity, mural hyperenhancement, and vasa recta engorgement, as well as overall assessment of the presence or absence of active disease. Two paediatric gastroenterologists reviewed the electronic records to evaluate for clinical recurrence within six months of MRE.
Results: 37 MRE studies performed in 36 asymptomatic patients were identified. 10 patients demonstrated clinical recurrence within 6 months of MRE. Overall assessment of disease activity by MRE was observed in a higher proportion of patients with clinical recurrence (80%) compared to patients without recurrence (29.6%) (p=0.01). Among individual imaging features, mural hyperenhancement demonstrated the highest accuracy (76%) and was observed in 80% of patients with 6-month clinical recurrence vs 26% without (p<0.01).
Conclusion: MRE evidence of active inflammation in asymptomatic CD patients is associated with future clinical recurrence, with mural hyperenhancement having a statistically significant association with recurrence within 6 months. These suggest a role for imaging in surveillance of asymptomatic paediatric CD patients.

B-0574 10:38

Fast acquisition abdominal MRI study for the investigation of suspected acute appendicitis in paediatric patients: prospective assessment of diagnostic accuracy and clinical efficacy

K. James, P. Duffy, R. Kavanagh, A. Feeley, D. Ryan, P. Murphy, C. Bogue, M. Maher, O.J. O'Connor; *Cork/IE (richkavanagh@rcsi.ie)*

Purpose: The purpose of this study was to investigate if a short duration, fast acquisition MRI scan of the lower abdomen is diagnostically superior and faster than ultrasound when investigating paediatric patients who present with suspected acute appendicitis.
Methods and Materials: After obtaining clinical research ethics committee approval, 17 patients aged between 7 and 16 were included in the study. All patients underwent US and MRI scanning. MRI protocol: Axial and coronal gradient echo T2 scans (SSFSE) from the renal hilum to the femoral heads followed by axial and coronal fat saturated SSFSE. Diffusion weighted imaging was also performed. Diagnostic accuracy, radiologist diagnostic confidence, and patient satisfaction were measured.
Results: Three males and fourteen females were included in the study. Mean age was 11.3 +/- 2.6 yrs. Mean BMI was 20.9 +/- 7 kg/m^2. The appendix was seen on only 12% of US scans but was seen on 88% of MRI scans (p<0.0005). Appendicitis was diagnosed on 12% of US and on 41% of MRI (p=0.05). Diagnosis remained uncertain after US in 88% of cases and after MRI in 12% (p<0.0005). No difference was found between the mean time for US 16.8+/-10 mins [95% CI: 11.6-22] and MRI 18.2+/-4.1 mins [95% CI: 16.1-20] (p=0.6). No significant difference was found in patient satisfaction between the modalities (p=0.87).
Conclusion: This fast acquisition MRI abdomen protocol was superior to US in the investigation of paediatric patients with suspected appendicitis with superior diagnostic performance and diagnostic confidence and similar patient satisfaction.

B-0575 10:46

Comparison of image quality of the abdominopelvic computed tomography in paediatric patients: low-osmolar contrast media vs less iodine-containing iso-osmolar contrast media

M. Kim[1], J.-Y. Hwang[1], K. Choo[1], H. Ryu[2], Y.-W. Kim[1]; [1]*Yangsan/KR*, [2]*Seoul/KR (maeran.kim@gmail.com)*

Purpose: The aim of this study was to evaluate the effect of iso-osmolar contrast media (CM) containing a low iodine dose on image quality for abdominal computed tomography in paediatrics.
Methods and Materials: The low-osmolar CM group and iso-osmolar CM group consisted of 101 and 102 CT scans, respectively, with patients less than 18 years old. Patient age, weight, radiation dose, peak tube voltage, and volume of CM were retrospectively reviewed. Objective measurement of the contrast enhancement and noise were analysed and contrast-to-noise ratios (CNRs) of the abdominal aorta, portal vein and liver were calculated. Four radiologists participated in subjective analysis. Regarding subjective measurement, a four-point scale system was devised to evaluate degrees of contrast enhancement, image noise, beam hardening artefact, and overall image quality. Reader performance for correctly differentiating the groups was evaluated.
Results: Regarding the objective measurement, contrast enhancement and noise were significantly higher in the low-osmolar CM group (*P*<.02). In subjective analysis, there was no significant difference in contrast enhancement, and overall image quality between groups. Image noise, however, was worse in the low-osmolar CM group (*P*=.003). Overall sensitivity and specificity for correctly differentiating iso-osmolar CM were 58.3% and 51.7%, respectively. Especially, among subjects that used 120kVp, contrast enhancement was significantly stronger in the low-osmolar CM group (*P*=.008), and sensitivity to differentiate the iso-osmolar CM was as high as 75%.
Conclusion: Application of iso-osmolar CM was found to be feasible for performing paediatric abdominopelvic CTs. Subjective contrast enhancement and image quality assessments were not statistically different between groups.

B-0576 10:54

CT colonography in the diagnostic algorithm of examination of children with defaecation dysfunction

V. Ermolaeva, N. Marochko, A. Pinigin; *Khabarovsk/RU (ermolaeva.valent@gmail.com)*

Purpose: The goal of the research was to analyse the anatomical features of the distal colon, pelvic muscle diaphragm by CT colonography in children with defecation dysfunction.
Methods and Materials: We examined 121 patients, including 13 children after surgical correction of the anal atresia. CT colonography was performed using a CT Toshiba Aquilion64 . Children were divided into three age groups: 0-4 years (young), 5-10 years (middle) and 11-17 years (older).

Results: The research showed a significant increase in anorectal angle in the group of children with encopresis: 115 ± 8° and in the group of operated children: 122 ± 9°, as a sign of puborectalis muscle dysfunction. Anorectal angle was 94 ± 2.5° in the young and the middle-age groups and 86 ± 5° in the older group with constipation. External anal sphincter was considerably thicker in children with constipation, than in children with encopresis. The research revealed a significant shortening of the puborectal muscle in patients with constipation and its lengthening in patients with encopresis. We offered to use the ratio of the length to width of the puborectalis muscle (PR coefficient) that was 10 ± 2 in the patients with encopresis and 19 ± 5.5 in operated patients, which was significantly different from the control group: 7.5 ± 0.6.
Conclusion: CT colonography allows to determine the role of pelvic diaphragm and distal colon in the development of defecation disorders in children, including in patients after surgical correction of the anal atresia.

B-0577 11:02

Value of structured report form for appendix ultrasound in paediatric patients: can we reduce negative appendectomy and additional CT?
H. Kim, H. Kim, S. Jang; *Seongnam-si/KR (rabafrap@naver.com)*

Purpose: To evaluate the rate of negative (unnecessary) appendectomy and additional CT exams after structured report (SR) versus free text report (FTR) for ultrasound (US) exams in paediatric patients with suspected appendicitis.
Methods and Materials: Between January 2009 and June 2016, 1150 paediatric patients with suspected appendicitis who underwent appendix US were included. On November 2012, we deployed a SR form delivering the likelihood of appendicitis in a 5-point Likert scale for appendix US. The patients were classified into two groups according to the US report form (SR and FTR). The patients of each groups were categorised into three grades according to the likelihood of appendicitis (1=not appendicitis, 2=equivocal appendix, and 3= acute appendicitis) based on described US report. Primary outcome (negative appendectomy rate) and secondary outcome (percentage of additional CT exam following US to diagnose appendicitis) were compared between two groups.
Results: We identified 550 patients in the FTR group and 600 patients in the SR group. Negative appendectomy rates was decreased by 8.4% between two groups: 16.2% (19 of 117 patients) in FTR and 7.8% (8 of 102 patients) in SR ($p = 0.028$). And there was also decrease in the proportion of additional CT exam by 5.3% between two groups: 13.5% (74 of 550 patients) in FTR and 8.2% (49 of 600 patients) in SR ($p = 0.003$).
Conclusion: Using the SR based on the likelihood of appendicitis for paediatric appendix US can decrease the rate of negative appendectomy and additional CT exam.

B-0578 11:10

Liver regenerative nodules in paediatric patients: diagnostic value of Gd-EOB-DTPA
E. Petrash, E.V. Mikhaylova, D. Sevrjukov, A. Nikulina; *Moscow/RU (cherkun.ekaterina@gmail.com)*

Purpose: To describe radiological patterns of multiple liver lesions in hepatospecific phase in children after cytostatic and immunosuppressive therapy to analyse their nature.

Methods and Materials: Nine children aged 10 to 17 with multiple liver lesions were included in retrospective study with the following diagnoses: Ewing's sarcoma (n=1), vaginal rhabdomyosarcoma (n=1), neuroblastoma (n=1), nephroblastoma (n=1), dermatofibrosarcoma (n=1), Li-Fraumeni syndrome (n=1), glomerulonephritis (n=2), juvenile rheumatoid arthritis (n=1). 6 patients underwent chemotherapy, 2 high-dose chemotherapy, 1 radiation therapy on abdominal area, 3 immunosuppressive therapy. All children underwent MRI at 3T using body coil. Contrast agent Gd-EOB-DTPA was used at dose of 0.1ml/kg.
Results: Liver lesions appeared in the interval 2 to 14 years after special treatment for oncology patients, 2 to 9 years from the beginning of treatment for patients continuously receiving immunosuppressive therapy. Most of the nodules accumulated contrast agent in hepatospecific phase (i.e. have hepatocyte nature). Among multiple hepatocyte-nature lesions in patient with Li-Fraumeni syndrome the 3rd tumour (PEComa) has been revealed. It had different pattern of contrast enhancement compared to other lesions in hepatospecific phase. Diagnoses were confirmed histologically for non-hepatocyte lesions, by dynamic control for hepatocyte lesions.
Conclusion: Multiple liver hepatocyte nature lesions in children may be assigned to hepatotoxic therapy and were described as regenerative nodules. However, we should not forget about the possibility of appearance of new primary tumours in these patients. Hepatospecific contrast agent can explain nature of the liver lesions and provide the possibility to avoid biopsies in some cases.

B-0579 11:18

Simplified cystography protocol for dose exposure reduction in paediatric patients for the diagnosis of vescicoureteral reflux
G. Zanirato Rambaldi, M. Baldazzi, L. Pierotti, F. Carfagnini, M. Zompatori; *Bologna/IT (giuseppe.zanirato@gmail.com)*

Purpose: Vesicoureteral reflux (VUR) is the most common indication for voiding cystourethrography (VCUG) in paediatric patients. The aim of this study was to evaluate whether a simplified cystography (SC) protocol, consisting of only two images, can lead to the correct diagnosis of presence and degree of VUR, to save dose exposure.
Methods and Materials: We retrospectively reviewed VCUG from 243 patients (164 male, 79 female; aged between 2 days and 24 years, median 7 months) performed in our centre over a period of two years, from July 2015 to June 2017. The SC consisted of two images acquired at maximum filling and post-urination. The first image to reveal passive VUR and the second for active VUR. VUR was graded in the SC unaware of the result of the traditional VCUG. K Cohen and Chi-square tests were applied to analyse the agreement between the SC and traditional VCUG.
Results: The agreement between SC and VCUG was “very good” with k value of 0.952 (95%CI 0.91-0.99). SC, moreover, confirmed the exact degree of VUR in almost all cases ($p < 0.001$ at Chi-square test). Only 7 cases of grade 1 VUR were not diagnosed at SC. SC was 93.7% sensitive (95%CI 88.7-98.7) and 100% specific.
Conclusion: The SC protocol revealed to be accurate in the diagnosis of VUR in paediatric population. Acquiring only two images instead of a traditional VCUG can lead to a drastic reduction in dose exposure to paediatric patients, when the clinical indication is VUR.

B-0580 11:26

Non-contrast-enhanced MR angiography for detecting crossing renal vessels in infants and young children (< 6 years old): comparison with CE angiography and surgery
F. Sertorio[1], M. Damasio[1], V. Incarbone[2], M. Wong[1], A. Pistorio[1], G. Mattioli[1], G. Magnano[1]; [1]*Genova/IT*, [2]*Varese/IT (fiammetta.sertorio@gmail.com)*

Purpose: Evaluate a new non-contrast-enhanced MR sequence, the bTRANCE (balanced-SSFP-triggered angiography non-CE), for the identification of crossing renal vessels (CRVs) in children under 6 years of age, comparing with data obtained from contrast-enhanced MR angiography (CE-MRA) and surgery.
Methods and Materials: A retrospective review of pre-operative MR urography (MRU) of 29 children (1 month to 6 years old) with monolateral hydronephrosis was conducted by two independent readers. Presence or absence of CRVs at the ureteropelvic junction (UPJ) was identified with T2w, BTFE, bTRANCE sequences and 3D CE-MRA and compared with surgical findings. Intra- and inter-reader agreement was calculated using Cohen’s kappa coefficient. Image quality, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), positive likelihood ratio (LR+) and negative likelihood ratio (LR-) were evaluated.
Results: Image quality was fair/good in more than 85% of cases for the bTRANCE, 95% for the CE-MRA. The agreement with surgical findings resulted 83% for the bTRANCE and 75% for the CE-MRA. The bTRANCE had a sensitivity, specificity, NPV, PPV, LR+, LR- of 70%, 92.9%, 81.3%, 87.5%, 9.8, 0.32, respectively, vs 55.6%, 90.9%, 71.4%, 88.3%, 6.11, 0.49 of the CE-MRA. Inter- and intra-reader agreements for the identification of CRVs were both 100% for the bTRANCE, and 88% and 90.9%, respectively, for CE-MRA.
Conclusion: The bTRANCE has proven to be superior to the contrast-enhanced sequences compared with the surgical gold standard in infants and young children under 6 years of age, with UPJ obstruction. Thus, it is a reliable, valid and safe alternative to CE-MRA for identifying CRVs.

B-0581 11:34

Coexistence and relation of congenital and acquired urinary tract pathologies in Jarcho Levin syndrome: comparison to spina bifida aperta
I. Karalok, I. Alatas, H. Canaz, S. Sabet, C. Sever, A. Gayef, N.I. Gurcan; *Istanbul/TR (dr.igulcan@hotmail.com)*

Purpose: Our aim was to evaluate the coexistance and relation of congenital and acquired urinary tract pathologies in Jarcho Levin Syndrome with comparison to spina bifida aperta.
Methods and Materials: 60 Jarcho Levin Syndrome and 55 spina bifida aperta patients, between 2013-2017, were evaluated and compared for congenital and acquired urinary tract pathologies by ultrasonography.
Results: There was a significant increased incidence of position anomaly secondary to rotoscolyosis($p<0,005$), horseshoe kidney($p=0,007$) and congenital anomaly($p<0,005$) in Jarcho Levin Syndrome compared to spina bifida aperta. We also depicted a significant correlation between renal scar and parenchymal thinning($p=0,001$), increased renal parenchymal echo($p=0,028$), atrophy($p=0,006$) and pelviectasis($p=0,049$). Increased echogenity of renal

parenchyma was positively related with existance of parenchymal thinning(p<0,001), scar(p=0,028), atrophy(p<0,001), hydronephrosis(p<0,001) and bladder wall thickening(p=0,014). Ectopic kidney anomaly was found to be related with renal hypogenesia(p<0,001). Horseshoe kidney anomaly demonstrated a significant correlation with hydronephrosis(p=0,024) and acquired renal pathologies(p<0,001).
Conclusion: Position anomaly secondary to rotoscolyosis, horseshoe kidney and congenital anomaly are more frequent in Jarcho-Levin syndrome compared with spina bifida aperta. Renal scar and increased renal parenchaymal echogenity are the most important predictors of subsequent renal parenchymal disease. Horseshoe kidney is the only congenital anomaly which increases the risk of acquired renal pathologies. Congenital and acquired urinary tract pathologies are more frequent in Jarcho Levin Syndrome than normal population. Long term and carefull follow-up is essential in order to o reduce the risk of probable renal insufficiency in this group especially in cases with increased echogenity of renal paranchyma and renal parenchymal scar.

B-0582 11:42

Quantitative evaluation of testicular stiffness with shear-wave elastography

Z. Bayramoglu, E. Çaliskan, R. Yilmaz, I. Adaletli; *Istanbul/TR (incezuhal@yahoo.com)*

Purpose: We aimed to evaluate the testicular parenchyma in terms of stiffness in paediatric patients with testicular microlithiasis by shear-wave elastography and compare the values with normal control subjects.
Methods and Materials: Nineteen patients previously diagnosed with testicular microlithiasis under follow-up for 18±10 months were included in study group. In control group, 21 patients with no medical history that could affect testicular tissue were prospectively included. 38 testes in the study group and 42 testes in the control group were evaluated with grey-scale ultrasound and shear-wave ultrasonography.
Results: There were no differences in ages and testis volumes between the study and control groups. The mean SWE values of all testes based on elasticity and speed parameters in the study group were 8.24 ± 2.36 kPa and 1.56 ± 0.16 m/s, respectively; while in the control group mean SWE values were 4.66 ± 1.07 kPa and 1.21 ± 0.12 m/s, respectively. Elasticity values were significantly higher in testes with microlithiasis compared to the control group (p<0,001).
Conclusion: Shear-wave elastography evaluation demonstrate effects of ultrastructural changes in elasticity that are not detected on grey-scale ultrasound. Shear-wave elastography is a further reliable method in follow-up examination of paediatric testicular microlithiasis.

B-0583 11:50

Application of ADC Value of MR DWI in the evaluation of children's renal function

W. Bai, G. Ning, X. Li; *Chengdu/CN (huaxi_bwj@163.com)*

Purpose: To discuss the application of ADC value of MR DWI in the evaluation of children's renal function.
Methods and Materials: 9 patients of 1 stage purpura nephritis (group A: 5 male and 4 female, 7~15 years old) and 6 healthy volunteers (group B: 3 male and 3 female, 6~11 years old) were underwent routine MRI and coronal DWI (b=600s/mm^2). For every child, the ADC values of cortex and medulla in the two kidneys were measured in ADC images, with setting the region of interest (ROI) of about 20mm^2 to the upper, the middle, the lower regions and calculating the average values. Independent-samples t test was made in the ADC values of cortex and medulla from the two groups. And paired-samples t test was made in the ADC values of cortex and medulla from the same group.
Results: (1) the mean ADC value of cortex in group A (178.73×10^{-5}m^2/s±14.04) was lower than that in group B (202.78×10^{-5}m^2/s±11.11), with statistically significant differences (P=0.004).(2) the mean ADC value of medulla in group A (161.48×10^{-5}m^2/s±20.33) was lower than that in group B (193.56×10^{-5}m^2/s±17.67), with statistically significant differences (P=0.008). (3) In group A and B, the ADC value of cortex was higher than that of medulla, without statistically significant differences (p=0.114 in group A and p=0.265 in group B).
Conclusion: MR DWI is a noninvasive method to evaluate children's renal function. The ADC value can early detected the abnormality of renal function in the patient of 1 stage purpura nephritis, before the morphological change.

B-0584 10:30

Comparison of ^{18}FDG PET/CT and ^{18}FDG PET/MRI for thoracic staging in lung cancer patients

J. Kirchner[1], L.M. Sawicki[1], A.F. Tschischka[1], L. Umutlu[2], K. Herrmann[2], B.M. Schaarschmidt[1], G. Antoch[1], P. Heusch[1]; [1]*Düsseldorf/DE*, [2]*Essen/DE (Julian.Kirchner@med.uni-duesseldorf.de)*

Purpose: To compare the diagnostic potential of ^{18}F-FDG PET/MRI and ^{18}F-FDG PET/CT for primary and locoregional lymph node staging in lung cancer patients.
Methods and Materials: A total of 101 patients (64 men, 37 women, mean age 62.5±9 years) with histopathologically confirmed NSCLC were included. All patients underwent ^{18}F-FDG PET/CT and subsequently ^{18}F-FDG PET/MRI. Two readers performed T and N staging in separate sessions according to the eighth edition of the American Joint Committee on Cancer Staging manual for ^{18}F-FDG PET/CT and PET/MRI, respectively. Histopathology served as the reference standard. The mean and maximum standardised uptake value (SUVmean and SUVmax) and the maximum diameter of the primary tumour were measured and compared in PET/CT and PET/MRI.
Results: PET/MRI and PET/CT agreed on T stages in 55 of 56 (98.2 %) patients. Compared with histopathology, PET/CT determined correct T-stage in 89.3% and PET/MRI in 87.5%, respectively. For definition of thoracic N stages, PET/MRI and PET/CT were concordant in 100 of 101 patients (99%). PET/CT determined the N stage correctly in 91 of 101 patients (90.1 %). PET/MRI determined the N stage correctly in 90 of 101 patients (89.1%). No statistically significant difference between PET/CT and PET/MRI for primary tumour or lymph node metastases detection was seen. The tumour size and SUVmax measurements derived from PET/CT and PET/MR imaging exhibited an excellent correlation (r=0.968 and r =0.817, respectively; p<0.01).
Conclusion: ^{18}F-FDG PET/CT and ^{18}F-FDG PET/MRI perform equally well for T and N staging in patients suffering from NSCLC.

B-0585 10:38

Impact of waiting times on tumour growth and pathological upstaging at surgery

I.H. Bhat; *London/UK (insha.bhat24@gmail.com)*

Purpose: There is no objective data on tumour growth or pathological upstaging in early lung cancers awaiting surgery. Our study aims to evaluate if the current waiting times under '62-day' lung cancer pathway are associated with tumour growth or pathological upstaging.
Methods and Materials: 121 consecutive patients with early stage NonSmall Cell lung cancer who underwent resection were analysed. The difference between maximum diameters at diagnostic & preoperative CTscans was calculated to obtain diameter change. Increase in size of ≥ 5 mm or ≥ 20% was considered significant. Time interval between baseline & repeat CT (CT-int), & between baseline CT and surgery (Surg-int) were calculated. CT-int & Surg-int were compared between upstaged & non-upstaged patients. Other potential prognostic indices (SUVmax, smoking status etc.) were also evaluated as categorical variables, p value <0.05 considered significant.
Results: Median CT-int and Surg-int were 2.6 and 2.4 months respectively. 44.6% patients had a tumour growth ≥ 5 mm, 22% had tumour growth ≥ 20%. 36% patients were upstaged at surgery due to nodal/pleural invasion, satellite nodules or increase in tumour diameter. There was no significant difference between median CT-intervals in patients who had a tumour growth <20% or ≥ 20%: 2.4 months vs 2.6 (p=0.06). Surg-int was not correlated with growth ≥ 20% either (p=0.24).
Conclusion: Current cancer pathway waiting time practices are not associated with significant tumour growth or pathological upstaging in this cohort. Adenocarcinomas have an increased risk of pathological upstaging, however when considering only tumour size, this risk was not significant.

B-0586 10:46

The 8th edition IASLC staging system for lung cancer, a step beyond current imaging accuracy?

M. Murphy, C. Barry, C. Cronin, D. Healy; *Dublin/IE (markmurphy1608@gmail.com)*

Purpose: The International Association for the Study of Lung Cancer (IASLC) has recently developed an 8th edition of its lung cancer staging. This further sub divides the T-status component into ever smaller size ranges. This was developed on pathology specimen measurements from a large population database. Many clinical decisions are made in the pre-operative domain however, with the T status dependent on radiology measurement. We wanted to determine if contemporary clinical staging based on radiology would accurately predict the proposed T-status from post-operative specimens.
Methods and Materials: We performed a retrospective analysis of 150 primary lung cancer cases that proceeded to surgical resection. Determination of size on the diagnostic CT scan was compared with the post-operative pathological size. Factors such as interval between imaging and surgery were also assessed.
Results: There was a discrepancy between the pre-operative CT tumour size and the post-operative pathology. The average difference was 0.567cm. This had consequences on staging accuracy. Based on size alone, CT accurately assessed T status in 65.3% of patients using the 7th edition IASLC, whereas only 54% of patients were accurately staged with the 8th edition. There was no correlation between time to surgery and tumour size.
Conclusion: We conclude that although the 8th edition of the IASLC TNM lung cancer staging system is an evolution at a population level, in lung cancer management, implementing the 8th edition as proposed may reduce the staging accuracy to as low as 54%. This evolution may prove an obstacle to utilisation of neoadjuvant strategies

B-0587 10:54

Iodine density obtained with spectral detector CT is a predictor for lesion dignity of pleural thickening

S. Lennartz[1], M. Le Blanc[1], N. Grosse Hokamp[1,2], D. Maintz[1], T. Persigehl[1]; [1]*Cologne/DE*, [2]*Cleveland, OH/US (simon.lennartz@uk-koeln.de)*

Purpose: To examine whether iodine density (ID) provided by spectral detector computed tomography (SDCT) is a valid parameter for differentiation between benign pleural thickening (BPT) and pleural carcinomatosis (PC).
Methods and Materials: In total, 30 contrast-enhanced SDCT scans of the chest were included at this retrospective, IRB-approved study. In detail, 15 SDCT scans of oncologic patients with PC confirmed by histopathology, FDG-PET or change during treatment, as well as 15 SDCT scans of patients with BPT confirmed by prior or follow-up CT (≥6 months). ROI-based quantitative image analysis was performed by two radiologists that determined attenuation (HU) and standard deviation (SD) in conventional polyenergetic images (PI). ROIs were than copied to identical position in iodine density reconstructions to determine the iodine density (mg/ml). The following ROIs were used: pleural lesion, adjacent skeletal muscle (thoracic wall, diaphragm, myocardium), subcutaneous fat, air, aorta, lung, pleural effusion. Statistical analysis was performed using student's t-test and multivariate linear modelling.
Results: Iodine density was significantly higher in PC (2.26±0,83 mg/l) compared to BPT (0.58±0,49 mg/ml, p≤0.0001). Although attenuation in PI differed significantly between PC and BPT as well, multivariate linear modelling showed that ID was the more powerful predictor for lesion dignity (p≤0.05). Both contrast-to-noise ratio (CNR) and difference in ID of PC in relation to the adjacent skeletal muscle of the thoracic wall were significantly increased compared to BPT (p≤0.0001).
Conclusion: Iodine density reconstructions provided by SDCT are a powerful predictor for differentiation between benign pleural thickenings and pleural carcinomatosis in oncologic patients.

B-0588 11:02

Comparison of overall-survival in squamocellular-NSCLC patients treated with Nivolumab assessed with RECIST1.1 and iRECIST

E. Raimondi, L. Belluomini, A. Cartuan, M. Bassi, R. Rizzati, M. Tilli, A. Frassoldati, M. Giganti, G. Benea; *Ferrara/IT (edoardo.raimondi@unife.it)*

Purpose: To compare the survival data, consisting of overall-survival (OS), for squamocellular-NSCLC patients treated with Nivolumab with RECIST1.1 and iRECIST criteria response categorisation.
Methods and Materials: After IRB approval, the CT-images of 15 squamocellular-NSCLC patients treated with Nivolumab were retrospectively evaluated at baseline, 3-months and 6-months by RECIST1.1 and iRECIST criteria. Patients were categorised as responders and non-responders as per RECIST1.1. For iRECIST, patients showing complete-response, partial-response or 6-months ongoing stable-disease were considered responders, while those showing progressive-disease were considered non-responders. Unconfirmed progressive-disease by iRECIST was considered as stable-disease for categorisation purposes. Kaplan-Meier analysis for these response categories was performed for OS.
Results: According to RECIST1.1, 5/15 (33.3%) patients were categorised as responders and 10/15 (66.6%) patients as non-responders. According to iRECIST, 11/15 (73.3%) patients were categorised as responders and 4/15 (26.6%) patients were categorised as non responders. Significant differences between responders and non-responders for OS were observed for both radiological response criteria (Log-rank test: p<0.05). Median OS following RECIST1.1 was 22 months for responders and 10 months for non-responders (HRs: 0.5796; 0.2101-1.5991). Median OS following iRECIST was 21 months for responders and 7 months for non-responders (HRs: 0.1774; 0.02127-1.4795).
Conclusion: The OS curves for RECIST1.1 were similar to the one observed in iRECIST. For non-responders, the OS observed in RECIST1.1 was longer than the one observed in iRECIST; this difference may suggest that iRECIST better identifies progression of disease.

B-0589 11:10

Can perfusion heterogeneity in CT perfusion maps of NSCLC flaw clinical considerations based on global mean blood flow values?

S. Malavasi[1], D. Barone[2], G. Gavelli[1], A. Bevilacqua[1]; [1]*Bologna/IT*, [2]*Forli/IT (s.malavasi@unibo.it)*

Purpose: Tumour heterogeneity is one of the key features regarding progression disease, diagnosis, and therapeutic response. CT perfusion (CTp) studies are usually based on mean perfusion values, computed on a single slice or the whole tumour. The aim of this work is to determine to what extent the heterogeneity pouring out from single slices can flaw studies using global mean values only.
Methods and Materials: 10 patients with single NSCLC lesions (26 examinations) were enrolled and underwent CTp. ROIs were drawn on aorta and on five central slices of each lesion. Mean global BF values were calculated on each slice (mSBF) and for the whole tumour (mWBF). The entropy E (i.e., a direct measure of data information content) was computed on BF values to assess the hemodynamic heterogeneity. For each lesion, the equivalence between each mSBF and mWBF was checked to assess whether mWBF of a lesion could represent the perfusion characteristics of a slice.
Results: Five slices only, all pertaining to different lesions, were represented by the mWBF, none of them bringing the highest information content in its tumour (i.e., the maximum E). 11 couples of lesions having the same mWBF were found, but with slices with very different perfusion patterns, mSBF and E values.
Conclusion: While global perfusion values computed on whole tumours may improve reproducibility, they cannot allow for tumour haemodynamic heterogeneity. Tumours with same mWBF could have very different response to therapies. Accordingly, additional parameters like BF entropy are needed to support mWBF in clinical considerations.

Single-source dual-energy CT as part of 18F-FDG PET/CT: direct comparison of iodine-related and metabolic parameters in lung cancer

J. Baxa[1], T. Matouskova[1], J. Ludvík[1], B. Schmidt[2], M. Sedlmair[2], J. Ferda[1]; [1]*Plzen/CZ*, [2]*Forchheim/DE (baxaj@fnplzen.cz)*

Purpose: To assess possible correlation of FDG uptake and iodine-related attenuation values derived from PET/CT using single-source dual-energy CT scan (DE-CT) in non-small cell lung cancer (NSCLC).
Methods and Materials: 48 patients with histologically proven NSCLC underwent 18F-FDG-PET/CT within the staging. PET/CT included single-source DE-CT in late post-contrast phase. Direct comparison of FDG uptake and DE-related values was performed. Sub-study regarding different histological types and various thresholds for volume metabolic values quantification was also performed.
Results: A strong correlation was found between volumetric FDG parameters (MTV - metabolic tumour volume and TLG - total lesion glycolysis) and total iodine content using Pearson correlation analysis with various thresholds for FDG lesion segmentation (r=0.965-0.983; p<0.0001). The strongest correlation of MTV and TLG with iodine content was reached using 10% threshold for segmentation. Only weak correlation was found between iodine content and SUVmax. Significant difference between adenocarcinomas and other histological subtypes was proved in selected parameters of metabolic and DE data.
Conclusion: Our study demonstrated the strong correlation of the iodine content calculated from single-source DE-CT with volumetric FDG parameters in NSCLC without a significant effect of the threshold value for FDG lesion segmentation. This fact indicates the possible prognostic value of iodine content that could be used as another parameter for therapy-response monitoring.

Value of the first day PET/CT in post thermal ablation of lung tumours

W. Tantawy, A. Zarea, A.S. Ibrahim, M. Abdel Kawi, Y. Hussein, M. Nasr, M. Barsoum; *Cairo/EG (oyehiaomar@gmail.com)*

Purpose: to evaluate the role of the first day PET/CT imaging done immediately post CT guided microwave thermal ablation (TA) of lung tumors.
Methods and Materials: Thermal Ablation of lung tumors by using microwave technique guided by CT was performed for all 26 patients followed by post ablation PET/CT that was done immediately within the first day. Twenty-six patients were included in the study (16 females, 10 males) including 32 lesions, two lesions were ablated in 6 cases and single lesion in 20 cases.
Results: PET/CT examination done within the first day post ablation for all cases following microwave ablation (MWA), showed complete loss of metabolic activity of whole ablated lesions (i.e. SUV= equal or lesser than the physiological background lung activity). Sensitivity and specificity of first day PET/CT following adequate ablation was 100%.
Conclusion: First day PET/CT examination is an excellent and accurate imaging modality for the evaluation of adequacy of microwave ablation of lung tumors and should be considered the modality of choice with a sensitivity and specificity of 100%.

B-0593 11:34

Predicting nodal activity and clinical outcome of non-small cell lung cancer using 18-FDG PET-CT in the age of EBUS-FNA: initial results

G. Chambers, S. Vaidyanathan, F.U. Chowdhury; *Leeds/UK (g.chambers@nhs.net)*

Purpose: 18F-FDG PET-CT has an established role in the staging of lung cancer and helps guide Endobronchial ultrasound-guided fine needle aspiration (EBUS-FNA), increasing the positive yield and informing management. This study aims to correlate FDG PET-CT with EBUS-FNA to assess patient outcomes in discordant cases.
Methods and Materials: Images of 177 patients who underwent both EBUS-FNA and 18-FDG PET-CT, between 2010 and 2012, were analysed for nodal disease status using maximum standardised uptake values (SUVmax) above mediastinal background as a marker for positivity. Assessors were blind to the EBUS-FNA outcomes during this analysis. 354 EBUS-FNA sampled nodes were then correlated with the PET-CT findings and categorised as concordant or discordant. Survival analysis was performed comparing the patients with concordant and discordant results to determine if discordant results (FDG PET-CT false positive) conferred a survival benefit over a 5 year follow-up period.
Results: FDG-positive nodal disease and EBUS-FNA were concordant in 91 patients (51%) and discordant in 86 (49%) patients (6 up-staged by EBUS, 80 down-staged by EBUS). Survival analysis showed that there was no significant survival benefit when EBUS-FNA down-staged nodal disease, compared to those with concordant findings (p=0.91). Overall sensitivity, specificity, positive predictive value and negative predictive value for PET-CT were 0.88, 0.60, 0.56 and 0.88 respectively, compared to EBUS-FNA.
Conclusion: Initial results suggest that even when EBUS-FNA downstages FDG PET avid disease, no statistically significant survival benefit is conferred over a 5 year follow up period. The reasons for this are likely to be multifactorial.

B-0594 11:42

DWI-based radiomics for prediction of chemotherapy outcomes in lung cancer: a pilot study

Z. Li; *Kunming/CN (lizhenhui621@qq.com)*

Purpose: To investigate the wealth of radiomics for pretreatment DWI in prediction of treatment response of lung cancer with chemotherapy.
Methods and Materials: Thirty patients with lung cancer confirmed by pathology were enrolled. According to the RECIST, all patients were divided into good response group (GR) and non-good response group (non-GR) after the second cycle of chemotherapy. ADC imaging (b=600, 800 and 1000 s/mm^2) were collected. Totally, 19 985 radiomics features were extracted in the ADC imaging. The lasso was adopted in feature selection and used in classifier model. ROC was used to evaluate the capability of the three models to predict GR.
Results: 16 patients were divided into GR, while 14 patients were divided into non-GR. The AUC, sensitivity and specificity of the radiomics based on the ADC imaging (b=600, 800 and 1000 s/mm^2) for GR prediction were 0.875, 0.895 and 0.750, 0.924, 0.947and 0.938, 0.918, 0.895 and 0.875, respectively. The AUC among the three groups had no difference (P>0.05).
Conclusion: It is possible to predict GR after chemotherapy in lung cancers based on the radiomics of pretreatment DWI.

Added value of diffusion-weighted imaging in hepatic tumours and its impact on patient management

J. Taron, J. Johannink, M. Bitzer, K. Nikolaou, M. Notohamiprodjo, R. Hoffmann; *Tübingen/DE (taronjana@yahoo.com)*

Purpose: To investigate the diagnostic value of additional diffusion-weighted imaging (DWI) of the liver and its impact on therapy decisions in patients with hepatic malignancy.
Methods and Materials: Interdisciplinary gastrointestinal tumour board cases concerning patients with hepatic malignancies discussed between 11/2015 and 06/2016 were included in this retrospective, single-center study. Two radiologists independently reviewed the respective liver MR examination first without, then with DWI. The readers were blinded regarding number, position and size of hepatic malignancies. Cases in which DWI revealed further findings to conventional sequences on hepatic tumour status were presented to the members of the interdisciplinary tumour board. In this setting, the changes in treatment decisions based on these additional findings in the DWI sequences were recorded.
Results: A total of 87 patients were included. DWI revealed additional findings in 12 patients (13.8%) which had a direct effect on the therapy in 8 patients (9.2%): in 6 patients (6.9%) the surgical/interventional treatment was adapted (n=5: extended resection, n=1: with transarterial chemoembolization of a single hepatocellular carcinoma only detectable in DWI); 2 patients (2.3%) received systemic therapy (n=1: neo-adjuvant, n=1: palliative) based on the additional findings in DWI. In 4 patients (4.6%) additional findings did not affect the therapeutic decision. Definite confirmation of malignancy was not possible in two cases during follow-up.
Conclusion: DWI is a relevant diagnostic tool in oncologic imaging of the liver. By providing further information regarding tumour load in hepatic malignancies it can lead to a significant change in treatment.

B-0602 14:08

MRI liver surface nodularity score: optimising spline stiffness to non-invasively stage fibrosis

K. Cox[1], S. Nandwana[1], B. Olaiya[2], P. Mittal[1], O. Ibraheem[1], A. Smith[3]; [1]*Atlanta, GA/US*, [2]*Marshfield, WI/US*, [3]*Birmingham, AL/US (klcox2@emory.edu)*

Purpose: Determine ideal preprogrammed liver surface nodularity (LSN) spline stiffness (SS) for differentiating fibrosis stages in viral chronic liver disease (vCLD).
Methods and Materials: vCLD patients with 2009-2015 MRI were cross-referenced for liver biopsy within 6 months or prior to cirrhosis biopsy. LSN score was obtained on post-contrast MRI with increasing preprogrammed SS (S15, S18, S21, S24). Patients excluded for slice thickness >3mm, frequency matrix <256. Median LSN score calculated for fibrosis stages and splines. ANOVA and receiver operator characteristic curve (AUC) analysis for accuracy of LSN score per SS for differentiating fibrosis stages. Wilcoxon rank-sum test explored associations between LSN scores and Scheuer staging. Exploratory cutoff values were investigated.
Results: 244 patients (153 male); mean age 53.8 (range 24-79). Patients per fibrosis stage: F0=41, F1=16, F2=24, F3=29, F4=134. LSN scores increased with increasing SS (p<0.001). AUC increased with increasing fibrosis. S21 had the highest AUC for F0-1 versus F2-4 (AUC=0.794), F0-2 versus F3-4 (AUC=0.807), and F0-3 versus F4 (AUC = 0.855). Using S21, median LSN scores were higher in advanced versus early fibrosis (4.06 versus 3.54), and cirrhosis versus non-cirrhosis (4.26 versus 3.54), p <0.001. S21 advanced fibrosis cutoff LSN score 3.83 had 67% sensitivity and 88% specificity. Cirrhosis cutoff LSN score 3.99 had 66% sensitivity and 92% specificity.
Conclusion: LSN scores increase with increasing SS. S21 LSN score demonstrated highest AUC for most fibrosis stages and can differentiate early from advanced fibrosis; cirrhosis from non-cirrhosis. Optimizing SS may differentiate early stages of fibrosis with improved accuracy, potentially eliminating the need for liver biopsy.

Association between multi-phasic MRI radiomic features and treatment response after stereotactic body radiation therapy

R. Du, M.S. Alam, V.H. Lee, V. Vardhanabhuti; *Hong Kong/HK (du94@hku.hk)*

Purpose: In this study, we analyse the association of radiomic features extracted from multi-phasic MRI scans and treatment response of patients who underwent stereotactic body radiation therapy (SBRT) and overall survival (OS).
Methods and Materials: A prospective cohort of 24 patients diagnosed with hepatocellular carcinoma (HCC) who underwent SBRT was analysed. Each patient received multi-phasic MRI scans at pre-treatment and 3-months post-treatment using gadoxetic acid (gadoxetate) contrast agent. Several sequences were analysed including pre-contrast, dynamic phases, 10 minutes and 20 minutes post-contrast, and T2W for radiomic features (103 extracted features). Volumetric ADC values were also extracted for each lesion. Univariate logistic regression model was used to analyse the association between pre- and post-treatment radiomic features/ADC and treatment response (infield recurrence and overall survival). The performance of the features was assessed by ROC analysis using leave-one-out cross-validation.
Results: Radiomic features from GLCM texture features were found to be most associated with treatment response. Features extracted from 10-minute delayed phase scans were found to be highly associated with infield recurrence (AUC = 0.7-0.85). For OS, GLCM features extracted from arterial phase scans and portal venous phase scans were found to the most associated (AUC = 0.65-0.76). No significant association was found with features extracted from pre-contrast, T2W and 20-minute delayed phases. No association was found between SBRT dose and changes in ADC values.
Conclusion: We have found a strong association in radiomic features extracted from different MRI phases and infield recurrence in HCC patients treated with SBRT and overall survival. No association was found between ADC values and treatment parameters.

B-0604 14:24

Liver fibrosis vs cholangiocarcinoma MRI appearance and distinguishing features based on the DWI and ADC map

A. Sciuk[1], R. Kidzinski[2], E. Frankowska[2]; [1]*Houston, TX/US*, [2]*Warsaw/PL (adam.sciuk@bcm.edu)*

Purpose: Benign confluent hepatic fibrosis and cholangiocarcinoma can have a similar morphologic appearance at CT and MRI. DWI offers a new method for making this distinction more reliable.
Methods and Materials: We retrospectively reviewed 18 abdominal MRI done with conventional T2, T1-precontrast, and dynamic postcontrast as well as DWI performed using b values of 0 and 500 sec/mm^2. Diagnoses: 12 cholangiocarcinomas, 3 primary sclerosing cholangitis and 3 diffuse liver cirrhosis. Both quantitative (ADC values) and qualitative reviews of DWI data (comparing SI of lesion to liver and spleen) were performed.
Results: All 12 cases with cholangiocarcinoma demonstrated increased relative signal intensity (SI) of the lesion relative to liver on the b-500 DWI in comparison to the b-0; nine cases had SI equal or higher than the SI of the spleen. Three cholangiocarcinomas despite a relative increase in SI on the b-500 images were slightly darker than the spleen. All benign cases showed decrease in relative signal intensity on the b-500 images in relation to the b-0, and were similar to the spleen. Quantitative assessment demonstrated a significant overlap.
Conclusion: Preliminary work indicates that cholangiocarcinoma displays a “relative brightening” of SI on b-500 in relation to b-0, whereas the benign cases showed a “relative darkening”. Furthermore, the SI of nine out of twelve malignant cases was equal or higher the SI of the spleen; three potential false positives can occur with PSC. A SI equal to liver on b-500 image has a high negative predictive value despite positive T2 and contrast-enhanced imaging results.

B-0605 14:32

Initial experience with magnetic resonance elastography of liver

I. Csemez, M. Ujlaki, M. Gödeny; *Budapest/HU (imcsemez@gmail.com)*

Purpose: Mechanical tissue properties of the liver can be quantitatively assessed using magnetic resonance elastography (MRE). These parameters change in pathological conditions of the liver. We aimed to investigate the potential benefits of MRE with focal liver lesions, post-treatment changes and cirrhosis in focus.
Methods and Materials: Scans were performed on a 3 Tesla GE Discovery MR750w MRI scanner using the MR Touch Standard sequence. The system produces elastograms, i.e. liver maps indicating tissue stiffness. MRE was performed on 43 patients: 20 patients with histologically confirmed malignant liver tumors, 7 patients undergoing intervention (5 metastasectomies and 2 radiofrequency ablations), 3 patients with hemangioma, 2 patients with cirrhosis, and 11 patients with chemotherapy followup.
Results: In 13 cases of malignant liver lesions, tissue stiffness was significantly higher compared to the surrounding liver parenchyma (> 4.5 kPa). No abnormal stiffness was measured in the case of benign lesions or post-treatment changes except one patient. In both cases of cirrhosis, significant increase in liver stiffness was observed. In 10 cases, the study was not interpretable, due to small lesion size (< 2 cm) or motion artifacts.
Conclusion: Areas of high tissue stiffness can be easily distinguished from soft tissue on elastograms. Unlike ultrasound-based elastography techniques, MRE provides quantitative information on tissue stiffness of nearly the whole liver. It may provide additional information to conventional MR sequences on focal liver lesions greater than 2 cm. By decreasing motion artifacts MRE may be used to estimate hepatic functional reserve in patients scheduled for major hepatectomy.

B-0606 14:40

Improved DWI of the liver at 3T using respiratory triggering with simultaneous multi-slice acceleration

A.A. Tavakoli, U. Attenberger, J. Budjan, S.O. Schönberg, P. Riffel; *Mannheim/DE (s.tavakoli@gmx.de)*

Purpose: To compare respiratory triggered diffusion weighted imaging with simultaneous multi-slice acceleration (SMS-RT-DWI) of the liver with a standard free-breathing echoplanar-DWI (s-DWI) protocol regarding a reduction of imaging artefacts associated with diffusion weighted imaging at 3T.
Methods and Materials: 23 patients who underwent an MRI study of the liver were included in this retrospective study. Examinations were performed on a 3T whole-body MR system (Magnetom Skyra, Siemens). In all patients both s-DWI and SMS-RT-DWI of the liver were obtained. Images were qualitatively evaluated by two independent radiologist with regard to overall image quality, liver edge sharpness, sequence related artefacts and overall scan preference. For quantitative evaluation signal-to-noise ratio (SNR) and apparent diffusion coefficient (ADC) values were measured in different areas of the liver. We performed the Chi^2-test for statistical analysis of qualitative parameters and the paired students t-test for analysis of quantitative parameters.
Results: Overall image quality, liver edge sharpness and sequence related artefacts of SMS-RT-DWI were rated significantly better compared to s-DWI (for all $p < 0.05$). For 82.6% of the examinations (19/23), both readers preferred SMS-RT-DWI overall to s-DWI with excellent inter-reader agreement (kappa=0.83). SNR values were significantly higher for SMS-RT-DWI than for s-DWI (151±122 vs. 69±46, p=0.0006), while mean ADC values did not differ significantly between the two sequences (994±129x10^{6}mm^2/s vs. 1002±123 x10^{6}mm^2/s, p=0.75).
Conclusion: By exploiting a simultaneous multi-slice technique at 3T, respiratory triggered DWI of the liver could be acquired with substantial image quality improvements compared to s-DWI while maintaining acquisition time.

B-0607 14:48

How to avoid gadoxetic acid-related artefacts? Prospective multi-institutional study in 1994 patients

U. Motosugi[1], M. Hori[2], S. Goshima[3], K. Kozaka[4], T. Hyodo[5], Y. Nakamura[6], A. Nishie[7], T. Tamada[8], A. Kanki[8]; [1]*Yamanashi/JP*, [2]*Suita/JP*, [3]*Gifu/JP*, [4]*Kanazawa/JP*, [5]*Ōsakasayama/JP*, [6]*Hiroshima/JP*, [7]*Fukuoka/JP*, [8]*Kurashiki/JP (umotosugi@nifty.com)*

Purpose: To prospectively investigate the potential solution of gadoxetate disodium-induced imaging artefacts using the data from multi-institutional study in Japan.
Methods and Materials: This prospective observational study was performed in eight institutions in Japan. In total, 1,994 dynamic contrast-enhanced MR examinations of the abdomen were performed either with gadoxetate disodium (gadoxetate group, n = 1,647) or with other gadolinium-based contrast agents (other GBCA group, n = 347). MR technologists recorded breath-hold fidelity using a respiratory monitor on MR scanners. Breath-holding during the scan was classified as either a success or a failure based on the shape of the monitored respiratory motion. Any adverse effects (self-report) were also recorded. The severity of respiratory motion-related artefacts in the liver on the pre-contrast and arterial phase images were evaluated: substantial artefact or not. The risk of gadoxetate-induced substantial artefacts was evaluated with multivariate logistic analysis.
Results: Substantial artefacts in the arterial phase were more frequently observed in the gadoxetate group (8.3% [136/1647]) compared with the “other GBCA” group (3.2% [11/347], p=0.001). Gadoxetate-induced substantial artefacts in patients who successfully held their breath in pre-contrast scans were independently related to older age (odds ratio [OR]=1.04, p<0.001), female (OR=0.57, p=0.032), longer acquisition time (OR=2, p=0.009), and multiple arterial phase acquisitions (OR=0.47, p=0.048).
Conclusion: Gadoxetate induces breath-hold failure and substantial artefacts in arterial phase scans. Gadoxetate-induced substantial artefacts can be avoided using a shorter acquisition time sequence and multiple arterial phase acquisitions.

B-0608 14:56

High-field-strength MR imaging of the liver at 3.0T: comparative study with 1.5 T in cirrhotic population

K. Koryukova[1], M. Rossi[1], M. Di Martino[1], L. Saba[2], S.G. Ginanni Corradini[1], C. Catalano[1]; [1]*Rome/IT*, [2]*Cagliari/IT (micdimartino@hotmail.it)*

Purpose: To prospectively evaluate whether magnetic resonance (MR) imaging of the liver at 3.0 T is comparable to that at 1.5 T in terms of detection and characterization of focal liver lesions in cirrhotic patients.
Methods and Materials: This prospective study was approved by the institutional review board. A comparative study between two groups of cirrhotic patients, composed, respectively, with 58 and 56 elements with 109 and 97 lesions, was conducted. Patients were examined at 1.5- and 3.0-T MR imaging. The imaging protocol consisted of T2-weighted turbo spin-echo (SE) sequences with or without fat suppression, as well as T1-weighted gradient-echo (GRE) sequences with or without gadoxetic acid contrast agent. All images were rated independently by two radiologists.
Results: Excellent interobserver agreement was found (κ=0.86 1.5T and 0.81 3T). The mean sensitivity of MR was similar between 1.5T and 3T (85% vs 86.2%) as well as the mean positive predictive value (98% vs 97.8%). The diagnostic accuracy was significantly greater at 3T (0.88 vs 0.995).
Conclusion: MR imaging of the liver at 3.0 T, compared with that at 1.5 T, is feasible with equivalent diagnostic utility in terms of detection and characterization of focal liver lesions in cirrhotic patients.

B-0609 15:04

The influence of intravenous non-specific gadolinium-based contrast media application on image quality of T2-weighted MRC in preoperative evaluation of living liver donors

A. Jarczewski, I. Reimers, D. Geisel, T. Denecke; *Berlin/DE (anne.frisch@charite.de)*

Purpose: To investigate the influence of gadobutrol (Gd-DO3A-butrol, Gadovist®, Bayer-Schering Pharma AG, Germany), gadoterate dimeglumine (Gd-DOTA, Dotarem®, Guerbet GmbH, Germany) and gadofosveset trisodium (Vasovist®, Bayer-Schering Pharma AG) on image quality of heavily T2-weighted single-shot thick-slab and multisection-thin-slice MRC in preoperative evaluation of living liver donors.
Methods and Materials: In this retrospective study, 58 patients (30 female, 28 male, mean age 35 years) underwent MRC before and after intravenous injection of non-specific contrast agents at 1.5 and 3 Tesla (T). Assessment included the evaluation of signal to noise ratio (SNR) and contrast to noise ratio (CNR) performance of the left and right bile duct, hepatic hilum as well as common bile duct (CBD). The assessment of image quality and duct visualization (each 5-point Likert scale) was analysed independently by three blinded readers. Reasons for impairment of image quality (e.g. movement artefacts and superimposing signals) were noted, if applicable.
Results: SNR, CNR, image quality and degree of duct visualization do not differ significantly before and after intravenous injection of non-specific gadolinium-based contrast agents. Overlapping signals caused by intrahepatic vessels that diminish the image quality of MRC were reduced by 8% in single-shot thick-slab MRC and by 3% in multisection MRC, respectively.
Conclusion: T2-weighted MRC in preoperative evaluation of living liver donors should be acquired after an intravenous application of non-specific gadolinium-based agents since the pre-contrast MRC does not bring any benefit in image quality and the incidence of superimposing intrahepatic vessel signals are lower in post-contrast MRC.

B-0610 15:12

Transient arterial phase respiratory motion-related artefact in liver MR imaging gadoxetic acid vs extracellular gadolinium. A within-patient cohort comparative study

A. Darnell, J. Rimola, E. Belmonte, A. Forner, V. Sapena, C. Ayuso, J. Bruix; *Barcelona/ES (ANDARNEL@clinic.cat)*

Purpose: To compare the frequency and severity of transient arterial phase (TAP) respiratory motion-related artifact following gadoxetic acid (EOB) and extracellular gadolinium [(EC-Gd), Gadobutrol] in a cohort of cirrhotic patients.
Methods and Materials: Eighty-two cirrhotic patients from prospective series underwent liver MR with EC-Gd and EOB within 1 month. Two readers, blinded to all data assigned a respiratory motion-related artifact score (0 [none], 1 [mild, no impact on reader confidence interpretation], 2 [moderate, causing decrease in reader confidence interpretation], and 3 [severe, non-diagnostic]) for non-enhanced, arterial and portal-venous phase. Scores for each phase were averaged and definitions for TAP, severe TAP and post-contrast motion-related artifacts were established. The frequency of motion-related artifacts was compared for each pair of examinations.
Results: The mean motion scores for EC-Gd and EOB for non-enhanced phase were 0.68 vs. 0.73 (p=0.3), for arterial phase 0.91 vs. 1.26 (p<0.0001), and for portal-venous phase 0.73 vs. 0.87 (p=0.04). The frequency of TAP observed on EOB was superior to EC-Gd (19.5% vs. 6%; p=0.013), but there were no differences in frequencies for severe TAP (p>0.99) between both contrast agents. EOB was associated to a higher frequency of post contrast motion-related artifacts (7.3% vs. 0%; p=0.03).
Conclusion: TAP respiratory motion-related artifact is more frequently observed on liver MRI with EOB than with EC-Gd and it may affect 19.5% of the patients. However, the rate of severe TAP was very low and similar for both contrast agents.

Respiratory motion artefact affecting hepatic arterial phase MR imaging: comparison between gadoxetate disodium and gadobenate dimeglumine

K. Koryukova[1], L. Saba[2], M. Di Martino[1], C. Catalano[1]; [1]*Rome/IT*, [2]*Cagliari/IT (micdimartino@hotmail.it)*

Purpose: To compare frequency and severity of arterial phase respiratory motion-related artefact following gadoxetate disodium and gadobenate dimeglumine in patients with cirrhosis.
Methods and Materials: This prospective study was approved by the institutional review board and was compliant with HIPAA. The requirement to obtain informed consent was waived. One-hundred and six consecutive MR examinations were evaluated, 48 performed with gadoxetate disodium and 58 performed with gadobenate dimeglumine. All examinations were performed with the same magnet (1.5 T) and acquisition protocol. Two radiologists blinded to the contrast material rated motion artefacts on a scale of 1 (no motion) to 5 (non-diagnostic images) for the pre-contrast, the arterial, the venous and the late dynamic phases. Mean motion scores were compared using the Wilcoxon signed rank test. The number of patients with TSM, as well as the number of those with “adequate” arterial phases, was compared with the χ^2 or Fisher's exact test, as appropriate.
Results: The arterial phase reported significantly more MTS compared to the other acquired sequences with both contrast agents. Mean motion scores in the arterial phases in the gadoxetate disodium cohort were significantly worse than those in the gadobenate dimeglumine cohort (P =0.029). TSM occurred at a higher rate with gadoxetate disodium than with gadobenate dimeglumine (20.8% [10 of 48 examinations] vs 3.4% [two of 58 examinations], P<.001).
Conclusion: Motion-related artefact occurs significantly more often than after gadobenate dimeglumine in patients with cirrhosis.

Diffusion tensor imaging (DTI) in the evaluation of peripheral nerve sheath tumours: is it valuable for surgeons?

I. Capretti[1], F. Bruno[1], S. Quarchioni[2], E. Cannizzaro[1], C. Gianneramo[1], S. Mariani[1], F. Arrigoni[1], A. Barile[1], C. Masciocchi[1]; [1]*L'Aquila/IT*, [2]*Teramo/IT (ilaria_capretti@hotmail.it)*

Purpose: To demonstrate the preoperative role of MR in the localization and characterization of tumoral peripheral nerve sheath lesions and the identification of nervous fibers and the relationship with adjacent structures.
Methods and Materials: Twenty-six patients, suspected of having tumoral lesions, underwent contrast enhanced MR (3Tesla). They were evaluated with morphological sequences such as PD, FSE T1, FSE T2, FSE T2-weighted fat-saturated and postcontrast T1- weighted fat-saturated, but also with Spin-echo-single-shot EPI sequences (b-value 1000 s/mm^2; 25 diffusion gradient orientations). We used quantitative parameters derived from DTI : apparent diffusion coefficient (ADC) and fractional anisotropy (FA) and reconstructed the nervous fibers involved in the lesion. All patients were subjected to surgical treatment and we studied the correlation between MR imaging and surgical findings.
Results: In all the patients, morphological sequences showed that lesions involved peripheral nerves and they appeared hyperintense in T2-weighted

sequences with enhancement in postcontrast T1- weighted fat-saturated sequences. DTI techniques allowed the visualization and relationship between tumour and normal axons of peripheral nerves with high sensitivity (78.9%), specificity (71.4%) and positive predictive value (88.2%). During surgery, a good correlation between MR images and intraoperative aspects was observed with sensitivity of 90%, specificity of 83% and positive predictive value of 95%.
Conclusion: According to our experience, preoperative DTI techniques are useful to plan the safest surgical resection in order to minimize post-operative neurological deficits.

B-0614 14:17

Feasibility of shear wave elastography (SWE) in diagnosing carpal tunnel syndrome (CTS)
S. Rauch; *Innsbruck/AT (stefanrauch@gmx.at)*

Purpose: To evaluate longitudinal and axial plane measurements of shear wave elastography (SWE) at a proximal and distal Level in determining median nerve (MN) elasticity and diagnosing carpal tunnel syndrome (CTS).
Methods and Materials: 27 healthy volunteers (three male, mean 37 yrs., range 24-37; 24 female, mean 54 yrs., range 43-78) and one hand of 27 CTS patients (twelve male, mean 72.0 yrs., range 43-82; 15 female, mean 65 yrs., range 29-82) were examined by using a 18-5 MHz transducer. Cross sectional (CSA) area of MN was determined at the level of pronator quadratus muscle (CSAp) and at the level of the maximum CSA in the carpal tunnel (CSAd). Δ-CSA was determined as the difference between both measures. SWE measurements were performed for MN both at proximal and distal levels in axial and longitudinal orientations. Measures were compared between CTS patients and controls at both levels in both orientations (axial and longitudinal).
Results: Both the SWE values and CSA in CTS patients were significantly higher than that of healthy volunteers (P <0.001). Longitudinal SWE was superior to axial SWE measurements (P=<0,001). The presence of CTS was predicted by a share wave velocity of 10,41 cm/s (mean) (P=<0,001) with a cut-off value of 9,85 (sensitivity 0.93, specificity 0.63) and an area under the curve (ROC) of 0.85.
Conclusion: SWE proved to be sensitive in CTS patients and a single longitudinal SWE measurement at the carpal tunnel is sufficient for the diagnoses of CTS.

B-0615 14:25

Ultrasound of the Thenar Motor branch in Carpal Tunnel Syndrome
F. Zaottini, R. Picasso, S. Airaldi; *Genova/IT (federico.zaottini.fz@gmail.com)*

Purpose: This study was aimed to investigate the ultrasound (US) appearance of the thenar motor branch (TMB) of the median nerve (MN) in patients with carpal tunnel syndrome (CTS) and thenar muscle weakness at physical examination and electrophysiology.
Methods and Materials: Twenty-two consecutive wrists from n=15 patients (mean age 61±5) who had clinical and electrophysiological diagnosis of CTS and signs of thenar muscle weakness were included. In each patient, the CSA of the MN and the caliber of the vertical segment of the TMB were measured with 17-5MHz US. In addition, the thenar muscles echotexture and the appearance of the intermuscular segment of the TMB were recorded. Electrophysiology included standard needle technique and sampling of motor and sensory conduction velocities of the MN. Correlation between US findings and electrophysiologicy was then obtained.
Results: US was able to identify the TMBs in all but one wrists. The mean TMB diameter was 0.9±0,28mm (95% CI). In 43% of cases, the vertical segment of the TMB resulted to be larger than normal, ranging between 0.7mm to 2mm. The intramuscular segment of the TMB appeared swollen in 9% of cases. Overall, the mean CSA of the MN at wrist was 16,1mm2. No correlation was observed between TMB caliber and either CSA of the MN or electrophysiologic signs of denervation of thenar muscles.
Conclusion: The TMBs often appear swollen in patients with CTS and signs of thenar muscle weakness. There is no significant correlation, however, between thenar muscle weakness and abnomal appearance of the TMB.

B-0616 14:33

High resolution Ultrasound of the Motor Branch of the Ulnar Nerve beyond the Guyon tunnel
R. Picasso[1], F. Zaottini[1], S. Airaldi[2]; [1]*Genova/IT*, [2]*Savona/IT (riccardo.picasso@gmail.com)*

Purpose: To illustrate the ultrasound (US) findings of distal entrapment neuropathy of the motor branch of the ulnar nerve (UNMB) beyond the Guyon tunnel.
Methods and Materials: A dissection study was performed on n=3 cadaveric hands to assess the regional anatomy of the UNMB beyond the pisiform. US was perfomed in a group of n=10 healthy subjects to examine the nerve at the hamate hook, pisohamate ligament and within the palm. A series of n=10 consecutive patients with motor symptoms in the territory of innervation of the UNMB in the hand (zone 2) were examined with US using a linear 17-5MHz transducer. These patients had neurophysiologic, 1.5T MR imaging and surgical correlations.
Results: US was reliable to depict the UNMB from its origin to the midpalm. Two levels of entrapment were identified. In five patients, the UNMB was compressed on the outside slope of the hamate hook by ganglion cysts. Four other patients had more distal compression in the palm by fibrous bands (n=1) and ganglion cysts (n=3). One had multiple neurofibromas affecting the nerve and its divisional branches. In midpalmar entrapments, there was selective denervation of the III/IV dorsal interosseous muscles. Overall, US gave useful preoperative information on the level of injury.
Conclusion: US may help the diagnostic work-up of distal ulnar neuropathies giving information on the level and nature of constricting findings. In patients with suspected zone II syndrome, US should include a through evaluation of the UNMB at the level of the hamate hook and the midpalm.

B-0617 14:41

MRI assessment of the microstructural integrity of the peripheral nerves in Charcot-Marie-Tooth disease
F.I. Rozalli, F. Fadzli, T. Krisnan, K. Rahmat, L.K. Tan, N. Shahrizaila, N. Ramli; *Kuala Lumpur/MY (farhana.fadzli@yahoo.com)*

Purpose: Charcot-Marie-Tooth (CMT) is one of the most common inherited causes of peripheral neuropathy. Our goal was to investigate the microstructural integrity of sciatic and peroneal nerves in CMT using diffusion tensor imaging (DTI), and evaluate muscle atrophy.
Methods and Materials: A total of 9 CMT patients and 9 age- and gender-matched healthy controls were recruited. DTI using 3-tesla MRI machine was performed to evaluate the sciatic and peroneal nerves. Post-processing produced DTI values for each nerve. Axial in-out phase of the calf was used to classify muscle atrophy (tibialis anterior) using Goutallier classification.
Results: The FA values were significantly reduced (0.330±0.036 vs 0.408±0.023, p<0.001, for sciatic nerve; 0.3575±0.107 vs 0.5484±0.107, p<0.001, for peroneal nerve) and RD values were significantly increased (1.149±0.102 vs 0.852±0.472, p=0.04 for sciatic nerve; 2.291±0.6417 vs 1.103±0.329, p<0.001 for peroneal nerve) in CMT patients. The mean muscle atrophy value was significantly increased in CMT patients (0.78±0.833 vs 3.33±0.707, p<0.001). We also found correlation between DTI values (FA and RD) and muscle atrophy grading.
Conclusion: DTI was able to detect degenerative and demyelination changes in CMT, which corresponds to the nature of the disease. MRI also supports that there was significant muscle atrophy in CMT patients. MRI-DTI could emerge as a useful screening tool for asymptomatic high-risk patients with family history of CMT for early detection of neuropathy and as an adjunct to EMG in the prognostication of CMT.

B-0619 14:49

Core muscle composition and fat distribution in Parkinson's disease
C.-K. Wang, H.-L. Chen, W.-C. Lin; *Kaohsiung/TW (moonrbt@gmail.com)*

Purpose: Sarcopenia and alteration of fat distribution were known in PD patients, but the intramuscular fat distribution has not yet been well established. The aim of this study was to investigate fat distribution in core and extremity muscle and its relationship with clinical severity and frailty.
Methods and Materials: Twenty-five patients with PD and 20 age- and sex-matched healthy volunteers were recruited. All subjects underwent MRI study using IDEAL sequence to determinate the fat distribution in core and extremity muscles (including psoas muscles and the thigh). PD patients received clinical survey to evaluate disease severity and frailty. The alternation in the fat content in core and extremity muscles, frailty and clinical severity were correlated.
Results: The fat content in measured muscles exhibited higher in PD patients (psoas muscles: p=0.014, anterior compartment of thigh: p=0.006, medial compartment of thigh: p<0.001, posterior compartment of thigh: p=0.003). The fat infiltration of measured muscle was significantly correlated with clinical severity and items of frailty. The average percentage of fat content of bilateral medial compartment of thigh showed correlation with UPDRS-1 (r=0.707, p<0.001) and average percentage of fat content of bilateral anterior compartment of thigh showed correlation with weakness and exhaustion (r=0.519, p=0.019).
Conclusion: Higher percentage of fat content in core and extremity muscles is a significant phenomenon in PD patients. The pathophysiology of sarcopenia and frailty in PD might be a consequent process of neuromuscular degenerative changes and, therefore, PD patients were limited their daily activity due to decreased muscle strength.

B-0620 14:57

Ultrahigh field (7T) diffusion tensor imaging of healthy skeletal muscles: a quantitative comparison with 3T

C. Giraudo[1], S. Motyka[1], M. Weber[1], T. Feiweier[2], S. Trattnig[1], W. Bogner[1]; [1]*Vienna/AT*, [2]*Erlangen/DE (chiara_giraudo@hotmail.it)*

Purpose: To compare diffusion tensor imaging (DTI) with 7T and 3T of the human calf muscles.
Methods and Materials: Ten volunteers (5 males; mean age 29.1±4.7 years), without any history of muscle disease, were examined twice (i.e. during the same day, without repositioning) at 3T (MAGNETOM Prisma, Siemens Healthcare) and 7T (research scanner, Siemens Healthcare), using a STEAM-DTI sequence. SNR, DTI metrics (tracks' number ($tracks_n$), length ($tracks_l$), volume ($tracks_v$), fractional anisotropy (FA), and mean (MD), axial (AD) and radial diffusivity (RD)) of the entire datasets (*entire_calf*), of tibialis anterior (*TA*), gastrocnemius medialis (*GM*) and lateralis (*GL*) were collected. Student's *T* test was used to compare SNR and DTI metrics obtained at 3T and 7T. Intraclass-correlation coefficients (ICC) were derived to assess the reliability of DTI measurements at 3T and 7T.
Results: The SNR was higher at 7T (+105.11%; p<.001). At 7T, $tracks_n$, $tracks_v$,and $tracks_l$ were higher for *entire_calf*, *GM* and *GL* ($tracks_n$: +5.5%, +3.1%, +8.5%; $tracks_v$: +12.1%, +12.2%, +14.7%; $tracks_l$: +13.3%, +16.4%, +19.2%; p<.05, each); *TA* showed only higher $tracks_n$ and $tracks_v$ (+6.3%, +16.4%; p<.05 each). MD and RD were higher at 7T for the *entire_calf* (+1.3%; +1.8%; p<.05, each) and for *TA* (+7.3%, 8.9%; p<.05, each). *TA* showed higher FA at 3T (+3.1%; p=.001) and higher AD at 7T (+5.6%; p<.001). *GM* demonstrated lower MD and RD at 7T (-2.8%; -3.4%; p<.05). ICC was excellent (>.750) for both 7T and 3T regarding *GM*'s and *GL*'s $tracks_n$, $tracks_v$, RD, *entire_calf*'s RD, *TA*'s RD and FA. Excellent ICC values were obtained only at 3T for the *entire_calf*'s and *GL*'s MD and AD, and *GL*'s FA and *GM*'s AD. *GM*'s $tracks_l$ and *TA*'s $tracks_v$ had excellent ICC only at 7T.
Conclusion: Ultrahigh field demonstrated higher SNR and an overall improvement in fibre tracking metrics. Further studies are necessary to better characterize the advantages and the challenges in specific muscles.

B-0621 15:05

Compression garments in delayed-onset muscle soreness (DOMS): randomised controlled trial with acoustic radiation force impulse (ARFI), contrast-enhanced ultrasound (CEUS) and MRI

R. Heiß[1], M. Kellermann[1], B. Swoboda[1], C. Grim[2], A.M. Nagel[1], M. Uder[1], T. Hotfiel[1]; [1]*Erlangen/DE*, [2]*Osnabrück/DE (Rafael.Heiss@uk-erlangen.de)*

Purpose: To investigate the influence of compression garments on changes in muscle perfusion, stiffness and oedema in DOMS.
Methods and Materials: DOMS was induced in fifteen healthy participants using an eccentric exercise protocol. After exercise, a conventional sports compression garment (class I) was worn on one randomized calf for 60h. ARFI (shear wave velocities (SWV)), CEUS (peak enhancement (PE) and wash-in area under the curve (WIAUC)) and MRI (normalized T2 signal intensity and T2 time) of the gastrocnemius muscle (GM) were assessed at baseline and 60 h after exercise at both calves.
Results: After exercise the normalized T2 signal intensity (1.0±0.30 vs 1.94±1.05, p=0.008) and the T2 time (37.52±9.67 vs 55.64±12.72 ms, p=0.015) were significantly higher in the GM in the compressed calf; but no change for WIAUC (p=0.88), PE (p=0.51) and ARFI SWV (p=0.60) were observed. For the non-compressed calf all assessed parameters changed significantly: T2: 1.0±0.16 vs 2.20±1.16, p=0.001; T2 time: 37.75±9.28 vs 55.67±14.78 ms, p=0.005, WIAUC: 2461±660 vs 5297±743, p=0.01, PE: 328±45 vs 753±31, p=0.005, ARFI SWV: 2.2±0.26 vs 1.78±0.24m/s, p=0.008. No significant difference was observed in normalized T2 signal intensity (p=0.397), T2 time value (p=0.953), WIAUC (p=0.93) and PE (p=0.730) in the GM comparing the compressed and non-compressed lower leg after exercise. Only ARFI SWV values in the same comparison revealed a statistically significant difference (p=0.001).
Conclusion: Wearing conventional compression garments after inducing DOMS may shorten the normalization of muscle stiffness, but have no significant effect on the degree of intramuscular oedema or perfusion of the gastrocnemius muscle.

Feasibility study of microwave ablation system: localisation and eradication of tumourous lesions

T.J. Vogl[1], C. Reimann[2], M. Puentes-Damm[2], F. Hübner[1], B. Bazrafshan[1]; [1]*Frankfurt a. Main/DE*, [2]*Darmstadt/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: To investigate the difference between the dielectric properties of normal and malignant liver tissue by measuring the permittivity of freshly excised samples from liver resection.
Methods and Materials: A microwave ablation system is proposed with a microwave sensor at the tip of the applicator as an additional information source for accurate localization of the targeted tumour during the intervention. A measurement procedure was developed to evaluate the broadband dielectric properties of a liver sample containing healthy and tumour tissue. In total, 22 measurements were performed by touching the surface under test with a dielectric probe (2.1 mm in diameter) connected to a network analyser. Measurement points were recorded on normal (8), tumour (8), and tumour boundary (6) locations.
Results: At 12GHz, the permittivity mean value ± standard deviation of normal tissue was ϵ_n=33.8±0.86 and of tumour tissue ϵ_t=44.33±5.49, which results in a relative difference of =31.15%. The proposed applicator is able to distinguish between healthy and tumour tissue exhibiting a sensitivity of 10%. During thermal ablation measurements, a lesion zone of approximately 3 cm^3 was obtained with an input power of 20W for 4 minutes when the functional model was inserted into the liver sample. By detecting tumour tissue, an additional source of information is provided for the interventional radiologist and could lead to a reduced number of insertions and readjustments. Moreover, the high operation frequency leads to an efficient heat generation for thermal ablation treatment.
Conclusion: The new microwave system possibly allows simultaneous diagnostic and therapeutic microwave application.

B-0623 14:08

Microwave ablation (MWA) of pulmonary neoplasms: clinical performance of MWA with spatial energy control vs conventional low-frequency MWA

T.J. Vogl, L. Basten, N.N.N. Naguib, N.-E.A. Nour-Eldin; *Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: To evaluate the clinical performance of a new microwave ablation (MWA) technology with spatial energy control (SEC) for treatment of lung malignancies in comparison to a conventional low-frequency (LF) MWA technology.
Methods and Materials: In this retrospective study, 59 consecutive patients (mean: 58.9±12.7 years) were treated in 71 sessions using SEC-MWA. Parameters collected were technical success and efficacy, tumour diameter, tumour and ablation volume, time, energy, complication rate, 90-day mortality, local tumour progression (LTP) at 3-month follow-up, ablative margin size and ablation zone sphericity. Results were compared with the same parameters retrospectively collected from the last 71 conventional LF-MWA sessions (n=56 patients; mean 60.3±10.8 years). Statistical comparison was done using Wilcoxon-Mann-Whitney test.
Results: Technical success was 98.6% for both technologies; efficacy was 97.2% (SEC-MWA) and 95.8% (LF-MWA). The 90-day mortality rate was 4.2% (3/71) in both groups without any intraprocedural death. Complications were recorded in 21.1% (15/71) of SEC-MWA and in 31% (22/71) of LF-MWA, of which 4.2% (3/71) and 9.9% (7/71) were major (all p>0.182). The median deviation from ideal sphericity (1.0) was 0.195 (SEC-MWA) vs 0.376 (LF-MWA) (p<0.001). Absolute minimal ablative margins per ablation were on average 7.5±3.6 (SEC-MWA) vs 4.2±3.0 mm (LF-MWA) 8p<0.001). LTP until 3-month follow-up occurred in 5.6% (4/71) and 7.0% (5/71), respectively (p>0.7).
Conclusion: SEC-MWA of lung malignancies and conventional LF-MWA technology are safe and effective independent of the used system. However, SEC-MWA achieves more spherical ablation zones with larger ablative margins vs LF-MWA (p<0.001).

B-0624 14:16

Renal tumour cryoablation beyond T1a: outcomes for 56 T1b biopsy-proven RCC lesions

T.A. Gibson, N. Patel, N. McGill, A. King, D. Breen; *Southampton/UK (tagibson0@gmail.com)*

Purpose: Percutaneous image-guided renal cryoablation (CRA) represents an alternative nephron-sparing technique for renal tumours. The majority of published data has focused on its application specifically to T1a disease. Hence, our purposes are to: a) provide results of a single-centre prospective study of the technical and oncological outcomes of CRA for T1b (<7cm) lesions and b) compare these results with our equivalent data for T1a (</= 4cm) renal masses.
Methods and Materials: 433 patients with 486 T1 renal lesions treated between 2008 and 2016 were identified from a prospectively maintained tumour registry. A subset of 56 patients with stage T1b (4-6.9cm) sporadic biopsy-proven RCC were selected for further analysis. Exclusion criteria: previous history of RCC or heritable disease; <3 months follow-up.
Results: a) Demographics: 39 male, 17 female; average age = 70yrs; average tumour size = 4.8cm. b) Technical outcomes: technical success i) primary ablation rate = 51/56 (91.1%), ii) secondary ablation rate (where performed) = 2/2 (100%); complications (Clavien-Dindo grade III+) = 3/56 (5.4%). c) Oncological outcomes: mean length of follow-up = 26 months. No significant difference between T1a and T1b cohorts in overall survival (p= 0.43), late local recurrence-free survival (p = 0.45), or metastasis-free survival (p = 0.50).
Conclusion: Our findings of no statistical difference for CRA in the treatment of T1a or T1b renal masses concur with those of other studies in the literature. CRA, therefore, seems a reasonable treatment option for sporadic RCC tumours of <7cm. Further (follow-up) data are needed for comparison with partial nephrectomy.

B-0625 14:24

CT-guided percutaneous cryoablation treatment of renal cancer: an outcome analysis from our experience

S. Gitto, G. Calareso, T. Cascella, G. Greco, G. Greco, M. Vaiani, S. Stagni, R. Salvioni, C. Spreafico; *Milan/IT (sal.gitto@gmail.com)*

Purpose: To perform an outcome analysis from our experience in CT-guided percutaneous cryoablation(PCA) treatment of renal cancer(RC).
Methods and Materials: We evaluated patients with a minimum follow-up of one year after PCA of RC or extrarenal metastasis from RC performed between 10/2007 and 10/2016. All patients were inoperable or refused surgery and cases were discussed multidisciplinary. A biopsy was performed in patients without a previous diagnosis of RC. Post-operative monitoring included biochemistry 4, 8, 24 hours and a non-contrast CT scan 24 hours after PCA. Follow-up consisted of contrast CT scans 1, 3, 6, 9, 12 months after PCA and then every 6 months for 3 years. Absent/persistent mass contrast-enhancement indicated response/recurrence, respectively.
Results: Eighty-five patients were included (27F; mean age 68[35-86] years; 25 with a solitary kidney): 80 with RC and 5 with an extrarenal metastasis. Mean follow-up was 51(12-116) months. Mean mass diameter was 30(10-100) mm. Biochemical parameters were normal after PCA. Major early complications included: 1 sepsis, 1 ureteral fistula, 1 duodenal fistula, 1 arteriovenous fistula, 1 active arterial bleeding. No patients died for these complications. 93% of patients (79/85) showed complete response after PCA. Six patients had recurrent disease: 3 were successfully retreated with PCA, 1 underwent nephrectomy, 2 were not further treated and died for other causes. No significant difference in age (P=0.113;95%CI) and mass diameter (P=0.668;95%CI) was found between responsive and recurrent patients.
Conclusion: PCA is effective in the treatment of RC in patients ineligible for surgery and can be repeated in recurrent cases.

B-0626 14:32

Technical success and local control after image-guided microwave ablation (MWA) of T1a renal tumours with a new high-power generation system

M. Colombo, M.M. Panzeri, P. Marra, G. Brembilla, M. Venturini, U. Capitanio, F. Montorsi, A. Del Maschio, F. De Cobelli; *Milan/IT (colombo.michele@hsr.it)*

Purpose: MWA is a novel thermal ablation technique which allows larger and more uniform ablation zones (AZ) with shorter procedure time compared to other ablative techniques. High-power MWA may present advantages in term of local renal tumor control. In the present study we evaluated safety, technical success, local control, and survival after MWA of RCC with a new high-power generation system.
Methods and Materials: From October 2014 to March 2017 twenty-three patients (mean age 65 y; range 45-86 y) with 26 renal cancers (clear cell RCC = 21; papillary RCC = 10; chromophobe RCC = 3, oncocytoma=1) not eligible for surgical treatment were treated with MWA procedures (US/CT guided percutaneous = 23 lesions; laparotomic = 1; laparoscopic = 2), with a 2450 MHz/100 W generator with Thermosphere™ Technology (Emprint™, Medtronic). At follow up (FU), contrast-enhanced CT or MR was performed after one, six and twelve months. Technical success, AZ, complete ablation (CA) and clinical success were assessed.
Results: Mean diameter of the lesions was 2.3 cm ± 1.1; (range, 0.9-4.2 cm). Technical success was achieved in 100% of cases and mean AZ was 28.7 mm at 1 month FU. CA at 1 year was 96%. No severe complications and 6 mild complications (19%, all perirenal haematoma) were observed. One year morbidity and mortality were both 0%.
Conclusion: In our experience, MWA with Thermosphere™ Technology is effective and safe to treat RCC.

B-0627 14:40

Our experience in percutaneous ablative treatment of renal T1a e T1b lesions: results from 90 patients treated with MWA, RFA and CRA

E. Faiella, D. Santucci, A. Alfonsi, G. Pacella, C. Altomare, C. Bernetti, C. Rollo, R.F. Grasso, B. Beomonte Zobel; *Rome/IT (a.alfonsi@unicampus.it)*

Purpose: To evaluate efficacy and safety of ablation procedures for the treatment of kidney lesions <7cm.
Methods and Materials: 90 patients with single T1a and T1b lesions of the kidney, susceptible to ablative procedure, were retrospectively analyzed: 30 treated with Radiofrequency (RFA), 30 with Cryoablation (CA) and 30 with Microwave (MWA).Biopsy was perfomormed for all the lesions. Complications rate, local control in terms of Disease Free Survival (DFS) and renal function, and survival in terms of Cancer Specific Survival (CSS) and Overall Survival (OS), were evaluated.
Results: Mean age of patients was 68.8 years (29-94 years); mean tumor size was 26.51mm (6-102mm). Eighty-two lesions (91%) were T1a and 8 (9%) T1b. In 19 cases artificial dissection was performed. The treatment was effective in 96% of cases, with peri-procedural complications in 6 patients (5 haemorrhages and 1 hydro-ureteronephrosis). Ten patients (11.1%) reported a recurrence of disease (9 T1a and 1 T1b) (p> 0.05) in a mean time of 3 months: 6 (20%) underwent MWA, 2 (6.7%) RFA and 2 (6.7%) CA (p <0.05). 1 case of renal failure in mono-kidney patient. The only significant predictor of DFS in the multivariate analysis, was the histotype, with a higher recurrence rate in RCC (p <0.05). Nine (10%) patients died for other causes.
Conclusion: Safety and efficacy in short and long-term control of the three procedures are comparable. However, long-term surveillance is required, especially after MWA. Patient selection, based on tumor characteristics (size and location), and patient comorbidities remain crucial.

B-0628 14:48

Percutaneous ablative treatment of pelvic rectal cancer recurrence

C. Pusceddu; *Cagliari/IT (clapusceddu@gmail.com)*

Purpose: To retrospectively evaluate the technical feasibility, safety and efficacy of percutaneous ablative treatment of painful pelvic rectal cancer recurrent in patients unfit for surgery and no longer susceptible to radiotherapy or chemotherapy.
Methods and Materials: Fourteen patients, mean age 61 years, with pelvic recurrence of rectal carcinoma, mean size 4.7 (2.5-9cm) underwent RFA (11 cases) and cryoablation (2 cases) to reduce pain and to limit local progression of disease. All the procedures were performed under CT guidance using local anaesthesia and conscious sedation. The therapeutic outcomes were evaluated by CT or MRI at 1-, 3-, 6- and 12-month intervals. Complete lack of tumour enhancement images after injection of contrast media was considered an indication of complete tumour necrosis.
Results: Total necrosis of the tumour was observed in 7 patients, partial in the remaining 7. Complete pain relief was obtained in eight patients and a significant reduction of pain in the remaining patients (mean VAS score from 7.8 before treatment to 1.4 after treatment). In two patients an abscess in pre-sacral space and a bladder-rectal fistula after RFA was observed. During the mean follow-up of 40 months (7-55 months) 10 patients died due to local or distant tumour progression whereas four patients are still alive and 2 of them disease free.
Conclusion: In selected cases, percutaneous ablative treatment of pelvic rectal cancer recurrence can be considered a safe and effective treatment capable of obtaining satisfactory control of pain and stabilization of the relapse.

B-0629 14:56

Microwaveablation (MWA) of liver metastases from pancreatic neuroendocrine tumour (pNET): preliminary results with a new generation system

P. Marra, P. Diana, F. Ratti, S. Partelli, M. Salvioni, S. Gusmini, M. Venturini, L. Aldrighetti, F. De Cobelli; *Milan/IT (marra.paolo@hsr.it)*

Purpose: MWA is in the panel of treatment for pNET liver metastases in symptomatic oligometastatic patients. Many case series in the literature, most based on radiofrequency ablation, report variable rates of efficacy with

relatively high rates of local tumor progression (LTP). We aimed to report our preliminary results, using a new generation high-power MWA system.
Methods and Materials: In the last two years, seven patients underwent liver MWA in our institution for the treatment of synchronous (n=4) or metachronous (n=11) pNET metastases (total nodules=15). MWA procedures were performed either percutaneously (n=5) or during surgery (n=10), using a 100W/2450MHz Microwave Generator (Emprint, Medtronic). Resection of the pancreatic neoplasm was performed synchronously to MWA treatment in 2 patients. DCE-CT or MRI were used to assess 1-month complete ablation (CA) and LTP at follow up.
Results: CA was achieved in 100% of cases. No complications occurred. Overall LTP was 0% at a mean observation time of 11.8 months (9-18). One patient developed liver disease progression after 15 months, however without recurrence at ablation site.
Conclusion: In our preliminary experience, MWA performed with a new generation system provided excellent results for the treatment of pNET liver metastases. During follow up, although limited, no LTP was observed. Even if the utility of loco-regional treatment of pNET liver metastases is still debated, we believe that MWA with a new generation system provide good cost-benefit ratio in oligo-metastatic patients.

B-0630 15:04

MR-guided focused ultrasound (MRgFUS) ablation of painful osteoid osteoma: perfusion imaging as predictors of clinical outcomes associated with complete bone integrity restoration
S. Bednarova, A. Napoli, R. Scipione, S. Dababou, C. Marrocchio, H.-P. Erasmus, C. Catalano; *Rome/IT (sandra.bednarova@gmail.com)*

Purpose: To correlate quantitative and semi-quantitative perfusion parameters of post-ablation osteoid osteoma (OO) nidus with treatment outcome and bone remodelling.
Methods and Materials: Thirty-nine subjects with radiologically confirmed symptomatic OO were treated with MRgFUS in an institutional review board-approved clinical trial, according to the intention-to-treat principle. Bone-forming changes were evaluated before and after MRgFUS procedure; annual CT and dynamic contrast-enhanced MRI (DCE-MRI) scans were performed over a period of 3 years. Quantitative and semi-quantitative parameters of OO nidus perfusion were analysed for significance with regard to post-procedural complete/partial bone restoration. Multivariate analysis was conducted to investigate imaging and demographic (age, sex, BMI) variables in relationship with clinical outcomes (VAS for pain).
Results: 31 of 36 patients underwent MRgFUS ablation of OO nidus; 29 encountered a complete clinical response (VAS score 0 during follow-up); 2 patients with residual pain at 1-month follow-up (VAS 1-3) required re-treatment using RFA. At 36-month follow-up, MRI showed no residual nidus perfusion in 76.7% of cases, with bone restitution-ad-integrum in 30% of cases. Multivariate statistical analyses demonstrate that both patients' age (<18 years) and no residual perfusion of nidus on post-procedural DCE-MRI are significant favorable prognostic factors in terms of clinical outcome and complete bone restoration. Variable relationship between clinical outcome and bone remodelling was found in older patients (>18 years).
Conclusion: MRgFUS is an effective and safe treatment for painful non-spinal osteoid osteoma; patients' age shows significant impact on clinical outcome as well as on bone integrity restoration when total nidus ablation is achieved.

B-0632 15:12

Percutaneous US- and CT-guided thermal ablation of 20 adrenal metastases: treatment effectiveness in short- and intermediate-term imaging follow-up with CT and MRI
G. Frauenfelder, E. Faiella, D. Santucci, B.B. Beomonte Zobel, R. Grasso; *Rome/IT (giulia.frauenfelder@gmail.com)*

Purpose: To retrospectively evaluate efficacy and safety of adrenal metastasis percutaneous ablation, in terms of clinical outcomes and imaging follow-up. To evaluate additional contribution of DWI and subtracted MR sequences during radiological follow-up.
Methods and Materials: A total of 20 adrenal metastases were treated through RTA, CA or MWA. Probes were inserted under US-/CT-guidance. Type of ablation and treatments parameters were influenced by lesion size and location. Each patient was evaluated with a short-term (3 months) and intermediate-term (after 6 months) imaging follow-up through contrast-enhanced CT and/or MRI. Technical success, complications, local tumour progression and overall survival were analysed on a per-patient basis. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPP) and accuracy of CT and MR enhancement, DWI and subtraction sequences were separately evaluated during short- and intermediate-term intervals.
Results: Technical success (within 24 hours) was obtained in 100% of cases. Complications were recorded in 20% of patients (15% hypertensive peak; 5% sub-glissonian haematoma). There were 15% cases of short-term progression (recidive): all these patients had undergone RTA (62,5% of efficacy). In short-term follow-up, accuracy for CT enhancement, MR enhancement, DWI and subtraction was, respectively, 83.3%, 80%, 75% and 90% while in intermediate-term was 84.2%, 89.5%, 94.7% and 94.7%. Overall survival was 92% after 12 months.
Conclusion: Percutaneous US- and CT-guided thermal ablation may be a safe and effective procedure in metastatic adrenal lesion treatment. Short- and intermediate-term imaging follow-up could be performed with both CT and MR; DWI and subtracted sequences are essential to increase MR accuracy.

Individual and specific dose-level selection using dual-source computed tomography of the chest and its impact on image quality and radiation dose
A. Wressnegger[1], C. Schestak[1], H. Prosch[1], G. Apfaltrer[2], H. Ringl[1], P. Apfaltrer[1]; [1]*Vienna/AT*, [2]*Graz/AT* *(alexander.wressnegger@meduniwien.ac.at)*

Purpose: The purpose of this study was to evaluate the value of individual and specific dose-level selection in dual-source computed tomography (DSCT) of the chest and its impact on image quality and radiation dose.
Methods and Materials: This retrospective study included 105 patients (57.1% male, 52.5±13.3 years). All patients had received routine unenhanced chest CT for follow-up examination reasons on both, a 2nd-generation DSCT (2nd DSCT) (Somatom Definition Flash, Siemens Healthineers) and a latest generation DSCT (Somatom Drive, Siemens Healthineers). 2nd DSCT scans were performed with 120kV and 100-150ref mAs, Care dose enabled, and FBP. Latest generation DSCT were performed with variable kV (Care kV enabled) and 50-70ref mAs, Care dose enabled, and iterative reconstruction (Admire). Signal/noise (SNR) was assessed in 6 thoracic regions. Subjective image quality (IQ_{sub}) was graded on a 5-point Likert scale. Group comparisons were performed using t test or Wilcoxon-rank-sum-test as appropriate.
Results: Dose length product (DLP) and effective dose (ED) were 208.5±63.3mGy*cm and 3.8±1.1mSv versus 112.2±34.7mGy*cm and 2.0±0.6mSv for 2nd DSCT and latest generation DSCT, respectively (P<.001), corresponding to a radiation dose reduction of 54%. SNR was 5.4±3.5 versus 6.5±3.4 for 2nd DSCT and latest generation DSCT, respectively (P=0.01), indicating a superior IQ for the latest generation scanner despite significantly less dose. IQ_{sub} was excellent for both scanners with a median score of 1[1-1] [25th-75th percentile] (P=0.7).
Conclusion: Use of latest generation DSCT enables personalized and specific dose level selection with an overall consequent radiation dose reduction of 54% while maintaining or exceeding image quality of former CT hardware.

B-0634 14:17

Model-based iterative reconstruction algorithm in low-dose CT pulmonary angiography in emergency setting: dose reduction and diagnostic quality images
L. Riva[1], D. Ippolito[1], C. Talei Franzesi[1], A. de Vito[1], C. Cangiotti[1], C. Maino[1], S. Sironi[2]; [1]*Monza/IT*, [2]*Bergamo/IT (luca.riva89@gmail.com)*

Purpose: To compare radiation dose and image quality of low-dose CT pulmonary angiography(CTPA) combined with Model-Based Iterative Reconstruction (IMR), with a standard dose CTPA-study, in patients with suspect of pulmonary embolism(PE).
Methods and Materials: Eighty-seven patients investigated for PE in emergency setting were enrolled. The study-group was evaluated using a 256-MDCT (iCT elite,Philips) with 80-kV, dose right index and automated tube-current modulation, low volume of CM (50mL;350mgI/mL) and IMR algorithm to reconstruct raw data. Control-group underwent a standard CTPA-study on 16-MDCT scanner, with the same volume of CM(120kV;150-250mAs;FBP-reconstruction).Two radiologists performed quantitative evaluation measuring vessels contrast-enhancement and calculating SNR and CNR. A 4-point scale

was used to perform qualitative evaluation. Radiation dose exposure data was recorded as DLP and CTDIvol.
Results: The intra-vessel density, SNR and CNR were significantly higher in study-group than in control-group (i.e.CNR: IMR 43.56±21.81 vs FBP-CTPA 23.21±12.11;p<0.05),while background noise was significantly lower(p<0.05) in study-group in comparison with control-group. DLP and CDTIvol in IMR-CTPA were significantly lower than those in FBP-CTPA (p<0.05),with a 56% reduction of CTDIvol (IMR-CTPA 6.41±1.41mGy vs FBP-CTPA 14.68±3.42mGy) for study-group. Raw data reconstruction time of the IMR was higher than FBP with a mean value of 2.08 minutes, otherwise acceptable for emergency setting. Moreover, the overall image quality rating score was higher for IMR-CTPA than FBP-CTPA both for the two readers (p<0.05;C.Alpha=0.91).
Conclusion: Low-kV setting combined with IMR can improve diagnostic image quality of CTPA in pulmonary embolism, compared to a standard CTPA reconstructed with FBP, allowing to reduce the radiation dose to patients.

B-0635 14:25

The impact of ASiR-V in different noise index in thorax CT imaging: comparison between normal dose and low dose
L. Jin, M. Li, Y. Sun; *Shanghai/CN (BrightDK@126.com)*

Purpose: To evaluate the impact of adaptive statistical iterative reconstruction-veo (ASiR-V) technique in thorax CT imaging between normal dose and low dose.
Methods and Materials: Randomly selected 42 patients sent to do thorax CT by clinical doctors from April-July 2017 were divided into three groups: (NI=14,120KV) group A, (NI=28,120KV) group B, (NI=28,80KV) group C. All groups were reconstructed by ASiR-V technique: weight from 0%-100%, interval was 10%, image slice and reconstruction interval was 0.625mm. Signal intensity was measured by placing a region of interest in 3cm upon the corner of the sternum, noise was measured in the thoracic aorta. Image quality was visually assessed by two radiologists over 15 experience using a 5-point scale. The inter-observer differences were determined by kappa statistics.
Results: The image noise of each group decreases with the increase of ASiR-V weight, and the contrast noise increases with the increase of ASiR-V weight. The image quality of all sequences in image analysis was above 3 points and above which was satisfied with diagnosis, 40% weight ASiR-V got the highest image quality. The ED of each group was (3.03±1.63)mSv, (3.86±0.74)mSv, (3.62±0.63)mSv; the ED of low-dose group (B&C) was decreased by 75% compared with normal group (A). There was perfect inter-observer concordance in terms of image quality (kappa=0.912).
Conclusion: ASiR-V technique for image reconstruction was obviously better than FBP, 40% weight was the best choice, specially under low-dose scanning; the effect of noise on image quality could be well compensated, so images met the diagnosis in lower radiation dose.

B-0636 14:33

Study of image quality in chest CT using prospective ASIR-V
Q.Q. Yuan; *Zhengzhou/CN (yuanqian10@163.com)*

Purpose: To explore the optimal prospective ASIR-V percentage in chest CT with good image quality and low radiation dose.
Methods and Materials: A phantom containing solid pulmonary nodule examined on GE revolution CT was randomly divided into six groups using prospective ASiR-V technique (0%, 20%, 40%, 60%, 80%, 100%). The quantitative analyses included objective noise and CNR. The subjective image quality was graded on a scale from 1 (worst) to 5 (best). CTDIVol, CNR, noise and image score were compared with ANOVA.
Results: CTDIVol had statistically significant differences of all groups (P<0.05). CNR, noise and image score of 40%, 60%, 80% and 100% ASiR-V were statistical difference between each group (P<0.05). However, the image score of 60%, 80% and 100% ASiR-V could not meet the diagnostic requirement with 3.40±0.51 vs 2.40±0.51 vs 1.20±0.41. 40% ASiR-V image score basically met the diagnostic requirement with 4.40±0.51, meanwhile mean dose reduction relative to 0% ASIR-V was 44%. There was no significant difference in CNR and image score between 20% and 0% ASiR-V, CNR was 1.36±0.16 vs 1.22±0.22 (P =0.17) and subjective image score was 4.80±0.41 vs 5.00±0.00 (P = 0.21), meanwhile mean dose reduction relative to 0% ASIR-V was 26%.
Conclusion: Images of prospective 60%, 80%, 100% ASiR-V provided the lower CTDIvol and noise, but the poor image quality could not meet the diagnostic requirement. Images obtained from 20% and 40% ASiR-V had the similar image quality with 0% ASiR-V producing lower radiation dose. 20% and 40% ASiR-V could be recommended for chest CT scan.

B-0637 14:41

Comparison of ultra-low-dose computed tomography (ULDCT) and standard-dose computed tomography (SDCT) for the detection of interstitial lung disease
S. Takehara[1], T. Iwasawa[1], T. Baba[1], T. Ogura[1], M.S. Oba[2]; [1]*Yokohama/JP*, [2]*Tokyo/JP (takehara198963@gmail.com)*

Purpose: To compare the ability of ultra-low-dose computed tomography (ULDCT) and standard-dose computed tomography (SDCT) for detecting interstitial lung disease (ILD).
Methods and Materials: Fifty-one patients were recruited prospectively. Each patient underwent computed tomography (CT) examinations at standard dose (auto electric current; below 350 mA, 120 kV) and ultra-low-dose (20 mA, 120 kV). The average effective doses were 5.8 and 0.37 mSV, respectively. Three board-certified radiologists diagnosed ILD based on SDCT images.The volume of a normal lung (N-pattern) and fibrosis (F-pattern) were measured using a Gaussian histogram normalized correlation (GHNC) system; volume ratios to the whole lung volumes were calculated. Receiver operating characteristic (ROC) curve analysis of the F-pattern volume ratio was used to examine the ability of ULDCT and SDCT to detect ILD.
Results: Out of 51 patients, 30 were diagnosed with ILD. The GHNC was used to analyse the ULDCT results of all patients.In the GHNC analysis, the N-pattern volume ratio on ULDCT was significantly larger than that on SDCT [median, 86.19% in ULDCT and 83.58% in SDCT (p<0.001)]. The F-pattern volume on ULDCT was significantly smaller than that on SDCT [median, 5.59% in ULDCT and 7.33% in SDCT (p<0.001)]. The areas under the ROC curve for F-pattern were 0.946 (95% confidence interval, 0.89-1.0) in ULDCT and 0.927 (95% confidence interval, 0.87-1.0) in SDCT.
Conclusion: The area of fibrosis might be underestimated when ULDCT is used. However, the F-pattern volume ratio measured using ULDCT is similar to that by SDCT in its ability to detect ILD.

B-0638 14:49

Ultra-low-dose CT with tin filtration for lung densitometry and emphysema detection
Y. Gao, X. Zhai, L. Zhang, K. Huang; *Beijing/CN (gaoyanli1997@msn.com)*

Purpose: The purpose of this study was to determine whether ultralow-dose CT with tin filtration can be used for quantification of lung density and for emphysema detection.
Methods and Materials: Fifty-two patients were prospectively enrolled and underwent both low-dose CT (120 kV, 50 effective mAs) and ultralow-dose CT. Ultralow-dose CT was performed with single-energy at 100kV using tin filtration (Sn100 kV, 100 effective mAs). Images were reconstructed by filtered back projection (FBP) for low-dose CT and FBP and advanced modelled iterative reconstruction (ADMIRE, strength level 3 and 5) for ultralow-dose CT. Radiation dose was recorded. Emphysema index, 15th percentile of lung attenuation, mean lung attenuation, total lung volume and image noise were measured in each image series and compared.
Results: The effective dose of low-dose CT was 2.0 ± 0.6 mSv, and that of ultralow-dose CT was 0.2 ± 0.1 mSv. Compared with the findings for low-dose CT, emphysema index was significantly overestimated by 4% on ultralow-dose CT FBP images, 2% on ADMIRE step 3 images, but no significant difference was observed on ADMIRE step 5 images. The 15th percentile of lung attenuation was significantly underestimated by 6 HU on ultralow-dose FBP images, while no significant differences were exhibited on ADMIRE images compared with low-dose CT. No significant differences were observed in mean lung attenuation and total lung volume. Image noise was significantly reduced using ADMIRE compared to FBP.
Conclusion: Ultralow-dose CT with tin filtration is feasible for lung density quantification and emphysema detection. ADMIRE improves the accuracy of ultralow-dose CT.

B-0639 14:57

Impact of iterative model reconstruction on the correlation between CT quantification of emphysema and airway measurements and pulmonary function test in the normal study cohort
D. Kim[1], C. Kim[2], K. Lee[1], J.-Y. Choo[2], E.-Y. Kang[2], Y.-W. Oh[2]; [1]*Ansan/KR*, [2]*Seoul/KR (dj8827@naver.com)*

Purpose: To compare the correlation between PFT and different reconstruction algorithms and to suggest useful guidance to optimize the reconstruction protocol in the CT quantification of the lung and airways in the normal study subjects.
Methods and Materials: Chest CT from 223 subjects were reconstructed using variable reconstruction algorithms including FBP, hybrid IR(HIR), and model-based IR(MIR) to determine the scan protocol best correlated with PFT. Measurements of each dataset were compared: emphysema index (EI) and wall area percentage (WA%). We compared the CT parameters between FBP, HIR and MIR with PFT parameters. Pearson correlation and linear regression

analysis were conducted to evaluate between different algorithms and PFT in the whole study subjects and subgroups according to smoking history.
Results: In the whole study subjects, EIs of all the reconstruction algorithms involving FBP, HIR, IMR-R1, and IMR-ST1 showed significant correlations with FEV1/FVC. Among these, EI of IMR-R1 showed the highest correlation with FEV1/FVC. WA% in IMR-SP1 showed significant correlation with both FEV1 and FEV1/FVC. In the subgroup analysis, EIs of all the reconstruction algorithms involving FBP, HIR, IMR-R1, and IMR-ST1 showed significant correlations with FEV1/FVC in both ever- and never-smokers. Among these, EI of IMR-R1 showed the highest correlation with FEV1/FVC in both ever- and never-smokers. WA% in IMR-SP1 showed also significant correlation with both FEV1 and FEV1/FVC in both ever- and never-smokers.
Conclusion: CT quantification of emphysema and airway using MIR showed best correlation with PFT compared to using HIR and FBP in the normal study cohort.

B-0640 15:05

Performance and radiation dose comparison of the recently introduced ultralow-dose chest computed tomography (CT), standard-dose CT and digital chest radiography
T. Svahn[1], T. Sjöberg[2], K. Shahgeldi[1], J. Nordström[1]; [1]*Gävle/SE*, [2]*Hudiksvall/SE (tony.svahn@regiongavleborg.se)*

Purpose: To evaluate diagnostic performance and absorbed radiation dose of ultra-low-dose CT (ULD-CT) in comparison to that of standard CT (SD-CT) and digital chest radiography (DR).
Methods and Materials: Pulmonary nodules were simulated in an anthropomorphic phantom (LungMan; Kyoto Kagaku). Thirty cases, 18 with lesions (45 lesions in total of 3-12 mm) and 12 without, were acquired at each imaging technique. Two radiologists interpreted the cases in a blinded detection study. Performance was assessed using the JAFROC figure-of-merit (FOM). Radiation absorbed dose to the lungs were measured using TLD-dosimeters. A systematic search was performed to identify patients examined by both ULD-CT and SD-CT for extraction and evaluation of radiation dose metrics.
Results: Performance was not significantly different between ULD-CT and SD-CT (FOMs: 0.824 vs 0.857; ΔFOM: 0.03). Significantly more lesions were detected with the two CT techniques in comparison to DR (FOM: 0.541; ΔFOM: 0.31 and 0.28). Depending on patient size, ULD-CT was found to yield two to twelve times higher dose to the lungs than DR (PA + lateral views), but only ~4-11% the dose from SD-CT. Paired radiation dose data was eligible for forty patients, which correlated with the measured dose differences, but with a wider dose range.
Conclusion: ULD-CT may serve as an alternative to both SD-CT and DR, considerably reducing dose in the first case and improving diagnostic accuracy in the second. Raised awareness of ULD-CT may lead to increased usage in the appropriate clinical setting at the local radiology department.

B-0641 15:13

Low-dose digital radiography in diagnosis of COPD's phenotypes
N. Gorbounov, A. Dergilev, V. Kochura, Y. Manakova, A. Sudarkina; *Novosibirsk/RU (a.sudarkina@mail.ru)*

Purpose: Determination of the features of low-dose digital radiography in the diagnosis of phenotypic variants of COPD.
Methods and Materials: 107 patients with COPD of varying severity were examined. The average age of the patients was 51.8 ± 1.5 years (46 - 59 years). All patients underwent low-dose digital radiography of the chest in the frontal projection in different phases of respiration. The electron optical density of the lungs was determined in the upper, middle and lower zones of both lungs.
Results: In patients with a predominance of emphysematous variant of COPD (n = 15) the most characteristic radiological symptom was lung emphysema (14% of 107 patients) and inspiratory electron optical density value was 748.18 ± 4.72 optical density units (ODU). In patients with a predominance of bronchitic variant of COPD (n = 43) the most common radiological symptom was the presence of amplification and deformation of lung pattern (40% of 107 patients) and inspiratory electron optical density value was 668.04 ± 12.26 ODU. For patients with mixed phenotypic variant of COPD (n = 49) it was characterized by a combination of X-ray symptom of amplification and deformation of lung pattern with lung emphysema (46% of 107 patients); the average value of inspiratory electron optical density value was 815.24 ± 17.25 ODU.
Conclusion: The technique of low-dose digital radiography can detect X-ray symptoms and determine electron optical density of the lungs in patients with COPD that allows optimizing the diagnosis of phenotypic variants of chronic obstructive pulmonary disease.

B-0642 15:21

Radiation protection: factors influencing compliance to referral guidelines in minor chest trauma
F. Louagé[1], A. Van Muylem[2], N. Howarth[3], P. Gevenois[2], D. Tack[4]; [1]*Ath/BE*, [2]*Brussels/BE*, [3]*Chênes-Bougeries/CH*, [4]*Braine-L'Alleud/BE (fabian.louage@ulb.ac.be)*

Purpose: To test the hypothesis that referral guidelines are not sufficiently known by prescribers and that medico-legal concerns could influence the prescription of radiographs in minor chest trauma.
Methods and Materials: We submitted a questionnaire including a typical clinical history and questions on reasons for prescribing radiographs of the ribs in minor chest trauma to 112 prescriptors (33 residents, 18 surgeons, 7 internists, 24 general practitioners and 30 ER physicians). All accepted to participate. Comparisons were performed by exact Fisher tests followed by a post hoc analysis and by a McNemar test.
Results: Fifty-eight percent of prescriptors proposed rib radiographs, most (89%) being unaware of the guidelines. Only 11% of them changed their intention to order radiographs after information on referral guidelines and radiation dose (P=0.057). The mean dose delivered by rib radiographs was 38 times higher than that of a chest X-ray. Legal and medico-legal concerns (requirements from insurance policies and avoidance of lawsuits) were the main reasons for requesting radiographs.
Conclusion: Unsharpness of guidelines in addition to social and medico-legal issues, rather than medical reasons or the lack of knowledge of the guidelines, strongly influence the prescription of radiographs of the ribs in minor chest trauma. As stated by the 2013/59 Euratom Directive, legal issues should be addressed specifically in future versions of referral guidelines.

Newly categorised seromucinous tumours of ovary: computed tomographic and magnetic resonance imaging features with pathological correlation
J. Han, K.A. Kim, C. Hyeyoon, J.W. Kim, Y. Park, J. Lee, J.W. Choi, C.H. Lee, C.M. Park; *Seoul/KR (seryjooin@hanmail.net)*

Purpose: To describe computed tomographic (CT) and magnetic resonance imaging (MRI) findings of newly established seromucinous ovarian tumors in the revised 2014 WHO classification, according to tumor type with pathological correlation.
Methods and Materials: We retrospectively reviewed the CT and MR images of 29 patients with seromucinous tumors of ovary for the following factors: size, configuration, signal intensity (SI), staging, and accompanying ovarian endometriosis.
Results: The mean age was 45.2 years (range, 20-84 years). 32 seromucinous tumors were found on CT or MRI (17 adenoma (A), 7 borderline (B), and 8 carcinoma (C)), and the mean size was 11.4 cm (A: 12.6 cm, B: 6.8 cm, C: 13.3 cm). Adenomas appeared as unilocular (n=10) or multilocular (n=7) cystic mass. Borderline tumors (n=6, 86%) and carcinomas (n=8, 100%) showed complex cystic and solid mass. The SI of solid portion on T2-weighted images (T2WI) was hyperintense in borderline and hypointense in carcinoma. The seromucinous carcinomas were FIGO stage IA (n=7, 88%) and stage IC (n=1). Endometriosis was accompanied with 18 tumors (A: 8; 46%, B: 5; 71%, C: 5; 63%).
Conclusion: The CT and MRI appearance of seromucinous tumors varied according to tumor type. T2WI high SI solid portion was useful for differentiating borderline tumor from carcinoma. Seromucinous tumors were frequently associated with endometriosis.

B-0645 14:17

Clinical value of low-kiloelectron volt monoenergetic images of dual energy computed tomography for evaluation of peritoneal seeding of ovarian cancer

T.M. Kim, S. Kim, J. Cho, S. Kim; *Seoul/KR (kjambong@gmail.com)*

Purpose: The purpose of this study was to compare the image quality of virtual low-kiloelectron volt (keV) monoenergetic (monoE) images with conventional images reconstructed from enhanced spectral computed tomography (CT) in detection of peritoneal implants.
Methods and Materials: Thirty patients who underwent serial pelvis CT scans due to ovarian cancer were included in this retrospective study. From spectral data, the two virtual low-keV monoE (40-keV and 50-keV) images were reconstructed. The conventional images using filtered back projection (FBP) and iterative reconstruction (IR) protocols were also evaluated. Two radiologists measured the attenuation and standard deviation of peritoneal implants, adjacent bowels and ascites. The mean attenuation, signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated and compared using paired t-test.
Results: The 201 peritoneal implants were measured and evaluated. The virtual low-keV monoE (40-keV and 50-keV monoE) images showed significantly higher mean attenuation values of peritoneal implants than conventional images. The all SNR and CNR values showed significantly higher in the virtual 40-keV monoE images. The virtual 50-keV monoE images showed the similar SNR and CNR values to IR images. In terms of contrast between peritoneal implants and adjacent bowels, the virtual 40-keV monoE images showed significantly higher image quality than virtual 50-keV monoE images.
Conclusion: The virtual 40-keV monoE images significantly increase the contrast of peritoneal implants. The low-keV monoE reconstructions from spectral CT can demonstrate excellent clinical value for detection and management of peritoneal seeding in ovarian cancer patients.

B-0646 14:25

Prediction of histological grade of endometrial cancer by means of MRI

M. Bonatti, B. Pedrinolla, F. Lombardo, G. Avesani, G. Bonatti; *Bolzano/IT (matteobonatti@hotmail.com)*

Purpose: To evaluate the capability of MRI in predicting histological grade of endometrial cancer (EC).
Methods and Materials: IRB-approved retrospective study; requirement for informed consent was waived. 90 patients with histologically proven EC who underwent preoperative MRI and surgery at our Institution between Sept2011 and Nov2016 were included. Myometrial invasion (</>50%) was assessed on T2-weighted images in association with diffusion-weighted images. Neoplasm and uterus volumes were estimated according to the ellipsoid formula using sagittal and para-axial images. Neoplasm/uterus volume ratio (N/U) was calculated. ADC maps were generated and histogram analysis was performed using commercially available software. MRI parameters were compared with the definitive histological grade (G1=28 patients, G2=29, G3=33) using ANOVA and Tukey-Kramer tests.
Results: Deep myometrial invasion was significantly more frequent in G2-G3 lesions than in G1 ones (p<0,005). N/U ratio was significantly higher for high-grade neoplasms (mean 0,08 for G1, 0,16 for G2 and 0,21 for G3; P=0,002 for G1 vs. G2-G3); a cut off value of 0,13 enabled to distinguish G1 from G2-G3 lesions with 50% sensibility and 89% specificity. ADC values didn't show any statistically significant correlation with tumour grade.
Conclusion: N/U ratio >0.13 and deep myometrial invasion are significantly correlated with high grade EC, whereas ADC values are not useful for predicting EC grade.

B-0647 14:33

Prediction of pathologic upgrading in biopsy-proven low-grade endometrial cancer: utility of diffusion-weighted imaging

J. Park[1], C. Kim[2]; [1]*Daejeon/KR*, [2]*Seoul/KR (jjskku@naver.com)*

Purpose: To investigate the utility of diffusion-weighted imaging (DWI) for predicting pathologic upgrading in endometrial cancer.
Methods and Materials: A total of 221 patients who underwent MRI before surgery for biopsy-proven grade I endometrial cancer were enrolled. The minimum apparent diffusion coefficient (ADC_{min}) was calculated using histogram analysis of the entire tumour. Clinical and imaging variables were compared between patients with and those without postoperative pathologic upgrading. The independent predictors of pathologic upgrading were determined using logistic regression analysis.
Results: Pathologic upgrading was identified in 42 patients (19.0%). Patients with pathologic upgrading had larger tumours, more frequently showed deep myometrial invasion on MRI, and had lower ADC_{min} values than those without pathologic upgrading (all P<0.001). The area under the receiver operating characteristic curve of ADC_{min} and tumour size was 0.812 (cut-off, $0.600\times10^{-3}mm^2/s$) and 0.758 (cut-off, 3cm), respectively. On multivariate analysis, tumour $ADC_{min} \leq 0.600\times10^{-3}mm^2/s$ (odds ratio [OR], 11.8; P<0.001) and tumour size on MRI>3 cm (OR, 3.24; P=0.009) were independently associated with pathologic upgrading. Upgrading occurred in 23 of 31 patients (74.2%) with $ADC_{min} \leq 0.600\times10^{-3}mm^2/s$ and tumour size>3cm, and in 7 of 114 patients (6.1%) with $ADC_{min} > 0.600\times10^{-3}mm^2/s$ and tumour size ≤3cm.
Conclusion: Tumour ADC and tumour size on MRI may be useful parameters for predicting pathologic upgrading in biopsy-proven grade I endometrial cancer.

B-0648 14:41

Utility of histogram analysis of apparent diffusion coefficient maps in differential diagnosis of uterine sarcoma and degenerated uterine leiomyoma

M. Huang; *Zhengzhou/CN (huangmengna1127@163.com)*

Purpose: To investigate the value of histogram analysis of apparent diffusion coefficient (ADC) maps for discriminating uterine sarcoma and degenerated uterine leiomyoma.
Methods and Materials: 43 patients with uterine sarcoma and 46 patients with degenerated uterine leiomyoma who underwent MRI and DWI scanning were retrospectively evaluated. Histogram data from regions of interest drawn on all slices of the ADC maps of parenchyma of different tumours were derived and statistically analysed by independent samples t test. The receiver operating characteristic (ROC) curve was analysed to determine the optimum threshold value for each parameter and its corresponding sensitivity and specificity.
Results: Uterine sarcoma demonstrated significantly lower mean values of ADC: 5%, 10%, 25%, 50%, 75%, 90% and 95% than degenerated uterine leiomyoma (P < 0.05). ROC curve analysis of the 90% yielded the best area under the ROC curve (AUC; 0.941), sensitivity of 91.3%, and specificity of 90.2%, with a cutoff value of $1.155\times10^{-3}mm^2/s$.
Conclusion: Histogram analysis of apparent diffusion coefficient maps is beneficial in differential diagnosis of uterine sarcoma and degenerated uterine leiomyoma.

B-0649 14:49

Diagnostic performance of MRI for assessing parametrial invasion in cervical cancer: a head-to-head comparison between oblique and true axial T2-weighted images

S. Woo[1,2], S. Kim[1], J. Cho[1], S. Kim[1]; [1]*Seoul/KR*, [2]*Daejeon/KR (j_crew7@hotmail.com)*

Purpose: To investigate whether oblique axial T2-weighted images (T2WI) provide added value compared with true axial T2WI for assessing parametrial invasion (PMI) in cervical cancer.
Methods and Materials: This retrospective study included 71 women with treatment-naive cervical cancer who underwent MRI (including oblique and true axial T2WIs) followed by radical hysterectomy. Two blinded radiologists (R1 and R2) independently assessed PMI on both sequences using a 5-point Likert scale. Receiver operative characteristic (ROC) curve analysis was performed. Subgroup analysis was done for tumours sized >2.5 and ≤2.5 cm. Inter-reader agreement was assessed with kappa (*k*) statistics.
Results: There were 15 patients (21.1%) with PMI at hysterectomy. Oblique axial T2WI showed significantly greater area under the curve (AUC) than true axial T2WI by R1 (0.941 [95%CI=0.858-0.983] vs 0.917 [95%CI=0.827-0.969], p=0.027) but not R2 (0.879 [95%CI=0.779-0.944] vs 0.827 [95%CI=0.719-0.906], p=0.153). In tumours >2.5 cm, AUC was greater using oblique than true axial T2WI (0.906 vs 0.860, p=0.046 and 0.839 vs 0.765, p=0.086). Agreement was almost perfect for oblique axial T2WI (*k*=0.810) and substantial for true axial T2WI (*k*=0.704).
Conclusion: Oblique axial T2WI may provide potentially greater diagnostic performance than true axial T2WI for determining PMI, especially in tumours >2.5 cm. The inter-reader agreement was greater when using oblique axial T2WI than when using true axial T2WI.

B-0650 14:57

Blood oxygenation level-dependent MRI for prediction of clinical outcome in uterine cervical cancer treated with radiotherapy

J. Lee, C. Kim, K. Gu; *Seoul/KR (jiyeong25.lee@samsung.com)*

Purpose: To investigate the value of blood oxygenation level-dependent (BOLD) magnetic resonance imaging (MRI) as a predictor of clinical outcome in cervical cancer patients treated with radiotherapy (RT).
Methods and Materials: Between October 2009 and August 2017, 98 patients with stage IB-IVB cervical cancer who received definitive RT with (n= 92) or without (n= 6) concurrent chemotherapy underwent BOLD MRI before treatment. BOLD MRI was obtained at 3T using a multiple fast field echo sequence to acquire 12 T2*-weighted images. The R2* value (rate of spin dephasing, sec^{-1}) was measured in the tumour. Cox proportion hazard model was used to evaluate the association of imaging and clinical variables with

progression-free survival (PFS), cancer-specific survival (CSS), and overall survival (OS).
Results: During a median follow-up of 3.8 years, disease progression was identified in 33 patients (33.7%) and 14 patients (14.3%) died of their disease. Tumour R2* value had a significant difference between with and without progression (P< 0.001). On multivariate analysis, tumour R2* value was significantly independent factor for PFS (hazard ratio [HR]= 1.18, P= 0.001), CSS (HR= 1.25, P= 0.003) and OS (HR= 1.22, P= 0.009), respectively. Of clinical variables, histologic type was significantly independent factor for PFS (HR= 1.02, P= 0.013). For predicting tumour progression, the area under receiver operating characteristic curve of R2* value was 0.724, which was significantly different with other variables (P< 0.001).
Conclusion: As an imaging marker, pretreatment BOLD MRI may be useful for predicting clinical outcome in patients with cervical cancer treated with RT.

B-0651 15:05

Primary vaginal malignancies: a single oncology centre experience
M. Lima[1], G. Rio[2], M. Horta[1], T.M. Cunha[1]; [1]*Lisbon/PT*, [2]*Braga/PT*
(mariana_talina@hotmail.com)

Purpose: Review the clinical and imaging features of primary vaginal neoplasms of a large oncologic referral centre.
Methods and Materials: Retrospective analysis of clinical and MR findings of primary vaginal cancers over a 11-year period (Feb/2006-Sep/2017).
Results: 35 cases were found. The most common histological type was squamous cell carcinoma (SCC) (77,1%), followed by adenocarcinoma (14,3%). Glassy cell carcinoma, melanoma and botryoid sarcoma occurred as single cases. There was no statistically significant difference (p=0,550) in the mean age at diagnosis between SCC (63y) and adenocarcinoma (58y), as well as in the mean size of the tumor (p=0,998; SCC:41.5mm; adenocarcinoma: 41.3mm). SCCs were homogeneous on T2-weighted images, while adenocarcinomas were heterogeneous (one also showed hyperintense areas on T1-weighted imaging). Regarding the location, both SCC(59%) and adenocarcinomas (80%) were predominantly confined to the upper third, while melanoma occurred in the lower third. All adenocarcinomas originated on the anterior vaginal wall, while the majority of SCC originated on the posterior wall (62.5%). The remaining SCCs preferentially involved the right (16.7%)/left vaginal wall (16.7%), however one case showed circumferential involvement. 54% of patients had previous hysterectomy. In the adenocarcinomas group, all were performed for benign pathology; in the SCCs group, 73% were associated with cervical dysplasia (83%CIN III).
Conclusion: The imaging distinction of histological subtypes of vaginal cancer is not possible, although their location and MR signal can provide some clues. Many patients with vaginal SCC had a previous hysterectomy with cervical dysplasia, probably because they may share HPV infection as a risk factor.

B-0652 15:13

Comparison of 18F-FDG PET/MRI and MRI alone for whole-body staging of 71 women with suspected recurrent pelvic cancer: a follow-up study
L.M. Sawicki[1], J. Kirchner[1], J. Grueneisen[2], V. Ruhlmann[2],
B.M. Schaarschmidt[1], M. Forsting[2], K. Herrmann[2], G. Antoch[2], L. Umutlu[2];
[1]*Düsseldorf/DE*, [2]*Essen/DE (Linomorris.sawicki@med.uni-duesseldorf.de)*

Purpose: To evaluate the diagnostic performance of 18F-FDG PET/MRI for whole-body staging of women with suspected recurrent pelvic cancers in comparison with MRI alone.
Methods and Materials: Seventy-one consecutive women (54±13 years) with suspected recurrence of cervical (32), ovarian (26), endometrial (7), vulvar (4), and vaginal (2) cancer underwent PET/MRI including a diagnostic contrast-enhanced MRI protocol. PET/MRI and MRI were separately evaluated regarding lesion count, localisation, categorisation (benign/malignant), and diagnostic confidence (3-point scale; 1-3) by two physicians. Reference standard was histopathology and follow-up imaging. Diagnostic accuracy and proportions of lesions rated correctly were retrospectively compared using McNemar's Chi^2 test. Differences in diagnostic confidence were assessed by Wilcoxon test.
Results: Fifty-five patients showed cancer recurrence. PET/MRI correctly identified more patients with cancer recurrence than MRI alone (100% vs 83.6%, p<0.01). Based on the reference standard, 241 lesions were detected in the study cohort (181 malignant, 60 benign). While PET/MRI provided correct identification of 181/181 (100%) malignant lesions, MRI alone correctly identified 135/181 (74.6%) malignant lesions, which was significantly less compared to PET/MRI (p<0.001). PET/MRI offered superior diagnostic accuracy (99.2% vs 79.3%, p<0.001) and diagnostic confidence in the categorisation of malignant lesions compared with MRI alone (2.7±0.5 vs 2.4±0.7, p<0.001).
Conclusion: PET/MRI demonstrates excellent diagnostic performance and outperforms MRI alone for whole-body staging of women with suspected recurrent pelvic cancer.

Investigating direction of effective connectivity in obsessive compulsive disorder with resting state fMRI
H. Li, X. Hu, L. Zhang, L. Lu, X. Bu, S. Tang, X. Huang; *Chengdu/CN*
(979280614@qq.com)

Purpose: Obsessive-compulsive disorder(OCD) is a common psychiatric disorder characterized by disruption in functional connectivity of certain brain networks. This study aimed to investigate direction of effective connectivity(EC) in OCD by estimating anomalous cross-structure causal effects and to further investigate whether those connectivities would correlate with the severity of clinical symptoms.
Methods and Materials: A total of 88 OCD patients and 88 sex and age matched healthy control(HC) were recruited. We performed bivariate voxel-wise and multivariate ROI-wise Granger Causality(GC) Analysis using the REST-GCA in the REST toolbox. The multivariate GC analysis incorporating regions identified in the bivariate GC analysis. The comparison of group difference were performed using a linear mixed-effects model and the correlations between effective connectivity and clinical variables were performed by Pearson correlation analysis.
Results: Compared with HC, OCD patients showed excitatory EC from pallidum and cerebellum to dorsolateral prefrontal cortex(DLPFC), and from DLPFC to posterior cingulate cortex(PCC), from superior parietal lobule(SPL) to PCC. While inhibitory EC start from middle temporal gyrus(MTG) point to DLPFC. In addition, there is a positive correlation between inhibitory EC from MTG to DLPFC and Hamilton Score for Anxiety in OCD patients.
Conclusion: Our findings for the first time demonstrated the either excitatory or inhibitory effects among these structures implicated in OCD brain network alterations and its correlation with clinical symptom. These findings shed light on our understanding of the OCD pathology from a cerebral network point of view.

Structural magnetic resonance imaging study on schizophrenic patients with violence risk
Y. Li, F. Fan, Z. Feng, W. Liang, S. Tan, F. Yang; *Beijing/CN*
(867840617@qq.com)

Purpose: This study utilized structural MRI with FreeSurfer to assess different brain cortical morphology changes (brain cortical thickness, surface area, volume and mean curvature) in schizophrenic patients with violence risk and to elucidate the correlation between the obtained brain characteristics and clinical parameters.
Methods and Materials: Sixty-six patients were classified into 2 groups (violence: nonviolence group =49:17) based on the MOAS to analyse the brain structure differences. Individuals in each group underwent structural MRI, then, FreeSurfer was used to carry out subsequent brain structure analysis. The statistical software used was SPSS22.0.
Results: There were no statistical differences in gender, age and other clinical information between two groups (P>0.05). Compared with nonviolence group, the violence group showed increased cortical mean curvature in left cingulate sulcus (0.0104±0.0132 vs 0.1131±0.0107, P=0.006), reduced cortical thickness in right postdorsal cingulate gyrus (3.2771±0.2993 vs 2.999±0.2637, P=0.001) and left occipital pole (2.2471±0.2237 vs 2.0971±0.1856, P=0.008). Brain volume showed reductions in left temporal middle gyrus (8734.12±1091.164 vs 7562.33±1195.055, P=0.001), left transverse temporal sulcus (567.71±143.795 vs 466.57±117.752, P=0.005) and right superior frontal sulcus (4503.53±737.935 vs 3856.24±799.814, P=0.005) in violence risk brains. The ROC demonstrated left cingulate and superior precentral sulcus mean curvature can diagnose the schizophrenic violence risk, the AUC is 0.715 (95%CI: 0.566-0.865, P=0.008) and 0.726 (95%CI: 0.578-0.875, P=0.006), respectively. The multinomial logistic regression model adjusting the general clinical information the right postdorsal cingulate gyrus cortical thickness is shown to be an independent factor predicting the violence risk of schizophrenia (OR: 0.003[0.000,0.174], P=0.005).
Conclusion: A reduction in the brain cortex thickness and volume and an increase in the cortical mean curvature may be associated with schizophrenia with violence risk. The right postdorsal cingulate gyrus cortex thickness could predict violence of schizophrenia as an independent factor.

B-0655 14:16

Meta-analysis of resting-state functional connectivity of major depressive disorder in youth

S. Tang, X. Hu, Q. Gong, X. Huang; *Chengdu/CN (731781233@qq.com)*

Purpose: To investigate neural dysfunction in youth with major depressive disorder (MDD) reported in existing resting-state functional connectivity (rsFC) studies.
Methods and Materials: Seed-based rsFC studies comparing youth with MDD with healthy controls (HCs) (published before September 30.2017) were retrieved from electronic databases (PubMed, Web of Science, and EMBASE). Articles that conducted a comparison of youth with MDD aged under 25 and HCs using seed-based rsFC were retained and coordinates of brain regions exhibiting different rsFC in youth with MDD compared with HCs were extracted. Anisotropic effect size-signed differential mapping (AES-SDM) meta-analysis was performed to assess rsFC alterations in 375 youth with MDD compared to 313 HCs.
Results: Compared with HCs, youth with MDD showed hyperconnectivity in the right postcentral gyrus(the main sensory receptive area), left superior frontal gyrus(in coordination with the action of the sensory system), and right heschl gyrus(processing incoming auditory information) and hypoconnectivity in the left middle orbital-frontal gyrus(referring to emotion and reward in decision making).
Conclusion: Increased connectivity in the right postcentral gyrus, left superior frontal gyrus and right heschl gyrus which all involve in sensory perception such as vision, hearing and touch may reflect the biased external to internal sense and cognition processing.Meanwhile,reduced connectivity in the left middle orbital-frontal gyrus implicated in emotion and reward in decision making may give an index to the deficits in internal to external emotion and salience executing. These findings paralleled to the core feature of MDD patients may underlie the cognitive and affective abnormalities in depressive disorder.

B-0656 14:24

Relationship between peripheral Interleukin 10 and white matter integrity in stable medicated schizophrenia

G. Fu[1], W. Zhang[1], J. Liu[1], Y. Xiao[1], L. Yao[1], J.A. Sweeney[1,2], S. Lui[1]; [1]*Chengdu/CN*, [2]*Cincinnati, OH/US (guifu08011991@163.com)*

Purpose: Deficits of white matter integrity have been widely reported in patients with schizophrenia, while the cause of such changes remains unclear. Interleukin 10 (IL-10) was reported to be associated with white matter integrity in animal model. However, it is unknown whether there is any change of IL-10 and related white matter integrity in schizophrenia patients. We aimed to investigate the relationship between peripheral IL-10 level and fractional anisotropy (FA) in stable medicated schizophrenia patients.
Methods and Materials: Diffusion tensor data scanned with 3T SKYRA and IL-10 data tested via quantitative chemiluminescent assay were acquired from 47 stable medicated schizophrenia outpatients and 49 healthy subjects. FA map was processed using FSL 5.0.6 and Tract-Based Spatial Statistics. Correlation analyses controlling for age and gender were conducted to explore the relationships between FA values and IL-10 levels.
Results: There was no significant difference in age and sex between the two groups. Decreased FA was found diffusively distributed, mainly including corpus callosum, bilateral posterior thalamic radiation, right longitudinal fasciculus and left inferior fronto-occipital fasciculus in schizophrenia compared with healthy controls (TFCE $p<0.05$). IL-10 level was higher in schizophrenia than healthy group ($p<0.001$). Interestingly, IL-10 level was negatively correlated with FA among all subjects mainly involving corpus callosum, right posterior thalamic radiation, right superior longitudinal fasciculus, and left inferior fronto-occipital fasciculus ($p<0.05$).
Conclusion: This study shows that dysregulation of IL-10 relates to the changes of white matter integrity in schizophrenia patients, which supports the role of the inflammatory processes in the pathogenesis of schizophrenia.

B-0657 14:32

Support vector machine-based classification of first-episode drug-naïve schizophrenia patients and healthy controls using structural MRI

Y. Xiao[1], Z. Yan[2], Y. Zhao[3], B. Tao[1], Q. Gong[1], S. Lui[1]; [1]*Chengdu/CN*, [2]*Wenzhou/CN*, [3]*Cheng Du/CN (xiaoyuancq@163.com)*

Purpose: Although regional brain deficits have been demonstrated in schizophrenia patients by structural MRI studies, one important question that remains largely unanswered is whether the complex and subtle deficits revealed by MRI could be used as objective biomarkers to discriminate patients from healthy controls individually.
Methods and Materials: To address this question, a total of 326 right-handed participants were recruited, including 163 drug-naïve first-episode schizophrenia (FES) patients and 163 demographically matched healthy controls. High-resolution anatomic data were acquired from all subjects and processed via Freesurfer software to obtain cortical thickness and surface area measurements. Subsequently, the support vector machine (SVM) was used to explore the potential utility for cortical thickness and surface area measurements in the differentiation of individual patients and healthy controls.
Results: The accuracy of correct classification of patients and controls was 85.0% (specificity 87.0%, sensitivity 83.0%) for surface area and 81.8% (specificity 75.0%, sensitivity 88.2%) for cortical thickness ($p < 0.001$ after permutation testing). Regions contributing to classification accuracy mainly included the grey matter in default mode, central executive, salience, and visual networks.
Conclusion: Current findings, in a sample of never-treated FES patients, suggest that the patterns of ill-related grey matter changes has potential as a biomarker for identifying structural brain alterations in individuals with schizophrenia. Future prospective studies are needed to evaluate the utility of imaging biomarkers for research and potentially for clinical purpose.

B-0658 14:40

LHPP gene polymorphism affects spontaneous brain activity in major depressive disorder

L. Cui[1], F. Wang[1], X. Gong[2], M. Chang[1], Z. Yin[1], G. Fan[1], Y. Tang[1], K. Xu[1]; [1]*Shenyang/CN*, [2]*Shanghai/CN (cmu00ring@163.com)*

Purpose: A single-nucleotide polymorphism at the LHPP gene (rs35936514) has been reported in genome-wide association studies to be associated with major depressive disorder (MDD). However, the neural system effects of rs35936514 that mediate the association are unknown. The present work conducts a neuroimaging analysis to explore whether and which brain neural systems are affected by the LHPP rs35936514 polymorphism.
Methods and Materials: A total of 160 subjects were studied: a CC group homozygous for the C allele (23 individuals with MDD and 57 controls) and a T-carrier group carrying the high-risk T allele (CT/TT genotypes; 22 MDD and 58 controls). All participants underwent resting-state functional magnetic resonance imaging (rs-fMRI) scanning. Brain activity was assessed using the amplitudes of low-frequency fluctuations (ALFF).
Results: MDD patients showed a significant increased ALFF in the left middle temporal gyrus and occipital cortex**.** The T-carrier group showed increased ALFF in the left superior temporal gyrus. Significant diagnosis × genotype interaction was noted in the bilateral lingual gyri, bilateral dorsal lateral prefrontal cortex (dlPFC) and left medial prefrontal cortex (mPFC) ($P < 0.05$, corrected).
Conclusion: MDD patients with LHPP rs35936514 CT/TT genotype may influence the regional brain activity. These findings implicate the effects of the rs35936514 variation on the neural system in MDD.

B-0659 14:48

Impaired mixed emotion processing in the right ventrolateral cortex in schizophrenia

A.G. Szabo, L.R. Kozák, K. Farkas, G. Rudas, G. Csukly; *Budapest/HU (szabadam@gmail.com)*

Purpose: My thesis is about the differences of brain activity between schizophrenic patients and healthy controls, when they are about to recognize mixed emotions. Schizophrenia has negative effect on the processing of emotional facial expressions, as proved by multiple previous studies. While most of these research used the standard Ekman dataset, we aimed to reflect on everyday life situations a more complex way than the limited set of facial expressions presented by Ekman's actors.
Methods and Materials: Age- and education-matched healthy controls (18) and patients with schizophrenia (19) were enrolled in an fMRI experiment, using a set of 10 fearful, 10 happy, 10 mixed fear (70% fear and 30% happy) and 10 mixed happy (70% happy and 30% fear) facial expressions, the mixed expressions created by the software Morph from Ekman images. The images were presented in a randomized order and subjects had to categorize expressions by button presses. Data analysis was performed in SPM, and resulting maps further analysed using *ICN_Atlasing* toolbox.
Results: The patient group showed decreased fMRI activation during fear, mixed fear and mixed happy conditions in the right ventrolateral prefrontal cortex (VLPFC) and the right anterior insula (RAI) at the voxel and cluster level after family-wise error correction. No difference was found between study groups in activations for happy faces.
Conclusion: Using mixed emotions opens a new avenue in schizophrenia research, pointing out the importance of VLPFC in emotion recognition and decision making, e.g. its decreased activation in schizophrenia affects fear recognition.

B-0661 14:56

A fMRI comparison of paediatric patients with obsessive-compulsive disorder and controls during a Stroop task

I. Duman, G. Ekinci, A.R. Arman, H. Aslan, E.B. Usta, G.O. Bilim, M. Kavus; *Istanbul/TR (edda_ikram@hotmail.com)*

Purpose: It has been suggested that abnormal inhibitory networks may be implicated in the pathophysiology of obsessive-compulsive disorder (OCD) and could account for the disorder's core symptom. The study aimed to investigate abnormalities in brain regions mediating cognitive response inhibition and attention allocation (basic demanding task) during the performance of coloured-card Stroop task using functional magnetic resonance imaging (fMRI) in children and adolescent with OCD compared to healthy controls.
Methods and Materials: Block-design fMRI was used to compare brain activation in 7 children and adolescents with OCD with that of 8 matched controls during a Stroop task of response inhibition and basic demanding conditions.
Results: No patient had comorbidity besides OCD. During the basic demanding task, participants with OCD showed reduced activation in the bilateral frontal, insular, parietotemporal regions ($p<0.05$, uncorrected). During response inhibition task, OCD group showed reduced activation in the left middle frontal gyrus (dlPFC), right frontal medial cortex (FMC), left anterior cingulate cortex (ACC), bilateral inferior frontal gyri, orbitofrontal cortices (OFC), insular, parietotemporal regions, basal ganglia, and thalamus ($p<0.05$, uncorrected). When we compared the basic demanding status with the response inhibition condition, the OCD group showed decreased activation only during the response inhibition task in the right FMC, left ACC, bilateral OFC, basal ganglia and thalamus.
Conclusion: The results of the present study support the hypothesis that frontostriatothalamic regions and ACC play effective role in response inhibition in childhood OCD, and also demonstrate dysfunction of left dlPFC, temporoparietal regions, and insular cortices during attention allocation.

B-0662 15:04

Posttraumatic stress disorder-related alterations in modular characteristic and white matter connectivity of brain structural networks

X. Suo[1], D. Lei[2], Q. Gong[1]; [1]*Chengdu/CN*, [2]*London/UK (1107229715@qq.com)*

Purpose: Although previous studies reported altered topology of brain network in posttraumatic stress disorder (PTSD), the modular organization of brain network remains largely unknown. This study aims to examine the topologic alterations of brain white matter structural network in PTSD at global, modular and nodal levels.
Methods and Materials: Diffusion tensor imaging and graph theory approaches were used to investigate the topologic organization of the brain structural network in 76 PTSD patients and 76 age-, gender-, and years of education-matched trauma-exposed non-PTSD controls. Individual white matter networks were constructed for each participant, and the global, modular and nodal measurements of the networks between two groups were compared with nonparametric permutation tests.
Results: At global level, the PTSD showed lower clustering coefficient ($P = 0.0156$) and normalized characteristic path length ($P = 0.0348$) compared with non-PTSD controls. At modular level, the patients demonstrated significantly increased between-module connections between fronto-parietal module, fronto-striatal-temporal module and default mode network. At node level, increased nodal centralities in the common frontal, temporal and occipital regions were found ($P < 0.05$, FDR corrected). The clinician-administered PTSD scale score was positively correlated with the nodal efficiency of left inferior temporal gyrus ($r = 0.354$, $P = 0.002$).
Conclusion: The structural brain network showed a shift toward 'randomization' in the PTSD group, indicated by increased between-modular connections with increased nodal centralities involving frontal-temporal-occipital regions. The disassociation between the current structural and previous functional connectome studies suggests that the neural activity is shaped, but not limited by the underlying anatomy.

B-0663 15:12

Structural and functional brain abnormalities in schizophrenia: a cross-sectional study at different stages of the disease

C. Zhao; *Beijing/CN (zhaochaoxy@163.com)*

Purpose: To investigate the grey matter volume (GMV) and neural activity alterations in subjects at 4 different stages of schizophrenia.
Methods and Materials: The subjects comprised 53 genetic high-risk (HR) individuals, 26 ultrahigh-risk (UHR) individuals, 58 first-episode schizophrenia (FES) patients, 41 chronic schizophrenia (ChSz) patients and 39 healthy controls (HC). They underwent structural and resting-state functional MRI scanning. GMV, amplitude of low-frequency fluctuations (ALFF) and regional homogeneity (ReHo) values were compared among the 5 groups using voxel-based morphometry and the software REST. Relationships between these alterations and symptoms in FES group were evaluated by partial correlation analysis.
Results: GMV decline was observed in the bilateral occipital lobe, left orbital frontal cortex, bilateral superior parietal lobule (SPL), right middle temporal gyrus (MTG), gyrus rectus and medial superior frontal gyrus (SFG) in FES group and in the bilateral occipital lobe in HR group. FES group showed increased ALFF in the caudate and decreased ReHo in the bilateral inferior parietal lobule (IPL) and precuneus. ChSz group showed increased ALFF in the right hippocampus. GMV of the right MTG and SPL and ReHo of the precuneus were negatively correlated with the general score, while GMV of the right MTG was negatively correlated with the total score on the positive and negative syndrome scale.
Conclusion: Structural and functional deficits are prior to symptoms and are more prominent at the onset of illness than other phases. The prefrontal cortex, right MTG, striatum and default mode network play important roles in the pathogenesis of schizophrenia.

Sonographic features of medullary thyroid carcinoma: application of Thyroid Imaging Reporting and Data System (TIRADS) classification

G. Yun, Y. Kim, S. Choi; *Seongnam-Si/KR (gabinyun@gmail.com)*

Purpose: To evaluate the performance of the Korean Thyroid Imaging Reporting and Data System (K-TIRADS) for medullary thyroid carcinoma (MTC) and to report the sonographic characteristics of MTC.
Methods and Materials: The ultrasound (US) images and medical records of MTC patients diagnosed on the basis of cytopathologic results from June 2003 to November 2016 were retrospectively reviewed. Four independent reviewers (two experienced radiologists and two 1st year residents) reviewed fifty-seven pre-operative US images of MTC patients for shape, composition, echogenicity, margin and calcification of the MTC nodules and categorized the nodules using K-TIRADS classification. The metastatic lymph nodes were assessed for cystic change, echogenicity, the presence of fatty hilum and microcalcification. Inter-observer agreement for K-TIRADS was assessed with weighted kappa statistics.
Results: Ninety-five percent of nodules were classified as having either high suspicion (68.4%) or intermediate suspicion (26.3%). K-TIRADS score was significantly higher in MTCs with lymph node metastasis ($p=.003$). The predominant sonographic findings of MTCs were solid content (87.7%) and hypoechogenicity (99.5%). Suspicious lymph nodes were present in 28% of MTCs, which showed solid component (81.3%), heterogeneous echogenicity (50%), loss of fatty hilum (93.7%), microcalcification (68.8%) and hypervascularity (86%). MTCs showing irregular shape, microcalcification and presence of ETE were associated with lymph node metastases ($p = .008$, .001, 021, respectively). The inter-rater agreement was good (weighted kappa 0.82) between the two experienced reviewers, and the inexperienced reviewers also showed good agreement with the most experienced reviewer (weighted kappa 0.73 and 0.81).
Conclusion: The K-TIRADS classification performed well in MTC nodules with good inter-observer agreement.

B-0666 14:08

Can valuable information be derived from the exploitation of quality maps along elasticity maps in SWE of thyroid nodules?

L. Chami[1,1], G. Bera[1], M. Lefort[1], J. Griffon[1], O. Lucidarme[1,1], C. Pellot-Barakat[2]; [1]*Paris/FR*, [2]*Orsay/FR (linda.chami@yahoo.com)*

Purpose: Quality maps are now provided together with elasticity maps on Shear wave elastography (SWE) Aixplorer systems (Supersonic Imagine, France). The purpose was to evaluate how to improve reliability and reproducibility of SWE measurements in thyroid nodules.
Methods and Materials: 50 thyroid nodules from 46 patients (33 w, 9 m, 56±15 yrs) scheduled for fine needle biopsy were prospectively included. 4 nodules with non- diagnostic cytology were excluded. 3 SWE measurements were obtained repetively in longitudinal and transversal plane resulting in 300 measurements. Mean elasticity values (ME), mean quality coefficients (MQC), ratio ME nodule/thyroïd and ME long/trans were computed. Coefficients of variation of elasticity values (CV_E) were computed for reproducibility study. Spearmans coefficients and Student T-tests were used for statistical analysis.

Results: Neither ME values nor the ratio ME nodule/thyroid were significantly different for benign (N= 34/50) and malignant (N=12/50) nodules (ME values: 18.4±9.7 kPa vs 21.1±8.6 kPa and 12.8±6.1 vs 8.5±3.5 kPa in the longitudinal and transversal plane respectively; ratio : 1.23+/-0.61 vs 1.25+/-0.72 (NS)). The ratio ME long/trans was significantly lower for benign nodules (1.55±0.91 vs 2.67±1.29 (p=0.05)). MQC values were significantly higher in the longitudinal plane than in the transversal one (0.73±0.11 vs 0.63±0.10, $p < 0.001$). A significant correlation was found between MQC and CV_E (r=0.46, $p = 0.0015$).
Conclusion: The ratio ME longitudinal/transversal was the only parameter that allowed to discriminate benign from malignant thyroid nodules. Quality maps were higher in longitudinal plane and SWE reproducibility was improved for the measurements with the highest quality.

B-0667 14:16

Atypical ultrasonographic patterns of papillary thyroid carcinoma: how to recognise them

E. Horvath, G. Aguilera, C. Silva, M. Droguett, V.S. Skoknic, H. Tala, S. Majlis, J. Slater, C. Whittle; *Santiago/CL (velimir.skoknic@gmail.com)*

Purpose: To analyse the atypical papillary thyroid carcinoma (PTC) US patterns, comparing them with typical cases, and to describe their main characteristics.
Methods and Materials: A retrospective review of thyroidectomies between 2013 and 2016 with PTC was conducted. Classical PTCs (Group A) were separated from those that showed atypical patterns (Group B). These were compared according to age, gender, size, histological subtype and association with Hashimoto's thyroiditis (HT). Shapiro-Wilk, chi-squared, Student's t tests or Mann-Whitney-Wilcoxon tests were used.
Results: A total of 453 PTC met inclusion criteria. In 51 cases (11.2%) [19 men (38%), median age 41 years (14-68)], an atypical pattern was observed. Median size: 14 mm (5-50 mm), 32 (63%)> 10 mm. 27% were associated with HT. A significant difference was found between Groups A and B in terms of gender ($p <0.025$), size ($p <0.001$) and histological subgroup ($p <0.01$), with more men, larger lesions and more follicular variant of PTC with atypical pattern. The dominant characteristics observed in Group B were: solid-cystic mixed structure, similar to colloid nodule but without hyperechoic foci in 23 (45%), isoechogenicity in 19 (37%) and presence of capsule in 20 (40%), findings that were shared in the majority of the cases, with or without association with calcifications. In addition, pooled microcalcifications without associated nodule were detected in 6 cases (12%).
Conclusion: One in every 10 PTCs has an atypical ultrasound appearance. It is important to recognise the characteristics described as concerning for malignancy to recommend FNAs in a timely manner, since 63% are macrocarcinomas.

B-0668 14:24

Can S-detect provide accurate differentiation of thyroid nodules? - assessing the impact on the assessment made by operators with different experience

G. Alagna, V. Cantisani, V. Forte, V. De Soccio, N. Di Leo, A. Rubini, M. Di Segni, F. D'Ambrosio, C. Catalano; *Rome/IT (gralagna@gmail.com)*

Purpose: To assess whether automatic TI-RADS assessment with S-Detect could be reliable in the differentiation of thyroid nodules.
Methods and Materials: One hundred seventy eight FNAB proven nodules in 106 patients (77 females, 29 males, aged 13-85 years, mean 55.3), were evaluated by a radiologist and a radiology resident. Operators assessed and categorized lesions without and with S-detect, using Kwak's TI-RADS. Sensitivity (SE), specificity (SPE), positive and negative predictive values (PPV, NPV), diagnostic accuracy through McNemar's test were calculated. Differences significance was assessed with Pearson's χ^2 test, with a $p= 0.05$ threshold.
Results: At FNAB, 13 nodules on 178 (7.3%) were malignant, 27 out of 178 (15.1%) at high risk, 110 on 178 (61.8%) probably benign and 28 out of 178 (15.7%) were certainly benign.Nodules categorization according to S-detect, radiologist and resident was as follows: TIRADS 2: 27, 26, 26; TIRADS 3: 112, 112, 105; TIRADS 4: 29, 30, 39; TIRADS 5: 10, 10, 8. When S-detect was not employed, SE, SPE, PPV and NPV were 83.5%, 93.5%, 85.2%, 89.6% for the experienced radiologist and 75.6%, 86.4%%, 70.4% and 96.9% for the radiology resident, respectively. When S-detect was employed, SE, SPE, PPV and NPV 84.8%, 97.1%, 90.7%, 95.1%, for the experienced radiologist and 84.8%, 97.1%, 90.7%, 95.1% for the resident. No statistically significant difference in diagnostic performance was noted for the radiologist, whereas it resulted significant for the resident.
Conclusion: According to these results, S-Detect is a useful tool since it improves thyroid nodule differentiation accuracy of the non-experienced operator.

Quantitative analysis of ADC values in differentiating papillary thyroid carcinoma and thyroid adenoma

S. Hu; *Zhenjiang/CN (hsd2001054@163.com)*

Purpose: To explore the differential diagnosis value of ADC value of PTC and thyroid adenoma (TA).
Methods and Materials: Routine MRI sequences and axial diffusion weighted sequences of neck with different b values (300,500,800 s/mm^2) were performed in 34 patients with 43 nodules (including 37 PTCs and 6 TAs) confirmed by pathology. The ADC value of the solid component of each lesion was measured respectively. Independent samples *t* test was used to evaluate whether the ADC values had significant differences between the two lesions. Receiver operating characteristic (ROC) curves were drawn and used to evaluate the diagnosis value of ADC values in PTC and TA.
Results: The ADC value of PTC is lower than the one of TA with a significant difference statistically in all different b values. The average ADC values of PTC and TA were 1.791±0.544×10−3 mm^2/s and 2.528±0.642×10−3 mm^2/s (b-value 300 s/mm^2), 1.510±0.453×10−3 mm^2/s and 2.138±0.656×10^{-3} mm^2/s (b-value 500 s/mm^2), and 1.305±0.419×10−3 mm^2/s and 1.906±0.643×10^{-3} mm^2/s (b-value 800 s/mm^2), respectively. The highest diagnostic accuracy can be obtained with a b-value of 300 s/mm^2 with the area under the curve of 0.815. When the b-value was selected as 300 s/mm^2 and the diagnostic threshold was 1.786×10−3 mm^2/s according to the ROC curve, the sensitivity, specificity, positive predictive value, negative predictive value and Youden Index were 62.6%, 100%, 100%, 30.0% and 62.6, respectively.
Conclusion: The ADC value is helpful in the differentiation of PTC and TA, and a better result can be achieved by using a DWI with a b-value of 300 s/mm^2.

B-0670 14:40

A novel mobile phone app to minimise bias and aid the FNAC decision-making process

A. McDermott, P. Navin, T. Tarmey, A. Weir, D. Bergin, J.F. Bruzzi, B. Voisin, D. Sheppard; *Galway/IE (ailbhemcdermott@gmail.com)*

Purpose: Ultrasound is the modality of choice to help differentiate between benign and malignant thyroid nodules. The investigation algorithm on whether or not to perform FNAC takes into account several sonographic features of different weighting, and is not clear-cut. The decision is facilitated by a number of international guidelines. This study aims to address the sensitivity of the available guidelines in recommending FNAC. We then present and assess the clinical utility of a novel user-friendly mobile-phone 'app' to facilitate decision-making.
Methods and Materials: 200 consecutive thyroid FNAC cases between 2013 and 2014 were retrieved. Imaging was blindly reviewed by 4 subjects. The decision regarding FNAC was determined: 1. using guidelines (AACE, ASRU, ATA, BTA, Korean) in read-only format; 2. using an interactive locally derived 'app' incorporating sonographic features and presenting various guideline recommendations, including TI-RADS. Statistical analysis was performed using 'R' and SPSS.
Results: In read-only format, the highest sensitivity was achieved with ATA (88.2%) and Korean (88.3%) guidelines. However, there was inter-user variability. The incorporation of specific sonographic features into an app (yes/no format) provides an overall sensitivity of 80% (new TI-RADS), 91% (AACE) and 96% (Korean), thus increasing the appropriateness of FNAC. In addition, the app significantly reduced inter-user variability ($p<0.001$), thus minimising discrepancy.
Conclusion: Even when presented with international guidelines there are inconsistencies in the decision on when to perform FNAC. We describe the performance of widely-applied international guidelines in clinical practice, and present a novel 'app' to standardise the decision-making process and minimise the potential for human bias.

B-0671 14:48

Comparison of the clinical utility of international guidelines to aid the decision on when to perform FNAC for thyroid nodules

A. McDermott, P. Navin, A. Weir, T. Tarmey, J.F. Bruzzi, B. Voisin, D. Sheppard; *Galway/IE (ailbhemcdermott@gmail.com)*

Purpose: Thyroid nodules are a common finding. The decision on whether to perform fine-needle aspiration cytology to dissociate benign from malignant nodules is complex. A number of international guidelines, including the recent ACR TIRADS, incorporate sonographic features of different weighting to facilitate the decision-making process. This study compares commonly used international guidelines and their clinical utility for appropriate nodule FNAC.
Methods and Materials: Consecutive thyroid FNAC cases between 2013 and 2014 were retrieved. Sonographic features were reviewed and the recommendation on whether to perform FNAC or not based on international

guidelines (ACR TIRADS, AACE, ASRU, ATA, Kim and Korean) was analysed. Data were analysed using R statistical software package.
Results: 200 patients who underwent thyroid nodule FNAC during the study time period were included. The mean age was 55.1±15.6 years, with 83% women. The new ACR TIRADS guidelines provided a sensitivity of 81% and a specificity of 32%. The best sensitivity (appropriate sampling of cancer cases) was achieved from the application of the Korean guidelines (96%, specificity 0.075%). However, the best specificity (true-negative rate) was achieved from the ASRU guidelines (49%, sensitivity 64%).
Conclusion: Despite numerous internationally available guidelines, no guideline satisfactorily achieves a combination of high sensitivity and specificity. The new ACR TI-RADS guidelines provide a sensitivity and specificity of 81 and 32%, respectively.

B-0672 14:56

Diagnostic performance of US-based fine-needle aspiration criteria for thyroid malignancy: comparison of three international society thyroid imaging reporting and data systems

S. Yoon, D. Na, H. Gwon; *Gangneung/KR (ysj-626@hanmail.net)*

Purpose: Thyroid imaging reporting and data system (TIRADS) is the quantitative scoring system for malignancy risk stratification of thyroid nodules. The aim was to compare the diagnostic performance of US-based FNA criteria for the detection of thyroid malignancy among recently proposed three international society TIRADS including Korean-TIRADS, ACR-TIRADS, and EU-TIRADS.
Methods and Materials: This study included a total of 1081 consecutive thyroid nodules (≥ 1 cm) in 898 patients with final diagnoses from January 2013 to December 2015. US features of thyroid nodules were retrospectively reviewed and classified according to the categories defined by the three international society TIRADS. The diagnostic performance of US-based FNA criteria for the detection of thyroid malignancy and unnecessary FNA rates were calculated and compared among the three TIRADS.
Results: Of the 1081 thyroid nodules, 940 (87%) were benign and 141 (13%) were malignant, with papillary carcinoma comprising 93.6% of all malignancies. The Korean-TIRADS (96.5%) and EU-TIRADS (92.9%) were more sensitive for the detection of malignancy than ACR-TIRADS (79.4%) ($p < 0.001$), while the ACR-TIRADS (67.4%) had a higher specificity than Korean-TIRADS (22.6%) or EU-TIRADS (23.2%) ($p < 0.001$). The unnecessary FNA rate was lower in the ACR-TIRADS (28.3%) than that in Korean-TIRADS (67.3%) or EU-TIRADS (66.8%). There was no significant difference in sensitivity, specificity, and the unnecessary FNA rate between Korean-TIRADS and EU-TIRADS ($p \geq 0.125$).
Conclusion: Korean-TIRADS and EU-TIRADS had a similarly higher sensitivity for malignancy than ACR-TIRADS; however, those had a lower specificity and higher unnecessary FNA rates than ACR-TIRADS.

B-0673 15:04

Ectopic parathyroids: incidence, localisation trends and diagnostic evaluation: retrospective study from a single tertiary institute

A.A. Singhal, S.S. Baijal, D. Sarin, S.K. Arora, A. Mithal, S. Mishra; *Gurgaon/IN (DR.ALKAASINGHAL@GMAIL.COM)*

Purpose: Aim is to evaluate the incidence of ectopic parathyroids, their localisation, diagnostic evaluation and surgical confirmation.
Methods and Materials: Retrospective study conducted at a tertiary institution, where 400 patients operated for hyperparathyroidism from 2012 to 2017 was analysed. Diagnostic findings of Sestamibi and ultrasound were compared with surgical findings. SPECT CT was used in select cases.
Results: Of 400 patients single adenoma was seen in 350 patients (87.5%), two or more nodules in 41 patients (10.2%), and carcinoma in 3 cases. Of the 350 solitary adenomas, 291 were juxtaposed to thyroid (83.1%), and ectopic in 59 (16.8%) cases. Ectopic along the thymic tract in 38 cases (10.8%), upper mediastinum 8 cases (2.2%), angle of jaw in 2 cases (0.5%), carotid sheath 2 cases (0.5 %),retroesophageal 2 cases (0.5%) and intrathyroidal in 7 cases (2%). Sestamibi was positive in localising parathyroid nodule in 297 (84.8%) cases, and ultrasound in 339 (96.8%) cases. Of the localised sestamibi nodules 82% were true and 3% were false localisation at surgery. Nodules localised by Ultrasound were true in 99 % and false in 1% cases. Ultrasound localised the nodules in sestamibi negative cases in 12% patients.
Conclusion: Identification of ectopic parathyroids and differentiation from thyroid nodules and other neck lesions is the key role of imaging. Ultrasound is complimentary to MIBI and offers significant value addition by precision anatomical localisation, characterisation and finding additional nodules. Using two imaging modalities of MIBI and ultrasound, the diagnostic sensitivity is 99% and specificity is 98%.

B-0674 15:12

The diagnostic value of 4D MRI for the localisation of parathyroid adenomas

M. Ozturk, A.V. Polat, C. Celenk, M. Elmali, C. Polat; *Samsun/TR (dr.mesutozturk@gmail.com)*

Purpose: The aim of this study was to assess the feasibility of 4-dimensional magnetic resonance imaging (4D MRI) for the localisation of parathyroid adenomas in patients with primary hyperparathyroidism.
Methods and Materials: Preoperative 4D MRI including dynamic contrast-enhanced (DCE) sequence and T2-weighted multipoint Dixon (T2-mDixon) sequence with in-phase, out-phase and, fat-suppressed images in 31 patients with surgically proved parathyroid adenomas were evaluated retrospectively. Two readers blinded to surgical findings independently reviewed the images in two sessions (T2-mDixon sequence alone and T2-mDixon + DCE sequence). MRI localisation of the suspected adenoma in each session was compared with the surgical results and interobserver variability (weighted kappa [κ]) was assessed.
Results: By interpreting the T2-mDixon images alone, reader 1 correctly detected 26 parathyroid adenomas (sensitivity: 84%, positive predictive value: 90%) and reader 2 correctly detected 24 parathyroid adenomas (sensitivity: 77%, positive predictive value: 92%). With the addition of DCE sequence, reader 1 correctly identified 27 parathyroid adenomas (sensitivity: 87%, positive predictive value: 90%) while reader 2 correctly identified 26 parathyroid adenomas (sensitivity: 84%, positive predictive value: 93%). Interobserver agreement was also superior in T2-mDixon + DCE sequence compared to T2-mDixon sequence alone (κ = 0.81 and 0.74, respectively).
Conclusion: 4D MRI with T2-mDixon and DCE sequence is a reliable method for identification of parathyroid adenomas.

Incidence and tumour characteristics of bilateral and unilateral interval breast cancers at screening mammography

R.M.G. van Bommel; *Eindhoven/NL (rob_van_bommel@hotmail.com)*

Purpose: Detected by screening mammography, bilateral breast cancer has a different pathological profile compared to unilateral breast cancer. We investigated the incidence of bilateral interval breast cancers and compared their characteristics with those of unilateral interval breast cancers.
Methods and Materials: We included all screening mammograms of women who underwent biennial screening mammography in the South of the Netherlands between January 2005 and January 2015. We collected breast imaging reports, biopsy results and surgical reports of all referred women and of all women who presented with interval breast cancer. The tumour with the highest tumour stage (index cancer) was used for comparison with unilateral interval cancers.
Results: A total of 753 interval cancers were detected, of which 24 (3.2%) were bilateral. Among the invasive interval cancers, bilateral cancers more frequently showed a lobular histology than unilateral cancers (37.5% (9/24) vs. 16.1 % (111/691), P=0.01). There is a trend towards a larger proportion of bilateral than unilateral interval cancers graded 1 (45.8% (11/24) vs. 27.8% (192/691), P=0.08). There were no other statistically significant differences in tumour characteristics. Also, the proportion of missed cancers on the latest screen was comparable for unilateral and bilateral interval cancers (23.0% vs. 25.0%, P=0.9).
Conclusion: Bilateral interval cancers comprise a small proportion of all interval cancers. Except of a higher proportion of invasive lobular cancers and a more favourable histological grade of invasive cancers, tumour characteristics are comparable for bilateral and unilateral interval breast cancers.

B-0676 14:08

Missed and true screen-detected and interval breast cancers in a population-based breast cancer screening programme

T. Hovda[1], Å.S. Holen[2], H. Bjørndal[1], S. Sebuødegård[2], S. Hofvind[2]; [1]*Drammen/NO*, [2]*Oslo/NO (tone.hovda@vestreviken.no)*

Purpose: To describe the distribution of missed and true screen-detected (SDC) and interval (IC) breast cancer after a retrospective informed consensus review in a biennial population-based breast cancer screening programme.
Methods and Materials: We performed a consensus-based informed review of randomly selected cases of SDC and IC detected at eight breast centers in BreastScreen Norway. Prior screening and diagnostic digital mammograms were used. A panel of five breast radiologists (minimum 1 year experience with high volume screen-reading), reviewed and classified 648 SDC and 532 IC cases according to visibility of the breast tumor at prior screening mammograms (missed, minimal sign actionable, minimal sign non-actionable, true, and occult), and mammographic density (BI-RADS 5th edition, a-d). We used descriptive statistics to describe the distributions of classification, stratified by detection mode (SDC and IC).
Results: Among the SDC, 163 (25%) were classified as missed, 95 (15%) minimal sign actionable, 108 (17%) minimal sign non-actionable, 281 (43%) true, and one case as occult. For the IC: 133 (25%) were missed, 79 (15%) minimal sign actionable, 77 (15%) minimal sign non-actionable, 178 (34%) true, and 65 (12%) occult. 67% of the SDC were classified as BI-RADS a or b and 33% as c or d. For IC, 50% were BI-RADS a or b and 50 % c or d.
Conclusion: In this retrospective informed review, 40% of cancers were visible at prior screening (missed or minimal sign actionable), regardless of detection mode. A higher mammographic density was observed among IC compared to SDC.

B-0677 14:16

Interval breast cancer rates and histopathologic tumour characteristics after false-positive screening result in a population-based screening programme

S. Sebuødegård, S. Hofvind; *Oslo/NO (solveig.hofvind@kreftregisteret.no)*

Purpose: To compare rates and tumour characteristics of interval breast cancers (IBC) detected after a prior screening negative versus false-positive result among women who participated in BreastScreen Norway.
Methods and Materials: The study included 497,694 women aged 49-71 years who underwent 1,179,645 mammographic screening examinations during 2004-2014. Rates and odds ratio (OR) of IBC among women with a prior negative (reference group) versus false-positive result were estimated using logistic regression models, adjusting for age at diagnosis, year of screening and county of residence.
Results: Among 1,999 IBC, 32 (2%) and 86 (4%) were detected in women with a false-positive result with and without needle biopsy, respectively. The rate of IBC was 16.4 (95%CI: 15.7-17.2) for women with a prior negative result, and 45.6 (95%CI: 32.3-64.5) and 43.0 (95%CI: 34.8-53.0) for women with a prior false-positive result with and without needle biopsy, respectively. Adjusted ORs of IBC were 2.9 (95% CI: 2.1-4.2) and 2.8 (95% CI: 2.2-3.4) for women with a false-positive result with and without needle biopsy, respectively, relative to women with a negative result. Women with a prior negative result had a lower proportion of tumours ≤10 mm and Grade I tumours compared to women with a prior false-positive result with benign biopsy (15% [248/1,634] versus 40% [8/20], p<0.01, and 14% [243/1,725] versus 45% [9/20], p<0.01).
Conclusion: Women with a false-positive screening result had a higher odds of IBC, but more favorable tumour characteristics of IBC compared to women with a prior negative screening result.

B-0678 14:24

Comparison between interval breast cancer (IBC) and screen detected cancer (SDC) in a single centre

F. Currò, M. Tonutti, F. Giudici, F. Zanconati, M. Bortul, M.A. Cova; *Trieste/IT (francescacurro86@gmail.com)*

Purpose: The introduction of the breast screening program (BSP) raised the problematic of interval breast cancer (IBC). The aim of this study was to evaluate the performance of BSP and the prognostic features of screen detected cancer (SDC) compared to IBC.
Methods and Materials: Women diagnosed with breast cancer (SDC and IBC) between January 2008 and December 2014 at a single unit of the BSP in Trieste (Italy) were included. We retrospectively collected data concerning patient's demographics, radiological patterns, tumour size, lymph node involvement, grading, and molecular biology. The proportional incidence of IBC was determined considering the incidence of expected breast cancers without BSP.
Results: There were 640 breast cancers included (626 women, 14 bilateral): 520 (81%) were SDC and 120 were IBC (19%). The proportional incidence of IBC was 15.3% and the sensitivity of the BSP was 83%**.** IBC presented more aggressive features compared to SDC, such as tumor invasion (95% vs 85%; *p*=0.005), tumor size (≥pT2 36% *vs* 20%; *p*=0.0003), grading (G3 38% *vs* 19%; *p*<0.001) and St.Gallen molecular subtype (triple negative 12% *vs* 6%; *p*<0.001). IBC were mostly diagnosed in women with dense breasts (density c and d: 45% vs. 24%; *p*<0.001) and were hardly detectable with mammography (R1 14% vs. 1%, *p*<0.001). There were no significant differences in lymph node involvement (p=0.4).
Conclusion: The proportional incidence of IBC and the sensitivity of the BSP, indicators of efficacy, were aligned to European standard. IBC had more adverse prognostic markers for overall survival when compared to SDC

B-0680 14:32

Detection of multiple cancers in a large UK screening population

S. Dumonteil, L.S. Wilkinson, S. Mohammadi, V. Scott; *London/UK (scott.victoria@gmail.com)*

Purpose: Imaging protocols at assessment of women recalled based on their screening mammograms are inconsistent across UK screening units. At our institution we carry out bilateral whole breast ultrasound on all women with a suspicious ultrasound lesion. The purpose of this study was to quantify the number of multiple cancers detected and how many of these were identified as a result of completion ultrasound imaging or further review of the screening mammogram.
Methods and Materials: The assessment results of 16,244 consecutive women assessed in screening clinic at the South West London Breast Screening Service between 2008 and 2016 were retrospectively analysed. Cancer detection rate and number of multiple cancers were calculated. Imaging from the multiple cancers was reviewed to assess how many extra cancers were detected due to local practice.
Results: From 2008 to 2016, 16,244 individual women were assessed in screening clinic and 8,136 (50%) women had at least 1 biopsy. 34% of assessment episodes (2,821 of 8,284) resulted in the detection of cancer. 351 (12%) were multiple cancers, 288 (10%) being ipsilateral and 63 (2%) being contralateral. A review of the imaging from the multiple cancers revealed that approximately one third of the extra cancers were identified as a result of our local protocols for women with a suspicious lesion on initial targeted ultrasound.
Conclusion: Bilateral whole-breast ultrasound and careful review of the screening mammograms in women with a suspicious lesion leads to significant increased detection rate of multiple breast cancers.

B-0681 14:40

Attendance in BreastScreen Norway by proportion of immigrants in a county

S. Bhargava, G. Mangerud, S. Hofvind; *Oslo/NO (sameer.bhargava@kreftregisteret.no)*

Purpose: To examine whether the attendance rate among immigrants and non-immigrants in BreastScreen Norway was associated with the proportion of immigrants residing in the counties.
Methods and Materials: We selected invitations sent to women living in counties with a low (<5% of invitations sent to immigrants) or a high proportion of immigrants (>10% of invitations sent to immigrants), hereafter referred to as low- and high-density counties, respectively. We merged data about birth country and socio-demographic factors from Statistics Norway with screening data from the Cancer Registry of Norway. The study period was 2005-2015. For both immigrants and non-immigrants, unadjusted and adjusted rate ratios (RR) with 95% confidence intervals (95% CI) compared attendance rates in low- and high-density counties.
Results: Women in the six low-density counties received 852,193 invitations, and women in Oslo, the capital city and the only high-density county, received 277,229 invitations. Attendance rates were 76.9% in low-density counties and 63.1% in Oslo. Using Oslo as reference, RR of attendance was 1.26 (95% CI 1.24-1.28) for immigrants and 1.16 (95% CI 1.16-1.16) for non-immigrants in low-density counties. Adjusted RR was 1.16 (95% CI 1.14-1.17) for immigrants and 1.14 (95% CI 1.14-1.14) for non-immigrants.
Conclusion: Immigrants and non-immigrants in Oslo had lower attendance than the same groups of women living in low-density counties. Efforts to increase attendance in urban areas should target both immigrants and other low-attending groups.

Comparison of phantom target detectability for digital mammograms, tomosynthesis and synthetic mammograms

L. Vancoillie, L. Cockmartin, N. Marshall, H. Bosmans; *Leuven/BE (liesbeth.vancoillie@uzleuven.be)*

Purpose: To compare target detectability in digital mammography (FFDM), digital breast tomosynthesis (DBT) and synthetic mammograms (SM) using two contrast detail phantoms: CDMAM (homogeneous background) and a 3D

phantom developed in-house with calcification and mass lesion-like inserts ('L1') in a structured background.
Methods and Materials: Detectability was measured for FFDM, DBT and SM acquisitions of the phantoms on a Siemens Inspiration Prime. Dose settings were derived from automatic exposure control (AEC), and then manually set at three levels: AEC/2, AEC and 2xAEC, with 10 acquisitions per dose level. Both phantoms were read manually using the 4 alternative forced choice (4-AFC) method. Threshold thickness (T_T) was established for CDMAM while threshold diameter (d_T) was found for L1, both calculated for a 62.5% correct score. Software (CDCOM-based) scoring of the CDMAM images was also performed.
Results: CDCOM followed human reading and ranked threshold thickness as a function of dose the same way as did the human readers. Both the CDMAM T_T results for 0.1 mm diameter discs and the L1 d_T results showed small detail (~microcalcification) detectability was greatest for FFDM, followed by DBT and then SM ($p<0.0001$). The L1 phantom (i.e. with structured background relevant to mass lesion detection) showed better mass-like lesion detection for DBT, followed by SM, with FFDM having the worst performance ($p<0.0001$).
Conclusion: For detection of microcalcification-like details, both phantoms ranked imaging modality detectability as FFDM>DBT>SM. For detection of mass-like lesions in a structured background, the L1 phantom ranked detectability as DBT>SM>FFDM.

Screening mammography's pitfalls: a retrospective review of false positive recall
F. Leone, M. Orsi, A. Presazzi, D. Mariani, M. Cellina, G. Oliva; *Milan/IT (federica-leone@live.it)*

Purpose: To analyse the most common feature in false positive recall in order to suggest a strategy for assessment of challenging screening mammogram.
Methods and Materials: We reviewed a retrospective cohort of 6830 patients involved in screening program for breast cancer between November 2015 and September 2017. We included the false positive recall which at second level exam have been classified as BIRADS 1 or 2. We evaluated two different groups according to agreement recall(AR) or disagreement recall(DR).We compared the differences among tumoural imaging features between the two groups and considering also the overall findings prevalence in screening recall(SR).
Results: we obtained a final cohort of 1157 suspicious findings whose 416(35,9%) have been in AR group and 741(64,1%) in DR group. In the AR group we found, as single or one of multiple features in suspicious lesion, 287(69%) mass, 26(6,25%) calcifications, 78(18,75%) architectural distortion and 25(6%) asymmetric density; in the DR group we detected 578(78%) mass, 89(12%) architectural distortion, 43(6%) asymmetric density, 31(4%) calcifications. Differences in tumour imaging features between the two groups were statistically significant ($p<0.05$).
Conclusion: Our results show how mass is the most common feature in false positive recall with no changes between one or two readers. Calcification, when classifided as BIRADS 2, is a rare challenging feature, mostly due to the expertise of breast radiologist. Our study proves how screening program is a good tool to avoid false positive recall for architectural distortion and asymmetric density, condsidering the higher prevalence of these findings in recall group.

The impact of image quality and mammographic breast density on missed cancers in organised screening
M. Abdolell, P. Brown, J. Caines, J.I. Payne, K. Tsuruda, P. Barnes, M. Rivers-Bowerman, S.E. Iles; *Halifax, NS/CA (Sian.Iles@nshealth.ca)*

Purpose: The aim of this study was to explore the relationship between image quality and breast density with the risk of missing cancers in a breast screening practice.
Methods and Materials: The study sample included women diagnosed with missed interval cancers (n=45) and non-cancer controls (n=2475) identified from a 3:1 age- and screen-matched case-control study that included all breast cancer cases diagnosed between 2009-2015 in a provincial breast screening program offering digital mammography to women aged 40-75 (n=9388).Image quality and breast density were determined for each mammogram using fully automated algorithms (Densitas Inc.). Data were partitioned into training (two-thirds) and test (one-third) datasets. Women with inadequate (versus adequate) image quality were compared on their status of true missed cancers vs non-cancers, controlling for breast density. Logistic regression analysis was conducted, modeling cancer status as the dependent variable with image quality and percent mammographic density as independent variables. Odds ratios were estimated for risk of missed cancers using the test dataset.
Results: Women with mammograms of inadequate quality are 1.56 times more likely (OR=1.56, 95% CI(0.97,2.46), adjusted for breast density) to have a missed cancer; including an interaction term of quality*density generates an OR=0.92, 95% CI(0.29,2.75).
Conclusion: Image quality affects risk of missing cancers in mammographic breast exams differentially by breast density. The results of this study indicate that it may be clinically important to evaluate both image quality and breast density routinely during mammographic screening.

Piloting an international self-test: assessment of international mammography screening skills (AIMSS)
M. Broeders[1], B. Yankaskas[2], J. Timmers[1], D.L. Miglioretti[3], R.A. Smith[4]; [1]*Nijmegen/NL*, [2]*Chapel Hill, NC/US*, [3]*Davis, CA/US*, [4]*Atlanta, GA/US (m.broeders@lrcb.nl)*

Purpose: To pilot a mammography self-test, developed to measure radiologists' screening performance and provide feedback, in different translations and international settings and evaluate the logistical challenges of implementing a self-test.
Methods and Materials: Nine countries varying in language and organisation, participated: USA, Canada, Norway, Italy, Spain, Mexico, Brazil, Taiwan and Japan. For each country, a local coordinator targeted recruiting 30 radiologists. A web-based system was developed to support the self-test and pre- and post-test questionnaires to gather information on radiologists, practice characteristics, feedback on experience and performance. Each site received IRB exemption or approval.
Results: To date, 133 radiologists have consented, 71 completed the self-test, 114 completed the pre-test questionnaire and 54 completed the post-test questionnaire. Early recruitment was good, however, currently, only 41 of 133 (31%) participants completed all pilot items, despite multiple reminders. The self-test, including teaching points, was well-received with 95% rating it a good tool for evaluating performance and 88% saying they would recommend it to others; 54% thought they performed better than the results indicated; 27% expected worse results. Main problems reported were downloading the images to the workstations, delays from IRBs, and in some countries, delay due to the technical testing and translation of the self-test. Performance was generally good with mean women-level sensitivity 85%, breast-level sensitivity 80% and specificity 82%.
Conclusion: The self-test was well-received, was considered a good teaching tool, and translations worked well. We experienced logistical and technical problems which resulted in inability for some radiologists to complete the self-test.

Effect of carotid endarterectomy on the distribution and value of cerebral blood flow: evaluation by territorial arterial spin labelling
H. Xu, Y. Liu, H. Yuan; *Beijing/CN (84498843@qq.com)*

Purpose: To evaluate the cerebral blood flow(CBF) changes on distribution and value of brain feeding arteries after carotid endarterectomy(CEA) using territorial arterial spin labelling(t-ASL).
Methods and Materials: 1. Twelve patients diagnosed with carotid artery stenosis scheduled for CEA were recruited (mean age 60±7;8 males, 4 females). 2. MR imaging was performed with a 3.0T MR system 1 week before and after CEA. Cerebral perfusion territory maps were obtained by labelling bilateral internal carotid arteries and basilar artery using super-selective ASL. These images were then combined into a 3-colored territorial CBF maps. 3. The CBF values were obtained from the same size ROI ($70mm^2$))respectively in the same position of different individual vascular perfusion images before

and after surgery. To assess the changes in CBF after CEA(ΔCBF), we calculated the following difference: $\Delta CBF = CBF_{postoperative} - CBF_{preoperative}$.
Results: 1. The contribution to perfusion in the hemisphere via the collateral circulation is reduced after CEA. 2. The CBF values of both the lesion carotid artery perfusion sides and contralateral sides were increased after CEA($P<0.5$).
Conclusion: 1. CEA improves cerebral perfusion in patients with carotid artery stenosis, and patients with greater perfusion deficits prior to CAS have greater improvement in perfusion after CEA. 2. tASL has potential as a noninvasive imaging tool for the quantitative evaluation of hemodynamic changes after CEA, as well as demonstrate the relative role of collateral pathways before surgery and redistribution of blood flow after surgery.

Added value of c-arm contrast-enhanced cone-beam CT to routine contrast-enhanced MRI in evaluation of sporadic intracranial cavernous malformations for detecting associated DVAs

B. Kocak, A. Zeynalova, O. Kizilkilic, N. Kocer, C. Islak; *Istanbul/TR (drburakkocak@gmail.com)*

Purpose: Association of intracranial cavernous malformations (CMs) and developmental venous anomalies (DVAs) has a significant impact on preoperative planning and postoperative prognosis. In routine clinical practice, T1-weighted contrast-enhanced MRI (CE-MRI) is generally considered the gold standard. C-arm contrast-enhanced cone-beam computed tomography (CE-CBCT) is a relatively new technique and increasingly used to investigate vascular pathologies. Our purpose was to explore the added value of CE-CBCT to CE-MRI in detecting associated DVAs.
Methods and Materials: Between July 2011 and September 2017, one hundred and fifty patients with intracranial CMs were evaluated with CE-CBCT in our department. Applying the inclusion and exclusion criteria, retrospective review revealed 56 patients with sporadic intracranial CMs (53 with single; 3 with double CMs) who had both CE-MRI and CE-CBCT studies. DVAs were evaluated first on CE-MRI,and then along with CE-CBCT. The diagnosis was made by consensus. McNemar's test was used in statistical analysis.
Results: Of 56 patients, 37 (66%) had associated DVAs on CE-MRI. On the other hand, 19 (33%) patients had no DVA. Of 19 patients with no DVA on CE-MRI, 10 (52.6%) had DVA on CE-CBCT as a new diagnosis. The remaining 9 patients had no DVA on CE-CBCT either. Differences in the proportions of associated DVAs on CE-MRI and CE-CBCT was statistically significant, *p<.05*.
Conclusion: C-arm CE-CBCT evaluation may be a useful imaging technique especially in patients with negative routine CE-MRI in terms of detecting associated DVA. Nearly in half of those particular patients, CE-CBCT can reveal an associated DVA as a new diagnosis.

B-0688 14:16

MRI agreement of SVS of thrombi

R. Bourcier[1], L. Détraz[1], J.-.M. Serfaty[1], B. Guyomarc'h Delassale[1], M. Mirza[2], I. Derraz[1], F. Toulgoat[1], O. Naggara[3], H. Desal[1]; [1]*Nantes/FR*, [2]*Dublin/IE*, [3]*Paris/FR (lili.detraz@gmail.com)*

Purpose: The susceptibility vessel sign (SVS) on MRI is related to thrombus location, composition and size, in acute stroke. No study has questioned its inter-MRI agreement. We aimed to compare in vitro the diagnostic accuracy of 4 different MRI for thrombus histological characterisation.
Methods and Materials: 35 thrombi analogs of different composition that was histologically categorised as fibrin-dominant, mixed, or red blood cell (RBC)-dominant. We scanned these manufactured thrombi on four different MRI with T2* sequence constructor's parameters. Nine radiologists, blinded to thrombus compo sition and MRI scanner model, classified twice, in a two-week interval, the SVS of each thrombus as absent, questionable, or present. We calculated weighted kappa with 95% confident interval (CI), the sensitivity, specificity and accuracy of the SVS on each MRI scanner to detect RBC dominant thrombi and compared it between MRI scanners.
Results: The SVS was present in 42%, absent in 33%, and questionable in 25%. The inter-scanner agreements were moderate to good, ranging from 0.45 (CI : 0.37-0.52) to 0.67 (CI : 0.61 - 0.74). The correlation between the SVS and the thrombus composition was moderate κ : 0.50 (CI: 0.44 - 0.55) to good κ: 0.76 (CI: 0.72-0.80). Sensitivities, specificities and accuracy to identify RBC-dominant clots were significantly different between MRI ($p<0.001$).
Conclusion: The diagnostic accuracy of the SVS to determine thrombus composition varies significantly among MRI scanners. Normalization of T2*sequences between scanners may be needed to better predict thrombus composition in future multicenter studies.

B-0689 14:24

Dynamic evaluation of notch signaling-mediated angiogenesis in ischemic rat using magnetic resonance imaging

J. Tian, Y. Yang; *Shanghai/CN (tjqhehe@126.com)*

Purpose: Notch signaling pathway is involved in angiogenesis induced by brain ischemia and can be efficiently inhibited by the γ-secretase inhibitor DAPT. The aim of the present study was to non-invasively investigate the effect of DAPT treatment on angiogenesis in brain repair after stroke using MRI.
Methods and Materials: Sprague-Dawley rats were subjected to 90 minutes of transient middle cerebral artery (MCA) occlusion and treated with saline (n=20) or with DAPT (n=20) at 72 hours after onset of ischemia. MRI measurements including T2-weighted imaging (T2WI), susceptibility-weighted imaging (SWI) and cerebral blood flow (CBF) were performed at 24 hours after reperfusion and weekly up to 4 weeks using a 3-Tesla system. Histological measurements were obtained at each time point after MRI scans.
Results: Brain edema and ischemic lesions was significantly reduced in the DAPT-treated rats, as demonstrated by T2WI. SWI showed that DAPT treatment significantly enhanced angiogenesis in the ischemic boundary zone (IBZ) especially in the ipsilateral striatum compared to control group, with local cerebral blood flow in the angiogenic area elevated, along with increases in vascular density confirmed by histology.
Conclusion: Treatment of ischemic stroke with DAPT significantly augments angiogenesis, which promotes post-stroke brain remodeling by elevating CBF level, and these processes can be dynamically monitored and evaluated by MRI.

B-0690 14:32

Delayed postoperative changes after intracranial aneurysm surgery

E. Grigorieva, V. Krylov, V. Dashyan, V. Lukyanchikov; *Moscow/RU (iara333@yahoo.com)*

Purpose: Main strategies of intracranial aneurysm treatment are microsurgical clipping or coiling complicated by angiospasm and ischaemia with microcirculation deficits. Our purpose was to estimate the long-term changes after treatment both non-rupted aneurysms and after angiospasm.
Methods and Materials: 69 patients (40 women, 29 men, 19-71y.o.) were examined more than 12 months after surgery with native brain CT, CT angiography and whole brain CT perfusion followed by estimating of cerebral blood flow, cerebral blood volume and mean transite time in similar areas of the cortex.
Results: 56 patients underwent surgical clipping, including 10 patients (14,5%) with rupted aneurysms. In 13 cases (18,8%) aneurysms were coiled, in 1 patient with stent assisting. In 43 of 56 cases native CT revealed postoperative brain changes, in 90,7% at the access level with 36 cases (83,7%) of the perfusion deficits. The deformities of the parent artery was determined in 22 patients (31,9%) with hypoperfusion in 68,2% of cases. 11 patients demostrated the residual aneurysm sac with hypoperfusion of temporal lobe in 54,5% ($p< 0,005$). 10 patients were treated after aneurysm rupture and angiospasm. In 50% of patients perfusion deficits were revealed with arteries deformity, independent of the aneurysm size, localization or treatment strategy. No residual sac was found.
Conclusion: The parent vessel postoperative deformity was more common after the ruptured aneurysm closure while the residual aneurysmal sac was revealed after non-rupted aneurysms. Perfusion disturbances correlated with post-ischaemic changes and vessel deformity ($p<0,001$) but not with residual aneurysm or method of treatment.

B-0691 14:40

Epidemiology of intracranial vertebral artery calcification observed on computed tomography in a cohort of trauma patients

C. Lucci[1], R. Kockelkoren[1], D. Bos[2], A. Van der Lugt[2], M. Geerlings[1], J. Hendrikse[1], P.A. de Jong[1]; [1]*Utrecht/NL*, [2]*Rotterdam/NL (carlo.lucci@hotmail.com)*

Purpose: Intracranial vascular disease is the leading cause of ischemic stroke worldwide. In this light, substantial research has been performed on calcification in the carotid artery while data available on vertebral artery calcification (VAC) are limited. Considering its possible role in the development of symptomatic cerebrovascular disease, we examined VAC prevalence and distribution according to sex and age in a cohort of trauma patients.
Methods and Materials: Unenhanced head CT scans of patients admitted from July 2007 to August 2016 to the University Medical Center Utrecht for trauma were examined. We randomly selected 1016 patients (49.2% men) aged 0-99 years (mean±SD, 47.8±28.6; approximately 50 men/women per age decile). Calcifications were assessed visually (Modified Woodcock) and volumetrically (mm^3) from the foramen magnum till the basilar artery bifurcation.

Results: The overall prevalence of VAC was 16% and the mean volume (±SD) was 11.27±57.06 mm^3. At logistic regression, increasing age was significantly associated with the presence of VAC (p<0.001). Age was also related to VAC volume (Spearman's rho= 0.212, p=0.007). There was a statistically significant association between female sex and VAC prevalence (18.6% in women and 13.4% in men; Chi-Square=5.107, p=0.024).
Conclusion: Prevalence of VAC in our cohort is high and increments proportionally with ageing. It also seems to affect women more than men but further studies must investigate the aetiology behind this finding. VAC evaluation is easy on non-contrast head CT scans and could be implemented in clinical radiology in behalf of the creation of a stroke risk assessment scale.

B-0692 14:48

Standard diffusion-weighted imaging on the brain detects cervical internal carotid artery dissections

G.G.A. Adam, C. Cognard, F. Bonneville; *Toulouse/FR (gilles.adam31@gmail.com)*

Purpose: To assess the capacity of a standard diffusion-weighted sequence performed on the brain and to detect dissecting haematoma related to cervical internal carotid artery (ICA) dissections.
Methods and Materials: Retrospective study of a cohort of 110 patients under 55 years of age (40 women, mean age: 46.79 years) admitted at the acute phase of a neurological deficit, headache or neck pain, and investigated by at least a standard 3 Tesla diffusion-weighted sequence on the brain. Among them were included 50 patients (14 women, mean age: 46.72) who subsequently had an internal carotid artery dissection, as confirmed by ultrasound, MRI or DSA. In the whole anonymized cohort, a senior and a junior radiologist separately assessed on the diffusion-weighted sequence only, the presence of a crescent-shaped or circular hypersignal projecting on the subpetrosal segments of the ICA arteries, assuming that it would correspond to a dissecting haematoma related to ICA dissection.
Results: The senior radiologist found 46 subpetrosal hyperintensities in 43/50 patients with ICA dissection, none in patients without dissection (sensitivity 86%, specificity 100%). The junior radiologist found 48 subpetrosal hyperintensities in 45/50 patients with dissection, none in patients without dissection (sensitivity 90%, specificity 100%). The interobserver kappa, calculated at 0.99, was excellent.
Conclusion: In our cohort, a standard diffusion-weighted sequence performed on the brain, at the acute phase of a stroke or a clinical suspicion of dissection detected nearly 90% of the ICA dissections.

B-0693 14:56

Diagnosticperformance of three-dimensional high resolution magnetic resonanceimaging for intracranial aneurysms: comparison with digital subtractionangiography

Y. Yim, J.Y. Kim, S.C. Jung, B.E. Lee, S.J. Kim, H.S. Kim, D.H. Lee, C.G. Choi, J.E. Park; *Seoul/KR (youngheeyim@gmail.com)*

Purpose: To evaluate diagnostic performance of three-dimensional high-resolution magnetic resonance imaging (3D HR-MRI) for intracranial aneurysms compared to digital subtraction angiography (DSA).
Methods and Materials: A total of 299 patients (M:F= 37:262; age range, 27-79) who underwent 3D HR-MRI, DSA, TOF-MRA from January 2012 to December 2016 were retrospectively enrolled. Two neuroradiologists independently evaluated TOF-MRA (3D MIP and axial source), CTA, 3D HR-MRI, and DSA for the determination of intracranial aneurysms or infundibula which were suspected of having on TOF-MRA within circle of Willis, bilateral ophthalmic arteries, bilateral posterior communicating arteries, bilateral anterior choroidal arteries, basilar artery and bilateral superior cerebellar arteries. Diagnostic performances for TOF-MRA, CTA, and 3D HR-MRI were assessed with DSA as the reference standard. Inter-observer agreements are calculated.
Results: Of 452 lesions on TOF MRA, aneurysms of 173 (38%) and infundibula of 276 (61%) , and no aneurysm of 3 (1%) were diagnosed on DSA. Sensitivity, specificity, positive predictive value, and negative predictive value were 61%, 81.3%, 73.8%, 76% for TOF 3D MIP, 73.7%, 89.4%, 81.5%, 84.3% for TOF-MRA source, 65.9%, 99%, 97.7%, 82.7% for CTA, and 70.2%, 97.6%, 94.9%, 83.8% for 3D HR-MRI, and with the exception of ophthalmic arterial lesions, 53.7%, 87.3%, 60.9%, 83.6% for TOF 3D MIP, 65.1%, 92.5%, 76.2%, 87.7% for TOF-MRA source, 64.6%, 100%, 100%, 83.7% for CTA, and 90.6%, 98.5%, 95.6%, 96.6% for 3D HR-MIR. Readers showed good inter-observer agreement (*K*=0.637).
Conclusion: 3D HR-MRI shows superior diagnostic performance for intracranial aneurysms except ophthalmic arterial lesions compared to TOF-MRA and CTA.

B-0694 15:04

Scannographic density of intracranial venous sinuses in healthly patients and diagnosed with venous thrombosis at 2600 meters above sea level from 2008 to 2016

S. Andrade, S. Velasco, S. Bermúdez, N. Useche, A.J. Morillo; *Bogota/CO (santiandrade_1985@hotmail.com)*

Purpose: Intracranial venous sinus thrombosis is a rare pathology in which diagnostic imaging plays a crucial role. Simple brain scanning is the initial choice imaging study because it is a rapid method to evaluate the morphology and quantification of venous sinus density. Actually, only quantitative reference values of attenuation of sinus have been documented at geographic altitudes below 500 meters above sea level. According to the correlation between hematocrit and vascular density, the available values may be inaccurate for populations living at higher altitudes. The purpose of this research is to document the attenuation of venous sinuses in healthy patients and the intracranial venous thrombosis in Bogotá-Colombia (located at 2600 mts above sea level), to obtain quantitative information that allows an objective analysis in patients with suspicion of this pathology, values that could be used as reference in similar geographic altitude at world-wide level.
Methods and Materials: Cross-sectional, retrospective and analytical studies performed from January 2008 to June 2016. Accessible population were patients with a simple brain scannography with diagnosis of venous sinus thrombosis and healthy patients in Bogota-Colombia.
Results: Hematocrit and intravascular scanographic attenuation has been demonstrated again. There were higher densities in healthy patients as previously reported in the literature (70 HU).
Conclusion: Reference values for patients living at higher altitudes than those already reported have a direct impact on diagnosis of intracranial venous thrombosis, decreasing neurological sequelae secondary to late diagnosis; these values also help to define which patients should be subjected to confirmatory studies.

B-0695 15:12

Virtual non-contrast CT derived from dynamic CTA in acute stroke

E.J. Smit, F.J.A. Meijer, M.M. Prokop; *Nijmegen/NL (ewoudsmit@gmail.com)*

Purpose: To assess if virtual non-contrast CT derived from dynamic CTA may obviate separately performed non-contrast CT images for acute stroke assessment.
Methods and Materials: In our hospital, all patients with suspected stroke undergo non-contrast CT and dynamic CTA/CT perfusion imaging if they 1) are eligible for i.v. thrombolysis or 2) have evidence of intracerebral hemorrhage on non-contrast CT (clinical trial). We selected 27 consecutive patients from this database. Virtual non-contrast images were reconstructed as the precontrast images of dynamic CTA after applying a 4D-similarity noise reduction filter. An experienced observer scored all images in a blinded manner for the presence and location of hemorrhage, midline shift, loss of gray white-matter differentiation, dens-vessel sign, old infarcts and hydrocephalus. Standard non-contrast images served as the reference standard.
Results: Virtual non-contrast images could not be derived in one case because of severe motion artefacts. Five patients had an intracranial hemorrhage which were all detected on virtual non-contrast CT. Also midline shift (four cases), loss of gray white-matter differentiation (one case), old infarcts (two cases) and hydrocephalus (none) were scored equal on both techniques. Dens vessel signs could not be reliably assessed on the virtual non-contrast images because of occasional artefacts or early contrast arrival.
Conclusion: It seems feasible to replace non-contrast CT by virtual non-contrast CT images for acute stroke assessment, allowing for a single-acquisition dynamic CTA stroke protocol from which haemorrhage, artery occlusion, and tissue perfusion can be evaluated.

Neuroimaging signs and features of brain lesions in patients with CADASIL

N. Kurochkina, A. Moroz, R. Konovalov, M. Krotenkova, S. Illarioshkin; *Moscow/RU (nadia_sk@mail.ru)*

Purpose: To evaluate specific changes in MRI of the human brain, associated with either cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) or hypertensive microangiopathy (HM).
Methods and Materials: We enrolled 24 patients with genetically confirmed CADASIL (19-81 y.o.) and 25 patients with HM (46-79 y.o.). The following MRI sequences were performed for every subject: T1 MPR, T2, FLAIR, DTI with calculation of fractional anisotropy (FA), mean, axial and radial diffusivity maps. Brain tissue lesions were assessed using STandards for ReportIng Vascular

changes on nEuroimaging (STRIVE). Voxel-wise group analysis was carried out using SPM12 software to study the white matter microstructure.
Results: In the CADASIL group the following changes were observed (in % of patients): recent small subcortical infarcts - none; lacunes - 54%; white matter hyperintensities (WMH) by Fazekas 1 - 12%, Fazekas 2 - 17%, Fazekas 3 - 71% (sites of predilection: anterior temporal lobe and external capsule); cerebral microbleeds - 42%; enlarged perivascular spaces - 88%; brain atrophy - 27%. Morphometry analysis revealed differences in diffusivity maps and FA as well as volumes of brain structures in patients with moderate and severe WMH (Fazekas 2 and 3) between CADASIL and HM groups.
Conclusion: Neuroimaging signs of brain lesions are common for all types of cerebral small vessel disease, including CADASIL. However, the distribution of WMH and patterns of microstructural alterations specify the differences observed in CADASIL in comparison with HM, that reflects their various morphopathology.

Can conventional MRI help to rectify grading of soft-tissue sarcomas (STS) on needle-core microbiospy (NCB)?
A. Crombe[1], P.-J. Marcelin[2], F. Le Loarer[1], E. Stoeckle[1], A. Italiano[1], J.-M. Coindre[1], M. Kind[1]; [1]*Bordeaux/FR*, [2]*Saint-Pierre/FR*
(amandine.crombe@ens-lyon.fr)

Purpose: Prognosis and management of STS strongly rely on histopathological grading. The European Society for Medical Oncology recommends NCB to assess grading, despite the risk of underestimation due to sampling. Our aim was to identify combination of MRI features associated with high-grade (III) and how it reclassified grade I-II STS on NCB into true high-grade STS on surgical specimen.
Methods and Materials: Of the 498 patients diagnosed with a STS in the Conticabase (CONnective Tissue in Cancer NETwork database) and followed-up in our sarcoma reference center between 2008 and 2015, we retrospectively included 130 patients with: available MRI with gadolinium-chelates injection, pathological grade on final surgical specimen, no neoadjuvant treatment. 66 had NCB. Visceral sarcomas, well-differentiated liposarcomas, angiosarcomas were excluded. Two radiologists evaluated: location, size, heterogeneity, margins, architecture, surrounding tissue and bone-vessel-nerve invasion.
Results: Final pathological grade was 69 grade III, 47 grade II, 14 grade I. On multivariate analysis, 3 criteria were associated with true grade III: ill-defined margins >10% of tumor surface on post-contrast T1-WI (p=0.026, OR=2.93, IC95%=(1.14-7.56)), necrotic signal (p=0.013, OR=2.28, IC95%=(1.24-6.43)), enhancement of surrounding oedema (p=0.004, OR=3.55, IC95%=(1.51-8.32)). Inter-observer agreements were 0.66(0.52-0.79), 0.78(0.65-0.90) and 1(1.00-1.00), respectively. Among the 43 patient with grade I-II on NCB, presence of at least 2 of these 3 criteria would correctly reclassify 12/14 (85.7%) true grade III but would ill-classify 15/29 (51.7%) true grade I-II (p=0.047).
Conclusion: Conventional MRI can help evaluate STS grading but additional features from other imaging modalities are required to improve reclassification after NCB.

B-0698 14:08
Machine learning approach on semantic and texture MRI features for early response evaluation in patients with high-grade soft-tissue sarcomas undergoing neoadjuvant chemotherapy
A. Crombe[1], C. Perier[2], O. Saut[2], B. Denis de Senneville[1], F. Le Loarer[1], E. Stoeckle[1], S. Cousin[1], A. Italiano[1], M. Kind[1]; [1]*Bordeaux/FR*, [2]*Talence/FR*
(amandine.crombe@ens-lyon.fr)

Purpose: To evaluate the feasibility and added value of machine learning and radiomics approaches to early predict the response after 2 cycles of anthracycline-based neoadjuvant chemotherapy (NAC) in soft-tissue sarcomas (STS)
Methods and Materials: This retrospective single-center study included 52 uniformly patients (4-6 cycles NAC) with locally advanced high-grade STS, between 2008 and 2015. Good histological response (GHR) was defined as ≤10% stainable cells on final surgical specimen. All benefited from baseline (t0) and post-2 cycles 1.5T-MRI (t1) with gadolinium-chelates injection. MRI post-processing consisted in histogram-based intensity normalisation and voxel standardisation. Random forest classifier was applied on: initial clinico-biological data, features from radiologist's visual assessment (semantic features: tumour architecture, margins, periphery), shape, histogram and textural features from T2-weighted-imaging at t1 and their changes (absolute or relative from t0 to t1). Areas under the receiver operating curve (AUC) and diagnostic performance of tested classifiers were compared.
Results: 17 GHR and 35 poor-responders (PHR) were analysed. According to RECIST1.1, 3/35 (8.6%) PHR showed progressive disease and 0/17 (0%) GHR showed partial or complete response at early evaluation. 77 features were assessed. The best classification performance was obtained using absolute changes of radiomics features giving: accuracy=75%, sensibility=91%, specificity=48%, positive predictive value=77%, negative predictive value=69%, AUC=0.67 (0.60-0.74).
Conclusion: Machine learning and radiomics approaches can substantially improve the NAC response prediction in high grade locally advanced STS and should be evaluated in prospective studies on additional imaging modalities.

B-0699 14:16
Calcium suppression in spectral detector computed tomography improves visualization of bone metastasis
N. Grosse Hokamp[1,2], N. Abdullayev[1], V. Neuhaus[1], J. Holz[1], D. Maintz[1], J. Borggrefe[1]; [1]*Cologne/DE*, [2]*Cleveland, OH/US*
(nils.grosse-hokamp@uk-koeln.de)

Purpose: To investigate a benefit from calcium suppression images (VNCa) in spectral detector computed tomography (SDCT) for assessment of bone metastases using MRI as a gold standard.
Methods and Materials: 24 patients with vertebral metastases that underwent SDCT for oncologic staging purpose and MRI examination of the spine were included in this retrospective, IRB-approved study. Images were reconstructed as conventional images (CI) and using a prototype algorithm for calcium suppression (Philips Healthcare) with 3 different presets ($VNCa^1$, $VNCa^2$ and $VNCa^3$). In each patient, normal bone (as determined by MRI) served as intra-individual standard-of-reference. Circular regions of interest were drawn in metastatic bone, normal bone and subcutaneous fat in CI and copied to identical positions in $VNCa^{1-3}$, attenuation and standard deviation were recorded. Attenuation was compared using t test and receiver operator characteristics (ROC) were analysed to assess performance of the different VNCa algorithms.
Results: In conventional images attenuation in normal bone was higher than in metastatic bone (140.9±65.7 vs 86.1±33.6; p≤0.05), after subtraction of calcium attenuation in metastatic bone was higher (e.g. $VNCa^1$: -240.0±60.6 vs -80.5±70.5, p≤0.05); the absolute difference between normal and metastatic bone increased from 54.8 in CI to 159.5 (p≤0.05), while noise remained constant (p≥0.05). This resulted in a significant increase of the area under the curves as depicted by ROC analysis in $VNCa^{1+2}$ as compared to CI and $VNCa^3$ (0.95/0.98 vs 0.74/0.73, respectively, p≤0.05).
Conclusion: Virtual non-calcium images provided by SDCT can be helpful in differentiating bone metastasis and non-metastatic bone if calcium suppression is adjusted to an appropriate level.

B-0700 14:24
A deep learning-based radiomics model for classification of mammography mass lesions in breast cancer patient
I. Shiri, P. Geramifar, A. Bitarafan-Rajabi, A. Mohammadzadeh, H. Pouraliakbar, S.P. Shayesteh; *Tehran/IR (Shayeste_sajad@yahoo.com)*

Purpose: Breast cancer is the most commonly diagnosed cancer with high mortality and morbidity. There are different biomarkers which can be obtained from breast tissue to classify mass lesions. The main aim of this study was to classify malignant and benign breast cancer using convolutional neural network (CNN).
Methods and Materials: In this study, we used 315 mammography images of breast cases (148 benign and 167 malignant) from CBIS-DDSM database. Image patches are extracted around each lesion and used as train and test data set. The neural network consists of convolutional blocks composed of Convolutions, Batch Norm, ReLU, and Max Pooling Blocks followed by FC layers. The final layer is a soft-max layer for binary classification. We evaluate the CNN performance using free response receiver operating characteristic (FROC) analysis.
Results: CNN performance evaluation and accuracy of the model was performed using free response receiver operating characteristic (FROC) analysis. The analysis shows the deep learning approach achieves FROC value of 82.3% with accuracy of 85.3%.
Conclusion: CNN in hierarchically way uses a set of nonlinear transformations, to represent the visual content of an image automatically from scratch. Deep learning takes advantage of no need for segmentation, feature extraction, feature reduction and classification manually against conventional radiomics methods. Thus, deep learning-based radiomics model can be used instead of hand crafted texture feature analysis in radiomics processing.

B-0701 14:32

IVIM MRI of oestrogen-receptor-positive breast cancer: association with quantitative IVIM parameters and Ki-67 proliferation status

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: Investigate association of IVIM MRI-derived quantitative parameters with Ki-67 proliferation index in patients with oestrogen receptor (ER)-positive breast cancers.
Methods and Materials: 67 patients with ER-positive breast cancer were included in the study. All patients underwent IVIM MR imaging along with regular diffusion and DCE MRI on 1.5 Tesla scanner. IVIM-derived parameters: f the perfusion fraction, D the pure diffusion coefficient, D* perfusion-related pseudo-diffusion and IVIM-derived ADC were analysed and correlated with Ki-67 status. High (gt14%) and low Ki-67 (lt14%) proliferation indices were obtained.
Results: f values (perfusion fraction) were significantly elevated in high Ki-67 index group (Plt0.001). D and ADC values were lower in high Ki-67 group (P &lt0.001). Low Ki-67 index tumours had lower f values but not statistically significant high D or ADC values. High f values (14%) were seen in grade 3 tumours which were larger (gt2cm) and had greater propensity for axillary nodal metastases and were associated with high Ki-67 proliferation index. f fraction had greater confidence interval 1.756-42.24 for correlation with Ki-67 index.
Conclusion: f and true diffusion coefficient values can be used as independent biomarkers to correlate Ki-67 proliferation status in oestrogen receptor-positive breast cancers.

B-0702 14:40

Metastatic axillary lymph nodes in patients withbreast cancer: value of quantitative shear wave elastography

Y. Kabin, O. Kostash, V. Kapustin, A. Gromov; *Moscow/RU (wwkapustin@yandex.ru)*

Purpose: To evaluate the usefulness of LN tissue elasticity quantitative assessment by shear wave elastography (SWE) for detection of axillary lymph node (LN) metastatic involvement in women with breast cancer (BC).
Methods and Materials: 172 women with verified BC were included in this study. In every case the most suspicious LN was chosen, using B-mode ultrasonography (BUS) for the further elasticity parameters assessment. Tissue elasticity (kPa) was measured at the most suspicious hypoechoic portion of LNs, detected by BUS. LN tissue changes type (benign or malignant) were subsequently proved by ultrasound-guided fine-needle aspiration biopsy or postoperative histological evaluation in all cases. These data were retrospectively compared for two groups of patients (with benign and metastatic LN) using Mann-Whitney test. Statistical measures of performances (Se, Sp) of SWE elasticity for LN metastases detection were calculated using receiver operating curve (ROC) analysis.
Results: "Tissue elasticity" value in metastatic LNs was significantly higher comparing to benign LN changes (p= 0.000). This quantitative SWE parameter showed high diagnostic efficacy for axillary LN metastases detection [area under curve (AUC) - 0.924]. The best diagnostic performance (Se=0,87, Sp=0,81) was received at 31,5 kPa cut-off value.
Conclusion: Tissue elasticity parameter (kPa), assessed by SWE, gives valuable diagnostic information (adjunctive to the diagnostic performance of BUS) for the axillary LN metastasis detection in patients with BC.

B-0703 14:48

Quantitative PET parameters in predicting event free survival in patients with hodgkin lymphoma

I. Kriachok[1], O. Novovsad[1], T. Skrypets[1], A. Gorbach[1], Y. Kmetyuk[1], O. Kozlova[1], M. Novikov[1], L. Mikhalska[1], V. Kozlov[2]; [1]*Kiev/UA*, [2]*Odessa/UA (nicknovi@gmail.com)*

Purpose: To analyse whether quantitative metabolic PET parameters, their negative predictive value (negative PET scan and no treatment failure, NPV) and positive predictive value (positive PET scan and treatment failure, PPV) were associated with EFS.
Methods and Materials: SUVmean, MTV (computed with 41% threshold algorithm) and TLG were retrospectively calculated at baseline (PET-1), interim (PET-2) and end of treatment (PET-3) metabolic PET/CT studies of 45 patients with Hodgkin lymphoma. 53% of patients had stage I-II disease and 47% - stage III-IV disease. All patients were treated with ABVD or BEACOPP-14/esc chemotherapy regimens.
Results: The ORR in the group was 95.5%. There were 73% patients with negative and 27% with positive PET-2 studies, which yielded an NPV of 82% and PPV of 18%, p< 0.05.Multivariate analysis showed PPV to be the only variable significantly influencing EFS with HRs of 1.07 [95% confidence interval(CI) 1.0-1.15, p = 0.00008].According to Cox regression, MTV and SUVmean at PET-3 were the variables significantly influencing EFS with HRs of 1.07 [95% confidence interval(CI) 1.0-1.13, p = 0.005] and 2.0 [95% (CI)1.4-2.82, p = 0.0001), respectively. Unfortunately, quantitative parameters at PET-1 and PET-2 were not statistically significant in predicting clinical outcome in this study.
Conclusion: Quantitative PET parameters may play a predictive role in identifying patients at high risk of treatment failure. Further studies will be conducted to investigate PET quantitative data predictive value.

B-0704 14:56

Diagnosis of diffuse spleen involvement in haematological malignancies using a spleen to liver attenuation ratio in CECT

C.P. Reinert, C. Hinterleitner, K. Nikolaou, M. Horger; *Tübingen/DE (christian.reinert@med.uni-tuebingen.de)*

Purpose: To assess the mean attenuation values of the normal spleens vs. involved spleens in haematological malignancies and to try to discriminate the two groups by using attenuation ratios to the normal liver parenchyma in the potal-venous enhancement phase on CECT.
Methods and Materials: Included were 60 (27 male; mean age 55.0y) consecutive patients with known malignant haematologic diseases who underwent CECTs for staging before and after chemotherapy and 60 controls (31 male; mean age 62.2y). We calculated in all patients the spleen index (LxBxDx0.5) and measured the attenuations of the spleen and liver in the portal-venous enhancement phase calculating the spleen-to-liver ratios. Standard-of-reference was the significant reduction (>20%) of the spleen index following successful chemotherapy or normalization of FDG-uptake in a subgroup undergoing 18F-FDG-PET/CT for staging.
Results: The spleen-to-liver attenuation ratios in involved spleens were significantly lower over the controls, respectively (0.94 vs. 0.98, p<0.0045). The pre- to posttreatment attenuations in the spleen in the involved group were significant lower (93.70 HU vs. 113.15 HU, p<0.0001) as well as the pre- to posttreatment spleen to liver attenuation ratios (0.94 vs. 1.17, p<0.0001). Using a cut-off-value of 100.9 HU the positive predictive value was 0.81 (95% confidence interval). The spleen index significantly dropped down after successful treatment (574.87 cm^3 to 287.64 cm^3, p<0.0001).
Conclusion: Spleen-to-liver attenuation ratios in haematological malignancies with diffuse involvement of spleen are significantly lower as in controls and could therefore be used complementary to the spleen index as an indicator of spleen involvement at staging.

B-0705 15:04

Is whole body ^{18}FDG-PET/CT including the extremities routinely warranted in melanoma patients?

C. Riedl[1], H. Schoder[1], G.A. Ulaner[1], T. Saidon[1], K. Juluru[1], W. Weber[1], K. Pinker[2]; [1]*New York, NY/US*, [2]*Vienna/AT (riedlc@mskcc.org)*

Purpose: ^{18}FDG-PET/CT of melanoma patients is often performed as a whole body (WB) study including the upper and lower extremities. This causes increased examination time and radiation dose and is of questionable clinical value. The aim of this study was to investigate the value of ^{18}FDG-PET/CT imaging of the extremities in melanoma patients**.**
Methods and Materials: The hospital database was searched for melanoma patients who underwent WB ^{18}FDG-PET/CT between 2012-2016. Imaging reports were searched for findings in the extremities that would not have been included in a scan ranging from the skull base to mid thighs, the range routinely used in most other malignancies. Findings in the extremities considered less likely to be malignant (<25%) were considered clinically irrelevant. Findings in an extremity related to the primary tumour were also considered clinically irrelevant.
Results: 1975 ^{18}FDG-PET/CT scans in melanoma patients were identified. There were 276 (14%) findings in the extremities that were classified as a malignant (primary/recurrence, local or distant metastases). In 1.6% (32/1975) patients we identified metastases in an extremity that would not have been covered by an "eyes-to-thighs" scan or a scan of the extremity afflicted by the primary tumour. In 93.8% (30/32) of these patients there was disseminated disease. Thus WB ^{18}FDG-PET/CT detected clinically relevant metastases in the extremities in only 0.1% (2/1975) of melanoma patients.
Conclusion: WB ^{18}FDG-PET/CT almost exclusively detected metastases in the extremities in patients with disseminated disease or in the extremity afflicted by the primary tumour.

B-0706 15:12

Integrated ^{18}F-FDG PET/MR for the initial detection of lymph node metastases in malignant melanoma: is sentinel lymph node biopsy still necessary?

B.M. Schaarschmidt[1], J. Grueneisen[2], V. Stebner[2], L.M. Sawicki[1], C. Buchbender[1], P. Heusch[1], L. Umutlu[2], G. Antoch[1], T. Poeppel[2]; [1]*Düsseldorf/DE*, [2]*Essen/DE*

Purpose: To evaluate the performance of 18F-FDG PET/CT, 18F-FDG PET/MR and 18F-FDG PET/MR including diffusion-weighted imaging (DWI) in

sentinel lymph node metastasis detection after primary tumour resection in malignant melanoma patients.
Methods and Materials: In this retrospective analysis, 52 patients (female: n=30, male: n=22) that underwent 18F-FDG PET/CT and subsequent PET/MR including DWI 18F-FDG prior to radioguided SPECT/CT sentinel lymph node mapping and resection were included. In separate sessions, 87 sentinel lymph nodes were identified using SPECT/CT in PET/CT, PET/MR PET/MR+DWI datasets and their dignity (benign/malignant) was determined by increased tracer uptake (PET/CT), increased tracer uptake and suspicious morphological appearance (PET/MR) as well as reduced apparent diffusion coefficients in DWI (PET/MR+DWI). Histopathological results served as reference standard.
Results: Of 136 resected lymph nodes, 87 could be identified in SPECT/CT. Seventeen metastatic lymph nodes were detected by histopathology (size: <0.1mm: n=4, 0.1-1mm: n=7, >1mm: n=6). Sensitivity, specificity, positive predictive value and negative predictive value were 17.7%, 95.6%, 50.0% and 82.3% for PET/CT, 23.5%, 96.9%, 66.7% and 82.3% for PET/MR and 0%, 93.3%, 0%, 82.4% for PET/MR+DWI. PET/MR+DWI performed worse than the other methods as contradictory information between PET and DWI reduced the number of true-positive findings.
Conclusion: 18F-FDG PET/MR is unable to improve initial lymph node metastasis detection in malignant melanoma patients in comparison to PET/CT and will not be able to replace sentinel lymph node resection for diagnostic purposes in malignant melanoma patients. The additional analysis of DWI even worsen the performance of PET/MR due to contradictory Information.

B-0707 15:20

Usefulness of spleen size and volume measured by computed tomography for predicting clinical outcome in chronic myeloid leukemia
M. Seo, S.-E. Lee, J.-I. Choi, D.-W. Kim; *Seoul/KR (minkook.seo@gmail.com)*

Purpose: Spleen size is one of well-known prognostic factors for chronic myeloid leukemia (CML) patients and many scoring systems include the spleen size as a parameter. The purpose of this study is to evaluate whether spleen diameter on axial (ASD) and coronal (CSD) CT imaging and spleen volume (SV) measured using CT images would accurately predict the prognosis of initially diagnosed CML patients.
Methods and Materials: A total of 89 CML patients who were initially diagnosed and treated by imatinib were enrolled. ASD and CSD were measured on axial and coronal CT imaging by measuring the longest diameter of spleen. SV was quantitated by the semi-automatic volume measurement software. Conventional measurement of spleen by palpation, ASD, CSD and SV were analyzed for cumulative incidence (CI) of complete cytogenetic response (CCyR), major molecular response (MMR), failure-free survival (FFS), progression-free survival (PFS) and overall survival (OS) using the Kaplan-Meier methods and the log rank test.
Results: Measurements by palpation and ASD were statistically significant for CI of CCyR and MMR (p<0.001 for all parameters). However, they were not significant for FFS, PFS and OS. On the other hand, CSD was significant for CI of CCyR (p=0.003), MMR (p<0.001) and PFS (p=0.038). SV was significant for CI of CCyR (p<0.001), MMR (p<0.001), FFS (p=0.040) and PFS (p=0.033). However, no measurement was significant for OS.
Conclusion: Spleen volume measurement using CT images is superior to conventional palpation or 2-dimensional measurement of spleen size for predicting the prognosis of CML patients treated by imatinib.

Intravoxel incoherent motion diffusion-weighted MR imaging in gastro-esophageal cancer: correlation with ^{18}F-FDG-PET and histopathology
K. Schawkat[1], B.-R. Sah[1,2], G. Delso[3], E. Ter Voert[1], P. Schneider[1], C.S. Reiner[1], M. Huellner[1], P. Veit-Haibach[4]; [1]*Zurich/CH*, [2]*London/UK*, [3]*Waukesha, WI/US*, [4]*Toronto, ON/CA (khoschy.schawkat@usz.ch)*

Purpose: To evaluate the relationship of multimodality parameters derived from intravoxel incoherent motion (IVIM) diffusion-weighted MR imaging and ^{18}F-FDG-PET in patients with gastro-esophageal cancer and to investigate their histopathological correlation.
Methods and Materials: Twenty-two consecutive patients (19 male; mean age 64.9±11.7 years; range 37-84 years) with adenocarcinoma (n=15) and esophageal squamous cell carcinoma (n=7) were analyzed prospectively. PET-parameters (SUVmax, mean tumor volume (MTV), total lesion glycolysis (TLG)) and IVIM parameters (pseudodiffusion (D*), perfusion fraction (fp), true diffusion (D), b-value (bval)) were determined, correlated to each other and to histopathology (staging, grading, regression). The relationship of these parameters was evaluated using Spearman's correlation with Bonferroni correction to exclude false positive results under multiple testing.
Results: IVIM and PET-parameters showed significant negative correlation for: MTV ǁ bval (r_s= -0.643, p=0.002), TLG ǁ bval (r_s=-.699, p=0.000) and TLG ǁ fp (r_s=-0.577, p=0.006). Negative correlation was also found for bval ǁ staging (r_s=0.590, p=0.005). TLG ǁ Dt showed positive correlation (r_s=0.705, p=0.000). After Bonferroni correction no significant correlation was found for MTV ǁ fp (r_s=-0.527, p=0.014) and for MTV ǁ Dt (r_s= 0.487, p=0.025).
Conclusion: IVIM parameters (fp, Dt) provide useful quantitative information and correlate with the PET-parameter total lesion glycolysis (TLG). In addition, bval significantly correlates with staging. IVIM might be a valuable tool for non-invasive pre-therapeutic characterization of gastro-esophageal cancer.

B-0709 14:08

The concentration of iodine in perigastric adipose tissue: a novel index for assessment of serosal invasion in patients with gastric cancer after neoadjuvant chemotherapy
L. Yang; *Shijiazhuang/CN (64502240@qq.com)*

Purpose: This study aims to explore the association between iodine concentration (IC) in perigastric adipose tissue (PAT), quantified by dual-energy computed tomography (DECT), and serosal invasion (SI) in patients with gastric cancer after neoadjuvant chemotherapy (NAC)
Methods and Materials: 43 patients with T4-staged gastric cancer (with SI) were enrolled in the 4th Hospital of Hebei between January 2015 and December 2016. IC and standard IC in PAT (IC_{PAT} and SIC_{PAT}) were quantified by DECT pre- and post-NAC. Postoperative pathologic examination was performed to stage gastric cancer. IC_{PAT} and SIC_{PAT} between patients at T1-T3 stages (group A, without SI) and patients at T4 stage (group B, with SI) were compared subsequently, with receiver operating characteristic (ROC) curve applied for evaluating the accuracy of the ΔSIC_{PAT} in identifying post-NAC SI.
Results: The accuracy of conventional computed tomography (CT) in identifying SI was 72.09%. Differences of variations between pre- and post-NAC IC_{PAT}, SIC_{PAT}, ΔIC_{PAT} and ΔSIC_{PAT} were observed, respectively (P<0.05). Intragroup IC_{PAT} and SIC_{PAT} also changed significantly after NAC (P<0.05), except the SIC_{PAT} in group B (P>0.05). The area under the ROC curve (AUC) was 0.929, with the threshold of ΔSIC_{PAT} reaching 0.095. The sensitivity, specificity and accuracy of SIC_{PAT} in identifying post-NAC SI were 92.30 %, 86.70 %, and 88.37%, respectively.
Conclusion: These results showed that SIC_{PAT} is an accuracy index for identifying post-NAC SI, by which it might be used to assess the effectiveness of neoadjuvant chemotherapy and the optimal timing for the operation.

B-0710 14:16

Use of CT perfusion parameters in assessment of early response of gastric cancer to neoadjuvant chemotherapy
P. Pilius, I. Shrainer, A. Klimenko, V.E. Sinitsyn; *Moscow/RU (polishka1903@gmail.com)*

Purpose: To assess whether the changes of CT Perfusion (CTP) parameters of gastric cancer could be used as biomarkers for evaluation of early response of gastric cancer to neoadjuvant chemotherapy.
Methods and Materials: 21 patients with local advanced adenocarcinoma of stomach were analyzed. The patients received 2-5 courses of neoadjuvant chemotherapy (EOX or XELOX schemes) before surgery. CTP scans were performed prior and after the first course of chemotherapy. CTP parameters (blood flow (BF), blood volume (BV) and permeability surface (PS)) of the tumor were computed on a dedicated workstation with a consensus between two radiologists.
Results: 7 patients (33.3%) with good pathological response to treatment (grade 1-2 accordingly to Mandard score) consisted the 1st group. Other 14 patients (66.6%) with poor response (grade 3-5) made the 2nd group. All studied CTP parameters decreased in the both groups after treatment, but all these changes were not significant. CTP values before and after chemotherapy In the 1st group: BV 5.5 and 5.2 (p=0.83), BF 68.5 and 56.8 (p=0.21), PS 39.5 and 31.3 (p=0.3); in the 2nd group: BV - 7.3 and 5.9 (p=0.83), BF - 73.2 and 68.6 (p=0.58), PS - 35.0 and 30.7 (p=0.24), corr.
Conclusion: CTP parameters of the gastric cancer decreased after the first course of chemotherapy both in patients with good and poor response. Further improvements in CTP protocols and analysis are needed in order to make it a valuable tool to assess results of chemotherapy in gastric cancer.

B-0712 14:24

The CTP for detection of primary oesophageal carcinoma

M. Kantarci, A. Levent, R. Sade, S. Eren, H. Ogul, F. Guven, G. Bayraktutan; *Erzurum/TR (akkanrad@hotmail.com)*

Purpose: The purpose of this study was to investigate the efficiency of computed tomographic perfusion (CTP), contrast-enhanced computed tomography (CECT) and ^{18}F- fluorodeoxyglucose positron emission tomography (PET/CT) in the diagnosis of oesophageal cancer.
Methods and Materials: This prospective study consisted of 33 patients with pathologically confirmed oesophageal cancer of which 2 had oesophageal abscess. All the patients underwent CTP, CECT and PET/CT imaging and the imaging findings were evaluated. Sensitivity, specificity, positive predictive and negative predictive values were calculated for each of the three imaging modalities relative to the histological diagnosis.
Results: Thirty three tumours were visualized on CTP; on CECT:29, on PET/CT:27. Six tumours were stage 1 and the two and four tumours were missed by CECT and PET/CT, respectively. The significant differences were between the CTP and CECT (p:0.02), and CTP and PET/CT (p:0.04), for stage 1 tumours were found. Sensitivity, specificity, positive predictive. Corresponding values for and negative predictive value of CTP were 100%, 100%, 100% and 100%, respectively. Corresponding values for CECT were 93.94%, 0%, 93.94% and 0%, respectively, and those of PET/CT were 87.88%, 0%, 93.55% and 0%, respectively. Hence, the sensitivity, specificity, positive predictive and negative predictive values of CTP were better than those of CECT and PET/CT.
Conclusion: The CTP had an advantage over CECT and PET/CT in detecting small lesions. The CTP was valuable especially in stage 1 tumours.

B-0713 14:32

The value of dual-detector spectral CT imaging in the identification of gastric carcinoma and gastric lymphoma

S. Jiang, Y. Ren, H. Yan, X. Lu; *Shenyang/CN (1904451977@qq.com)*

Purpose: To explore the value dual-detector spectral CT scan in the differential diagnosis of gastric cancer (GC) and gastric lymphoma (GL).
Methods and Materials: 32 patients with gastric cancer and 12 patients with gastric lymphoma were retrospectively analysed. All patients were performed enhanced abdominal CT scanning with spectral CT. The attenuation values of virtual monochromatic energy 40 ~ 140 keV, iodine concentration and effective atomic number (Z_{eff}) of the two groups were measured. The normalized iodine concentration (NIC, lesion iodine concentration / aorta abdominalis iodine concentration) and the slope of the spectral curve (λ_{HU})were calculated in arterial phases and venous phases.
Results: In arterial phase, attenuation values of 40 ~ 70 keV of GL group were lower than that in GC group, the difference was significant at 40 keV, attenuation values of GC group was statistically higher than that in GL group (131.3 ± 67.6 HU vs 81.3 ± 40.4 HU; t = 2.56, P<0.05). λ_{HU} on 40 ~ 100 keV monochromatic images was higher in GC group than that in GL group (1.37±0.98 vs 0.65 ± 0.59; t=2.64, P<0.05). The NIC in GC group was higher than GL group (0.125±0.1 vs 0.061±0.06; t=2.34, P<0.05). The Z_{eff} in GC group was higher than GL group (8.1±0.47 vs 7.6±0.51; t=3.39, P<0.05).
Conclusion: Gastric cancer and gastric lymphoma have different energy spectrum CT characteristic parameters that can provide the reference value for clinical imaging to identify.

B-0714 14:40

Prognostic significance of systemic inflammation and FDG-PET bone marrow uptake in patients with oesophageal cancer

R.J. Pallas, K.G. Foley, T. Crosby, P.A. Fielding; *Cardiff/UK (robbyfromtherock-2@yahoo.co.uk)*

Purpose: Systemic inflammation is regarded as a poor prognostic indicator in cancer patients. FDG uptake is increased in areas of inflammation. Early research suggests novel immunotherapy techniques may be beneficial in selected cancer patients and treatment decisions could be guided by PET/CT. The aim of the study is to investigate the prognostic significance of bone marrow (BM) uptake in patients with oesophageal cancer (EC) and correlate serum haematological results with recorded standardised uptake values (SUV).
Methods and Materials: Consecutive patients with biopsy-proven esophageal cancer staged with PET/CT between October 2010 and July 2015 were considered. All patients underwent definitive chemoradiotherapy. Patients with haematological disorders and BM metastases were excluded. Mean BM SUV was calculated from regions of interest placed in 5 adjacent vertebral bodies. Cox regression models assessed the prognostic significance of clinical, metabolic and haematological variables. P values <0.05 were considered statistically significant. Primary outcome was overall survival (OS).
Results: Seventy-eight patients (median age 71 (range 35-81), 54 males, 38 adenocarcinomas, 35 squamous cell carcinomas) were included. Median OS was 25.0 months (95% confidence intervals 13.6-36.4). Radiological stage was significantly associated with OS (X^2 14.735, df 6, p=0.022). Age, tumour location, SUVmax of primary tumour, mean SUV of vertebrae, Hb, WCC, neutrophils, lymphocytes, platelets and albumin were not associated with OS (p=0.561, 0.971, 0.656, 0.869, 0.584, 0.216, 0.344, 0.324, 0.165, 0.378, respectively).
Conclusion: Radiological stage was significantly associated with OS. However, metabolic and haematological variables were not statistically significant. A larger cohort of EC patients is required to test this hypothesis.

B-0715 14:48

MRI of the gastric antrum for the quantification of gastric motility: comparison between obese and normal weight patients

S. Picchia, M. Rengo, D. De Santis, D.M. Bellini, S. Badia, A. Laghi; *Latina/IT (simona.picchia87@gmail.com)*

Purpose: To compare gastric motility in obese and normal weight patients with magnetic resonance imaging (MRI).
Methods and Materials: This is a non-randomized single-centre study. CineMRI for motility analysis was obtained by 1.5T MRI using 2DtrueFISP (coronal and axial planes) after 650-ml liquid meal (Nutridrink) plus 2 yolks, 1 albumen and 150 ml of water over 10 minutes. This 525-kcal meal was composed of 25% fat, 25% protein, and 50% carbohydrate. Images were acquired before and immediately after the meal and every 20 minutes, for a total exam time of 100 minutes. Each gastric motility scan lasted 60 seconds, with 100 images acquired in free breathing. Antral length, maximal contraction amplitude and contraction frequency were evaluated on a dedicated software. Results obtained in obese and normal weight patients were compared.
Results: Twenty patients (10 obese and 10 normal weight) were included in the study. Motility antral scans showed that during fasting and postprandial period, in obese patients the three parameters evaluated were significantly lower (mean basal antral length in obese patients: 6.75±0.8cm/in normal weight patients: 8.12±0.43cm, p value<0.05; mean postprandial antrum length in obese patients: 7.56±1.03cm/in normal weight patients: 9.4±0.12mm, p value<0.05; mean basal maximal contraction amplitude in obese patients: 7.1±0.72mm/in normal weight patients: 8.97±0.43, p value<0.05; mean postprandial maximal contraction amplitude in obese patients: 8.3±1.5mm/in normal weight patients: 9.76±0.76mm, p value<0.05; mean basal contraction frequency in obese patients 8.7±0.98cpm/in normal weight patients: 10.3±0.9, p value<0.05; mean postprandial contraction frequency in obese patients: 9.8±1.4cpm/in normal weight patients: 11.2±1.2cpm, p value<0.05).
Conclusion: MRI is able to identify differences in antral motility between obese and normal weight patients.

B-0716 15:56

Prediction of gastric cancer with synchronous hepatic metastasis by enhancement pattern of primary lesion using multiphasic contrast-enhanced computed tomography

D. Tsurumaru, Y. Nishimuta, T. Muraki, Y. Asayama, H. Honda; *Fukuoka/JP (tsuru-d@radiol.med.kyushu-u.ac.jp)*

Purpose: To examine contrast-enhanced computed tomography (CECT) features of primary site of gastric cancers with synchronous hepatic metastasis.
Methods and Materials: One hundred and eleven consecutive patients with pathologically proven advanced gastric cancers who were evaluated with CECT were enrolled. CT images were obtained 40s (arterial phase), 70s (portal phase) and 240s (delayed phase) after injection of nonionic contrast material. Eleven patients were diagnosed having hepatic metastasis at the time of diagnosis. Two radiologists in consensus determined the “peak enhancement phase” in which the lesion showed the highest attenuation value among the three phases for each case. The readers traced the entire tumour as the region of interest (ROI) of the gastric lesion, and measured the CT attenuation value for each phase. We compared the peak enhancement phase of positive hepatic metastasis group (n=11) and negative hepatic metastasis group (n=100) using Chi-square tests, and compared the CT attenuation values of the two groups in each phase using analysis of variance (ANOVA).
Results: The peak enhancement was significantly different between the two groups (p=0.0007); most of the positive hepatic metastasis cases had peak enhancement in the arterial phase. The CT attenuation values of positive hepatic metastasis cases were significantly lower than those of negative hepatic metastasis cases in the delayed phase.
Conclusion: Hepatic metastasis of gastric cancer may be predictable according to enhancement pattern of primary lesion on multiphasic CECT.

B-0717 15:04

MRI for response assessment after neoadjuvant chemoradiotherapy in oesophageal cancer: added value of diffusion-weighted imaging

S.E. Vollenbrock, F.E. Voncken, D.M. Lambregts, M. Maas, L.C. ter Beek, B.M. Aleman, R.G.H. Beets-Tan, A. Bartels-Rutten; *Amsterdam/NL (s.vollenbrock@nki.nl)*

Purpose: High accuracy is needed to select oesophageal cancer patients with a complete response (CR) after neoadjuvant chemoradiation (nCRT) for organ-preserving treatment instead of oesophagectomy. Performance of T2-weighted MRI (T2W-MRI) without and with diffusion-weighted MRI (DW-MRI) for response assessment after nCRT was determined.
Methods and Materials: Thirty-two patients with locally advanced oesophageal cancer underwent MRI (1.5T; T2W-MRI and DW-MRI(b-values=0,200,800 s/mm^2)) before and after nCRT with a maximum of 21 days between MRI and surgery. Three radiologists first scored only T2W-MRI. Secondly they rescored with DW-MRI. A 5-point score was used (1=definite CR, 3=inconclusive, 5=definite residual tumour). Histopathology after oesophagectomy represented the reference standard (Mandard tumour regression grade 1=CR, 2-5=residual tumour). Area under the ROC (AUROC), sensitivity and specificity were calculated considering MRI scores 3-5 as tumour-positive.
Results: Two out of 32 patients were excluded due to poor image quality. Seven (23%) of 30 patients achieved a CR. AUROCs for the 3 radiologists individually were 0.57, 0.67, 0.64 for T2W-MRI only and 0.76, 0.69, 0.72 with DW-MRI (p=0.06, 0.57, 0.60). Sensitivity for detecting residual tumour was 100%, 91%, 87% on T2W-MRI and 96%, 96%, 87% with DW-MRI. Specificity was 14%, 43%, 43% on T2W-MRI and 57%, 43%, 57% with DW-MRI.
Conclusion: T2W-MRI with DW-MRI shows fair accuracy of response assessment after nCRT in oesophageal cancer patients while T2W-MRI only performs poorly. Sensitivity of the combination is high, indicating that the risk of missing residual tumour is minimal. However, specificity is lacking. Future studies investigate if addition of (echo-)endoscopy improves response assessment.

B-0718 15:12

Perivascular infiltration and histologic difference: is it helpful to determine T stage of advanced gastric cancer in CT?

J. Kim, W.S. Chung, H.Y. Jang, H.C. Kim, T.S. Kang, H.J. Lee, J.S. Sohn; *Daejeon/KR (apple17171@naver.com)*

Purpose: This study aims to determine whether morphologic and histologic features are useful for CT T stage of advanced gastric cancer.
Methods and Materials: A review of medical records yielded the 160 patients with advanced gastric cancer, who had available preoperative stomach CT scans for review and were pathologically confirmed. Individual review of stomach CT scans was subsequently performed by two radiologists, who were blinded to pathologic stage. Using CT, they were classified according to standard T stage, perivascular T stage, and histologic T stage. Diagnostic accuracy of each T stage and time to progression (TTP) between positive and negative perivascular infiltration group were analyzed.
Results: Diagnostic accuracy of standard T stage, perivascular T stage, and histologic T stage was respectively 65%, 68.75%, and 77.5%. There was significantly different between diagnostic accuracy of standard T stage and histologic T stage. There was no significantly different between standard T stage and perivascular T stage. However, in the subgroup analysis that was pathologically confirmed as T3 and T4a, there was significantly different between standard T stage and perivascular T stage. In pathologically confirmed T3 and T4a group, TTP of negative perivascular group was longer than positive perivascular group.
Conclusion: Considering histologic differentiation and perivascular infiltration could be useful option for pre-operative CT T staging of AGC. Especially, perivascular infiltration is more useful option for differentiation of T3 and T4a gastric cancer.

Posterior tibial tendon dysfunction: clinical and magnetic resonance imaging findings having histology as reference standard

C. Messina[1], D. Albano[2], A. Corazza[1], S. Rapisarda[1], N. Martinelli[1], A. Bianchi[1], L.M. Sconfienza[1]; [1]*Milan/IT*, [2]*Palermo/IT (carmelomessina.md@gmail.com)*

Purpose: To investigate the correlation between MRI, clinical tests, histopathologic features of posterior tibial tendon (PTT) dysfunction in patients with acquired adult flatfoot deformity surgically treated with medializing calcaneal osteotomy and flexor digitorum longus tendon transposition.
Methods and Materials: Nineteen patients (11 females; age: 46years, range: 18-75) were pre-operatively evaluated using the single heel rise (HR) and the first metatarsal rise (FMR) sign tests. Two reviewers graded the PTT tears on a I-III scale and measured the hindfoot valgus angle on the pre-operative ankle MRI. The specimens of the removed portion of PTT were histologically analysed by two pathologists using the Bonar and Movin score. Linear regression, Spearman's rank order, and intraclass correlation coefficient (ICC) statistics were used.
Results: ICC for MRI was excellent (0.952). Correlation between FMR and HR tests was at limit of significance (r=0.454; P=0.051). HR and FMR significantly correlated to the Movin score (r=0.581; P=0.009 and r=0.538; P=0.018, respectively), not to the Bonar score (both with r=0.424; P=0.070). PTT tendinopathy grading at MRI significantly correlated to the FMR (p=0.041), but not to the hindfoot valgus angle (p=0.496), the HR (p=0.943), the Bonar (p=0.937) and Movin score (p=0.436). The hindfoot angle did not correlate to any of the other variables (p>0.264).
Conclusion: For PTT dysfunction, HR and FMR tests showed high correlation with histology evaluated using the Movin score, without correlation with the Bonar score. Semiquantitative grading of PTT dysfunction at MRI only correlates to the FMR and not to histology. The hindfoot valgus angle is not correlated to any of the considered variables.

Factors related to bone marrow oedema of accessory navicular bone in the evaluation with MR imaging

M. Tsuchiya, T. Masui, M. Katayama, M. Sasaki, K. Kawamura, Y. Hayashi, T. Yamada, H. Sakahara; *Hamamatsu/JP (D16018@hama-med.ac.jp)*

Purpose: A symptomatic accessory navicular bone was reported to show bone marrow oedema pattern (BMEP) in magnetic resonance imaging (MRI), but the relationship between BMEP and the characteristics of the accessory navicular bone and feet might not be clear. This study examined the relationship between accessory navicular-related BMEP and MRI-based measurements.
Methods and Materials: Patients with accessory navicular bone were enrolled from January 2004 to September 2017, including 20 patients with BMEP (8 females; mean age ± SD, 22.2 ± 15.1 years) and 29 control subjects without BMEP (14 females; mean age ± SD, 32.9 ± 19.6 years). The maximum length of the accessory navicular bone, protrusion percent, and arch height index (AHI), an indicator of flat feet, were obtained from MRI. Two observers independently conducted these measurements. Uni-/multivariate analyses were performed.
Results: Univariate analysis revealed that patients with BMEP showed longer maximum length (p<0.001), higher protrusion percent (p<0.001), and lower AHI (p<0.001) than those without BMEP. Multivariate logistic regression analysis revealed that patients with BMEP were more likely to show larger accessory navicular bones (odds ratio, 1.695; 95% confidence interval [CI]: 1.130, 2.544; p=0.011) and lower AHI (odds ratio, 0.759; 95% CI: 0.619, 0.930; p=0.008) than those without BMEP. The area under the receiver operating characteristic curve was 0.922.
Conclusion: Patients with accessory navicular bone with BMEP have larger accessory navicular bones and are more likely to have flat feet than those without BMEP. This information can be an objective basis for therapeutic strategy.

Detection of kinematic changes induced by sequential lateral ankle ligament section: a dynamic 4D-CT scan study

L. Buzzatti, B. Keelson, J. Apperloo, N. Buls, T. Scheerlinck, G. Van Gompel, J.P. Baeyens, J. De Mey, E. Cattrysse; *Brussels/BE (Luca.Buzzatti@vub.ac.be)*

Purpose: To investigate the potential of 4D-CT to detect kinematic changes induced by sequential lateral ankle ligament section.
Methods and Materials: The tibia of two fresh frozen specimens were fixed on a custom-made device and the ankle joint was moved at a pace of 25 cycles/minute. The anterior talo-fibular ligament, the calcaneo-fibular ligament and the posterior talo-fibular ligament were cut sequentially. Dynamic-CT scan image datasets of the intact ankle and after each ligament cut were acquired with a 256-slice GE Revolution CT-Scanner (80kV, 25mA, tube rotation time 0.28s, z-axis coverage 120mm, scanning time 3.92s). Rigid registrations of single bones (tibia, talus and calcaneus) were performed and transformation matrixes were derived. Using the global reference frame of the CT (x, y, z), the talo-crural (motion of talus relative to the tibia) and sub-talar (motion of calcaneus relative to the talus) joint kinematics were described as displacement of the centroid of the talus and calcaneus, respectively. Radiation dose was also recorded.
Results: The difference between the displacement of the intact ankle and the cut scenarios was up to 2.90mm, 1.19mm, 1.37mm (sub-talar joint) and up to 2.63mm, 2.58mm, 5.46mm (talo-crural joint) for the x-, y-, z-axes, respectively. Comparing the intact and injured ankle, deflections in the centroid displacement curves occurred at different time points. Each acquisition required a radiation dose ($CTDI_{vol}$) of 1.9mGy.
Conclusion: The present study showed that low-dose 4D-CT may allow to detect motion changes of the talo-crural and sub-talar joint induced by lateral ankle ligament lesions. This highlights the potential of 4D-CT to investigate dynamic functional joint laxity.

B-0722 14:24

Value of b-mode ultrasonography and real time sonoelastography for detecting injury of the lateral ligaments of the ankle joints

A. Karadayi, T. Ozer, N. Voyvoda, B. Fariz; *Kocaeli/TR (aysegulkaradayi@hotmail.com)*

Purpose: We aimed to demonstrate the effectiveness of Ultrasound Elastography(USE) in lateral collateral ligament (LCL) injury due to recurrent ankle sprain, to compare with LCL elastography findings of healthy individuals.
Methods and Materials: A total of 108 ankles in 54 patients with a clinical suspicion of ankle ligament injury and total of 60 ankles in 30 healthy volunteers were included. The LCL including ATFL, CFL, PTFL were divided into the following thirds for images evaluation: proximal, middle and distal. Longitudinal images of each tendon were obtained using ultrasonography (US) and USE. Each tendon were evaluated in four grades and measured for length and thickness in US images. USE images were evaluated in four grades for elasticity pattern, strain ratios(SR).
Results: The ATFL lengths were shorter in the patient group than the control group ($p<0.05$). The grades of ATFL, CFL, PTFL were found to increase in the patient group than the control group based on US findings ($p<0,05$). The elastogram types of ATFL and CFL were different from the control group ($p<0.001$). In the patient group, the values of SR and mean SR values for ATFL and CFL were found to be significantly lower than the control group ($p<0.001$)
Conclusion: US can be used as an effective non-invasive diagnostic method to demonstrate LCL injuries resulting from recurrent sprains of the ankle in active athletes. The USE examination is also a valuable US-based diagnostic method which can show alterations in the ligament structures during recurrent traumas of LCL in the asymptomatic period

B-0724 14:32

Subtalar instability and lateral ankle instability: the difference with emphasis on subtalar ligaments using 3-D isotropic MRI

D. Yoon, S. Moon; *Seoul/KR (ydy0222@gmail.com)*

Purpose: To investigate, using 3-D isotropic MRI, the difference between subtalar instability (STI) and lateral ankle instability (LAI) with emphasis on subtalar ligaments.
Methods and Materials: Preoperative MRIs of 10 patients with STI treated with arthroscopic subtalar reconstruction were compared with MRIs of 23 patients with LAI only. The thickness and width of the anterior capsular ligament (ACL), interosseous talocalcaneal ligament (ITCL), thickness of calcaneofibular ligament (CFL) and anterior talofibular ligament (ATFL) were measured (Mann-Whitney test). Abnormalities in the ACL, ITCL, CFL, ATFL, cervical ligament and inferior extensor retinaculum were analysed by two radiologists.
Results: Patients with STI had a significantly smaller ACL thickness (1.48mm vs 2.12mm in LAI; $p=0.012$) and smaller ACL width (7.30mm vs 8.64mm in LAI; $p=0.007$) compared with those with LAI. The ACL thickness of ≤1.8 mm had sensitivity of 80.0% and specificity of 75.0% and the ACL width of ≤8 mm had a sensitivity of 80.0% and a specificity of 85.0% for discriminating STI from LAI. The thickness of ATFL was significantly larger in patients with LAI ($p=0.001$). Absence or complete tear of ACL was more common in patients with STI (60.0% vs 13.0% in LAI; $p=0.010$). Complete tear of ATFL was more common in patients with LAI (60.9% vs 10.0% in STI; $p=0.008$).
Conclusion: Thin or narrow ACL in the tarsal sinus are suggestive of STI rather than LAI. Absence or complete tear of ACL was more common in patients with STI. Complete tear of ATFL is more common in patient with LAI.

B-0725 14:40

Usefulness of T2 mapping sequences for the evaluation of Achilles tendinopathy with 3T MRI

E. Cannizzaro, S. Quarchioni, F. Bruno, C. Gianneramo, S. Mariani, F. Arrigoni, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (estercannizzaro@hotmail.it)*

Purpose: To investigate the capability of T2 mapping sequences on a 3T scanner in evaluating quantitatively Achilles tendon (AT) composition.
Methods and Materials: 13 patients (8 male, 5 female, mean age 34.7 years, range 24-61) with clinical and instrumental evidence of tendinopathy of the AT and 13 healthy volunteers (9 male, 4 female, mean age 36.4 years, range 26-59) were examined on a 3T MR scanner with standard morphological and T2 mapping sequences. The AT was divided into 3 clinically relevant subregions: insertion (INS), midportion (MID) and muscle-tendon junction (MTJ).Regions of interest (ROI) were used for quantitative assessment and mean values of T2 relaxation times were recorded.
Results: In asymptomatic volunteers, we obtained mean T2 values of 42.27ms at the insertional area, 36.24ms in the midportion and 45.91ms at the muscle-tendon junction. In patients with low-grade tendinopathy the mean T2 values were: 45.8 at the MTJ, 54.86 at the MID, 44.90 at the INS, with statistically significant higher values in the midportion compared to the matched healty controls ($p<0.05$). In patients with high grade tendinopathy mean T2 values were significantly lower than the control group in all subregions: 25.90 at the MTJ, 16.56 at the MID, 23.85 at the INS ($p<0.05$).
Conclusion: Our study provides normal T2 values for asymptomatic AT and T2 values changes in degenerated tendons. These reference values can be used for comparison in order to diagnose subtle degeneration and can be a reliable tool to monitor treatment related tendon healing.

B-0726 14:48

Importance of sonoelastographic assessment of ruptured and contralateral achilles tendons - prevention of further injuries

I. Dumic Cule, G. Ivanac, D. Lemac, B. Brkljacic; *Zagreb/HR (ivodc1@gmail.com)*

Purpose: The concept of assessing the mechanical properties of the Achilles tendon after reconstruction using ultrasound shear wave elastography (SWE) and its positive correlation with standardised questionnaires has been recently introduced in the clinical practice. Since it was demonstrated that about 6% of patients with ruptured Achilles tendon experience the rupture of contralateral tendon in the future, the aim of this study was to estimate the risk for rupture of contralateral tendon in patients who underwent surgical reconstruction of ruptured Achilles tendon by using subjective questionnaires and ultrasound SWE.
Methods and Materials: Twenty-four patients who underwent surgical repair of the ruptured achilles tendon and twelve aged matched healthy controls were examined with ultrasound SWE. Functional outcomes were assessed with American Orthopedic Foot and Ankle Society (AOFAS) scoring system and subjective rating system which we introduced and validated.
Results: The elasticity of injured tendon was markedly decreased (by 42%) compared to contralateral tendon of the patient, as expected. Both AOFAS score and our novel subjective assessment scale positively correlate with ultrasound SWE values in ruptured Achilles tendons. The elasticity of contralateral Achilles tendons in patients is 23% lower than among healthy individuals.
Conclusion: Irrespective of the lack of difference in the subjective feeling assessed by AOFAS, the contralateral tendon in the patients with reconstructed Achilles tendon has significantly lower elasticity than healthy individuals. Therefore, contralateral tendons in patients who suffered from rupture are more prone to future ruptures.

B-0727 14:56

MRI T2 mapping: a sensitive and reliable approach to examine changes in muscle metabolism of extrinsic foot muscles

G. Bratke, S. Willwacher, K. Weiss, D. Maintz, G.-P. Brüggemann; *Cologne/DE (grischa.bratke@uk-koeln.de)*

Purpose: The aim of the study was to examine the sensitivity and reliability of T2 mapping demonstrating changes in metabolism of the extrinsic foot muscles through experimentally varied foot and ankle biomechanics in running.
Methods and Materials: Twelve volunteers completed three 75-min treadmill running sessions at constant speed in a neutral shoe (NS) and two experimental shoes. Experimental shoe 1 (ESm) has posts on the medial aspect of the midsole increasing the stiffness to control the foot eversion and moves the point of ground reaction force application (PFA) medially. Shoe 2 has posts on the lateral border and shifts the PFA laterally. T2 mapping was taken with a Carr-Purcell-Meiboom-Gill-sequence on a 3T Philips Ingenia Scanner before the run, after 2.5, 45 and 75 minutes. ANOVA was applied to identify differences related to the biomechanical intervention and the duration of exercise.
Results: For all muscles, T2 mapping identified a significant increase in T2 times after 2.5 min ($p<0.001$) and a decrease after 45 and 75 min ($p<0.001$). ANOVA showed a significant smaller increase in T2 times for the NS compared to ESm in the lateral and medial (MG) head of the gastrocnemius muscle, soleus, extensor digitorum longus and peroneus (e.g. MG: NS +13.17%; ESm +15.27% ($P<0.001$)).
Conclusion: T2 mapping documents sensitively experimentally induced changes in foot and ankle biomechanics during running and related muscle activation with higher spatial resolution than surface electromyography. The decrease of T2 times might be a correlate of an earlier described intramuscular lactate decrease during prolonged exercise.

Diabetic foot complicated by osteomyelitis: the role of multiparametric magnetic resonance tomography

M. Zamyshevskaya, V. Zavadovskaia, M. Zorkaltsev, V. Udodov, E. Grigoriev; *Tomsk/RU (Zamyshevskayamari@mail.ru)*

Purpose: To evaluate the possibilities of multiparametric magnetic resonance imaging for the identification of osteomyelitis (OM) in the diabetic foot (DF).
Methods and Materials: 90 patients (51 male (56.7%), 39 female (43.3%); mean age 56.43±13.20) with suspected diabetic foot bone infections were studied. MRI was performed by using the Siemens MAGNETOM Essenza MRI-scanner (1.5T) in the T1, T2, FSat. After native images, MR angiography with contrast enhance was performed (Gadobutrol, 15ml). Delayed post-contrast MR study was performed in T1-SE.
Results: Pyoinflammatory processes in patients with diabetic foot syndrome according to CE MRA were associated not only with accelerated contrast travel time (26.04±8.03s), but in ischemic form of complicated DF - with delayed contrast travel time (38.20±6.47s), other features were early venous visualisation because of arteriovenous shunting, long-time local increase of the contrast accumulation in the area of interest. Osteomyelitis in patients with diabetic foot syndrome characterised by junction ulcer/fistula to the bone with increased marrow signal in T2 and FSat for native MRI followed by the appearance of constant local increased contrast accumulation in the soft tissue area of interest in conjunction with the long-term increase of bone marrow signal for postcontrast MRI.
Conclusion: Multiparametric MRI is informative diagnostic method in diagnostics of osteomyelitis in the diabetic foot, because complex morphofunctional vascular assessment in combination with bone inflammatory process detection should help to decrease amputations and volume of the resected fragment.

B-0729 15:12

T2 mapping of Achilles tendinopathy: our experience using T2 mapping sequences in the diagnosis and evaluation of treatment response after PRP therapy

I. Capretti[1], F. Bruno[1], S. Quarchioni[2], P. Palumbo[1], S. Mariani[1], F. Arrigoni[1], L. Zugaro[1], A. Barile[1], C. Masciocchi[1]; [1]*L'Aquila/IT*, [2]*Teramo/IT (ilaria_capretti@hotmail.it)*

Purpose: To evaluate the capability of T2 mapping in evaluating semiquantitatively changes in Achilles tendon after PRP treatment.
Methods and Materials: We evaluated 15 patients (10 males and 5 females with mean age of 35.2 years, range 26-51) with Achilles tendinopathy at different degrees (mild-intermediate, 7 patients, group A ; moderate-severe 8 patients, group B). All patients were treated with US-guided intratendinous injection of Platelet-Rich Plasma (PRP). They were examined on a 3T MR scanner with standard morphological and T2 mapping sequences before and after six months from treatment.
Results: In patients with mild-intermediate grade tendinopathy the mean T2 values before treatment were: 46.2 at the muscle-tendon junction(MTJ), 53.70 at the midportion(MID), 42.70 at the insertion(INS), with statistically significant higher values in the midportion compared to the matched healty controls ($p<0.05$). After six months to treatment with PRP they showed an improvement of T2 values in midportions similar to normal values (36,24 ms). In patients with moderate-severe grade tendinopathy mean T2 values were significantly lower than the control group in all subregions: 23.94 at the MTJ, 15.10 at the MID, 20.50 at the INS ($p<0.05$) and after six months they didn't show significant variations of T2 values.
Conclusion: According to our preliminary results, T2 mapping shows an high capability to assess and follow-up Achilles tendon pathologies togheter with other standard morphologic sequences and is usefullness in predict Achilles tendon changes after PRP therapy.

Automatic computation of liver and lung perfusion parameters through the analysis of CT image sequences

S. Malavasi[1], G. Gavelli[2], V. Vilgrain[3], A. Bevilacqua[1]; [1]*Bologna/IT*, [2]*Meldola/IT*, [3]*Clichy/FR (s.malavasi@unibo.it)*

Purpose: The goal of this PhD thesis work is contributing to advance Computed Tomography perfusion (CTp) towards standardization by improving the accuracy of perfusion results(1), the clinical relevance of studies where global perfusion parameters are commonly utilised(2) and the reproducibility of results in multicentre studies(3).
Methods and Materials: 315 liver CTp examinations from 14 Centres and 34 lung CTp studies were considered. First, through a voxel-based analysis of the time-concentration curves, an error index capable to *measure* the quality of perfusion results was set up and validated. Thereafter, an adaptive algorithm exploiting that error index was developed to automatically detect on CTp maps misleading perfusion values (1). Then, a measure of tumour functional heterogeneity was conceived(2). Finally, data pertaining to a large multicentre study on liver CTp (PIXEL) were analysed to also investigate the effects of the sources of protocol heterogeneity(3).
Results: The algorithm developed was correctly able to identify and exclude from the analysis vessels, bronchi, and artefacts, allowing to improve perfusion results reliability(1). Global values cannot take into account haemodynamic heterogeneity proving to even mislead clinical considerations(2). Tentative guidelines were provided to help planning protocols(3).
Conclusion: Reliability of results improved by detecting and removing unreliable CTp values. A measure of functional heterogeneity must be provided together with mean perfusion values to improve the clinical representativeness of the studies. In conclusion, the automatic methods implemented and the tentative guidelines for multicentre studies represent a clear step forwards to CTp translation in the standard clinic.

Use of calcium chloride as a calibration phantom material to aid identification of clinically significant compounds with spectral CT

T.E. Kirkbride, N. Anderson, A.Y. Raja; *Christchurch/NZ (tracy.kirkbride@ara.ac.nz)*

Purpose: Material identification using spectral CT relies on scanning known concentrations of compounds of interest to enable calibration of the material decomposition software for spectral photon-counting CT (SPCCT). Clinically significant compounds, such as calcium hydroxyapatite (HAP), do not dissolve well and preparation requires creating a suspension, which may not be spatially stable. We show that calcium chloride can be used as a substitute for such compounds during this procedure, by comparing these solutions with commercial solid HAP rods, the advantage of the rods being the stable and uniform distribution of HAP.
Methods and Materials: A range of serially diluted concentrations of calcium chloride and commercially available solid inserts of HAP, with CT water as base material, were used. High-resolution images of the samples were generated using a preclinical MARS SPCCT scanner equipped with the Medipix3RX photon processing detector bonded to cadmium-zinc-telluride.

Images of the calibration phantom were obtained using energy thresholds 20, 30, 40 and 50 keV at 80 kVp. Theoretical attenuation coefficients of HAP and calcium chloride were used to determine the effective HAP concentration of the calcium chloride samples. This information, along with the MARS SPCCT signals from the calcium chloride, was used to calibrate the system.
Results: Concentrations of calcium chloride whose attenuation profile matches that of HAP have been determined. MARS SPCCT data from HAP rods shows calcium chloride can be used to substitute HAP.
Conclusion: Substitution of soluble compounds for insoluble compounds within a calibration phantom for spectral CT is possible, potentially improving material identification.

The effect of motion blur and noise on the precision and accuracy of wrist joint kinematics detection from 4D-CT scans
G.J. Streekstra, M. de Roo, S.D. Strackee, I. Dobbe; *Amsterdam/NL (g.j.streekstra@amc.uva.nl)*

Purpose: Recent developments in 4D CT acquisition techniques enable detection of kinematics of carpal bones in the wrist joint. Detection of carpal kinematics requires the patient to move the wrist, while multiple 3D CT scans are acquired. If the wrist motion is too fast, time frames in the 4D image sequence will become blurry and therefore, may become unusable for kinematics detection. We investigated the impact of motion blur and noise on kinematics estimates from 4D-CT images**.**
Methods and Materials: 4D CT images were acquired of a phantom representing a wrist joint, while moving with known rotational speed. For this purpose we used a dedicated 4D scan protocol on a regular Philips Brilliance 64 slice CT scanner. The wrist phantom was created by segmenting a wrists' anatomy from a CT-scan and subsequent 3D printing by additive manufacturing. Joint kinematics was estimated by 4D image analysis methods involving segmentation of wrist bones from a static CT scan and image registration of the segmented bones to the time frames in the 4D scan.
Results: The experiments reveal that, within a physiological range of carpal bone velocities, the accuracy of joint kinematics estimation are in the order of 1 degree for rotational and 0.2 mm for translational parameters. Systematic errors in kinematical parameters increase slightly with rotational speed.

Conclusion: The limited influence of wrist joint motion on kinematic parameters ensures sufficiently accurate estimation of carpal bone kinematics with regular 64 slice 4D CT scanners in patients.

B-0733 14:24

Context-sensitive organ-specific evaluation and analysis of dual-energy computed tomography (DECT)
S. Dorn[1], S. Chen[2], F. Pisana[1], M. Özdemir[1], J. Maier[1], S. Sawall[1], M. Knaup[1], A. Maier[2], M. Lell[3], M. Kachelrieß[1]; [1]*Heidelberg/DE*, [2]*Erlangen/DE*, [3]*Nürnberg/DE (marc.kachelriess@dkfz.de)*

Purpose: To combine various organ-dependent dual energy evaluation methods into an automatic and standardized analysis tool to facilitate radiologists' workflow.
Methods and Materials: There are many commercial DECT applications, which provide a multitude of information about the tissue type, material composition or function. However, all applications automatically process the entire dataset and the user needs to invoke each one separately. The proposed method automates and standardizes the DE applications using prior anatomical information. By means of a 3D convolutional neural network, the DECT data are classified into different organs. The ROIs that are required for patient-specific calibration of the algorithms can now be placed automatically into the corresponding anatomical structures and the applications are automatically selected and only applied to the specific organs. This context-sensitive analysis allows to simultaneously evaluate multiple organs and to show organ-specific dual energy overlays wherever appropriate.
Results: Ten contrast-enhanced DECT patient datasets are processed. The data are acquired with a dual source CT system. We are able to automate and standardize the spectral analysis of the DE data using prior anatomical information. Each tissue type is evaluated with its corresponding DE application simultaneously. The results are identical with those obtained by a user who manually calibrated, selected and applied the applications to various organs.
Conclusion: The proposed method is an important step towards the presentation of evermore increasingly complex information in spectral CT and towards improving the radiologists' workflow significantly. The method can readily be generalized to the automatic evaluation of multi energy CT data.

B-0734 14:32

Deep convolutional neural network (D-CNN) for efficient and automatic lung cancer detection
I. Shiri, P. Geramifar, A. Bitarafan-Rajabi, A. Mohammadzadeh, H. Pouraliakbar; *Tehran/IR (Isaac.sh92@gmail.com)*

Purpose: Lung cancer is one of the most widely cause of cancer death in the world. One of the most challenging task is the early detection of lung cancer in full 3D CT-Scans. In this study we present a deep learning framework for efficient and fully automated lung cancer detection in 3D CT-Scan images.
Methods and Materials: 750 CT scan of patients (430 non-cancers and 320 cancerous) from KDSB17 were used in this study. Image preprocessing such as variance reduction image re-sampling to an isomorphic resolution , Lung segmentation, Normalization, and Zero centering in order to reduce the problem of space were performed. The 3D Convolution layers perform 3×3×3 convolutions with stride 1×1×1 and no padding, and of 3D Pool layers perform with 2×2×2 max pooling with stride 2×2×2 (and no padding). ReLU function was used as activation functions, and soft-max layer was applied for binary classification of cancerous and noncancerous patient.
Results: The 3D deep convolutional neural network were performed on different iterations and epochs and the best accuracy of D-CNN was reached to 69.7 percent.
Conclusion: Accuracy of model was acceptable at CAD study, however the radiologist needs more detailed information than just one single series of CT scan for diagnosis (e.g., time series of CT scan over a few month, biopsy information, and metabolic imaging). Deep learning model need to use more data-set and also more information than just one single series of CT scan to improve its performance and reaching human observer level.

B-0735 14:40

A noise-robust and accurate measurement method for the wall thickness of small airways in low-dose CT scans
Z. Yang[1], H. Jin[1], J. Kim[1,2]; [1]*Suwon/KR*, [2]*Seoul/KR (yangzepa@snu.ac.kr)*

Purpose: Small airway dimensions are important biomarkers for evaluation of pulmonary diseases, such as asthma, COPD, etc. We present a novel method, attenuation profile matching (APM) technique, which provides accurate determination of small airway dimension as well as robustness to CT scan parameters.
Methods and Materials: The point spread functions of a CT were acquired and employed for generating synthetic attenuation profiles of an airway by taking convolution with the numerical airway models of varying wall thickness. Dimensions of a given airway were determined as those of the numerical model yielding minimum error between the measured and synthetic attenuation profiles across the airway.
Results: In a phantom study with airway tubes, proposed method was shown to be highly accurate in determining airway dimension. The measurement error for the 0.6 mm thick tube with 3 mm diameter was as small as 0.02 mm (3.3%) in wall thickness and 0.17 mm (5.6%) in lumen diameter. And for the wall thickness, error for the smallest (0.6 mm thick) tube was 0.02 mm (3.3%). In a pilot patient study, the proposed method could distinguish the airway thickness of COPD cases (1.16 ± 0.23 mm) from that of normal subjects (0.6 ± 0.18 mm) while the measurements with FWHM substantially overlapped (1.45 ± 0.32 mm vs. 1.28 ± 0.30 mm) and thus hardly be distinguished each other.
Conclusion: Our proposed APM technique has a potential to overcome the resolution limitations of current CT systems and determine the small airway dimensions of COPD patients accurately.

B-0736 14:48

Real-time x-ray scatter estimation for CT and CBCT using a deep convolutional neural network
J. Maier, S. Sawall, M. Kachelrieß; *Heidelberg/DE (marc.kachelriess@dkfz.de)*

Purpose: Scatter correction is crucial to maintain the diagnostic value and to obtain quantitative images in CT and CBCT. Current scatter correction approaches are either too inaccurate or too slow. Therefore, we developed the deep scatter estimation (DSE) algorithm: a deep convolutional neural network to derive accurate scatter estimates in real-time.
Methods and Materials: The gold standard of scatter correction is to subtract a scatter estimate derived by a Monte Carlo (MC) photon transport code. However, being computationally expensive, MC simulations cannot be used routinely. To combine high accuracy and real-time applicability, DSE uses a modified U-net that is trained to reproduce the outcome of MC simulations based on the acquired projection data. This study demonstrates the potential of DSE using simulations and measurements of an experimental CBCT system. Two conventional computationally efficient scatter estimation approaches were implemented as reference: A kernel based scatter estimation (KSE) and the hybrid scatter estimation (HSE).

Results: The mean absolute error (MAE) between MC and KSE, HSE and DSE was used as a performance measure. Considering the simulated data, we observe a MAE of 14.1 % (KSE), 7.2 % (HSE) and 1.1 % (DSE). Similar results are obtained for measured data with a MEA of 16.7 % (KSE), 7.8 % (HSE) and 2.8 % (DSE).
Conclusion: DSE clearly outperforms conventional scatter estimation approaches in terms of accuracy while requiring similar processing time. DSE performs nearly as accurate as Monte Carlo simulations but is superior in terms of speed by orders of magnitude.

B-0737 14:56

An innovative MRI harmonization method for multicentre radiomic analysis in glioblastoma

S. Reuzé[1], A.-S. Dirand[1], R. Sun[1], F. Orlhac[2], G. Louvel[1], S. Ammari[1], E. Deutsch[1], c. robert[1]; [1]*Villejuif/FR*, [2]*Orsay/FR*
(sylvain.reuze@gustaveroussy.fr)

Purpose: MR-based radiomic features show a great correlation with tumour heterogeneity and treatment outcome, but also a strong dependence on acquisition parameters.
Methods and Materials: 190 glioblastoma patients with multicentre T1-Gd MRI were retrospectively included. Two spheres were delineated in the white matter (WM). Tumour (GTV) was manually segmented. Post-processing was performed as follows: an intensity rescaling to [0–32767] to erase inter-patient differences in intensity range, then a resampling on a 0.5x0.5x0.5mm^3 grid. 39 radiomic features were extracted using LIFEx freeware. Wilcoxon analysis was performed between sets of feature values in WM to assess the robustness of features among different scanners. Different methods of discretization were investigated in GTV: relative (RD) or absolute (AD) with 32–256 levels. Spearman correlation coefficients ρ were computed in GTV between all features, and between each feature and tumour volume.
Results: Histogram characteristics extracted from WM highlighted a large scanner dependence ($p<0.05$). RD (32 or 64 bins) limited this dependence for textural features. Only two histogram features were robust among all devices, whereas 7 histogram and 7 textural features were robust depending on magnetic field strength ($p>0.05$). After postprocessing, RD highlighted correlations between features and tumour volume ($|\rho|>0.5$, 8 features). AD decreased these correlations and reduced the dependence of features between devices. For 25 couples of devices, there were at least 25 robust features, and 11 textural features were robust among magnetic field strength ($p>0.05$).
Conclusion: We proposed a simple and innovative MRI harmonization method which showed promising results on a large multicentre cohort.

B-0738 15:04

ROI-based phase analysis for neuronal current MRI

T. Yoneda, M. Iwata, H. Indo, N. Kurehana, S. Yoshinaga, M. Takeda, H. Terasawa; *Kumamoto/JP (tyoneda@kumamoto-u.ac.jp)*

Purpose: Functional MRI (fMRI) using BOLD effect is noninvasive tool for study of neuro activation in various areas. In this twenty years, alternative principle of BOLD was suggested so called Neuronal Current MRI (ncMRI). The ncMRI is designed so as to directly detect neuronal current on MRI. This study suggested an ROI-based analysis approach to sensitively detect neuronal current via MR-phase information.
Methods and Materials: We prepared axon imitated phantom in which cellophane tube with 1 mm diameter as axon was located. Potassium and Sodium were doped in the 20 %/w gelatin and it was filled in the phantom to realise source of neuronal current. The neuronal current (5 uA) was induced by alternative voltage with 40 Hz. MRI scan were carried out on 7T-MRI (BioSpec 20/70 USR, Bruker BioSpin, Germany) with FLASH sequence with solenoid transmit-receiver coil. All MR-images were acquired a plane perpendicular to long axis of axon. Phase image was derived in DICOM format and unwrapped by high-pass filter to remove unwanted phase bias. Phase around the axon was measured by setting circular ring ROI and phase signal was statistically evaluated by student's-t test between current on and off.
Results: Statistics showed significant difference ($p < 0.05$) when the charge carried by current during scan was larger than 100 nC, but no significant difference less than 50 nC.
Conclusion: The ncMRI with phase information could detect very small but biologically reasonable current. Our study showed limit of sensitivity depended on total charge during scan.

B-0739 15:12

MRI delta-radiomics feature robustness and reproducibility: the impact of image registration and day-to-day repeat-ability in GBM cancer patient

I. Shiri, G. Hajianfar, H. Abdollahi, S. Shayesteh, h. pouraliakbar, A. Bitarafan-Rajabi, A. Mohammadzadeh, P. Geramifar; *Tehran/IR (Isaac.sh92@gmail.com)*

Purpose: Delta-radiomics features can be used as prognostic models during therapy courses and time series data analysis. As the image registration is one of the main process in time series and multi-modality image analysis, the purpose of this study is investigate the impact of image registration on delta radiomics features.
Methods and Materials: Ten patients' data with recurrent GBM who underwent brain MRI were used in this study. T2w, T1w Images were registered by different methods including, Full affine (12 DOF), Full scale (9 DOF), Global scale (7 DOF) and Rigid body (6 DOF). Following image registration, GBM lesions were segmented and delineated using semi-automatic 3D region growing algorithms. 94 quantitative 3D features were extracted from each lesion, corresponding to size, shape, Intensity histogram and textural feature. All radiomics features were categorised into 3 groups based on coefficient of variation (COV) including a small (COV ≤10%), intermediate (10 % < COV ≤25%) and large (COV >25%) range of variation with respect to the mean.
Results: All shape features such as compactness, elongation and spherical disproportion and 71 (73%) features have good reproducibility. Eleven intermediate reproducibility and 14 remain features including difference entropy, entropy, difference variance, cluster shade, cluster prominence, inverse variance from GLCM and GLV from GLRLM, and Entropy from intensity have low reproducibility.
Conclusion: Delta-radiomics feature robustness and reproducibility in brain MRI due to image registration is feature-dependent. Delta-radiomics features with low COV are better candidates for robust tumour quantification in time series data analysis and clinical practice.

B-0740 15:20

Wavelet-based radiomics texture features stability in MRI of GBM patients: a test-retest study

I. Shiri, G. Hajianfar, S. Shayesteh, H. Abdollahi, H.R. Pouraliakbar, A. Bitarafan-Rajabi, A. Mohammadzadeh, P. Geramifar, A. Sanaat; *Tehran/IR (amir.sanaat@gmail.com)*

Purpose: Radiomics texture features have been recently introduced as quantitative image bio-markers which can be used potentially for diagnosis, prognosis and prediction of response to therapy in cancer patient. One of major challenges in this era is validity of this quantitative parameters. The main aim of current study was to evaluate stability of radiomics features in test retest study.
Methods and Materials: Fifteen patients with recurrent GBM who underwent repeated MR imaging with approximately two day interval were included to current study. All lesions were segmented to whole tumor, necrosis area and active tumor area. Following wavelet decompositions of image, eight images were derived. Following segmentation and decompositions of images, 632 quantitative 3D textures based on GLRLM, GLCM and GLSZM, were extracted from the 3D-tumor volumes of each segmentation. For every radiomics feature, test-retest was assessed with the intra-class correlation coefficient (ICC) and the concordance correlation coefficient (CCC) and finally the most reproducible and robust radiomics features were selected.
Results: 455 texture feature (71%) such as GLNUN from HHH_glrlm and Entropy from HHH_glcm had good reproducibility. 114 texture features (18%) had intermediate reproducibility and remain (11%) such as Autocorrelation from LLH_glcm, from LLH_glszm and Cluster Shade from LLL_glcm.
Conclusion: Test-retest and correlation analyses have identified redundant radiomics wavelet based textures which would be prone to errors if they employed as quantitative biomarker for GBM image analysis. Using reproducible texture warranted more advanced applications of this quantitative parameters as being used for treatment monitoring, outcome prediction or imaging biomarkers.

Relationships between image quality and radiation dose during paediatric pelvis radiography: a factorial phantom study

A.H. Mohammed Ali[1], P.H. Hogg[1], A. England[2]; [1]*Salford/UK*, [2]*Manchester/UK (p.hogg.@salford.ac.uk)*

Purpose: Paediatric pelvic radiography exposure factor selection is difficult due to age/size variations; this study evaluates image quality and dose for a range of acquisition parameters.
Methods and Materials: 2,016 DR images were acquired using a 5-year-old pelvis phantom. Acquisition parameters included: KVp (56-89, 3 kVp increments), mAs (1-16, 1 or 2 mAs increments), SID (100, 115, 130 and 145 cm) and filtration (0, 2 mm Al and 1mm Al + 0.1 mm Cu). Image quality (IQ) was assessed using physical and visual methods. Physical included SNR and CNR. Visual involved observers scoring sharpness and noise. Entrance surface dose was measured. Regression and main effect plots were conducted.
Results: Adjusted (R^2) was 0.76 for radiation dose; range = 0.31-0.78 for IQ. Increasing additional filtration had the greatest impact decreasing IQ (physical β=-6.72 and visual β=-1.13) and radiation dose (β=-50.0). mAs increased radiation dose (β=17.32) and IQ (physical β=0.63, visual β=17.32). Elevating KVp increases radiation dose (β=4.92); initially it increases IQ, then it reduces (physical β=-0.15, visual β=0.49). As SID increases dose reduces (β=-2.60) and IQ remained unchanged (physical β=-0.80, visual β=-0.09). Main effect plots for each exposure parameter showed different relationships when compared to others: either linear, or non-linear, with plateauing. SID=115cm produced the highest levels of image sharpness.
Conclusion: Paediatric optimisation studies should consider a full factorial design to identify the impact of all acquisition parameters. Increasing KVp whilst reducing mAs produces lower dose and maintains IQ, but only for specific levels of filtration and SID.

B-0742 14:08

PA vs AP positioning in digital radiography of lumbar spine: the impact of kVp in large-sized patient image quality

E.Y. Boateng[1,2], H.K. Shariati[1], R.K. Sharma[2], A. Sanderud[2]; [1]*Kongsvinger/NO*, [2]*Oslo/NO (emmboa@ous-hf.no)*

Purpose: Investigate differences in lumbar spine radiography when changing from AP to PA projection and impact of a large patient size and kVp.
Methods and Materials: The radiography was performed at a Canon Triathlon T3 with CXDI 401C detector using AEC with 100mAs cut-off, 50-100kVp to image a RS-113 pelvis phantom. Without modifications, the phantom had a 32-inch waistline. By adding 4 kg ox fat at the stomach region, and 1 kg on the back and buttock of the phantom, a large patient with a 44-inch waistline was simulated. With 10 observers, an absolute visual grading analysis (VGA) study using a 5-point Likert scale was performed to assess the images in sharpness, noise, and overall diagnostic quality. Effective dose was calculated using PCXMC.
Results: The VGA-study showed no significant difference between the image quality in AP and PA (p = 0.084). The best average VGA scores, AP=4.6 and PA=4.4, were at 70 kVp for the standard-sized images while effective dose was calculated to be reduced by 64% when changing from AP to PA projection. With the large-sized phantom the 80kVp had the best VGA scores, AP=3.8 and PA=3.7, and effective dose was reduced 44% in the PA projection. The PA projection magnification of the spine give a slight reduction in sharpness.
Conclusion: The result of the study shows that PA projection provides a lower effective dose to the patient compared with AP projection with no significant reduction in visible image quality. This is seen in both standard- and large-sized patient.

B-0743 14:16

Indexing DICOM metadata from medical imaging repositories: opportunities and challenges

M. Rodrigues dos Santos; *Aveiro/PT (mrs@ua.pt)*

Purpose: DICOM metadata, stored in medical image repositories, can be a very valuable source of information for the professional practice characterization. The enormous amount of data, as well as the diversity of informational environments, can make very problematic the DICOM metadata access and usage. It is therefore very relevant to identify the potentialities associated with indexing DICOM metadata as well as the main challenges that arise from the acquisition and management of huge volumes of data.
Methods and Materials: A meta-analysis was performed on the results of works supported in the indexing of DICOM metadata from different hospitals PACS archives using the Dicoogle application as a DICOM metadata indexing tool.
Results: Work supported by the indexation of metadata from several PACS of 7 health units was analyzed. The volume of data analyzed ranged from 85757 to 36562284 images, corresponding for the latter to more than 1324000 imaging studies performed on more than 438000 patients. The articles analyzed revealled the potential for the use of DICOM metadata, but also challenges associated with indexing and managing large volumes of metadata, namely the identification of medical imaging stakeholders, computational needs and information management, the quality of DICOM metadata, the analysis of individual and population exposure and the use of human and material resources.
Conclusion: It is possible to aggregate and consolidate huge amounts of DICOM metadata as a means to characterize professional practice. However, the success of its use depends on access and information management strategies as well as of the metadata quality.

B-0744 14:24

Patient radiation dose and fluoroscopy time during ERCP: a single-centre retrospective study of influencing factors

E. Saukko[1], J.M. Grönroos[1,1], P. Salminen[1,1], A. Henner[2], M.T. Nieminen[2,2]; [1]*Turku/FI*, [2]*Oulu/FI (ekaterina.saukko@tyks.fi)*

Purpose: The number and complexity with associated increased technical difficulty of therapeutic ERCP procedures have significantly increased resulting in longer procedural and fluoroscopy times. During ERCP, the patient is exposed to ionizing radiation and the consequent radiation dose depends on multiple factors. The aim of this study was to identify factors affecting fluoroscopy time and radiation dose in patients undergoing ERCP.
Methods and Materials: Data related to patient demographics, procedural characteristics and radiation exposure in ERCP procedures (n=638) performed between August 2013 and August 2015 were retrospectively reviewed and analysed. Statistically significant factors identified by univariate analyses were included in multivariate analysis with fluoroscopy time (FT) and dose area product (DAP) as dependent variables. Effective dose (ED) was estimated from DAP using conversion coefficient.
Results: The factors independently associated with increased DAP during ERCP were age, gender, radiographer, complexity level of ERCP, cannulation difficulty grade, bile duct injury and biliary stent placement. In multivariate analysis, the endoscopist, the complexity level of ERCP, cannulation difficulty grade, pancreatic duct leakage, bile duct dilatation and brushing were identified as predictors for a longer FT. The mean DAP, FT, number of acquired images and ED for all ERCP procedures were 2.33 Gy·cm^2, 1.84 min, 3 and 0.61 mSv, respectively.
Conclusion: Multiple factors had an effect on DAP and FT in ERCP. The awareness of these factors may help to predict possible prolonged procedures causing a higher radiation dose to the patient and thus facilitate the use of appropriate precautions.

Dose reduction with PA projection in lumbar spine radiography

E. Alukic, D. Škrk, N. Mekis; *Ljubljana/SI*

Purpose: The aim of the research was to determine the effect on radiation dose to the patient in lumbar spine radiography when using the PA projection instead of the conventional AP projection and how does that effect the image quality.
Methods and Materials: The research was conducted both, on an anthropomorphic phantom and on 100 patients, randomly divided into two equal groups of 50. In the first group the lumbar spine imaging was conducted in the AP projection, whereas in the second group the imaging was conducted in the PA projection. The dose was measured with dose area product (DAP) meter. The level of tissue displacement and patient height and weight was measured and image size was obtained. The image quality assessment was performed by three experienced radiologists with the use of ViewDEX imaging software and the effective dose was calculated using PCXMC2.0. Prior to the study the National medical ethic committee approval was obtained.
Results: When using PA projection, the average thickness of abdomen was reduced by 2.4 cm ($p < 10^{-3}$) in the PA projection, as did DAP by 16.3 μGy m^2 (p = 0.009) and the effective dose by 0.09 mSv ($p < 10^{-3}$). We did not find any significant difference in image quality between AP and PA projection of lumbar spine radiography (p = 0.690).

Conclusion: The results showed that the use of PA projection of lumbar spine reduces DAP (26.7 %) and effective dose (53.3 %) while preserving the image quality.

B-0746 14:40

Construction of obese phantoms for dose optimisation and image quality purposes

S.J.M. Algahtani[1,2], K. Knapp[1], R.M. Palfrey[1], J.R. Meakin[1]; [1]*Exeter/UK*, [2]*Najran/SA (salbeshri@hotmail.com)*

Purpose: To build obese phantoms that can be used in dose optimisation and image quality research.
Methods and Materials: Two sets of urethane based materials, along with other additives, priorly verified to be identical to fat and lean in terms of density, Hounsfield unit (HU) and linear attenuation coefficient, were used . Moulds were constructed using polystyrene design based on a 3D scan of a KYOTO phantom (PBU-50). The fat and lean mass in the abdominal region was calculated from DXA scans of 264 healthy female subjects. Two BMI groups, 38 and 46 kg/m^2, were constructed and tested for HU across different regions.
Results: The constructed phantom consisted of two layers of fat tissue-equivalent substitutes (FTES) which enscorned the abdominal region of the KYOTO phantom anteriorly and posteriorly each weighed 9.3 kg. Additionally, two thin layers of lean tissue-equivalent substitutes (LTES), each 1.9 kg, were added anteriorly and posteriorly to the previous FTES layers. This represented a BMI group of 38 kg/cm^2. Another two layers of FTES, total weight of 7.5 kg, along with two LTES layers, total weight 3.9kg, represent a 46 kg/m^2 BMI group. Across 4 levels of kvp (70,80,100 and 120 kvp) the HUfor FTES was -77.87 ± -16.7, in 9 different regions for each slab, while for the LTES, the HU was 23.25 ± 7.14, in 3 different regions for each slab.
Conclusion: Two obese phantoms were constructed. When used along with the KOYOTO phantom, dose optimisation work and image quality assessment can be conducted.

Personalised patient protocol for radiostereometric analysis

O. Muharemovic, A. Troelsen, M.G. Thomsen, T. Kallemose, K.K. Gosvig; *Hvidovre/DK (omarradiograf@hotmail.com)*

Purpose: Increasing pressure in the clinic requires a more standardised approach to radiostereometric analysis (RSA) imaging. The aim of this study was to investigate whether implementation of personalised RSA patient protocols could increase image quality and decrease examination time and the number of exposure repetitions.
Methods and Materials: Forty patients undergoing primary total hip arthroplasty (THA) were equally randomised to either a case or a control group. Radiographers in the case group were assisted by personalised patient protocols containing information about each patient's post-operative RSA X-ray. Radiographers in the control group used a standard RSA protocol.
Results: At 3 months, radiographers in the case group significantly reduced ($p<0.001$) the number of exposures (NE) by 1.6, examination time (ET) with 19.2 minutes, and distance between centrum of prosthesis (CP) and centrum of calibration field (CCF) with 34.1 mm when compared to post-operative (baseline) results. At 12 months, the case group significantly reduced ($p<0.001$) NE by 2.0, ET with 22.5 minutes, and CP to CCF distance with 43.1 mm when compared to baseline results. No significant improvements were found in the control group at any time point.
Conclusion: There is strong evidence that personalised RSA patient protocols have a positive effect on image quality and radiation dose savings. Implementation of personal patient protocols as a RSA standard will contribute to the reduction of examination time, thus ensuring a cost-benefit for department and patient safety.

B-0748 14:56

Large-sized patient chest radiography: a relative visual grading analysis study

F.P. Soares[1], E. Aymon[2], A.M. Burke[3], S. Dijkstra[4], J. Fosskaug[5], S.N. Sanders[4], A.F.N. Silva[6], A. Sanderud[5]; [1]*Florianopolis/BR*, [2]*Lausanne/CH*, [3]*Dublin/IE*, [4]*Groningen/NL*, [5]*Oslo/NO*, [6]*Lisbon/PT (s.n.sanders@st.hanze.nl)*

Purpose: To investigate the impact of different kVp and mAs values on image quality and effective dose in large-sized patient chest radiography.
Methods and Materials: A chest phantom (Kyoto) with simulated lesions and additional 30mm plates to simulate a large-size patient was imaged at various kept and mass values using a Canon CXDI digital detector. With 20 observers, a relative visual grading analysis (VGA) study was performed to assess image quality and nodule visibility in five chest radiographs asking worse, equal or better on eight image criteria adapted from the EU guidelines. The VGA study reference image was of the phantom at standard size without the chest plates using 125kVp, 2.4mAs by AEC and 24µSv. Effective dose was calculated using PCXMC. VGA scores were compared against signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR).
Results: An image obtained with 125kVp/4.0mAs/43µSv had the highest SNR, and the 125kVp/2.0mAs/21µSv had the highest CNR. In the VGA study, the 125kVp/4.0mAs/43µSv was seen as the most optimal image with 51% of scores from the observers being equal or better than the reference image. The image using AEC 125kVp/6.88mAs/74µSv was given the lowest score in VGA study with 23% score of equal or better. The scores with different kVp, 117kVp/2.5mAs/22µSv and 133kVp/2.5mAs/31µSv were 41% and 34%.
Conclusion: It is possible to get higher SNR, CNR and VGA scores in large-sized patient chest radiography at lower mAs than that given using standard AEC, due to post-processing. Changing the kVp did not improve the image quality.

B-0749 15:04

Radiation dose reduction on thyroid in mammography

D.C. Entradas, S. Rodrigues, R.P.P. Almeida, L.P. Ribeiro, A.F. Abrantes, M.V.C. Reis; *Faro/PT (monica14@live.com.pt)*

Purpose: To evaluate the entrance skin dose reduction in the thyroid using radiation protection in mammography exams.
Methods and Materials: In this experimental research, two anthropomorphic phantoms (full body and breast phantoms) were placed in the mammography equipment according with the standard positioning criteria. Optically stimulated luminescence (OSL) dosimeters were placed over the phantom thyroid region and a total of 40 radiation exposures were made for entrance skin dose measurements. The measurements were made on both standard projections for the breast study (cranio-caudal and medio-lateral oblique) with and without the use of the thyroid lead protection (0.5 mm).
Results: The entrance skin dose received by the thyroid was superior in medio-lateral oblique projection (44 µGy) compared to the cranio-caudal projection (36 µGy) without lead protection. With the lead protection there is a dose reduction of 83,3 % in the cranio-caudal projection (6 µGy) and 93,2% in the medio-lateral oblique projection (3 µGy). Therefore, in the mammography examination (total of four projections), the use of the lead protection reduces the entrance skin dose on thyroid by 89%.
Conclusion: The use of thyroid lead protection is highly recommended since it can reduce the radiation dose in this radiosensitive organ during mammography exams, attending the ALARA principle. However, we should also consider that the use of the shield might provide artefacts, making difficult the correct analysis of the breast tissue and leading to the examination repetition increasing the dose received in the mammary gland, as well as the other organs.

B-0750 15:12

Correlation measurements between positron emission tomography 18F-FDG dose and external exposure

Ž.R. Janulcikas; *Vilnius/LT*

Purpose: To evaluate correlation between administered ^{18}F - FDG dose and measured patient's emitted external exposure at different time.
Methods and Materials: In this study was analysed data of 101 adult patients: weight, administered ^{18}F - FDG dose, external exposure. Patient's emitted external exposure was measured at distance of 0,3 m and 1 m, also at different time. Pearson correlation coefficient was used to determine correlation strength.
Results: 101 Patient's weight was from 42 kg to 109 kg and injected ^{18}F - FDG was from 290 MBq to 438 MBq. Correlation between weight and dose was strong (r = 0,88) and statistically significant ($p<0,00$). Unfortunately, it is estimated that the correlation between the injected ^{18}F - FDG dose and external exposure (immediately after the injection) is very weak (r = 0,17) and statistically insignificant (p = 0,07) Also, correlation between the administered dose and the emitted external exposure before patients being released to home is very weak (r = 0,03) and statistically insignificant (p=0,731), and more weaker than correlation immediately after injection.
Conclusion: Correlation between injected ^{18}F - FDG dose and external exposure is estimated to be very weak and statistically insignificant. Radiation safety specialists and nuclear medicine radiographers should always gather external exposure data from patient at exactly same distance and body part. To testify this study results, there should be more further tests and data.

B-0751 15:20

Fabrication of fat tissue-equivalent substitutes (FTES) and lean tissue-equivalent substitute (LTES) to underpin obese phantom construction

S.J.M. Algahtani[1,2], K. Knapp[1], R.M. Palfrey[1], J.R. Meakin[1]; [1]*Exeter/UK*, [2]*Najran/SA (salbeshri@hotmail.com)*

Purpose: The literature reports high doses delivered to obese patients in projection radiography. This suggests more dose optimisation work is required for this group of patients. However, to date, there is no commercially available phantom representing obese patients. Therefore, this study outlines a fabrication method to build an obese phantom.

Methods and Materials: A urethane-based material, PMC 121/30 dry, was used for fat and lean tissue-equivalent substitutes (FTES and LTES). For the LTES, a 2.8% by weight of calcium carbonate was added to the PMC and mixed by hand for 25 minutes, while 2% of phenolic microspheres by weight was used instead for the FTES. Both FTES and LTES were tested for density and Hounsfield unit and compared to the ICRU 44. For linear attenuation coefficient, they were compared to slabs of lard and Perspex with identical thickness across a wide range of kVp (40 to 120 kVp).
Results: The density was 1.04 and 0.90 g/cm ^{3} for LTES and FTES, respectively. The Hounsfield unit for the FTES was -66.75 ± -4.26, and 30.08 ± 6.03 for LTES, both agreed with ICRU 44. The mass attenuation coefficient for the FTES against the lard and for the LTES against the Perspex was identical across the range of kvp.
Conclusion: The current study illustrates a method of constructing LTES and FTES that can be used in building different sizes of phantom for dose optimisation and image quality purposes.

Diagnostic accuracy between low and high tube voltage third-generation dual-source coronary CT angiography using tailored contrast medium injection protocols

M. Albrecht[1], C.N. De Cecco[2], K. Otani[3], J.W. Nance[2], A. Varga-Szemes[2], D. De Santis[4], P. von Knebel Doeberitz[2], T.J. Vogl[1], U.J. Schoepf[2];
[1]*Frankfurt a. Main/DE*, [2]*Charleston, SC/US*, [3]*Tokyo/JP*, [4]*Roma/IT*
(MoritzAlbrecht@gmx.net)

Purpose: To compare the diagnostic accuracy between coronary CT angiography (CCTA) using ≤100 vs >100 kV peak (kVp) settings and a kVp-tailored contrast medium injection protocol with catheter angiography as the reference standard.
Methods and Materials: One hundred-twenty patients were retrospectively enrolled in this study (mean age=62.6 years, mean BMI=29.0 kg/m2). Patients underwent CCTA and were separated into two cohorts (each n=60) based on the tube voltage (mean kVp=84.3 and 116.5, respectively). The contrast media was tailored to the kVp level: 70=40mL, 80=50mL, 90=60mL, 100=70mL, 110=80mL, and 120=90mL. Quantitative contrast-to-noise ratio (CNR) was measured. Two radiologists evaluated image quality and reported the presence of significant coronary stenosis (>50% luminal narrowing) in a segment-based fashion.
Results: Sensitivity/specificity for ≤100 vs >100 kVp CCTA were: per-patient=93.9/92.6% vs 90.9/92.6%, per-vessel=91.5/97.8% vs 94.0/96.8%, and per-segment=90.0/96.7% vs 90.7/95.2%, respectively, without significant differences (all P>0.64). Quantitative image quality was slightly higher (P>0.18) using lower kVp settings (mean CNR=12.0 and SNR=9.8) vs higher kVp CCTA (mean CNR=11.1 and SNR=8.9). No significant differences were found for subjective image quality among the cohorts (P=0.38). Contrast media requirements were reduced by 38.1% using low vs high kVp (53.6 vs 86.6mL, P<0.001). Radiation dose in ≤100 kVp was 59.6% less than >100 kVp examinations (4.3 vs 10.6 mSv, P<0.001).
Conclusion: Third-generation dual-source CCTA using a kVp-tailored contrast injection protocol can be robustly performed at ≤100 kVp in an overweight population while maintaining diagnostic accuracy for coronary stenosis detection compared to >100 kVp image acquisition, substantially reducing radiation and contrast dose.

Dual-energy coronary CT angiography: improved vascular contrast using noise-optimised virtual monoenergetic imaging

C. Arendt, D. Leithner, L. Lenga, S.S. Martin, T.J. Vogl, J.L. Wichmann;
Frankfurt a. Main/DE (crt.arendt@gmail.com)

Purpose: To evaluate the impact of different energy levels on image quality regarding visualization of coronary arteries and evaluation of coronary stenoses in traditional (VMI) and noise-optimized virtual monoenergetic imaging (VMI+).
Methods and Materials: Spectral DE-CCTA evaluation was performed in 50 cases by using standard linearly-blended (F_0.6), VMI and VMI+ algorithms at different energy levels (40-100 keV,10 keV-increments). SNR and CNR of main coronary arteries were assessed for objective image quality analysis. Diagnostic confidence was determined by 4 observers using a 5-point Likert scale. Diagnostic accuracy for the detection of >50% stenoses was performed by the same observers, taking into consideration invasive coronary angiography.
Results: Objective image parameters peaked at 40-keV VMI+ reconstructions (SNR: 46.3 [29.6]; CNR: 36.2 [20.3]), significantly superior (all p<0.001) compared with highest results at 70-keV VMI series (29.0 [15.8]; 18.4 [14.8]) and with F_0.6 images (23.7 [14.0]; 15.7 [10.2]). Diagnostic confidence (all p-values < 0.05) was highest at 40-keV VMI+ series with good subjective image quality (median: 4; ICC: 0.81), low noise (4; 0.82) and optimal plaque delineation (5; 0.85). 16 patients (32%) underwent additional ICA. Sensitivity and specificity for the detection of >50% stenoses were highest in 40-keV VMI+ reconstructions (98% and 96%) compared with 70-keV VMI (95% and 94%) and standard F_0.6 (94% and 94%) image series.
Conclusion: DE-CCTA with VMI+ reconstructions at 40 keV significantly increases objective image quality of coronary arteries, leading to improvement of plaque delineation compared with VMI-technique and standard linearly-blended image series. Consequently, diagnostic accuracy and confidence were increased.

Napkin-ring plaques can be identified on coronary CT angiography images using radiomic analysis

M. Kolossvary[1], J. Karady[1], B. Szilveszter[1], P. Kitslaar[2], B. Merkely[1], P. Maurovich- Horvat[1]; [1]*Budapest/HU*, [2]*Leiden/NL*
(marton.kolossvary@cirg.hu)

Purpose: Napkin-ring sign (NRS) is an independent prognostic imaging marker of major adverse cardiac events. However, identification of NRS is challenging due to its qualitative nature and, therefore, depends on reader experience. A more quantitative and reproducible approach is desirable. Therefore, our purpose was to assess whether radiomic parameters can differentiate between NRS and non-NRS plaques.
Methods and Materials: From symptomatic patients' coronary CT angiography images we identified 30 NRS plaques. We matched these with 30 non-NRS plaques with similar degree of calcification and stenosis, localization, tube voltage and image reconstruction settings. All plaques were segmented manually. 8 conventional (lesion length and volume, mean plaque burden, vessel wall remodeling index, lumen area stenosis, mean, minimum and maximum plaque attenuation) and 4440 radiomic parameters were calculated. We used permutation test of symmetry to assess differences between NRS and non-NRS plaques, while we calculated receiver operating characteristics' area under the curve (AUC) values to evaluate diagnostic accuracy. Bonferroni-corrected p<0.0012 was considered significant.
Results: None of the conventional quantitative parameters, while 20.6% (916/4440) of radiomic parameters showed a significant difference between NRS vs. non-NRS plaques. Almost half of these (418/916) reached an AUC value greater than 0.80. Short- and long-run low-grey-level emphasis and surface ratio of high-attenuation voxels to total surface had the highest AUC values (0.918, 0.894 and 0.890, respectively).
Conclusion: Radiomics can identify NRS plaques with excellent diagnostic accuracy. Radiomics could increase the reproducibility and accuracy of diagnostic image interpretation in the future.
Author Disclosures:
M. Kolossvary: Author; Márton Kolossváry is the software developer of Radiomics Image Analysis (RIA) program which was used for radiomic calculations. **P. B-0755 14:24

Diagnostic accuracy of coronary CT angiography performed with a novel whole-heart coverage high-definition CT scanner in patients with coronary artery bypass graft

D. Andreini, S. Mushtaq, G. Pontone, A.D. Annoni, A. Formenti, M.E. Mancini, M. Guglielmo, A.L. Bartorelli, M. Pepi; *Milan/IT (daniele.andreini@ccfm.it)*

Purpose: To evaluate interpretability, radiation exposure and diagnostic accuracy of CCTA compared to invasive coronary angiography (ICA) in the assessment of grafts and non grafted or distal runoff coronary arteries performed with the latest generation of cardiac-CT scanner.
Methods and Materials: We enrolled 100 consecutive patients with CABG who underwent ICA and CCTA (16-cm z-axis coverage with 256 detector rows,0.28 sec gantry rotation time). We assessed coronary segment interpretability, effective dose (ED) and diagnostic accuracy vs. ICA.
Results: Mean HR during the scan was 70±11 bpm. 26 patients were in atrial fibrillation and 74 in sinus rhythm. Among the latter, 27 patients had a HR>75bpm. CCTA CABG interpretability was 100%, independently from the type of graft (arterial or venous). After comparison with ICA, CCTA was able to correctly detect the occlusion or significant stenosis of all CABG. The overall interpretability of non-grafted and distal runoff coronary arteries was high (95.5%). Sensitivity, specificity, positive predictive value, negative predictive value and accuracy of native coronary arteries were 98.3%, 98.6%, 96.2%, 99.4%, and 98.5%, respectively. Mean effective dose was 2.5±0.8mSv.
Conclusion: The novel whole-heart coverage CT scanner allows to evaluate CABG and native coronary arteries with excellent diagnostic accuracy and low radiation exposure also in the presence of atrial fibrillation and high heart rate.

B-0756 14:32

Cardiac CT for demonstrating non-calcified coronary atherosclerotic plaque: effect of knowledge-based iterative model reconstruction on image quality

T. Li, L. Yang; *Beijing/CN (litaofeivip@163.com)*

Purpose: The purpose of this study was to assess image quality of demonstrating coronary plaques using iterative model reconstrucion (IMR), a knowledge-based iterative reconstruction algorithm, the latest reconstruction technique.
Methods and Materials: Sixty-six patients (53 male and 13 female) with single-vessel disease with non-calcified plaques or non-calcified predominant plaques and significant coronary stenosis (≥50%) using prospective electrocardiogram-gated coronary 256-slice CT angiography were selected. Paired image sets were created using two types of reconstruction: hybrid iterative reconstruction (HIR) (iDose4; Philips Healthcare) and IMR. Signal-to-noise ratio (SNR) of image was calculated and contrast-to-noise ratio (CNR) between plaque and adjacent fat tissue was measured on a cross-sectional multi-planar reconstruction image of the plaque.
Results: Seventy-seven non-calcified plaques or non-calcified predominant plaques with significant coronary stenosis were detected. Two plaques were located on LM, 51 plaques on LAD, 23 on RCA and 1 on LCX. x^2 test showed there was no significantly statistical difference to present positive remodeling, low density plaque and spotty calcification with HIR and IMR reconstructed method, still there was significantly statistical difference to discern napkin-ring sign between two algorithms ($x^2$12.12,p<0.001). The image noise of IMR was lower than that of HIR (10±2 versus 13±2) (p<0.01),and SNR of image and CNR between plaques and surrounding fat tissue on IMR were better than that on HIR (SNR: 46±15 versus 37±11) (CNR: 16.0±4.6 versus 12.0±3.6) (p<0.01).
Conclusion: IMR can significantly decrease the image noise and improve image quality compared with HIR for the coronary atherosclerotic plaques demonstration on coronary 256-slice CT angiography.

B-0757 14:40

Iodine quantification at rest and stress to differentiate ischaemic, infarcted and normal myocardium using dual-energy CT

M. van Assen[1], C.N. De Cecco[1], R. Vliegenthart[2], M. Oudkerk[2], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Groningen/NL (m.van.assen@umcg.nl)*

Purpose: The aim of this study was to evaluate the potential of rest-stress dual-energy CT (DECT) iodine quantification to discriminate between normal, ischemic, and infarcted myocardium.
Methods and Materials: Patients underwent rest-stress DECT on a second-generation dual-source scanner. Rest-stress perfusion single photon emission CT (SPECT) and rest-stress cardiac magnetic resonance (CMR) imaging with late gadolinium enhancement (LGE) were performed to identify ischemic and infarcted myocardium. Patients were categorized into an ischemic, infarcted, and control group based on SPECT and CMR results. Regions of interest (ROI) were placed in the septal area of the iodine maps to assess iodine concentrations in normal/remote myocardium. ROIs were sampled in ischemic and infarcted areas detected on perfusion and LGE-images. In addition, variations in iodine concentration were analyzed on a per-segment basis according to the AHA-16-segment model in the control group.
Results: 42 patients were included: 10 ischemic, 17 infarcted, and 15 controls. There were no significant differences in iodine concentrations between segments. Iodine concentrations in both ischemic and infarcted myocardium were significantly lower than in normal myocardium (*p* value 0.005 and <0.001), ranging from 1.3 mg/mL (0.9-1.8) and 0.6 mg/mL (0.4-0.8) at rest and stress in ischemic myocardium, and 0.3 mg/mL (0.3-0.5) and 0.5 mg/mL (0.5-0.7) at rest and stress in the infarcted myocardium, respectively. At rest, iodine concentration of ischemic myocardium was significantly higher compared to infarcted myocardium (*p* value<0.001).
Conclusion: DECT quantification of iodine concentration from rest-stress imaging is able to distinguish between normal, ischemic, and infarcted myocardium and holds potential as an imaging biomarker for tissue characterization.

The value of wide-detector helical CT combined with adaptive statistical iterative reconstruction-V in patients with high heart rate during coronary CT angiography

H. Zhao; *Zhengzhou/CN (kindergirl@sina.cn)*

Purpose: To compare the radiation dose and image quality of wide-detector helical CT combined with ASIR-V with stand-detector helical CT with ASIR in patients with high heart rate (HR) during coronary CT angiography (CCTA).
Methods and Materials: Eighty high heart rate patients (HR-during the CT scans≥80bpm) underwent CCTA were randomly divided into two scan groups (n=30 each;the study group: detector coverage of 160mm,100 kVp,50% pre-ASIR-V; the control group, detector coverage of 40mm,120 kVp,50% ASIR).Quantitative parameters [image noise (SD of AA),SNR,CNR,CT values of ascending aorta (AA),left main coronary artery (LM),proximal segment of left anterior descending (LAD-p),circumflex proximal segment (LCX-p),right coronary artery(RCA-p)] and effective dose (ED) were compared with two sample t tests.The image quality of coronary artery was evaluated using a four-point scale based on the 15-segment model after using SSF technique reconstructions when necessary and then compared with χ^2 test.
Results: The study group and control group showed no significant differences in image noise, SNR, CNR and CT values of AA, LM, LAD-p, LCX-p, RCA-p.No significant differences were found for the diagnostic image quality of coronary artery segments(546/551 *VS* 552/559) and the ratio of SSF technique reconstructions(27/40 *VS* 31/40) among the two groups.The ED for the study group and the control was (2.16±0.79)mSv and (9.74±3.89)mSv, respectively. There was significant difference in ED among this two groups.
Conclusion: Comparing with stand-detector helical CT in patients with high HR, the wide-detector helical CT combined with 50% pre-ASIR-V could reduce 78% radiation dose while maintain overall image quality.

B-0759 14:56

Study on the optimum keV and different contrast agent concentration in coronary stent imaging using spectral CT: in vitro study

L. Yang, Y. Hou, Y. Ma, Z. Jia, X. Lu; *Shenyang/CN (8609469@qq.com)*

Purpose: To investigate optimally visual combination of different keV and concentration of contrast agent (CT) in the coronary artery stent using sprctral CT in vitro study.
Methods and Materials: Fifteen coronary artery stents (internal diameter of 2.5 - 4.0 mm) were randomly divided into artificial coronary artery, respectively filled six different concentrations of contrast agent(12.85, 6.59,5.29,4.43,3.80 and 3.33 mgI/ml).All artificial coronary artery scanned with dual-detector CT, obtain images from 40 to 200 keV (interval of 10 keV) .Subjective image quality was evaluated by two doctors using Likert 5 method. Objective image quality assessment including artificial lumen narrowing(ALN), signal to noise ratio (SNR), contrast to noise ratio(CNR) .
Results: The image quality of 6.59mgI/ml+60 keV group was the highest total score(P<0.05). The ALN value was (21.33 ± 12.48)% in 6.59mgI / ml + 60 keV group, which was significantly lower than that in other groups (P <0.05). In 6.59mgI / ml + 60 keV group ,the SNR of stent lumen was 26.08 ± 3.74, which was significantly higher than that of 3.93 ~ 12.85mgI / ml + 70 ~ 200keV group (P <0.05). The CNR of 6.59mgI / ml + 60 keV group was significantly higher than that of 3.33 ~ 12.85mgI / ml + 70 ~ 200keV group (P <0.05).
Conclusion: In vitro scans, at concentration of 6.59 mgI / ml with 60 keV, image quality was better, stent diameter measurement results closer to real diameter, can be recommended for clinical diagnosis.

B-0760 15:04

Assessment of image quality of coronary artery and left ventricular function and volume using low kVp, mA modulation and advanced model based iterative reconstruction

K. Choo, Y.-J. Jeong, M. Kim; *Busan/KR (jyj107@hanmail.net)*

Purpose: To compare 3rd generation dual source CT (DSCT, Somatom force, Siemens Medical Solution, Forchheim, Germany) using 70 or 80 kVp and ECG-based maximum tube current modulation and advanced modeled iterative reconstruction with echocardiography (ECHO) for the determination of left ventricular ejection fraction (LVEF), end-diastolic volume (EDV), end-systolic volume (ESV) as well as assessing coronary artery image quality and patient radiation dose.
Methods and Materials: Forty consecutive patients (M:F = 32:8, mean age, 57.1 ± 6.4 years) with chest pain were enrolled in this study. EF, EDV and ESV were measured by both DSCT and ECHO, and the correlation coefficients were assessed. In addition, subjective image quality of coronary artery segment (1, excellent; 4, poor) and radiation dose were recorded.
Results: Comparison of LVEF, EDV, and ESV between DSCT and ECHO showed a significant correlation ($p < 0.01$) and the LVEFs measured by DSCT and ECHO were not statistically different. However, LV, EDV and ESV from DSCT were statistically higher than those from ECHO ($p < 0.05$). The average subjective image quality score of the coronary artery segment was 1.10 and the mean patient radiation dose was 2.07 ± 0.4 mSv.
Conclusion: DSCT with low kVp, mA modulation and advanced model based iterative reconstruction offers comparable results to ECHO for LVEF and LVV and good image quality of coronary artery with a low radiation dose.

B-0761 15:12

Effect of image reconstruction algorithms on cardiovascular radiomic features using coronary CT angiography

M. Kolossvary, B. Szilveszter, J. Karady, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (martonandko@gmail.com)*

Purpose: Radiomic analysis is an emerging analytical approach to identify new imaging biomarkers of specific phenotypes and outcomes. Little is known how novel image reconstruction algorithms might affect radiomic characteristics. Therefore, our objective was to assess the effect of image reconstruction settings on radiomic features of coronary atherosclerotic lesions.
Methods and Materials: 60 coronary atherosclerotic lesions were reconstructed using filtered-back projection (FBP), hybrid iterative reconstruction (HIR) and model-based iterative reconstruction (MIR). Images were segmented using a semi-automated software. Segmentations were manually adjusted if needed. Voxels containing plaque tissue were exported as an original DICOM dataset. Overall, 114 grey level co-occurrence matrix (GLCM) and 11 grey level run length matrix (GLRLM) statistics were calculated using the Radiomics Image Analysis (RIA) software package. Using linear regression analysis, the effect of FBP and MIR as compared to the reference HIR technique corrected for additional imaging settings was investigated. A p value smaller than 0.05 was considered significant.
Results: Among GLCM statistics 14.0% (16/114) was differed between FBP-HIR, while 19.3% (22/114) showed a significant difference between HIR-MIR. However, among GLRLM statistics only short run emphasis, and run percentage was significantly different between HIR and MIR reconstructions.
Conclusion: Image reconstruction algorithms affect several radiomic statistics, therefore standardization of imaging protocols is needed to achieve robust and reproducible results.

Motion elimination in low-dose 4D myocardial computed tomography perfusion (CTP) using the automated smooth temporal registration for analysis of 4D image data (ASTRA) algorithm

S. Lukas, S. Feger, M. Rief, E. Zimmermann, M. Dewey; *Berlin/DE*

Purpose: We propose a four-dimensional (4D) motion elimination algorithm for joint temporal alignment and denoising of a 4D CTP sequence to provide physiologically meaningful local time attenuation curves (TACs) for subsequent myocardial perfusion quantification.
Methods and Materials: Dynamic contrast-enhanced 320-row CTP was performed in 31 patients with suspected or confirmed coronary artery disease (CAD). In a unified approach we decouple cardiac deformation from temporal intensity changes due to contrast enhancement by iteratively performing a local polynomial kernel regression temporally and a 4D principal component analysis (PCA) spatially. A multi-resolution two-stage rigid and deformable B-spline registration model was applied by minimizing the temporal misalignment measured by the weighted sum of the eigenvalues of the inter-volume correlation matrix. Registration performance was assessed by measuring temporal smoothness, spatial noise, and degree of local volumetric deformation (determinant of the spatial Jacobian) at four distinct regions at the left-ventricular wall for each patient. Solely PCA-based registration without temporal regression served as the reference standard.
Results: The proposed ASTRA registration algorithm provided superior registration performance when compared to the benchmark. The algorithm consistently improved temporal smoothness (32.5±12.4 vs. 185.1±103.8, $p<0.001$) and spatial noise (21.8±13.2 vs. 27.6±12.4, $p<0.001$) at the myocardial target regions at comparable local deformation behaviour (0.997×/1.073 vs. 0.999×/1.055, $p=0.169$, geometric average) and improved overall temporal alignment of the registered sequence (20.93±2.60 vs. 21.86±2.94, $p<0.001$).
Conclusion: The novel ASTRA registration algorithm for a 4D CTP sequence outperforms the benchmark with 80% temporal and 20% spatial noise reduction without introducing strong volumetric deformations.

Fast magnetic resonance imaging (MRI) of invasive lung aspergillosis in immunocompromised children: comparison with HRCT

T. Akbas[1], S. Ulus[2], B.S. Karagun[1], T. Arpaci[1]; [1]*Adana/TR*, [2]*Istanbul/TR (tugana.akbas@acibadem.edu.tr)*

Purpose: To compare the diagnostic accuracy of fast lung MRI with high resolution computed tomography (HRCT) in immunocompromised children with invasive pulmonary aspergillosis.
Methods and Materials: Twenty seven children (14 boy, 13 girl, mean age= 12.8; range age 5-17 years) with suspected invasive pulmonary aspergillosis after chemotherapy and hematopoietic stem cell transplantation underwent 1.5 Tesla MRI and HRCT. Pulmonary MRI study protocol included T2 weighted half-Fourier single-shot turbo spin echo (HASTE) and T1 weighted volumetric interpolated breath hold examination (VIBE) sequences. The average MRI scanning time was three minutes. Both the location and the type of lesion (halo sign, air crescent sign, peribronchial consolidation, bronchopneumonia, centrilobular and tree in bud nodules) were assessed on MRI and HRCT blinded to patient's data by two radiologists. Kappa test, sensitivity, specificity, accuracy, positive and negative predictive values were used to determine the compliance.
Results: The location of the lesion in HRCT were concordant with T2 HASTE sequence (κ_w:0,550 p=0,0001) and T1 VIBE sequence (κ_w:0,550 p=0,0001) corresponding to a negative predictive value of 100%, positive predictive value of 95%, sensitivity of 100%, specificity of 40%, accuracy 95%. The type of lesion in HRCT were concordant with T2 HASTE sequence (κ_w:0,447 p=0,0001) and T1 VIBE sequence (κ_w:0,442 p=0,0001) corresponding to a negative predictive value of 33%, positive predictive value of 100%, specificity of 100% and accuracy 93%.
Conclusion: According to our study; MRI is a fast, radiation free examination for detecting of pulmonary invasive aspergillosis lesions with high accuracy rate in immunocompromised children.

B-0764 14:08

Pulmonary MRI: diagnostic performance and detection of structural abnormality using ultrashort echo time in cystic fibrosis patients

M.S. Kraus, M. Esser, M. Teufel, S. Fleischer, J. Riethmueller, C. Ruff, I. Tsiflikas, J.F. Schäfer; *Tübingen/DE (mareen.kraus@med.uni-tuebingen.de)*

Purpose: To evaluate the diagnostic performance of a coronal 3D Ultra Short Echo time sequence (UTE) in pulmonary magnetic resonance imaging in cystic fibrosis patients in comparison to the in-house standard; a morphological axial PDw Flash 3D in breath-hold, coronal T2w TSE with double tiggering and functional sagittal PDw Flash 2D in submaximal in- and expiration.

Methods and Materials: Twenty five CF patients who underwent pulmonary MRI (1.5 Tesla scanner) were included. Coronal UTE sequences were acquired in submaximal in- and expiration as well as the standard pulmonary protocol. Two independent readers assessed overall image quality, cardiac respiratory motion artifacts (using a 3-point Likert scale), bronchiectasis abnormality and the degree to which airways and vessels were visible. For both MR protocols typical cystic fibrosis pathologies were semi-quantitatively assessed using the
`MRI-CF-Score`including bronchiectasis, mucus plugging, centrilobular opacity, consolidation, saccualtion and air trapping.
Results: Diagnostic performance based on overall image qualtiy, motion artifacts and airway/vessel visibility was rated higher by the independent readers for the UTE sequence. There were no significant differences in total MR-CF-Scores considering the different protocols. Significant ($p<0.001$) reduction of acquisition time was noted for the singular plane UTE in submaximal breathing conditions.
Conclusion: Pulmonary MRI with UTE offers increased depiction and delineation of peripheral pathologic lung manifestations in patients with cystic fibrosis with improved image qualtiy compared to the conventional standard protocol, whilst significantly reducing the acquisition time, which is particularly relevant in the pediatric patient group.

B-0765 14:16

World Health Organization guidelines for achieving high-quality paediatric chest radiographs for use in epidemiological studies

S. Lacey[1,1], K. Mulholland[1], N. Fancourt[1], K. O'Brien[2], J. de Campo[1], M. de Campo[1]; [1]*Parkville/AU*, [2]*Baltimore, MD/US (stephen.lacey@rch.org.au)*

Purpose: Consistent high-quality chest radiographs are essential for reliable case definitions in epidemiological studies of childhood respiratory disease. However, there is no centralised resource on chest radiograph acquisition relevant to study investigators and site staff. Previous experience suggests that suboptimal quality radiographs can be minimised through early collaboration between radiology departments and research staff.
Methods and Materials: The World Health Organisation Chest Radiography in Epidemiological Studies or "WHO-CRES" project was formed in 2015. A major objective of the project was to develop appropriate resources for investigators and facility staff in remote and under-resourced regions to enable them to safely obtain high-quality paediatric chest radiographs. These resources were developed by the Quality and Safety co-investigator and finalised by a technical working group consisting of radiologists and investigators.
Results: The technical guidelines are divided into three sections: 1. The Pre-Study Survey evaluates the current technical parameters, capabilities and processes of individual radiology facilities and their suitability for participation in paediatric epidemiological studies. 2. The Study Guidelines review the major factors contributing to quality paediatric chest radiographs, identifying issues that are most important and/or require adjustment by a research team. Recommendations for achieving quality chest radiographs in studies involving children aged 0-59 months are provided. 3. The Quality Control Guidelines include the recommended performance and documentation of quality control measures for continual optimisation of equipment and facility processes.
Conclusion: These WHO-CRES guidelines provide an easily accessible and unique resource to better facilitate the acquisition of consistent, high-quality chest radiographs in epidemiological studies.

B-0766 14:24

Value of paediatric chest CT in a representative patient cohort of 2019 examinations

M. Esser, S. Hess, M. Teufel, S. Gatidis, I. Tsiflikas, J.F. Schäfer; *Tübingen/DE*

Purpose: To test if chest CT delivers useful results according to the clinical question and which examinations are possibly dispensable.
Methods and Materials: In this retrospective study at a clinic with maximum care facilities, 2019 chest CT examinations in 973 patients (median age, 10.5 years; range, 2 days to 17.9 years) were analysed over 7 years with regard to the application of contrast agents and information about the referring department including the clinical question and CT findings. For this purpose electronically stored documents were evaluated. For each examination it was identified if the clinical question was answered and if additional findings relevant for therapy were detected.
Results: Most CT scans were performed without contrast enhancement (n=1251; 62%). Most examinations (n=987) were requested from the Department of Haematooncology. The most frequent indication was a suspected pneumonia (n=380; 19%). In 1411 CT scans (70%) anomalies according to the suspected diagnosis were found, 608 examinations (30%) gave a negative reply to the question. There were predominantly negative results (62%) when the question was for an infection process prior to bone marrow transplant. In 81 scans without relevant findings concerning the primary question, an additional finding relevant for therapy was detected (19% of all additional findings). Overall, CT provided findings with a conclusive result and clinical relevance in 97.6% of all scans.
Conclusion: Based on an appropriate clinical question, paediatric chest CT in specialised centres has a high informative clinical value. The strict indication and clinical evaluation appears crucial for the prevention of dispensable CT examinations.

B-0767 14:32

Influence of reconstruction algorithms to chest CT examination in children: comparison of image quality among standard-, reduced- and ultra-low-dose CTs in chest phantom study

E. Suehiro[1], T. Sekitani[1], W. Tani[1], N. Negi[1], K. Fujii[2], T. Yoshikawa[1], Y. Ohno[1]; [1]*Kobe/JP*, [2]*Tokyo/JP*

Purpose: To determine the influence of reconstruction algorithm to image quality and radiation dose reduction capability on chest CT in chest children phantom study.
Methods and Materials: A commercially available chest CT phantom was simulated as 5-year-old children were scanned with a 320-detector row CT with automatic exposure control (AEC). Performance of 3D AEC was performed by targeted SDs, which were tested from 10 (CTDIvol: 16.6mGy) to 110 (CTDIvol: 0.5mGy) at every 20 intervals, although other scan parameters were constant. Then, each SD data was reconstructed as 1mm and 5mm contiguous section thickness with filtered back projection (FBP), commercially available hybrid-type iterative reconstruction (IR) (i.e. AIDR 3D), and model-based IR (FIRST) methods. Then, actual image noise determined by ROI measurement was compared at each targeted SD data by Tukey's HSD test. Finally, mean visualization scores were compared between CT obtained at targeted SD as 10 and reconstructed by FBP (i.e. standard CT) and all other CT data by Wilcoxon signed-rank test.
Results: On both section thickness CT images at each targeted SD, image noise of FBP was significantly higher than that of AIDR 3D and FIRST ($p<0.05$). When compared lung parenchyma visualization capability, both section thickness CT data obtained at targeted SD as 70, 90 and 110 and reconstructed by FBP had significant difference with standard CT ($p<0.05$).
Conclusion: This phantom study shows reconstruction algorithm had significantly affected the radiation dose reduction at chest CT examination using 3D AEC in children.

B-0768 14:40

Technical challenges of quantitative chest MRI data analysis in a large cohort paediatric study

A. Nguyen[1], A. Perez-Rovira[1], L. Duijts[1], M. De Bruijne[1], A. Aliverti[2], F. Pennati[2], T. Ivanovska[3], H.A. Tiddens[1], P. Ciet[1]; [1]*Rotterdam/NL*, [2]*Milan/IT*, [3]*Göttingen/DE (354271an@student.eur.nl)*

Purpose: To evaluate the effect of geometric distortion on MRI lung volume quantification and evaluate available manual, semi- and fully automated methods for lung segmentation.
Methods and Materials: A phantom was scanned with MRI and CT. GD was quantified as difference in phantom's volume between MRI and CT, with CT as gold standard. Dice scores were used to measure overlap in shapes. Furthermore, a subset of 11 subjects with MRI measurements from a large prospective population-based cohort study was used to test lung segmentation methods on 2D and 3D Gradwarp corrected scans. Intra-Class Correlation coefficient, Bland-Altman plots, Wilcoxon, Mann-Whitney U and paired t-tests were used for statistics.
Results: Using phantoms, volume differences between CT and MRI varied according to MRI positions and 2D and 3D Gradwarp correction. With the phantom located at isocenter, MRI overestimated the volume relative to CT by 5.56±1.16% to 6.99±0.22% with body and torso coils, respectively. Higher Dice scores and smaller intra-object volume differences were found for 3D Gradwarp corrected MR images. In subjects, semi- and fully automated segmentation tools had high agreement with manual segmentations (ICC=0.971-0.993 for end-inspiratory scans; ICC=0.992-0.995 for end-expiratory scans). Manual segmentation time per scan was approximately 4 hours and 2-3 minutes for automated methods.
Conclusion: Volume overestimation of MRI due to GD can be quantified. Existing semi- and fully automated segmentation methods allow accurate, reproducible and fast lung volume quantification. Chest-MRI can be a valid radiation-free imaging modality for lung segmentation and volume quantification in large cohort studies.

Imaging findings of Loeys-Dietz syndrome in paediatric population

H.O. Özdemir, A. Sanchez-Montanez Garcia-Carpintero, A. Sabate Rotes, I. Delgado Alvarez, L. Riaza Martin, A. Coma, L. Riera Soler, A. Castellote, E. Vazquez Mendez; *Barcelona/ES (onurkont88@gmail.com)*

Purpose: Loeys-Dietz syndrome is a rare autosomal-dominant connective tissue disorder with multisystemic radiological manifestations. The purpose of our study was to describe radiological findings of LDS in 3 groups; cardiovascular, neuroradiological and musculoskeletal findings which can help to correct diagnosis and follow-up.
Methods and Materials: Three paediatric radiologists retrospectively reviewed cardiovascular MRI, cranial MRI/MRA, cervical MRA/CTA and plain film studies of 12 patients all of whom had positive genetic testing and clinical characteristic of LDS. All patients were under 18 years old at diagnosis. All of them had cardiovascular MRI and nine had neurovascular imaging modalities.
Results: Eleven patients had aortic root dilatation which is the most common cardiovascular finding of the syndrome. 6 patients had also dilatation of the other parts of thoracic aorta, 2 had main pulmonary artery dilatation, 2 had coronary artery dilatation, 1 had abdominal aortic dilatation and 1 had bicuspid aortic valve. 2 patients had aortic dissection (cause of death). One patient had normal cardiovascular MRI. In between 9 patients who had cranial imaging, all patients had tortuosity of vertebrobasillary and carotid arteries, hypertelorism and microretrognathia. Other neuroradiological findings: craniosynostosis (5 patients), upper cervical spine abnormalities (3), gliotic foci (2), ventriculomegaly (1), intracranial aneurysms and intracranial haemorrhage (1, cause of death). As musculoskeletal findings, 10 patients had scoliosis, 7 had pectus deformities and 1 had joint contractures.
Conclusion: Aortic root dilatation, neurovascular tortuosity, hypertelorism, microretrognathia are the most common imaging findings associated with LDS. Aortic dissection and intracranial haemorrhage are the most common causes of mortality.

B-0770 14:56

Aortic & carotid intima-media thickness in term small for gestational age newborns and term normal newborns

S.M.s.a. Revanna, V. Kenchanahalli Rangaswamy, V. Devappa, V.K. Shamachar; *Bangalore/IN (sinumr25@gmail.com)*

Purpose: To compare the intima media thickness of abdominal aorta (aIMT) & carotid arteries (cIMT) in small for gestational age (SGA) term newborns with appropriate for gestation age term newborns
Methods and Materials: In our study the newborns are divided into 2 groups: Group I included 50 AGA normal term newborns with birth weight between 50-90th centile (control group) and group II included 50 SGA term newborns with birth weight less then 10th centile (patient group). All measurements are performed by a single observer by using high resolution ultrasonography.
Results: Mean abdominal aIMT and cIMT values of normal term newborns (AGA) were 0.40 ± 0.042 mm (n = 50) and 0.32 ± 0.031 mm (n = 50), respectively. Maximum and minimum aIMT and cIMT values of term newborns were 0.45 and 0.35 mm and 0.35 and 0.25 mm, respectively. The mean aIMT and cIMT were higher in SGA group (0.45 ± 0.058 mm) and 0.40 ± 0.047 compared with the control group.
Conclusion: Small for gestational age fetuses have a thicker aortic and carotid wall than AGA fetuses, which possibly represents preclinical atherosclerosis and a predisposition to later cardiovascular disease.

B-0771 15:04

What is the underestimation of radiation dose to the paediatric thyroid from contrast-enhanced CT, if contrast medium uptake is not taken into account?

K. Perisinakis, S. Pouli, A. Tzedakis, K. Spanakis, A.A. Hatzidakis, M. Raissaki, J. Damilakis; *Iraklion/GR (stellapouli@gmail.com)*

Purpose: Administration of iodine-based contrast in CT has been shown to increase radiation dose in enhanced organs. The current dose calculation methods ignore contrast administration. The aim of our study was to assess the underestimation of radiation dose to the thyroid of children undergoing contrast-enhanced CT if contrast medium uptake is not taken into account.
Methods and Materials: Paediatric head/neck or chest CT examinations involving pre- and post-contrast imaging were retrospectively selected from our department database to identify those CT image series where the thyroid was visible. CT density of thyroid tissue in HU was measured in pre- and post-contrast images at the corresponding positions. The resulting ΔHU was recorded for each patient. Utilizing recently published data, ΔHU corresponded to % w/w iodine concentration and subsequently to % dose increase induced by contrast uptake.
Results: The thyroid gland was visible in 11 chest and 3 neck CT scans. The estimated increase in radiation dose absorbed by thyroid tissue due to contrast accumulation ranged from 12% to 46%, with a mean value of 23%.
Conclusion: The radiation dose to the paediatric thyroid gland due to contrast enhancement may be underestimated by up to 46% if contrast medium uptake is not taken into account. Scanning of the upper lung fields should be avoided during paediatric chest CT whenever possible to prevent thyroid exposure. Whenever this is unavoidable, estimation of radiation dose to the gland should take into consideration contrast medium uptake.

B-0772 15:12

Dose distribution to radiosensitive organs using advanced thoracic CT imaging techniques

A.F. Halaweish[1], M. Siegel[2], I. Duba[1], K. Grant[1], B. Schmidt[3]; [1]*Malvern, PA/US*, [2]*St. Louis, MO/US*, [3]*Forchheim/DE*

Purpose: To examine how various Thoracic CT techniques affect radiation dose distribution in pediatric-sized phantoms, with particular focus on especially radiosensitive organs like the lungs and breasts.
Methods and Materials: In two anthropomorphic phantoms (1- and 5-year-old equivalents), radiation doses in 38 sites (six organs) were measured using metal oxide semiconductor field effect transistors (MOSFETs) paired with a mobileMOSFET measurement system (model TN-RD-70-W, Best Medical Canada Ltd.). The phantoms were scanned using routine single-energy, dual-energy, ultra-fast pitch spiral and ultra-low dose tin-filtered CT imaging protocols. Organ dose distribution was calculated as a percentage of the dose length product, facilitating inter- and intra-protocol comparisons.
Results: Compared with single-energy scans, dual energy CT demonstrated lower relative organ doses for both phantoms. Dual-energy scanning reduced lung dose by 27.3% and 21.9% and breast dose by 37.8% and 31.3 % in the 1- and 5-year-old phantoms respectively. Ultra-low dose Sn100kV scans reduced lung dose by 31.63% (1-year-old phantom) and 14.74% (5-year-old phantom) when compared to 70kV scans, and 13.79% (1-year-old phantom) and 1.89% (5-year-old phantom) when compared to 80kV scans. Ultra-low dose Sn100kV imaging in combination with ultra-fast pitch spiral produced the largest dose reduction for lung and breast compared to single-energy CT at 70 kV in the 5-year-old phantom (25.66% and 48.44% for lung and breast respectively).
Conclusion: Dual-Energy CT, ultra-low dose tin-filtered and ultra-fast pitch spiral scanning demonstrated a decreased dose to the lungs and breasts of pediatric size phantoms when compared with routine single-energy scans, while providing clinically diagnostic image quality.

Study of the feasibility of DAP-to-body-weight ratio as diagnostic reference level in paediatric interventional cardiology

F. De Monte, L. Riccardi, A. Boschini, B. Castaldi, L. Baffoni, O. Milanesi, M. Paiusco; *Padova/IT*

Purpose: To investigate the feasibility of the dose-area product to body weight ratio (DAP/BW) as dose index for Diagnostic Reference Level (DRL) in paediatric Interventional Cardiology (IC) procedures.
Methods and Materials: IC procedures (91 diagnostic,166 therapeutic) performed on patients <18 years old were stratified into BW classes every 10 kg. DAP values were extracted from the Structured Dose Report using a dose-tracking software. Mean, median, σ and 75th values of DAP and DAP/BW were calculated. ANOVA was used to determine whether there were any statistically significant differences between DAP corresponding to BW classes both for diagnostic and interventions. Correlations DAP *vs.* BW were investigated for diagnostic and therapeutic procedures and also for homogeneous subgroups of interventions. DAP/BW ratios were compared between procedure groups (Mann-Whitney test).
Results: When diagnostic and therapeutic procedures are considered as a whole, DAP differences among BW classes were not statistically significant and, in addition, a low correlation DAP *vs.* BW was found (R=0.533 and R=0.265, respectively). Strong correlations did appear when procedures were stratified by type: R coefficient varied from 0.730 (angioplasty) to 0.859 (PDA closures). Highest DAP values resulted for highly complex interventions (angioplasty) performed on <10 kg babies. DAP/BW values derived from ASD closures were statistically different from all the other investigated interventions.
Conclusion: When a robust correlation between DAP and BW exists, the DAP/BW ratio is a reliable DRL in IC procedures overcoming BW stratification method. An effort is necessary in order to define appropriate criteria of procedures stratification, considering different implanted devices.

The image quality of turbo high-pitch dual-source CT coronary angiography in patients with free-breathing, free heart rate and any BMI

K. Sun, B. Lu; *Beijing/CN (Henrysk@163.com)*

Purpose: To evaluate the image quality and effective radiation dose of turbo high-pitch dual-source CCTA in patients with free-breathing, free heart rate and any body mass index.
Methods and Materials: Between July 2015 and December 2015, 1179 consecutive patients (body mass index (BMI) range: 14.53-37.65 kg/m^2) (597 female, mean age: 58±10 years) undergoing clinically indicated CCTA were included. No β-blockers were administered for all patients before the examinations. CCTA was performed with a 3rd-generation dual-source CT system. The image acquisition phase was manually set at 60% of the RR interval for patients with HR≤70 beats per minute (bpm) and at 30% of the RR interval for the patients with HR>70bpm. The image noise, contrast-to-noise ratio (CNR), image quality scores and effective radiation dose were assessed.
Results: The average heart rate was 76±12 bpm (range: 40-133 bpm). A total of 3537 coronary arteries were evaluated in 1179 patients. The mean image quality scores was 1.21±0.72 for all coronary arteries. Based on patient analysis, the proportion of non-diagnostic coronary artery segments was 8.54%. The average image noise and CNR of aortic root were 24.6±6.7 HU (range:7-52 HU) and 30.8±9.8 (range 8.3-110.8), respectively. The effective radiation dose was 0.61±0.16 mSv (range: 0.14-1.41 mSv).
Conclusion: In conclusion, in patients with free-breathing, free heart rate and any body mass index, the turbo high-pitch dual-source CT coronary angiography provides a good image quality and low rate of non-diagnostic coronary segments, while being associated with significant reduction of radiation exposure.

Machine-learning on-site CT-derived fractional flow reserve (FFR) compared to invasive FFR: influence of myocardial mass on accuracy

M. Albrecht[1], S. Baumann[2], J.W. Nance[3], C.N. De Cecco[3], A. Varga-Szemes[3], R. Vliegenthart[4], C. Schwemmer[5], T.J. Vogl[1], U.J. Schoepf[3], S.S. Martin[1]; [1]*Frankfurt a. Main/DE*, [2]*Mannheim/DE*, [3]*Charleston, SC/US*, [4]*Groningen/NL*, [5]*Erlangen/DE (simartin@outlook.com)*

Purpose: To investigate the impact of myocardial mass on accuracy of on-site machine-learning CT-derived fractional flow reserve (CT-FFRml) for the determination of lesion-specific ischaemia using invasive FFR as the reference standard.
Methods and Materials: In total, 458 vessels from 301 patients were evaluated. The correlation of myocardial mass was correlated to the discrepancy of CT-FFRml and FFR. Diagnostic accuracy of CT-FFRml for the detection of lesion-specific ischaemia (FFR < 0.8) was analysed according to the amount of myocardial mass.
Results: Greater myocardial mass was associated with an underestimation of CT-FFRml values (r = 0.307, P < 0.001). The incremental value of CT-FFRml in diagnostic accuracy compared to visual CCTA assessment was greater (P = 0.04) in the cohort with higher myocardial mass (increase in accuracy, 18.0 %) in comparison with lower myocardial mass values (increase in accuracy, 16.8 %).
Conclusion: Machine-learning on-site CT-FFRml has greater incremental value for the detection of lesion-specific ischaemia compared to CCTA evaluation in patients with higher myocardial mass. Simultaneously, higher myocardial mass is correlated to a slight underestimation of CT-FFRml values.

Extra-cardiac findings at cardiac MR imaging: a single-center retrospective study over 14 years

F.C. Sokolowski, P. Karius, A. Lembcke, P.M. Wagner, A. Rodríguez Sánchez, M. Dewey; *Berlin/DE (felix.sokolowski@gmail.com)*

Purpose: To determine the prevalence and significance of extra-cardiac findings (ECF) in a large set of cardiac magnetic resonance (MR) imaging-examinations.
Methods and Materials: The institutional review board approved this retrospective, single-center study. A total of 4376 cardiac MR imaging reports of 3553 patients (age 37.4 ± 20 years, 60.8 % male) from 2000 to 2014 were included. Findings with a recommendation for follow-up were considered "major ECF". To analyze the association of indication, age and gender of patients with ECF, Poisson regression and computed incidence rates ratios (IRR) were evaluated.
Results: The overall prevalence of ECF was 34% (95% confidence interval (CI) 32.5-35.6). Major ECF were present in 3.4% (95% CI 2.9-4.1) while findings that changed patient management were found in 0.9% (95% CI 0.7-1.3). In the cases of congenital heart disease (CHD), the prevalence of ECF was higher as compared to myocarditis (IRR 6.0, p<0.001) while the prevalence for major ECF was lower (IRR 0.2, p<0.05). Increased patients' age was associated with more non-vascular ECF (p<0.001). Female patients had the same probability of having an ECF as male patients (IRR 1.04 (95% CI 0.95 - 1.14)).
Conclusion: ECF in cardiac MR are present in about every third examination while relevant ECF that change patients' management can be found in about one in hundred patients. Our data suggest that it is important to involve well-trained radiologists in reading cardiac MR images, which often contain ECF if congenital heart disease is the clinical indication.

Incremental diagnostic value of myocardial perfusion stress testing for intermediate obstructive lesions on coronary CT angiography in acute chest pain

E. Feldman, J. Bai, E. van Staalduinen; *Stony Brook, NY/US (eric.Feldmann@stonybrookmedicine.edu)*

Purpose: The purpose of our study is to evaluate the diagnostic yield of nuclear medicine stress testing in acute chest pain patients deemed to have borderline obstructive (50-69%) stenosis by coronary CT angiography (CCTA).
Methods and Materials: We retrospectively reviewed 4769 patients who presented to our emergency department (ED) with acute chest pain and had a CCTA. All patients had normal initial troponin levels, EKG and no prior history of obstructive coronary artery disease. The interpreting physicians' recommendations and any subsequent testing such as myocardial stress/rest perfusion imaging and coronary artery catheterization were recorded.
Results: Patient demographics included a mean age of 53.3 years and 53.3% (N= 2544) were female. The interpreting CCTA physicians recommended stress testing 8% (385/4769) of the time with 54% (209/385) of these patients receiving nuclear medicine myocardial perfusion imaging (MPI) within 30 days of the coronary CT. Of the patients receiving MPI, 93.8% (N=196) were interpreted as normal and 6.2% (N=13) abnormal. Of the patients with an abnormal MPI 62% (N=8) had a coronary catheterization with 37.5% (N=3) of these requiring percutaneous coronary intervention (PCI).
Conclusion: The vast majority of acute chest pain patients (93.8%) with intermediate (50-69%) obstructive lesions on CCTA will have normal findings on contemporaneous MPI.

B-0779 14:16

Subclinical coronary and carotid atherosclerosis in asymptomatic high-risk patients

M. Guglielmo[1], A. Guaricci[2], V. Lorenzoni[1], S. Mushtaq[1], G. Muscogiuri[1], E. Maffei[3], F. Cademartiri[4], R. Mark[5], G. Pontone[1]; [1]*Milan/IT*, [2]*Bari/IT*, [3]*Monastier di Treviso/IT*, [4]*Montreal, ON/CA*, [5]*Maywood, IL/US (marco.guglielmo@ccfm.it)*

Purpose: The aim of the study was to evaluate the incremental prognostic benefit of carotid artery disease and subclinical coronary artery disease (CAD) features in addition to conventional clinical evaluation in asymptomatic population.
Methods and Materials: Over a six-year period, 10-year-Framingham risk score (FRS) together with carotid ultrasound (CUS) and coronary computed tomography angiography (CCTA) were evaluated for the prediction of coronary heart disease (CHD) events.
Results: We enrolled 517 consecutive asymptomatic patients (63% male, 64±10 years of age). Median CACS was 34 [0-100]. Over a median follow-up of 4.4 [3.4-5.1] years there were a total of 53 CHD events (10%). Patients experiencing CHD had higher CACS, higher incidence of carotid disease, presence of CAD≥50%, and remodeled plaque as compared to patients without CHD events. At multivariable analyses, presence of CAD≥50% (HR=5.14, 95%CI: 2.1-12.4) and percentage of segment with remodeled plaque (HR=1.04, 95%CI: 1.03-1.06) independently predict CHD risk (P<0.001). The models adding CAD≥50% or percentage of segments with remodeled plaque resulted in higher discrimination and reclassification ability compared to a model based on 10-year FRS, carotid disease and CACS. Specifically, the C-statistic improved up to 0.75 with the addition of CAD and 0.84 when adding percentage of segments with remodeled plaque, while net reclassification improvement index was 0.86 and 0.92, respectively.
Conclusion: In an asymptomatic population, carotid disease assessment and CACS provide incremental prognostic value as compared to FRS. CAD- and plaque-positive remodeling further increase the CHD events prediction as compared to a model based on 10-year-FRS, carotid disease, and CACS estimation.

B-0780 14:20

Comparison of sports activity between ambitious triathletes with and without myocardial late gadolinium enhancement

J. Stáreková, B. Scherz, E. Tahir, M. Avanesov, M. Patten, J.M. Weinrich, K. Müllerleile, G. Adam, G.K. Lund; *Hamburg/DE (j.starekova@uke.de)*

Purpose: Long-term intensive training leads to functional and morphological adaptation of the heart. Incidence of myocardial fibrosis detected by cardiac MRI (CMR) is variable in competitive athletes. The purpose of this study was to analyse the differences in sports activity between triathletes with and without LGE.
Methods and Materials: 54 competitive healthy male triathletes (44±10 years) underwent a CMR performed on 1.5T Achieva (Philips), including LGE imaging. Image analysis was performed on cvi42 (Circle). CMR parameters are given as the mean of two independent observers. Physical fitness was determined by an exercise test. Competition history was reported using a standardised questionnaire with information about the number, distance and duration of completed events.
Results: In 9 out of 54 triathletes (17%) a non-ischaemic focal myocardial fibrosis of the left ventricle (LGE+) was detected. LGE+ triathletes had higher peak exercise systolic blood pressure (213±24 vs 194±26mmHg, p<0.05) and higher LV mass index (93±7 vs 84±11g/m2, p<0.05) compared to LGE- triathletes. They participated more often in middle- and long-distance competitions and completed longer cumulative race distances at cycling (4418±3094 vs 1490±1114km, p<0.0001) and swimming (64±32 vs 31±25km, p<0.01).
Conclusion: There is high prevalence (17%) of focal non-ischaemic myocardial fibrosis among male triathletes. An increased systolic blood pressure during exercise, the amount and extent of race distances as well as unapparent myocarditis might be cofactors in the genesis of myocardial fibrosis. The clinical relevance of myocardial fibrosis in triathletes is currently unclear; however, it might be a foundation for future heart failure and arrhythmia leading to sudden cardiac death.

B-0781 14:24

Evaluation of dark blood LGE in assessing sub-endocardial MI and papillary muscle scar

L. Song[1], X. Ma[1], X. Zhao[2], L. Zhao[1], Y. Fan[1], B. Wu[1], Z. Wang[1], H. Chen[1]; [1]*Beijing/CN*, [2]*Kunming/CN (linsheng.s1992@yahoo.com)*

Purpose: To investigate whether modified dark blood late gadolinium enhancement (DB-LGE) technique can provide complementary diagnostic information in patients with subendocardial myocardial infarction (MI) and papillary muscle scars.
Methods and Materials: 37 patients (52±10 years, 34 male) with definitely diagnosed MI, were prospectively included. All patients underwent 3.0 T-cardiac-MR (Discovery MR 750W, GE, WI) with conventional LGE and DB-LGE acquisition. The image quality and infarcted size quantitative measurement were compared using paired *T* test and Bland-Altman analysis. The level of agreement between reviewers was assessed using intraclass correlation coefficients.
Results: Modified DB-LGE performed better on a visual assessment of the ability to differentiate MI from the blood pool. The images provided significantly higher contrast to noise ratio (6.3±2.3 vs 2.1±1.4, *P*<0.001) and a 4-fold higher signal intensity ratio (4.9±1.8 vs 1.3±0.3, *P*<0.001) between MI and blood pool signals. DB-LGE detected more subendocardial MI (26 segments, 263 vs 237) and papillary muscle with scars (21 vs 7). Combined with echocardiography, papillary muscle with scars was associated with potential mitral valve insufficiency. Infarcted size compared between conventional LGE and DB-LGE showed no statistically significant difference (18.7±10.1 vs 19.4±10.5, *P*=0.096). The interobserver agreement was good to excellent for MI detection.
Conclusion: DB-LGE improves the contrast between the MI and blood pool and helps in the identification of subendocardial MI and papillary muscle scars. The quantitative and qualitative comparison in this study revealed that DB-LGE may be an alternative method to LGE in clinical use.

Stress-rest CMR for the assessment of myocardial perfusion reserve index modification after coronary sinus stent implantation

A. Palmisano, G. Benedetti, F. Giannini, L. Baldetti, A. Del Maschio, F. De Cobelli, A. Esposito; *Milan/IT (palmisano.anna@hsr.it)*

Purpose: The management of patients with angina refractory to revascularisation procedures and medical therapy is a challenge. The implantation of a hourglass-shaped coronary sinus stent named "Reducer" seems to improve patients' symptoms. However, the physiopathological mechanism underlying clinical benefit is not clear. Aim of the study was to evaluate the modification in myocardial perfusion reserve occurring after "Reducer" implantation using a stress-rest CMR study.
Methods and Materials: 11 patients eligible for implantation of the "Reducer" underwent clinical evaluation (CCS Angina Class and 6minutesWT) and a stress-rest CMR study with dipyridamole before the implantation and after 3 months. Segmental and transmural distribution of inducibile hypoperfusion and LGE was visually assessed. Myocardial perfusion reserve index (MPRI) of each segment and each myocardial layer (endocardium, midwall and epicardium) was measured using stress-rest CMR.
Results: All patients reported an improvement of ≥2CCS (p <0.0001) and a 60% increase in the average distance during the 6 minutes WT (p=0.004). MPRI significantly increased after "Reducer" implantation (1.29 vs 1.48; p<0.05). The analysis per cardiac segments showed an increase of MPRI in the ischemic territories (p=0.02334 for subendocardial ischaemia, and p=0.0001 for transmural ischaemia) while post-infarction necrotic area and healthy myocardial did not show significant changes (p=0.14 and p=0.12, respectively).
Conclusion: These preliminary data provide a new insight about the physiopathological mechanism of action of coronary sinus stent, suggesting its ability to determine a reduction of the inducible ischaemia of viable myocardial segments, associated to an improvement of angina symptoms and exercise tolerance.

Myocardial fibrosis imaging based on T1-mapping and ECV measurement in diabetes: diagostic value compared with LGE imaging

Y. Gao, Z. Yang, X. Liu; *Chengdu/CN (304789161@qq.com)*

Purpose: The objects of this study were: (i) evaluate the sensitivity and extent of myocardial fibrosis by extracellular volume fraction (ECV) and late gadolinium enhancement (LGE) in diabetes mellitus (DM) patients; (ii) ECV in diabetic individuals would be associated with the level of glycosylated hemoglobin (HbAlc) and duration of diabetes.
Methods and Materials: Thirty-six DM patients and 15 health controls who underwent cardiovascular magnetic resonance (CMR) including ECV measurement and LGE imaging were included. The 36 DM patients were classified in two group: a higher HbAlc group (HbA1c (%) ≥7.0; n=15) and a lower HbAlc group (HbA1c (%) <7.0; n=21). The independent-samples T test and Spearman rank correlation test were used for comparison and evaluated the relation.
Results: CMR measured ECV value was significantly higher in DM group compared with control group (36.1±3.8% vs. 31.1±1.7%, p<0.05), while the LGE percent was no difference in the two group (p=0.234). Between the higher HbAlc group and lower HbAlc group, the value of ECV was higher in the higher group (36.2±4.72 vs. 32.67±2.61, p<0.05). The spearman test showed a

moderate relationship between ECV and high HbAlc (r=0.331, p<0.05) and the same between ECV and duration of diabetes (r=0.348, p<0.05).
Conclusion: For DM patients, ECV might be more sensitive to early detect myocardial fibrosis than LGE. In addition, ECV was associated with HBALC and duration disease time, which could help to early heart condition monitoring.

B-0785 14:36

Prevalence of subclinical coronary artery disease by coronary computed tomography among low risk women after preeclampsia

G.A. Zoet[1], L. Benschop[2], R.P. Budde[2], C.J.M. de Groot[3], A.H.E.M. Maas[4], J.E. Roeters van Lennep[2], B.B. van Rijn[1], B.K. Velthuis[1], A. Franx[1]; [1]*Utrecht/NL*, [2]*Rotterdam/NL*, [3]*Amsterdam/NL*, [4]*Nijmegen/NL* *(gzoet@umcutrecht.nl)*

Purpose: The risk of coronary artery disease (CAD) is increased after preeclampsia, although traditional cardiovascular risk models often classify these women as low risk. This study compared prevalence of coronary artery atherosclerosis in low risk women with a history of preeclampsia to a population-based reference cohort.
Methods and Materials: Formerly preeclamptic women aged 45-55 years and low risk according to National Cholesterol Education Program (NCEP) were included in this analysis of a multicenter, prospective cohort study. Data were compared with women of similar age and ethnicity in the Multi-Ethnic Study of Atherosclerosis (MESA). Coronary artery calcium score (CACS) was calculated and contrast-enhanced coronary computed tomography angiography (CCTA) was performed in addition to routine cardiovascular risk assessment. Primary outcome was prevalence of CACS >0 Agatston Units (AU) and/or any coronary atherosclerotic plaques on CCTA. CACS were converted to adjusted MESA percentiles. Increased cardiovascular risk was defined according to the 2016 European guideline definition as CACS >300AU or >75th MESA percentile.
Results: Of 131 asymptomatic low risk women (mean age 48.3+/-2.8 years) with prior preeclampsia; 28% had CACS >0, 46% had coronary atherosclerotic plaques on CCTA, and 3.9% showed >50% luminal stenosis. Compared with the reference group, women after preeclampsia showed increased prevalence of CACS >0AU (OR 2.3; 95% CI 1.4-3.8), any plaque on CCTA and increased cardiovascular risk (28% versus 15%; OR 2.2, 95% CI 1.4-3.7).
Conclusion: Asymptomatic women after preeclampsia aged 45-55 years commonly show subclinical CAD with increased cardiovascular risk compared with women from a population-based reference cohort.

B-0786 14:40

Quantitative oedema and late gadolinium enhancement thresholds for the diagnosis of myocarditis in suspect cases

M. Ali, C.B. Monti, F.S. Carbone, F. Secchi, P.M. Cannao', F. Sardanelli; *Milan/IT (marco.ali90@gmail.com)*

Purpose: To quantify and evaluate left ventricle oedema and late gadolinium enhancement (LGE) percentages in patients with acute myocarditis in order to establish thresholds for Lake Louise Criteria in cardiac magnetic resonance (CMR).
Methods and Materials: A total of 96 patients, 48 of which having a diagnosis of myocarditis and two CMR examinations from acute phase and follow-up (at least 3 months apart), and 48 age- and sex- matched healthy subject as control group with one CMR examination, were retrospectively analyzed. For both groups left ventricle oedema and LGE percentages were quantified after manual contouring using the semi-automated Medis Suite MR Software. After the assessment of data distributions' normality, parametric and non-parametric tests were used for comparison among groups. Thresholds were established using ROC curves formed comparing data from acute phase and controls.
Results: Comparison between oedema in acute phase (12.76%, IQR 8.73%–19.10%) and follow-up (6.69%, IQR 5.41%–9.00%), or with controls (6.41%, IQR 5.27%–7.67%), showing significant differences with both p<0.001. The comparison between LGE in acute phase (6.30%, IQR 4.51%–9.08%) and follow-up (4.29%, IQR 3.22%–7.19%), or with controls (4.27%, IQR 3.00%–5.09%), showed significant differences with a p-value of 0.001 and <0.001, respectively. Thresholds were established for oedema at 7.9% with 93% sensitivity and 73% specificity, and for LGE at 4.30% with a sensitivity of 80% and specificity of 55%.
Conclusion: Quantitative thresholds of oedema and LEG may be used as clinical information useful in case of suspected myocarditis.

B-0787 14:44

Correlation between liver density and epicardial fat volume: biomarkers of coronary artery disease

C. Ferrari[1], G. Milanese[1], M. Silva[1], N. Giovanardi[1], M. Goldoni[1], E. Maffei[2], F. Cademartiri[3], N. Sverzellati[1]; [1]*Parma/IT*, [2]*Urbino/IT*, [3]*Rotterdam/NL* *(cate.ferr@gmail.com)*

Purpose: To test correlation between liver density and metabolic visceral adipose depot of epicardial fat, and whether it can act as biomarker of coronary artery disease (CAD) in patients undergoing cardiac computed tomographic angiography (CCTA).
Methods and Materials: The mean liver density (MLD) was quantified averaging density of three manual regions of interest (ROI; one in the left and two in the right lobe) on non-contrast computed tomography (CT) scans. Patients were stratified in steatotic (MLD ≤40 HU) and non-steatotic (MLD >40 HU). Epicardial fat volume (EFV) was quantified as the sum of voxels with density between -190 and -30 HU, within the volume outlined by the epicardial sheet. CAD was qualitatively evaluated and stratified in three groups: no CAD, non-obstructive CAD, and obstructive CAD. Continuous variables were reported as median and its interquartile range (IQR).
Results: In 1.181 patients, median MLD was 51.71 HU (IQR=13); median EFV was 87.19 ml (IQR=63.36). No CAD, non-obstructive CAD, and obstructive CAD were defined in 721 (61%), 296 (25.1%) and 164 (13.9%) patients, respectively. MLD and EFV were negatively correlated (r_s=-0.364; p<0.001); EFV was significantly higher in steatotic (114.21, IQR=84.02) compared with non-steatotic patients (82.03, IQR=58.23) (p<0.001). MLD was lowest in patients with obstructive CAD (p<0.001). In multivariate analysis, after adjustment for traditional clinical cardiovascular risk factors, MLD was associated with EFV (p<0.001) and with the presence of CAD (p<0.001).
Conclusion: MLD correlates with EFV and it can act as a potential biomarker for the stratification of CAD risk.

B-0788 14:48

Semi-quantitative evaluation of coronary microvascular dysfunction in paediatric patients with leukaemia using magnetic resonance first-pass perfusion imaging

Q. Zhao, X. Rong, Z. Yang, K. Diao, Y. Gao, Y. Guo; *Chengdu/CN* *(zhaoqin626@foxmail.com)*

Purpose: To evaluate the regional coronary microvascular dysfunction discrepancies in paediatric leukaemia patients with or without daunorubicin therapy by cardiac magnetic resonance (CMR) first-pass perfusion imaging.
Methods and Materials: Twenty-six paediatric patients with leukaemia, including 13 with daunorubicin therapy (treatment group) and 13 without daunorubicin therapy (non-treatment group) underwent CMR at rest. Imaging protocols included short axis cine, first-pass myocardial perfusion and late gadolinium enhancement (LGE). Left ventricular ejection fraction (LVEF), degree of LGE, perfusion parameters including maximal slope (Slopemax), time to peak (Tpeak) and peak signal intensity were all measured and compared by independent-sample t-test. The Spearman correlation test was used to calculate the relationships between LVEF, LGE, cumulative dose of daunorubicin and perfusion parameters.
Results: A total of 416 myocardial segments were analysed. Compared with non-treatment group, Slopemax decreased in treatment group (12.62±4.80 vs. 8.53±2.64, p < 0.05), while Tpeak increased (30.85 ±12.89 vs. 116.78±38.95, p < 0.001) in apical segments alone. LVEF and peak signal intensity were not shown significant difference in two groups. LGE was identified in 6 patients with daunorubicin therapy. In mid-ventricular segments, the cumulative dose of daunorubicin (mean 165.13±54.43 mg) was moderately associated with the degree of LGE (r = 0.682, p < 0.05).
Conclusion: Combined with LGE, CMR resting first-pass myocardial perfusion may help to achieve early diagnosis and clinical intervention of coronary microvascular dysfunction in paediatric patients with leukaemia, especially after the daunorubicin therapy.

B-0789 14:52

Cardiac magnetic resonance in prognostic stratification of patients with acute myocardial infarction and preserved ejection fraction

G. Dacquino, I. Carbone, N. Galea, L. Agati, G. De Rubeis, C. Catalano, M. Francone; *Rome/IT (gianmarcodacquino@gmail.com)*

Purpose: This study was designed to investigate the prognostic role of early post-infarction CMR on long-term risk stratification of STEMI patients with preserved ejection fraction (LVEF > 50%).
Methods and Materials: 55 PCI-reperfused STEMI patients were included. The median time between STEMI and CMR was 5 days (IQR 3 - 7). LV volumes and function, infarct size, early and late microvascular obstruction (MVO), and haemorrhage were measured. The primary endpoints were the incidence and CMR determinants of MACE at 5-year follow-up.

Results: During median follow-up of 2.5 years (range 1 to 5 years), 7 patients experienced MACE, yielding an annualized event rate of 2.71%. All CMR-based prognostic markers were no significantly different between MACE and no MACE patients, except for late MVO extent (0.9 ± 1.0 g vs. 0.07 ± 0.10 g; p = 0.003). Late MVO extent and the incidence of MACE at 5 years correlated moderately (r = 0.411; p = 0.003). ROC analysis identified late MVO extent > 1.4 g (AUC 0.647; 95% CI, 0.374 - 0.920; p = 0.036) as the best cut-off value for predicting the primary endpoint. Late MVO cut-off value > 1.4 g was a strong independent predictor of MACE at long-term follow-up (HR = 8.31; 95% CI, 1.52 -45.65; p = 0.015).
Conclusion: CMR-based late MVO extent after primary PCI is a strong predictor of MACE at 5-year follow-up in patients with LVEF > 50%. Remarkably, late MVO extent > 1.4 g provided prognostic insights leading to improved long-term risk stratification.

B-0790 14:56

4D flow MRI for the analysis of celiac trunk and mesenteric artery stenoses

F. Siedek, D. Giese, K. Weiss, S. Ekdawi, S. Brinkmann, W. Schröder, C. Bruns, D. Maintz, S. Haneder; *Cologne/DE (f.siedek@gmail.com)*

Purpose: This study aims to assess the feasibility of 4D-flow-MRI measurements in complex vascular territories; namely, the celiac artery(CA) and superior mesenteric artery(SMA).
Methods and Materials: In this prospective study, 22 healthy volunteers(HV) and 10 patients(PAT) were scanned at 3T. Blood flow parameters were compared between HV and PAT with stenosis of the CA and/or SMA as a function of stenosis grade characterised by prior contrast-enhanced computed tomography(CE-CT). 4D-flow-MRI acquisition covered the CA, SMA and adjusting parts of the aorta(AO). Measurements of velocity- (peak velocity[PV],average velocity[AV]) and volume-related parameters (peak flow[PF],stroke volume[SV]) were conducted. Further, stenosis grade and wall shear stress(WSS) in the CA, SMA and AO were evaluated.
Results: In PAT, prior evaluation by CE-CT revealed 11 low- and 5 mid-grade stenoses of the CA and/or SMA. PV and AV were significantly higher in PAT than in HV [PV:p<0.0001;AV:p=0.03,p<0.001]. PF and SV did not differ significantly between HV and PAT; however, a trend towards lower PF and SV could be detected in PAT with mid-grade stenoses. Comparison of 4D-flow-MRI with CE-CT revealed a strong positive correlation in estimated degree of stenosis (CA:r=0.86;SMA:r=0.98). PAT with mid-grade stenoses had a significantly higher average WSS magnitude than HV (p=0.02).
Conclusion: This study suggests that 4D-flow-MRI is a robust technique for the evaluation of complex flow characteristics in small vessels such as the CA/SMA. It approves comparable to the morphologic assessment of complex vascular territories using CE-CT but in addition offers the functional evaluation of flow parameters that goes beyond the morphology.

Comparison of biphasic DE-CT with virtual unenhanced dual energy reconstruction and triphasic CT with true unenhanced images in patients with suspected acute bleeding

S. Walter, S. Schneeweiß, M. Maurer, M. Lescan, F. Bamberg, K. Nikolaou, A.E. Othman; *Tübingen/DE (sven.walter@uni-tuebingen.de)*

Purpose: The comparison of biphasic DE-CT with arterial and venous phase and conventional triphasic CT in patients with suspected active hemorrhaging.
Methods and Materials: With suspected active bleeding, ninety-seven consecutive patients underwent routine triphasic CT with true unenhanced (TNE), arterial and venous dual-energy phase. For simulation of virtual unenhanced images (VNE), which were generated using dual-energy venous phase, we used commercially available software. Both noncontrast datasets were assessed on image quality, noise, artifacts, sharpness and diagnostic confidence on a 5-point-scale (5 = best possible outcome) by two blinded readers, individually. Furthermore, datasets with conventional triphasic CT and biphasic DE-CT with VNE were compared in respect to presence/absence of active bleeding and type of bleeding.
Results: Acute hemorrhage was diagnosed in 37.1% (75% arterial) of the included subjects (mean age: 66.3±14.5 years, 62% male). VNE images showed significantly lower overall image quality (p<.001) while compensation for artifacts was superior (p<.001) compared to TNE. No significant difference was seen in diagnostic confidence, both rated highly (p≤.012). Hematoma was found in 48.6% in virtual and true unenhanced scans with no discordant findings by the radiologists (Kappa=1.0). Regarding presence and type of hemorrhage, triphasic and biphasic CT datasets showed almost perfect agreement with concordant findings in almost all cases (Kappa>0.96).
Conclusion: VNE images showed comparable diagnostic confidence and an almost perfect agreement regarding presence and type of acute hemorrhage as TNE images. This indicates that biphasic DE-CT with VNE could replace triphasic CT for suspected acute bleeding, thus reducing scan time and radiation dose.

B-0792 15:04

Virtual monochromatic imaging improves the stent visualisation in lower extremity run-off CT angiography by dual-layer spectral detector CT

D. Zhang, Z. Jin, H. Xue, S. Yu, R. Wu; *Beijing/CN (cadina1984@163.com)*

Purpose: To evaluate the image quality and optimise keV level of VMI on stent visualisation in lower extremity CT angiography (CTA) compared with conventional 120 kVp image.
Methods and Materials: 24 patients undergoing run-off CTA on a dual-layer spectral detector CT were enrolled. All images were acquired at 120-kVp and monochromatic images from 40 to 150 keV with 10 keV increment and conventional 120 kVp images were reconstructed from the same scan due to the nature of spectral detector CT. The image quality was analysed on 12 monochromatic and conventional image sets. In-stent luminal diameter was measured twice using a calibre by 2 radiologists. The attenuation, noise, SNRs and CNRs were measured. Image quality was determined using a five-point scale.
Results: 30 stents were present. CNR and SNR were significantly higher with ≤70 keV-VMI (CNR: 16.0 ± 5.9-61.1 ± 27.5; SNR: 23.2 ± 11.7-48.6 ± 29.6) compared to conventional CT (CNR: 21.0 ± 8.6; all p = 0.000; SNR: 8.9 ± 10.4; all p < 0.003); there was no significant difference between 80keV-VMI (CNR: 16.0±6.4, p= 0.197; SNR: 17.4±6.0, p=0.417) and conventional CT on CNR and SNR. Luminal stent diameters were increased at ≥70 keV (5.26 ± 1.27-5.43 ± 1.32 vs. 5.09 ± 1.34, all p < 0.001). The score of image quality was highest at 80-90 keV-VMI (3.94 ± 0.25-4.00 ± 0.03 vs. 3.31 ± 0.48, both p = 0.000).
Conclusion: 80 keV-VMI improves image quality and accuracy for stent evaluation at run-off CT angiography by dual-layer spectral detector CT.

B-0793 15:08

Magnetic particle imaging: safe use of endovascular stents

F. Wegner, T. Friedrich, N. Panagiotopoulos, J.P. Goltz, F.M. Vogt, M.A. Koch, T.M. Buzug, J. Barkhausen, J. Haegele; *Lübeck/DE (franz.wegner@uksh.de)*

Purpose: Magnetic particle imaging (MPI) is a new three-dimensional imaging method. Cardiovascular imaging is seen as a promising future application of MPI. The purpose of this study was to evaluate the heating behaviour of endovascular stents as a safety aspect of cardiovascular MPI.
Methods and Materials: 21 commercially available endovascular stents of different sizes (diameter: 3-10mm, length: 11-99mm) and materials (stainless steel, nitinol, platinum-chromium, cobalt-chromium) were evaluated. They were implanted in silicone tubes matching the stent diameter and placed into a preclinical MPI scanner. The temperature change was measured with fiber optic thermometers over a period of 431 seconds of a standard imaging protocol.
Results: An increase of temperature of 0.1K (absolute accuracy of the temperature measurement) or more in relation to the reference temperature was defined as heating of the material. 12 stents showed heating of at least 0.1K or more. Four stents showed heating of more than 3.0K. The biggest temperature difference was 12.4K. The only significant predictor for the heating behaviour of the stents was their diameter. Pearson's correlation coefficient between the stent diameter and the square root of the temperature difference was r=0.96.
Conclusion: In principle, MPI in the presence of endovascular stents is safely possible as most of the stents showed no or mild increase in temperature. If the increase of temperature of stents with a larger diameter is still measurable under (blood) flow conditions and thus relevant in vivo has to be further evaluated.

Trajectories of imaging markers of the ageing brain: the Rotterdam study
E.J. Vinke, M. de Groot, V. Venkatraghavan, S. Klein, W.J. Niessen, M.A. Ikram, M.W. Vernooij; *Rotterdam/NL (e.vinke@erasmusmc.nl)*

Purpose: Brain changes in ageing may aid in better understanding of the ageing process and to distinguish normal ageing from age-related pathology. Longitudinal data in a broad age range are scarce, whereas these can provide important information on the rate of change. We estimated trajectories of several MRI markers based on longitudinal data and determined the sequence of these changing markers in ageing.
Methods and Materials: On 11,020 MRI scans (1.5T) from 5,428 persons aged 45 years and older from the population-based Rotterdam study, the following imaging markers were assessed: volumetric measures (total brain volume (TBV), grey matter (GM), white matter (WM), normal appearing white matter (NAWM), white matter lesion (WML), hippocampus), diffusion measures (fractional anisotropy (FA), mean diffusivity (MD)) and focal vascular lesions. Linear mixed models were used to estimate trajectories of change, for males and females separately. The sequence of changing MRI markers in ageing was determined by comparing these trajectories.
Results: Most markers show an exponential change with advancing age in the whole brain and per lobe, except for GM, which showed a more linear decrease with age. In general, females showed lower rates of change compared to males. The sequence in ageing markers was: TBV-MD-NAWM-WML-WM-hippocampus-GM-FA. The presence of vascular lesions shows an exponential increase with age, where males have a higher probability of having cortical and lacunar infarcts.
Conclusion: These data provide insight into the normal ageing process in the brain and its variability. Future studies can use this as a background to study pathology.

B-0795 16:04

The neural substrate of retinal neurodegeneration: the Rotterdam study
U. Mutlu, M. Ikram, G.V. Roshchupkin, P.W.M. Bonnemaijer, J.M. Colijn, W.J. Niessen, M. Ikram, C.C.W. Klaver, M.W. Vernooij; *Rotterdam/NL (u.mutlu@erasmusmc.nl)*

Purpose: There is a growing evidence that markers of retinal neurodegeneration such as thinner retinal nerve fiber layer (RNFL) and ganglion cell layer (GCL), assessed on optical coherence tomography (OCT), are reflective of global brain atrophy. Yet, little is known on the relation of these layers with specific brain regions. Using voxel-based analyses (VBA) of both grey matter density and white matter microstructure, we aimed to unravel which specific brain regions are associated with these retinal layers.
Methods and Materials: We included 2235 persons (mean age: 67.3 years, 55% women) from the Rotterdam Study (2007-2012), who had gradable retinal OCT images and brain magnetic resonance (MRI) scans. Thickness of RNFL and GCL were measured on OCT images. Voxel-based morphometry protocols were applied to process MRI data. We investigated the association of retinal sublayers with voxels in brain MRI by performing linear regression models adjusted for age, sex, subcohort, education, axial length of the eye, intracranial volume, and cardiovascular risk factors.
Results: We found that thinner RNFL and GCL were associated with lower grey matter density of the visual cortex, and with lower fractional anisotropy and higher mean diffusivity in white matter tracts that are part of the optic radiation. Furthermore, thinner GCL was associated with lower grey matter density of the thalamus.
Conclusion: Thinner RNFL and GCL are associated with grey and white matter changes in the visual pathway suggesting that retinal degeneration on OCT may be specific for atrophy in the visual pathway rather than global brain atrophy.

Multi-parametric 11C-methionine-MR/PET for brain tumour imaging utilising MR fingerprinting
L. Umutlu[1], M. Nittka[2], R. Kirsch[2], H. Quick[1], K. Herrmann[1], M. Gratz[1], M. Forsting[1], M. Forsting[1]; [1]*Essen/DE*, [2]*Erlangen/DE (Lale.Umutlu@uk-essen.de)*

Purpose: To investigate a novel approach of multiparametric tissue characterization of brain tumours based on morphologic, functional, metabolic and relaxometric properties utilizing integrated MR/PET and MR fingerprinting.
.
Methods and Materials: 25 patients with suspected brain tumours were enrolled in this trial. Examinations were performed on an integrated 3-tesla PET/MR system (Biograph mMR). PET and MR imaging was obtained simultaneously in one bed position after injection of 18F-FET. The (PET)MRI protocol included the following sequences: (1) TIRM, (2) FLAIR, (3) DWI, (4) SWI, (5) post-contrast MPRAGE imaging, (6) single-voxel spectroscopy and (7) MR fingerprinting. Histopathology served as the reference standard.
Results: An increase in malignancy from low-grade (grade 1-2) to high-grade glioma (grades 3, 4) was associated with increasing/positive PET uptake, contrast enhancement, increasing values in choline and choline/creatine as well as increasing T1 and T2 values. While low-grade astrocytoma did not show any pathologic tracer uptake or contrast enhancement, grade 3 gliomas showed increasing tracer uptake and increasing T1 and T2 values in MRF, respectively (mean values, grade 3 tumours: SUV_{max}:1.8 T/N: 1.3; T1: 1442/ T2: 122.9; mean values, grade 4 tumours: SUV_{max}: 3.4 T/N: 2.1; T1: 1752/ T2: 93.8).
Conclusion: The results of this novel approach of multi-parametric PET/MR imaging of brain tumours including MR fingerprinting demonstrate corresponding changes in tissue property based on the combined assessment of morphologic, functional, metabolic and relaxometric properties, indicating a correlation to the grading of brain tumours and leveraging tissue characterization to a unique level of multi-parametric assessment.

Sum score of cerebral small vessel disease relates to risk of stroke, dementia and mortality in the Rotterdam study
P. Yilmaz, M. Ikram, W.J. Niessen, M. Ikram, M.W. Vernooij; *Rotterdam/NL (p.yilmaz@erasmusmc.nl)*

Purpose: Cerebral small vessel disease (CSVD) is a major cause for brain damage leading to disability, morbidity and mortality. Markers of CSVD on magnetic resonance imaging (MRI) include white matter hyperintensities, lacunes, cerebral microbleeds and perivascular spaces. These have been separately associated with stroke, cognitive decline and dementia. However, combining the individual CSVD markers into a sum score might better capture the global CSVD burden. We investigated the association of CSVD sum scores with stroke, dementia and mortality.
Methods and Materials: 1655 stroke-free and non-demented participants (mean age 73.3 years, 54.4% women) of the prospective population-based Rotterdam Study underwent brain MRI (1.5 T) in 2005-2011 and were followed for major outcomes until 2015-2017. The CSVD sum score was composed by counting presence of each CSVD MRI marker (range 0-4). We determined the association of CSVD sum scores with risk of stroke, dementia and mortality using Cox models, adjusting for age, sex and also the Framingham Stroke Risk Profile (FSRP).
Results: During mean follow-up of 7.0 years, 66 participants developed stroke, 67 dementia and 308 died. CSVD sum scores ≥2 were associated with a higher risk of stroke and mortality (FSRP-adjusted hazard ratios (HR) 3.3, 95% CI 1.5-7.2; HR 1.5, 95% CI 1.0-2.0, respectively). A CSVD sum score of 3 showed an increased risk of dementia (FSRP-adjusted HR 2.8, 95% CI 1.1-7.3).
Conclusion: Higher CSVD sum scores on MRI are associated with a higher risk of stroke, dementia and mortality. Future steps are optimising the CSVD score including advanced imaging biomarkers.

B-0798 16:16

MRI brain atrophy can predict dementia in cognitively normal Parkinson's patients: a 7 year follow-up study
V. Pozdniakova[1], R. Zivadinov[2], T.O. Dalaker[1], I. Dalen[1], N. Bergsland[2], K. Oppedal[1], K. Pedersen[1], O. Tysnes[3], G. Alves[1]; [1]*Stavanger/NO*, [2]*Buffalo, NY/US*, [3]*Bergeb/NO*

Purpose: Dementia has a significant impact on mortality and prognosis in patients with Parkinson's disease (PD). Previous magnetic resonance imaging (MRI) studies have demonstrated cross-sectional associations of hippocampal atrophy and lateral ventricle enlargement with cognitive impairment in PD. In

this 7-year population-based prospective longitudinal study of an incident PD cohort, we explored whether early volume loss in these anatomic areas can predict future dementia development in cognitively normal Parkinson's patients.
Methods and Materials: This MRI study enrolled 123 newly-diagnosed and drug-naïve PD patients without mild cognitive impairment according to Movement Disorder Society (MDS) level 1 criteria. All underwent standardised 3D-T1 weighted brain MRI on a 1.5T or 1.0T scanners at baseline. MRI images were segmented using SIENAX and FIRST software. Patients were followed prospectively over a 7-year period. Dementia was diagnosed according to MDS criteria. Multiple logistic regression analysis with adjustment for age, sex and education was performed to calculate odds ratios (ORs) with 95% confidence intervals (CIs) for incident dementia during follow-up.
Results: We found that total hippocampal volume (OR 0.54 [CI 0.32-0.91], p=0.02), right hippocampal volume (OR 0.29 [CI 0.11-0.78], p=0.01) and lateral ventricle volume (OR 1.03 [CI 1.00-1.05], p=0.04) at time of diagnosis were significant predictors of dementia development during follow-up, independently of age, sex and education.
Conclusion: Hippocampal atrophy and lateral ventricular enlargement in patients with PD are early signs of evolving cognitive decline. Volumetric MRI may be helpful in the prediction of dementia associated with PD.

B-0799 16:20

Quantitative study of noninvasive prediction of glioma IDH1 gene status by APT combined with ASL imaging
J. Wen; *Shanghai/CN (wen123jianbo@163.com)*

Purpose: The purpose of the study was to explore whether amide proton transfer (APT) and arterial spin labeling imaging (ASL) helped to noninvasively predict isocitrate dehydrogenase 1 (IDH1) gene status of glioma.
Methods and Materials: MTRasym (3.5 ppm) values (APT values) and CBF values were measured in the tumour parenchyma region. Normalised CBF was calculated according to the formula nCBF = CBF tumour/CBF cerebellum. Independent samples t-test and ROC analysis were used in this study. Logistics regression analysis was combined with the effective parameters of APT and ASL to calculate the overall correct prediction rate.
Results: 90 patients with both APT and ASL data. In LGG, the APT and nCBF values of wild-type IDH1 gene were higher than those of IDH1 mutant group (p = 0.027, p<0.001). AUC= 0.802, 0.844, APT cutoff = 1.35 (%) and nCBF cutoff = 1.74, the sensitivity was 97% and 81.80%, the specificity was 60.2% and 62.2%. In HGG, the APT and CBF have statistical significance (p = 0.004, p = 0.005); AUC=0.695, 0.712, respectively. APT cutoff= 3.24 (%), the sensitivity and specificity were 67.4% and 72.2%, respectively. When CBF = 76.83 × ml/100 g/min, sensitivity and specificity were 64.2% and 69.4%, respectively. Logistics regression combined with APT values and nCBF values to obtain the overall correct prediction rate is 78.7% and 86.8%, respectively.
Conclusion: APT and ASL provide a valuable new method for the noninvasive diagnosis of the IDH1 gene state of brain glioma. Combination of APT and ASL can improve the overall IDH1 gene prediction rate of glioma.

Sex differences in resting-state cerebral activity alterations in internet gaming disorder
Y. Sun, Y. Zhou, Y. Wang, X. Han, W. Ding, J. Xu; *Shanghai/CN (cjs1119@hotmail.com)*

Purpose: Although there is evidence that the prevalence rates of internet gaming disorder (IGD) differs between males and females, no studies have examined whether such sex differences extend to brain function. This study was to explore the sex differences in resting-state cerebral activity alterations in IGD.
Methods and Materials: Thirty male participants with IGD (IGDm), 23 female participants with IGD (IGDf), and 30 male and 22 female age-matched healthy controls (HC) were recruited and underwent resting-state functional MR imaging. Maps of amplitude of low-frequency fluctuation (ALFF) and seed-based functional connectivity (FC) were constructed. A two-factor ANCOVA model was specified using SPM8, with sex (male, female) and diagnosis (IGD, HC) as the between-subject factors. When interaction effects occurred, post hoc pair-wise comparisons were performed using two-sample t tests within the interaction masks. We used Barratt impulsiveness scale-11 (BIS-11) to assess the behavioral inhibition function and Chen internet addiction scale (CIAS) to evaluate the severity of IGD. The correlations between the values of ALFF/FC and clinical scores were assessed using partial correlation analysis, respectively.
Results: The amount of ALFF in the orbit part of left superior frontal gyrus (SFG) significantly decreased selectively in IGDm, which was negatively correlated with BIS-11 score. Furthermore, orbit part of left SFG also showed decreased connectivity with posterior cingulate cortex, right angular gyrus, and right dorsolateral prefrontal cortex in IGDm.
Conclusion: Our findings suggest that sex-specific cerebral activity alterations existed in IGD, and these alterations have clinical relevance as a biomarker for the behavioral inhibition function of IGD.

B-0801 16:28

3D neuromelanin imaging for differential diagnosis between Parkinson disease and essential tremor: a multicenter retrospective study
Y. Kwon[1], W.-J. Moon[1], M. Park[1], H. Kim[1], J. Choi[2]; [1]*Seoul/KR*, [2]*Suwon/KR (quan01@gmail.com)*

Purpose: Differentiation between Parkinson disease (PD) and essential tremor (ET) can be difficult. As neuromelanin-containing SN can be visualised on 3D-neuromelanin-sensitive imaging, we aimed to evaluate SN T1 hyperintensity and its diagnostic accuracy in patients with PD and ET.
Methods and Materials: This retrospective study enrolled 36 patients with PD and 22 patients with ET from two hospitals, between August 2016 and February 2017. 3D neuromelanin-sensitive T1-weighted sequence was obtained using two 3-T scanners. Two observers evaluated the SN T1 hyperintensity of each side of SN using a seven-point scale (with 0.5 increments from 0 to 3) according to the extent and degree of signal reduction of neuromelanin. Diagnostic performance of visual assessment was investigated using receiver operating characteristic analyses. Intra-rater and inter-rater agreement were calculated by weighted kappa.
Results: Reduction of SN T1 hyperintensity was significantly more prominent in PD than in ET (p<0.001). The sum of neuromelanin scale from both sides provided AUC of 0.924 (95% CI, 0.823-0.977; sensitivity of 80.6% and specificity of 90.9%) with a threshold of at least 1.0. Inter-rater and intra-rater agreement was 0.902 and 0.900, respectively.
Conclusion: Visual assessment of SN T1 hyperintensity by expert reviewers provides high diagnostic accuracy in differential diagnosis between PD and ETs. We suggest that 3D neuromelanin imaging with a simple visual grading system can be helpful in clinically challenging cases.

B-0802 16:32

Ischaemic optic neuropathy: using track-weighted imaging to detect changes in the neuroretina
A. Attye[1], C. Jean[1], P. Remond[1], A. Lecler[2], F. Aptel[1], C. Chiquet[1], L. Lamalle[1], A. Krainik[1]; [1]*Grenoble/FR*, [2]*Paris/FR (aattye@chu-grenoble.fr)*

Purpose: Track-Weighted Imaging (TWI) was recently introduced as a tractography-based method with high anatomical contrast. We report the use of this method to explore the human retina in healthy volunteers and patients with anterior ischemic optic neuropathy (AION).
Methods and Materials: Twenty patients who had undergone MRI were included, and compared with 20 healthy volunteers. For the diffusion-weighted acquisition, we used a b-value of 1000 s/mm^2 and 60 directions distributed over four scans. We performed a constrained spherical deconvolution-based volumetric tractography method, whereby 10 million streamlines are initiated from seed points randomly distributed throughout the orbital area. We then reconstructed TWI maps with isotropic voxel size of 300 µm. We tested the effect of number of diffusion-weighted directions, ocular laterality, ocular dominance on healthy retinal fascicles distribution and the effect of the presence/absence of the fascicles on the visual field defect in patients with factorial analysis of variance.
Results: We found influence of ocular laterality, ocular dominance and number of diffusion-weighted directions on the neuroretinal healthy fascicle distribution. 8 out of 20 AION patients presented with complete absence of neuroretinal fascicle, side of the disease, which was correlated with visual field mean deviation at the 6 month-visit [$F_{(1, 17)} = 6.97$, p= 0.016]. 7 patients presented with a temporal fascicle in the injured eye, this fascicle presence was linked to visual field mean deviation at the 6 month-visit [$F_{(1, 17)} = 8.43$, p= 0.009].
Conclusion: The initial distribution of neuroretinal fascicle correlated with AION patients' visual outcome.

B-0804 16:36

Intracranial atherosclerotic plaque enhancement associated with ischaemic stroke: a study with three-dimensional high-resolution magnetic resonance vessel wall imaging
X. Bai, J. Lin; *Shanghai/CN (baixueqin1@126.com)*

Purpose: To evaluate the reproducibility of three-dimensional high-resolution magnetic resonance vessel wall imaging(HR-MRI)for demonstration of intracranial atherosclerotic plaque enhancement and to explore the relationship between plaque enhancement and ischemic stroke.
Methods and Materials: 52 patients with ischemic stroke underwent traditional head MRI, 3 dimensional -time of flight magnetic resonance angiography and HR-MRI on a 3.0T MRI scanner. Each identified intracranial plaque was classified as either culpritor non-culprit. The degree of plaque enhancement was graded by two independent radiologists,the degree of plaque enhancement and luminal stenosis were compared between culprit and non-culprit groups by using *Mann-Whitney U* test. Binary logistic regression

analysis was performed to assess the relation between the degree of plaque enhancement and culprit plaques.
Results: 118 plaques were identified in 52 patients with ischemic stroke(52 culprit and 66 non-culprit plaques). The degree of enhancement was rated as strong, moderate and none in 40,9 and 3 culprit plaques, and in 4,24 and 38 non-culprit plaques. Both intra-observer and inter-observer agreement were high for identification of plaque enhancement(kappa>0.75). For the group of culprit plaques, the degree of plaque enhancement(*Z*=-7.787,*P*<0.01) and luminal stenosis (*Z*=-5.327,*P*<0.01)were significantly higher than those in non-culprit group. Binary logistic regression analysis revealed that strong enhancement of plaques was independently associated with culprit plaques(OR:74.3, 95%CI:15.0-367.1, *P*<0.01).
Conclusion: Three-dimensional HR-MRI detects enhancement of intracranial plaques with high reproducibility. Enhancement is more common in culprit plaques and is associated with the likelihood of ischemic stroke.

B-0805 16:40

Quantitative measurement of brain iron deposition in patients with peritoneal dialysis using susceptibility mapping
A.-N. Lin; *Kaohsiung/TW (miracoli1126.al@gmail.com)*

Purpose: To evaluate different susceptibility of brain structures between patients with chronic kidney disease who underwent peritoneal dialysis & healthy controls using quantitative susceptibility mapping (QSM) & their correlations with clinical data.
Methods and Materials: For twenty-six patients (13 men & 13 women, mean age 54.46 year old) with peritoneal dialysis and twenty-six age & sex matched controls (12 men & 14 women, mean age 55.65 year old) were included in this prospective study. Magnitude image & phase image were reconstructed for susceptibility mapping to quantitate difference of iron deposition between patients & healthy controls. Partial correlation & stepwise multiple regression analysis between susceptibility & clinical parameters were calculated.
Results: The result confirmed that increased brain iron deposition in bilateral caudate nucleus, putamen, substantia nigra, red nucleus & right dentate nucleus in the patient group. There is no significant correlation between brain susceptibility & serum iron profile or dialysis efficiency. Also, negative correlation were found between susceptibility of basal ganglia and excecutive function, speech and language function and visuospatial function but positive correlation with Beck depression inventory which indicates increased iron deposition leads to cognitive impairment.
Conclusion: It is concluded that increased brain iron deposition in peritoneal dialysis patient was associated with cognitive dysfunction.

B-0806 16:44

Increased cerebral GABA concentration measured using ^{1}H MRS in the acute paediatric mTBI
P.E. Menshchikov, N. Semenova, I. Melnikov, M. Ublinskiy, T. Akhadov; *Moscow/RU (peeterem@gmail.com)*

Purpose: The vast majority of mild traumatic brain injury (mTBI) cases do not lead to abnormalities of brain structures. The correlation between early structural neuroimaging findings and long-term clinical outcomes is weak. The main aim of this work was to estimate changes in *in vivo* cerebral GABA and glutamate concentrations after acute mTBI using ^{1}H MRS.
Methods and Materials: Two groups of participants were included in the study: patients (n=11, mean age - 16±2 years, Glasgow Coma Score (GCS) - 15) with acute mTBI (mean time between trauma and MRI examination 40±20 hours); 8 healthy children (mean age - 16±1 years) without history of any TBIs. ^{1}H MR spectra were acquired on scanner Philips 3.0T Achieva TX using PRESS (NAA, creatine, choline signals) and MEGA PRESS (GABA and glutamate signals) pulse sequences. All voxels in size of 25×25×30 mm were located in the frontal lobe.
Results: The main effect on the [GABA] was found (Z=2.03, p<0.05), with the patients having higher [GABA] as compared to the control group (36%) (Fig. 2). Absolute concentrations of NAA, tCho, tCr and glutamate were unchanged.
Conclusion: This study for the first time revealed increased cerebral [GABA] as well as disorders in the [GABA]/[GLX] balance in the paediatric acute mTBI. The most likely cause of [GABA] increase is growth of free pool of GABA (non-related to GABA receptors). Postconcussion changes of neurotransmitter revealed in the present study could be promising for understanding of functional consequences of MRI-negative TBI.

B-0807 16:48

A preliminary study on non-invasive prediction of IDH1 gene status in glioblastoma by intravoxel incoherent motion MR imaging
J. Wen; *Shanghai/CN (wen123jianbo@163.com)*

Purpose: To investigate the value of intravoxel incoherent motion MR imaging (IVIM) in non-invasive judgment of IDH1 gene status of diffuse glioblastoma.
Methods and Materials: Prospective collection of diffuse glioma patients in 95 cases, the tumour real area of the IVIM imaging parameters: (F), average apparent diffusion coefficient (ADCmean), fast apparent diffusion coefficient (fastADC), diffusion coefficient (DDC), and pseudo-diffusion coefficient (D*). Calculate the parameters of the contralateral white matter area after the parameters: (NrF, nrD, nrD*nrADC). The effective parameters were used to plot the ROC curve. The correct predictive rate of IDH1 gene was calculated by logistic regression analysis.
Results: The values of F, ADCmean, nrADCmean and DDC were significantly higher in the low-level group than in the wild-type low-grade group (P <0.05).The F value and fastADC values of the mutant high-level group were significantly lower than those of the wild-type high-level group (P<0.05). The sensitivity and specificity of ROC AUC were 0.125, 0.67, 0.65 and 0.780; ADCmean were 1.182, 0.750, 0.875 and 0.842, respectively, and nrADCmean were 1.481, 0.762, 0.875 and 0.899, respectively, DDC were 1.193, 0.792, 0.750, 0.774, respectively. High-grade glioma combined with F and fastADC concluded that the correct predictive rate of IDH1 gene was 82.5% and the likelihood ratio was 46.07.
Conclusion: IVIM examination provides a new method for non-invasive diagnosis of diffuse glioblastoma IDH1 gene status before surgery.

B-0808 16:52

In vivo molecular profiling of human glioma using dynamic susceptibility contrast magnetic resonance perfusion imaging
J.-M. Hempel, J. Schittenhelm, B. Bender, M. Skardelly, G. Tabatabai, S. Castaneda Vega, U. Ernemann, U. Klose, C. Brendle; *Tübingen/DE (johann-martin.hempel@uni-tuebingen.de)*

Purpose: To assess the diagnostic performance of dynamic susceptibility contrast perfusion magnetic resonance perfusion imaging (DSC-MRI) for in vivo human glioma molecular profiling.
Methods and Materials: One hundred patients with histopathologically confirmed glioma who provided written informed consent were retrospectively assessed between 01/2016 and 02/2017 in two prospective trials that were approved by the local institutional review board. Cerebral blood volume (CBV) metrics from DSC-MRI were assessed, and histogram parameters of rCBV results were compared among WHO 2016-based histological findings and molecular characteristics. A classification and regression tree (CART) algorithm with 10-fold cross-validation was used to calculate the diagnostic accuracy.
Results: The 90th percentile (C90) of rCBV was significantly lower in patients with the isocitrate-dehydrogenase 1/2 (IDH1/2) mutation (2.86±1.21; p < 0.001) and loss of alpha-thalassemia/mental retardation syndrome X-linked (ATRX) expression (2.23±0.91; p < 0.001) than in those with the IDH1/2 wild type (4.78±2.34) and who maintained ATRX expression (4.30±2.02), respectively. The C90 of rCBV correctly predicted ATRX expression in 86.4% and the IDH1/2 mutation in 70.4% of patients. The standard deviation (SD) of rCBV was significantly higher in glioblastoma with methylated O6-methylguanine DNA methyltransferase (MGMT; 1.99±0.73; p = 0.001) than in those with unmethylated MGMT (1.20±0.45). The SD of rCBV correctly predicted MGMT methylation status in 81.8% of all primary glioblastomas.
Conclusion: DSC-MRI may provide insight into the human glioma molecular profile regarding IDH1/2 mutation status, ATRX expression, and the MGMT methylation profile. Thus, rCBV is a promising potential biomarker for glioma.

Prediction of postoperative cerebral hyperperfusion: a study using territory arterial spin labelling (tASL)
T. Lin, Y. Lyu, Z. Zuo, H. You, J. Qu, B. Hou, F. Feng; *Beijing/CN (jasminelty@163.com)*

Purpose: Cerebral hyperperfusion (CH) or hyperperfusion syndrome (CHS) is a rare complication after revascularisation, but may lead to intracranial haemorrhage. The objective of this study was to investigate the relationship between postoperative hyperperfusion and perfusion territories change.
Methods and Materials: We retrospectively reviewed 22 patients with severe unilateral or bilateral carotid stenosis. The perfusion volume and cerebral blood flow of each brain feeding vascular (left/right internal carotid artery and vertebrobasilar artery) before and within 3 days after carotid endarterectomy (CEA) were measured using tASL and ASL, respectively. Volume fraction (perfusion volume/brain volume) of each territory was calculated. Patients were classified into three groups: only with postoperative CBF increase≥100% (CH group, n=7), CBF increase with headache right after surgery on the ipsilateral side and/or with deteriorated consciousness, focal neurological deficits or seizure (CHS group, n=2) and normal perfusion group (n=13), both CH and CHS group were considered as hyperperfusion group (n=9).
Results: Perfusion volume fraction before CEA was significantly smaller in the hyperperfusion group compared to normal perfusion group (14.05%±11.51% vs 31.55%±11.45%, *P*=0.02). And perfusion fraction significantly increased after surgery in the hyperperfusion group compared to normal perfusion group (19.53%±9.76% vs 4.75%±7.65%, *P*=0.001).

Conclusion: Postoperative markedly increased CBF is associated with smaller perfusion volume before surgery and large perfusion volume increase after surgery in the stenosis side, which may be predictors for postoperative hyperperfusion.

Characterists of plaques and lenticulostriate arteries in stroke patients by whole-brain vessel wall

F. Wu, Q. Yang, C. Zhang; *Beijing/CN (chaozhang0328@hotmail.com)*

Purpose: The aim of the present study was to evaluate atherosclerotic plaque characteristics and lenticulostriate arteries (LSA) together by novel whole-brain high-resolution magnetic resonance imaging (WB-HRMRI) and to establish their relationship with different infarction patterns.
Methods and Materials: Stroke patients with artery-to-artery (A-to-A) embolism or branch atheromatous disease (BAD) were prospectively enrolled and WB-HRMRI was performed. The characteristics of the intracranial atherosclerotic plaques and distribution of LSA branches were compared between the two groups.
Results: Fifty-eight first-time stroke patients were finally enrolled including 32 A-to-A embolism and 26 BAD. Hyperintensity plaques (HIP) and plaque surface irregularity were more frequently observed in A-to-A embolism group than in the BAD group ($P < 0.001$ and $P = 0.028$, respectively). Patients with A-to-A embolism infarction had severer stenosis degree than patients with BAD infarction ($P = 0.001$). The average number and length of visualized LSA branches significantly reduced in patients with BAD compared with A-to-A embolism ($P = 0.025$ and $P = 0.029$). Logistic regression analysis showed that HIP was independently associated with A-to-A embolism infarction, while reduction in the numbers of LSA branches was independently associated with BAD infarction. Odds ratios for HIP and the numbers of LSA branches were 12.21 and 2.07 (95% confidence interval 2.41 - 61.83 and 1.06 - 4.07; $P = 0.002$ and 0.034) respectively.
Conclusion: A-to-A embolism infarction has distinct vascular pathophysiologies in terms of plaque and LSA characteristics compared with BAD. WB-HRMRI enables the combination of vessel wall and LSA imaging which can predict future stroke.

MRI assessment of brain grey matter structural changes in severe nicotine dependency

A. Dong; *Zhengzhou/CN (845516273@qq.com)*

Purpose: To evaluate brain structure changes in mild nicotine dependency by voxel-based morphological method.
Methods and Materials: In this study, 77 severe nicotine-dependent (FTND<6 score) and 37 non-smoking healthy volunteers were scanned with Siemens Skyro 3.0T magnetic resonance scanner. Subjects were routinely MRI (to exclude intracranial lesions) sequence and 3D-MPRAGE sequence. SPM8 pretreatment based on Matlab was used to analyse the data. The SPM8 software was used to analyse the independent sample t test (FWE correction, P<0.001) with the smoking group and the control group. The spearman correlation analysis was used to analyse the difference between severe nicotine-dependent group and smoking data with SPSS 17.0.
Results: Compared with the control group, the mild nicotine-dependent group exhibited decreased GMV in bilateral thalamus, bilateral supramarginal gyrus (right supramarginal gyrus, left supramarginal gyrus), and the area with elevated GMV was not found (FWE corrected, P<0.05, cluster size>318 voxels). Bilateral thalamus, right supramarginal gyrus GMV were significant negatively correlated with smoking index and tobacco years, and right thalamus was negatively correlated with daily smoking ($\alpha = 0.05$, P<0.05).
Conclusion: The changes of brain structure among smokers mainly focused on reward-related pathways and marginal systems, and part of the grey matter volume of brain regions is related to smoking behaviour data. The results would help for further study into the mechanism of brain function in chronic smokers.

Two year follow-up: results after acute stroke endovascular thrombectomy

A. Balodis, M. Radzina, K. Kupcs, E. Milglane, J. Savlovskis, H. Kidikas, A. Veiss; *Riga/LV (arturs.balodis7@gmail.com)*

Purpose: Endovascular thrombectomy(ET) in acute ischemic stroke treatment with large artery occlusion after 3 months has shown a good neurological result, however there are only few long term results available. The aim of our study was to analyze ET functional outcome after 2-years from initial treatment, in patients with acute ischemic stroke due to large artery occlusion.
Methods and Materials: The prospective study included 91 patients hospitalized within time window of 8 hours with middle cerebral artery M1 or internal carotid artery occlusion. Sixty-one (67%) of them received thrombolysis followed by ET, 30(33%) - thrombectomy solely. Modified Rankin scale (mRS) was used to evaluate early therapy results and late results at 3 months and 2 years.
Results: There were 44(48%) women and 47(52%) men analyzed with mean age 67.66±11,9(SD) years. Successful recanalization rate after ET was 90% (TICI-2b,3). Median mRS (0-2): after discharge was 29(32%), 3 months mRS was 36(40%), p=0.01 and 2 years mRS (0-2) was 34(37%), respectively. No statistical difference between 3mo and 2y, p=0.32. Two years follow up mortality was 32(35%) compared to 13(15%) in 3 months, difference was statistically significant. 44% of patients with severe disability mRS 4-5 at 3 months were with the same status after 2 years (3mo vs 2y: 23(25%) and 10(11%), respectively).
Conclusion: Our results show that after 2 years ET can show high number of good long term functional outcome. The majority of high mortality rates after 2 years resulted from patient group with severe neurological deficit mRS(4-5) at 3 months.

B-0815 08:34

Comparison between not-stent retriever and stent retriever mechanical thrombectomy for the intra-arterial acute ischemic stroke treatment

E. Puglielli, R. Lattanzi, V. Di Mizio, S. Roiati, F. Navarra, V. Di Egidio; *Teramo/IT (edopug@hotmail.com)*

Purpose: The objective of this work is to compare the ability to remove of the thrombus, the final TICI and outcomes for non-stent retriever nST and stent retriever ST thrombectomy for the AIS treatment.
Methods and Materials: between April 2009 and September 2017, 220 patients (mean age 62,7y) were treated for AIS with mechanical thromebctomy, fulfilled the classic inclusion criteria of EST, using retrievable stents or aspiration. NCCT, CTP-CTA and DSA were used for imaging. Primary outcomes were: the 90 days ≤ 2 mRS, the TICI recanalization rate, the incidence of symptomatic intracranial hemorrhages (ICHs). Patient's age, sex, etiology of occlusion, time of treatment, median NIHSS at presentation, mRS at discharge were correlated using univariate analysis and multivariate regression.
Results: mNIHSS at presentation was 24 (ranged 9-33). Sites of arterial occlusion before treatment were: M1-M2 156/220 (70.90%), intracranial carotid 8/220 (0.03%), M2-M3 14/220 (6.36%), tandem occlusion 6/220 (2.72%), extracranial internal carotid isolated occlusion 5/220 (2,27%), P1 7/220 (3.18%), basilar trunk 24/220 (10.90%). Statistical significant differences were observed between ST group 123/220 patients (55.90%) and nST 97/220 (44.09%) one in terms of ≤ 2 mRS at discharge (21.24% [nST] vs 64.73% [ST]; p<0.005) and high TICI Score 2b-3 recanalization rates (77.32% [NSR] vs 98.51% [SR]; p < 0.005).
Conclusion: clot composition and anatomic factors could explain the difference on nST vs ST outcomes. A combined multimodal approach for AIS treatment using the two different methods could lead to very high recanalization rates with low complications.

B-0816 08:38

Endoscopic ultrasound-guided hybrid therm ablation in patients with stage III pancreatic adenocarcinoma: a clinical study with radiological perspectives

M. Barbera, S. Testoni, E. Dabizzi, S. Gusmini, M. Petrone, A. Esposito, A. Del Maschio, P. Arcidiacono, F. De Cobelli; *Milan/IT (barbera.maurizio@hsr.it)*

Purpose: A third of cases of pancreatic cancer is locally advanced and unresectable (LAPC) at diagnosis. Endoscopic ultrasound-guided hybrid cryotherm ablation (EUS-HTP) combines radiofrequency with cryogenic cooling, reaching the pancreas also when inaccessible through percutaneous approaches. Aim of this ongoing study was to evaluate the feasibility, safety and post-procedural imaging findings of this novel therapy.
Methods and Materials: 35 consecutive patients with LAPC were prospectively enrolled at the Gastrointestinal Endoscopy Unit of our tertiary referral Center for a singular or repeated EUS-HTP session. The absolute tumor volume (ATV) and ablation necrotic volume (ANV) were measured in timely close follow-up CECT scans and, if suitable, MR images by an advanced visualisation tool. Data were analysed by descriptive and non-parametric statistics.
Results: EUS-HTP resulted feasible in 26 patients (74.3%), except in 9 cases due to tumor stiffness or vessel interposition. CT identified the ANV in 25 patients (96%), whereas MR in all cases when performed; no statistical difference was found in the ANV measure between CT and MRI (P = 0.664). The mean ANV was 12.44 mm^3 (range 1.3-56) with an average ablation percentage of 34.9% (range 3-65). The median post-HTP overall survival (OS) time was 6 months (range 1-22), increasing from 5 to 9 months with more than one session (P = 0.066). Early complications occurred in 11 patients (37%), all mild except one moderate, conservatively treated.
Conclusion: EUS-HTP is a safe and feasible therapy for patients with LAPC; both CT and MRI result useful for follow-up after treatment.

B-0817 08:42

Impacts of related risk factors on the efficacy of interventional treatment towards intractable postpartum haemorrhage

C. Zhao; *Beijing/CN (zhaochaoxy@163.com)*

Purpose: To investigate the risk factors that impact the efficacy of interventional treatment of intractable postpartum haemorrhage (IPH).
Methods and Materials: A total of 64 IPH patients were admitted and received interventional treatment, among whom 57 cases were successfully treated (bleeding stopped), while 7 cases failed. The clinical data of the success group and the failure group were observed for the multivariate analysis of the possible reasons that might cause haemostatic failure.
Results: The univariate analysis of each suspected factor of haemostatic failure showed that history of uterine scar, combined use of uterotonics, uterine inertia, and placenta exhibited statistically significant differences between the 2 groups (p<0.05); the multivariate logistic regression analysis showed that history of uterine scar and combined use of uterotonics were the risk factors for the interventional treatment failure of IPH, with OR values of 11.23 (95% CI 1.26~100.22) and 12.83 (95% CI 1.05-156.34), respectively.
Conclusion: History of uterine scar and combined use of uterotonics were the risk factors for interventional treatment failure of IPH.

B-0818 08:46

Is portal vein embolisation of liver segment IV mandatory before extended right hemihepatectomy?

C. Loberg, S. Keil, F. Goerg, C.K. Kuhl, P.L. Bruners; *Aachen/DE (cloberg@ukaachen.de)*

Purpose: Portal vein embolisation (PVE) is an established procedure to introduce hypertrophy of the future liver remnant (FLR) in patients scheduled for extended right hemihepatectomy (ERH). There is uncertainty as to whether PVE needs to include the branches to the left medial segment (S4), or whether induction of hypertrophy is sufficiently achieved if right PV branches (S5-8) are occluded. We analysed hypertrophy rates of patients undergoing PVE of S5-8 branches only.
Methods and Materials: PVE was done prior to ERH when the anticipated volume of FLR was < 30% of the total liver volume in patients with compromised, or < 25% of the total liver volume in patients with normal liver function. PVE of the right portal venous system (S5-8) was performed. Liver volumetry was done on contrast-enhanced CT acquired within 1 week before and 3-4 weeks after PVE.
Results: 140 patients were included. Technical success was achieved in (99%) of patients. At follow-up CT volumetry showed sufficient hypertrophy by an average of 36% (range, 25-39%) in (97%) . A total 98 of the 135 patients with sufficient hypertrophy (73%) went on to ERH. In 37/135 patients (27%), hepatectomy was ultimately not performed because of extrahepatic tumour spread. A total 8/135 patients (6%) had new lesions in the left liver (FLR) at

post-PVE-CT; these patients underwent ERH with additional percutaneous local ablation.
Conclusion: PVE of portal vein branches to segments 5-8 is sufficient to induce satisfactory hypertrophy of the FLR to allow extended right hepatectomy.

B-0820 08:50

Combined antegrade and retrograde approach in iatrogenic ureteral injuries: the rendez-vous technique

G. Pacella, E. Faiella, D. Santucci, A. Alfonsi, C. Altomare, B. Beomonte Zobel, R.F. Grasso; *Rome/IT (giuseppina.pacella23@gmail.com)*

Purpose: Ureteral injuries are the most common urologic complications occurring during abdominal and pelvic surgery, with an incidence ranging from 1% to 10%. The choice treatment is generally open surgery, but the rendez-vous technique represents an alternative strategy. Our study evaluates the feasibility and effectiveness of the rendez-vous technique in case of complete iatrogenic ureteral injuries.
Methods and Materials: From 2012 to 2017 we treated 20 patients with the rendez-vous technique for complete iatrogenic ureteral injuries: 12 patients underwent to radical hysterectomy, 3 to radical cistectomy, 5 to rectal anterior resection. The diagnosis was supported by CT-urography and antegrade pielography.The rendez-vous technique was performed by the introduction of a gooseneck snare through the nephrostomic access to capture the end of the retrograde ureteral wire, which was retrieved from the percutaneous sheath to gain a through-and-through access. A double J stent was antegradely inserted and a nephrostomy tube was kept in place.
Results: The rendez-vous technique was successful in all cases with resolution of the ureteral leak. In all patients the nephrostomy tube was removed after 30 days. After performing CT-urography the stent was removed permanently in 16 patients after 6 months and in 4 after 9 months. Only three cases showed a locale post-treatment stenosis treated with surgical ureteral reimplantation. In the other cases there was no ureteric stricture at the site of the previous injury.
Conclusion: The rendez-vous technique is an effective minimally invasive procedure that can be used to restore the continuity of the ureter avoiding open surgical.

B-0821 08:54

MR-guided focused ultrasound (MRgFUS) thalamotomy for the treatment of medically refractory essential tremor

S. Dababou[1], C. Marrocchio[1], C. Halpern[2], J. Henderson[2], A. Napoli[1], C. Catalano[1], K. Butts Pauly[2], V. Santini[2], P. Ghanouni[2]; [1]*Rome/IT*, [2]*Stanford, CA/US (susy150791@gmail.com)*

Purpose: Clinical outcome assessment of MRgFUS thalamotomy for the treatment of medically-refractory essential tremor.
Methods and Materials: 8 patients underwent unilateral transcranial MRgFUS(ExAblate-InSightec)ablation within the ventral intermediate nucleus of the thalamus for the treatment of medically refractory essential tremor. The primary endpoint was the reduction in the dominant hand tremor score, evaluated by Part A and Part B of the Clinical Rating Scale for Tremor(CRST) at 3 months. The secondary endpoints were the changes at 3 months in the quality of life(Questionnaire for Essential Tremor(QUEST)), and in the subject daily functionalities(Part C of the CRST); and in the durability of these changes at 6 and 12-month follow-up visits.
Results: At 3-month follow-up 8 patients were assessable. The dominant hand tremor decreased by 57% from a mean baseline score of 20.5+/-3.4 to 8.8+/-4.6(P=0.01). Quality of life scores improved by 25% from a pre-treatment value of 57.1+/-17.7 to 42.9+/-14.1(P=0.01), and disability scores also reduced by 65% from a baseline value of 18.9+/-4.4 to 6.6+/-4.0(P=0.01). Symptom improvement was durable with 9.0+/-3.6(P=0.01) and 9.3+/-5.0(P=0.01) dominant hand tremor score at 6 and 12 months respectively. The most common immediate adverse events were related to frame placement. At 12 months, 2 patients reported a mild sense of imbalance.
Conclusion: MRgFUS thalamotomy has shown positive and promising results in reducing dominant hand tremor in medication-refractory essential tremor.

B-0822 08:58

CT-guided percutaneous synovial cyst rupture using a 11G Jamshidi needle: early experience and results of a novel technique

S. Islam, D. Johnson; *London/UK (s.islam@imperial.ac.uk)*

Purpose: Lumbar synovial cysts are an increasingly reported cause of radiculopathy and back pain. Percutaneous treatment offers a minimally invasive alternative to high-risk surgery. Percutaneous techniques involve imaging to guide a small calibre needle into the facet joint. In our experience this leads to a high rate of recurrence requiring future surgery. We trialled a novel approach using a large bore needle under CT guidance in the hope of achieving increased disruption of the fibrocartilaginous wall and reducing recurrence. The purpose of the study was to review the early results of percutaneous synovial cyst treatment using a 11G Jamshidi needle.
Methods and Materials: 9 sedated patients underwent percutaneous synovial cyst rupture through a translaminar approach, using a 11G Jamshidi needle under CT guidance. Following rupture as demonstrated by contrast injection, 80mg depomedrone + 1ml bupivacaine was injected into the rupture bed. Patients were followed up from 6 weeks to 4.5 years post-procedure.
Results: At 6-week follow-up there were no significant complications and only 1 patient had required surgery for persistent symptoms. At long-term follow-up, 5 patients remained asymptomatic, with 3 patients requiring a repeat intervention.
Conclusion: There is currently no standardised technique for percutaneous synovial cyst treatment and the previously published outcome data are based on using small 20/22G needles. The number of patients requiring future surgery in these studies varies from 10 to 55%. This is the first time a large bore needle has been used to achieve cyst rupture, demonstrating its safety and efficacy.

B-0823 09:02

Performance and safety of pancreas biopsy: are there more complications made by routes of risk?

J.M. Sastoque G, S. Lombardo, J.J. Espejo Herrero, I. Domínguez Paillacho, M. Perez Montilla, L.J. Zurera Tendero; *Cordoba/ES (jorgem4402@hotmail.com)*

Purpose: Retrospective analysis of pancreas CNB performance and overall safety assessment comparing biopsies performed through risk routes (liver, gastrointestinal tract) in relation to a direct route (peritoneal or retroperitoneal).
Methods and Materials: Biopsies of pancreatic lesions performed between April 2010 and September 2017 were retrospectively analysed. Biopsies were performed with 16 and 18G needles. The CT images, histopathological results and details of the procedure as route of approach and the associated complications were evaluated. If the biopsy was negative for malignancy, the clinical history was reviewed to evaluate the final etiology of the pancreatic lesion.
Results: CNB was performed on 83 patients (50 men, 33 women) with mean age of 62.65 years through different routes with 16G (n = 35) and 18G (n = 48) needles. The sensitivity, specificity, positive and negative predictive value of the total study were 82.53%, 100%, 100% and 64.51%, respectively. A total of 24 biopsies were performed with transperitoneal approach, 1 retroperitoneal and 58 with risk routes (colon (n = 3), stomach (n = 34), duodenum (n = 1), jejunum = 8), pleura (n = 1) and the remainder combining these routes (n = 10). The rate of major complications was 4.81% (n = 4) and minor 3.61% (n = 3); without finding a significant difference between the direct peritoneal approach (n = 3) and through risk routes (n = 4), neither with the needle size.
Conclusion: Pancreatic percutaneous CNB using the trans-organ approach is a safe and effective technique to diagnose malignant pancreatic lesions.

B-0824 09:06

TACE using mitomycin with or without irinotecan for HCC in European patients

T. Gruber-Rouh, K. Eichler, N.-E. Nour Eldin, N.N.N. Naguib, M.C. Langenbach, T.J. Vogl; *Frankfurt a. Main/DE*

Purpose: To evaluate survival data and local tumour control in two groups with different chemotherapeutic agents in TACE treatment of HCC patients.
Methods and Materials: A total of 28 patients (mean age: 67.3 years) with HCC were repeatedly treated with chemoembolisation in four-week intervals. Twenty patients suffered of BCLC-stage-B, while eight patients obtained chemoembolisation for bridging purpose (BCLC-Stage-A). In total, 98 chemoembolisations were performed (mean 3.4 treatments/patient). The administered chemotherapeutic agent included either mitomycin only (n=14; 50%) or mitomycin in combination with irinotecan (n=14; 50%). Lipiodol plus DSM was used for all embolisations. Local tumour response was assessed by MRI using mRECIST criteria. Progression-free survival (PFS) was evaluated.
Results: In the mitomycin-irinotecan group, the CR was encountered in 21.4%, PR in 42.9% and SD in 28.6%, and PD in 7.1%. The local tumour control in the mitomycin group was: PR in 57.2%, SD in 21.4%, and PD in 21.4% (p=0.043). The PFS of patients after chemoembolisation with mitomycin was four months compared to the significantly higher PFS of twelve months in the mitomycin-irinotecan group (p=0.003).
Conclusion: Chemoembolisation of HCC with mitomycin and irinotecan is the preferred treatment option for achieving local control and PFS.

B-0825 09:10

Randomised controlled trial of free-hand vs robotic-guided needle positioning in CT-guided thermoablation of liver tumours

W.J. Heerink[1], S.J.S. Ruiter[1], M. Arnolli[2], J. Pennings[1], B. Lansdorp[2], R. Vliegenthart[1], M. Oudkerk[1], K.P. de Jong[1]; [1]*Groningen/NL*, [2]*Enschede/NL (w.j.heerink@umcg.nl)*

Purpose: Accurate needle placement and minimal needle manipulation is critical in microwave ablation (MWA) of liver tumours. In this randomized controlled trial, a novel robotic-guided needle positioning system (NPS) is compared to free-hand positioning.
Methods and Materials: 42 liver tumours were randomized in a free-hand group and a robotic-guided NPS (DEMCON Advanced Mechatronics, Enschede, the Netherlands) group. Primary endpoint was the number of needle repositionings before start of ablation. Secondary endpoints included Euclidian and lateral positioning error. Stratification between in-plane and out-of-plane (needle angle from axial plane ≥10 degrees) procedures was performed.
Results: For in-plane procedures, the median number of needle repositionings in the free-hand (n=13) and NPS group (n=10) was 1 (0-5) and 0 (0-0, p=0.012), the mean Euclidian error was 12.7±6.8mm and 11.0±4.7mm (p=0.514), and the mean lateral error was 6.1±2.9mm and 7.2±5.3mm (p=0.518), respectively. For out-of-plane procedures, the median number of needle repositionings in the free-hand (n=8) and NPS (n=11) group was 1 (0-7) and 0 (0-1, p=0.011), the mean Euclidean error was 15.7±5.7mm and 8.4±3.3 (p=0.003), and mean the lateral error was 11.6±2.8mm and 6.0±3.2mm (p=0.001), respectively. Tumour size and depth were comparable in all groups.
Conclusion: For all procedures, robotic-guided needle positioning required no needle repositioning before start of ablation. It is associated with a higher positioning accuracy, though only in out-of-plane approaches. Especially in these cases, the use of the novel robotic-guided NPS is advantageous.

Vertebroplasty with trajectory planning and 3D road map applications: first experiences

M. Inecikli; *Rize/TR (drinecikli@yahoo.com)*

Purpose: Trajectory planning and 3-dimensional road map (TP&3D-RM) advanced applications are two important software programmes installed in new-generation angio devices. The purpose of this study is to show that the x-ray exposure in vertebroplasty (VP) cases is reduced by the TP&3D-RM technique.
Methods and Materials: All VP operations were performed using a biplane angiography device. 52 patients were included in the study and divided into two groups. The TP&3D-RM technique of the angio device was used at 26 VP. In 26 VP cases, conventional VP operation was performed. The amount of dose used during the procedure was recorded. Complications during the procedure were noted. The data were analysed statistically. P <0.05 was determined to be statistically significant.
Results: The age of 22 female and 30 male patients was on average 67.5 years. In 39 cases left transpedicular, in 4 cases right transpedicular and in 9 cases bipedicular approach was used. VP treatment was performed between thoracic 5 and lumbar 5 vertebras. VP operation was performed mostly in the L3 vertebra (%17,3). The decrease in x-ray exposure in VP cases made with TP&3D-RM technique was statistically determined (p<0.001). There was no statistically significant difference in complication rates during the procedure (p> 0.05).
Conclusion: VP processing with TP&3D-RM technique increases the reliability of the process, reduces radiation exposure, and provides profit in terms of time and cost. Especially in cases with rotoscoliosis, for L5 vertebra and thoracic vertebrae on T8 and above, and traumatic vertebral fractures, this technique can contribute to a more controlled treatment.

B-0827 09:18

Stent retriever single shot study (4S): multivariable analysis for first-pass recanalization in acute stroke

F.J. Melendez[1,1], S. Rosati[2,2], S. Aixut Lorenzo[1,1], S. Remollo Friedemann[3,1], M.F. Werner Reyes[1,1], M. Ribó Jacobí[1,1], D. Hernández Morales[1,1], M. Martínez[1,1], A. Tomasello Weitz[1,1]; [1]*Barcelona/ES*, [2]*Madrid/ES*, [3]*Riells I Viabrea/ES (fernandomelendezun@gmail.com)*

Purpose: First-pass recanalization have been described as a predictor factor for the clinical outcome and mortality in acute stroke. It is necessary to identify optimal techniques that maximise recanalization in the first-pass. A multivariable analysis of technical aspects in thrombectomy is introduced.
Methods and Materials: 228 patients were treated by thrombectomy. A multivariable analysis was carried out in order to achieve recanalization in the first-pass. Stent-retriever, aspiration catheter, balloon catheter, adapt technique, combined techniques, diameter and length of devices were considered. TICI 2B-3 was the aim. A statistical analysis was done to find the best possible combination to get first-pass recanalization.
Results: We found statistically significant difference in the diameter of the stent but not the length, diameter less than 4 mm (,772 U.Mann-Whitney) when compared to more than 4 mm (,49 U.Mann-Whitney). Distal aspiration catheter (48.6%) vs without distal aspiration catheter (62.2%) (X^2= 3,884 p=,049). Bypass effect (61.1%) vs without bypass effect (52.4%) (X^2= 7,057 p= ,029) and thrombus protrusion into cell stent (65.3%) vs without protrusion (34.8%) (X^2= 10,477 p= ,005) also showed difference statistically significant.
Conclusion: In our study, we found that smaller diameters of stent, protrusion of thrombus into the cell stent with bypass effect and without aspiration catheter have better first-pass effect. Further manoeuvers may be helpful as the balloon catheter. This combination should increase the accuracy and successful recanalization after the first-pass.

B-0828 09:22

US-guided percutaneous renal biopsy: a 10 year retrospective analysis

J.A. Sheehan, R. Durganaudu, T. Tarmey, G.J. O'Sullivan, D. Sheppard; *Galway/IE (sheehan24@gmail.com)*

Purpose: To evaluate the indication and safety of US-guided percutaneous renal biopsy at our institution over a 10 year period.
Methods and Materials: A retrospective analysis was performed of 749 patients whom underwent renal biopsy between March 2006 and September 2016. All US-guided biopsies were performed with free hand technique, using a 5mhz curvilinear probe, and an 18-gauge core biopsy needle. Patient's vital signs were monitored during the procedure and 6 hours post biopsy to evaluate for signs of haemodynamic instability. All patients underwent a post procedure full blood count to ensure stable haemoglobin levels. In the case of ongoing pain or a drop in haemoglobin levels, further investigation with Ultrasound or Computed Tomography(CT) was performed to evaluate for the presence of acute haemorrhage.
Results: 749 patients underwent biopsy with a mean age of 53 and a range of 15 to 90. 443(59%) were male. 785 total biopsies were performed on both native(n=737) and allograft(n=48) kidneys. The majority (54.4%) of biopsies were indicated for renal impairment(n=408) followed by proteinuria(n=204), Haematuria(n=74), and renal mass (n=64). 11(1.4%) patients had a major complication requiring blood transfusion. 53(7%) patients had minor complications requiring subsequent imaging, but were managed conservatively without further intervention.
Conclusion: US guided renal biopsy is indicated for multiple reasons the majority of which are renal impairment. The procedure is safe with an acceptable low risk of both major and minor complications.

Treatment of intramural and submucosal uterine fibroids (UFs) using MRgFUS (magnetic resonance-guided focused ultrasound surgery)

S. Iafrate, I. Capretti, E. Cannizzaro, F. Arrigoni, M. Di Luzio, A.V. Giordano, S. Mascaretti, G. Mascaretti, C. Masciocchi; *L'Aquila/IT (sonia.iafrate87@gmail.com)*

Purpose: To evaluate the reduction of volume of submucosal and intramural uterine fibroids (UFs) by MRgFUS treatment and subsequent possible reduction of symptoms, during 1 years of follow-up.
Methods and Materials: Twenty-six women,(mean age 42), affected by symptomatic UF underwent MRgFUS between July 2015 and July 2016.All the patients were assessed by MRI and UFs were classified according to FIGO staging system.Twelve/26 patients showed submucosal UFs(GROUP 1,5 of type 0,4 of type 1 and 3 of type 2) experiencing reproductive problems, dismenoerrea.Fourteen/26 patients showed intramural fibroid (GROUP 2, 5 of type 3, 3 of type 4 and 6 of type 5)experiencing "bulk symptoms".We analysed non-perfused-volume (NPV) that represent the treated area after treatment; reduction of UFs volume,Symptoms severity score questionnaire (UFS-QOL),clinical symptomatology improvement.
Results: A good outcome was observed in all patients underwent MRgFUS, the mean initial value of the NPV was about 80-90 %. At the end of follow-up (1 year), in the GROUP 1,7/12 displayed a decrease of the UFs volume associated with a recovery of uterine wall morphology. A disappearance of the UF was observed in 5/12. In the GROUP 2 we observed a decreased in UFs volume, (5/14 about 70%, and 9/14 about 50%).All the patients showed a reduction of UFS-QOL with an improvement around 90%.No severe adverse events were recorded during the follow-up.
Conclusion: Patients affected by both submucosal and intramural UFs may benefit from MRgFUS, during follow-up of 1 year. A progressive reduction of UFs volume and a symptomatic improvement may be observed.

B-0830 09:30

Evaluation of a 3D printed anthropomorphic phantom for simulation of CT-guided procedures

P. Jahnke, F.B. Schwarz, M. Ziegert, O. Abdelhadi, T. Almasi, M. Nunninger, B. Hamm, M. Scheel; *Berlin/DE (paul.jahnke@charite.de)*

Purpose: Radiopaque 3D printing realizes detailed anthropomorphic phantoms of individual patients. We further developed this method to allow CT-guided needle placement. The aim was to evaluate such a phantom for realistic simulation of CT-guided procedures.
Methods and Materials: Experienced interventional radiologists (n = 10) performed periradicular infiltration on a radiopaque 3D printed phantom and rated different aspects regarding suitability of the phantom to simulate CT-guided procedures in a questionnaire. Additionally, quantitative parameters of their simulation procedures (number of images acquired, procedure time, needle tip visibility, and needle corrections) were compared with a retrospective cohort of 50 clinical cases performed by the same interventionalists. Descriptive statistics and Mann-Whitney U test were used for data analysis.
Results: Simulation procedures on the phantom were rated highly realistic for anatomic detail, needle navigation, and overall course of the procedure. Phantom haptics were characterized as most comparable to tight muscle tissue. All participants found the phantom suitable for training and learning purposes. Strong similarity of the simulation procedures to clinical procedures was supported by the comparative analysis of quantitative procedure parameters, with no significant differences in overall number of images acquired ($p > 0.5$), procedure time ($p > 0.5$) and needle corrections ($p > 0.05$) between procedures on the phantom and on patients.
Conclusion: A radiopaque 3D printed anthropomorphic phantom allows highly realistic simulation of CT-guided procedures and can be used for training, procedure optimization, and development of interventional techniques.

Recurrence and survival following image-guided percutaneous microwave ablation in primary lung malignancy

M. Tsakok, M. Little, R. Millington, G. Hynes, F. Gleeson, M. Anderson; *Oxford/UK (mariatsakok1@gmail.com)*

Purpose: Microwave ablation (MWA) is a relatively new alternative to radiofrequency ablation (RFA), that has been shown to produce larger ablation zones within a shorter time compared to RFA. There is a paucity of literature regarding recurrence and survival for this technique in primary lung cancer (LC).
Methods and Materials: Retrospective review yielded 53 patients with LC treated with MWA over a 6-year period at our tertiary referral centre. We defined LC on the basis of biopsy sample (45%) or imaging features (PET avidity/size increase, 55%). Patients were unsuitable for surgical resection or stereotactic body radiation therapy (SBRT) due to medical co-morbidities or tumour characteristics, and MWA was recommended by the MDT. The median age of patients was 76.3 (55-91), mean size of ablated lesion 25mm (12-50mm) and mean follow-up was 14 months (1-33 months).
Results: Local recurrence was identified in 11% (6/53), however in three patients, local control was subsequently achieved by re-ablation. Local recurrence was significantly more likely for larger tumour size >25mm ($p=0.002$). 78% patients demonstrated no evidence of recurrence at follow-up imaging (mean 14 months; 1-33). There were six cases of distant recurrences: three occurring to liver, one intrapulmonary recurrence, one nodal recurrence and two mixed recurrence (lung+liver, lung+peritoneum). 32/53 patients have deceased, median survival was 13 months (1-32) - cause of death was not cancer in 60% of cases.
Conclusion: MWA of primary LC is able to achieve local control rates that are equivalent to SBRT and superior to the literature using RFA.

B-0832 09:38

Sampling errors in image-guided liver biopsies: depiction of the biopsy site on immediate post-interventional CE MRI

G. Schneider, A. Bücker, L. Fenzl; *Homburg/DE (Lisa.Fenzl@uniklinikum-saarland.de)*

Purpose: Sampling errors in image-guided biopsies of focal liver lesions are a common problem in clinical routine. The purpose of our study was to evaluate if MRI may detect the exact location where a liver biopsy was taken and confirm sampling of representative tissue.
Methods and Materials: MRI-guided liver biopsy was performed in a total of 35 patients. Immediately post-biopsy unenhanced and CE-MRI (0.05 mmol/kg MultiHance) was performed in order to depict the exact biopsy site. Imaging included T1- and T2-weighted unenhanced sequences (T2-TSE, HASTE, T1w-flash-2D and 3D-VIBE-DIXON Sequences) as well as dynamic 3D-VIBE-DIXON imaging post-bolus CM injection. Furthermore a T1w-flash-2D sequence and a 3D-VIBE-DIXON sequence in the equilibrium phase and in the hepatobiliary phase (hb-phase) were acquired.
Results: In all patients the biopsy tract could be detected on post-biopsy imaging. On unenhanced imaging the biopsy tract was best detected on the T1w flash-2D sequences (30/35) followed by the 3D-VIBE-DIXON sequence (27/35). T2w-TSE and HASTE images could not delineate the biopsy tract sufficiently. On CE images the biopsy tract was depicted best in the equilibrium phase both on the T1w flash 2D and 3D-VIBE-DIXON sequence (34/35). In the biliary phase depiction of the sampling area (33/35) together with a more adequate depiction of the lesion that underwent biopsy was noted.
Conclusion: Immediate post-liver biopsy MRI allows for depiction of the biopsy tract both on unenhanced and CE MRI with advantages seen for CE images. T2w imaging does not reliably depict the biopsy tract.

Contrast-enhanced ultrasound (CEUS) as guidance system for ablative treatments of primary and secondary liver tumours: a multicenter study

G. Francica[1], F. Meloni[2], M. Pompili[3], F. Terracciano[4], E. Caturelli[5], I. de Sio[6]; [1]*Castel Volturno/IT*, [2]*Milan/IT*, [3]*Rome/IT*, [4]*San Giovanni Rotondo/IT*, [5]*Viterbo/IT*, [6]*Naples/IT (giampierofrancica@gmail.com)*

Purpose: To retrospectively characterise the prevalence of CEUS-guided ablation (CEUS-ABL) of liver tumours at six interventional ultrasound centres.
Methods and Materials: The six participating centres retrospectively selected all patients in whom therapeutic needles for percutaneous ethanol injection (PEI), radiofrequency (RF), microwave (MW) have been positioned into target lesions during CEUS. The prevalence of CEUS-ABL of each centre between 2008 and 2016, contrast agent consumption and safety, procedure indications, ablation effectiveness and complication rate were assessed.
Results: CEUS-ABL was carried out in 148 patients (103 M/45 F, median age 74 yrs.) with 151 liver targets (median size 15 mm) of which 86.7% were HCC tumours. PEI, RF and MW were performed in 35.2%, 46.3% and 18.5% of cases, respectively. CEUS-ABL represented 7.4% (range 2.5%-13.8%) of 2015 ablative sessions performed at the participating centres. Indications to the procedure were: improvement of conspicuity of the target (28.5%), target undetectable on non-enhanced ultrasound (29.8%), detection of vital area/s in nodules with either incomplete ablation or recurrent tumour (41.7%). A single dose (2.4 ml) of contrast agent was used in 72.2% of cases. No major complications or death occurred after CEUS-ABL. Complete ablation was obtained in 113 nodules (74.8%). Altogether hyperthermic techniques (RF and MW) performed better than PEI (86.7% vs. 51% of complete ablation).
Conclusion: The indications for CEUS-ABL for liver tumours are limited, but this procedure can be useful in challenging clinical scenarios, e.g. poorly visualised or invisible lesions, choice of vital area/s in nodules with previous incomplete ablation or local tumour progression.

MRI imaging of branch-duct IPMN: evaluation of agreement between observers with different degrees of experience

L. Bertuzzo, G. Zamboni, R. Negrelli, R. Pozzi Mucelli; *Verona/IT*

Purpose: The Sendai and Fukuoka consensus guidelines have defined the characteristics of high-risk mucinous lesions. Purpose of our study was to assess the agreement between an experienced and a non-experienced reader in recognising the main features defined by the guidelines in a series of IPMN.
Methods and Materials: IRB approval was waived for this retrospective study. We included 118 patients (45 M, 73 F, average age 68 years) affected by IPMN who underwent MRI and MRCP in our institution. Two readers, respectively with 10 and 4 years of experience in abdominal imaging, reviewed independently the scans assessing all cysts >5 mm for wall/internal septa thickening, solid mural nodules, dilation of the main pancreatic duct (MPD) and contrast enhancement. The readers were blinded to clinical and laboratory information. Kappa statistics was calculated.
Results: 10 patients had mixed-type IPMN and 108 branch-duct IPMN. Patients had a median of 2 cysts >5 mm each (range 1-20; mean 2.6). A total of 307 cystic lesions were reviewed, with a mean size of 11.8 mm (5-50 mm). The two readers showed very good agreement regarding MPD dilation (k=0.908), wall thickening (k=0.893), and presence of mural nodules (k=0.856). The agreement was good for presence of filling defects (k=0.721), wall enhancement (k=0.725) and presence of mural nodules (k=0.663).
Conclusion: Readers with different experience in abdominal imaging, when assessing IPMN at MRI-MRCP, show an interobserver agreement ranging between good (0.663) and very good (0.908) when applying the Fukuoka criteria, confirming their usefulness for lesion evaluation standardisation.

B-0835 10:38

Intraindividual interscanner variation of virtual unenhanced attenuation values derived from twin-beam dual-energy CT in comparison to dual-source dual-energy CT in 126 patients

A. Cosentino[1], M. Obmann[2], J. Gehweiler[2], V. Kelsch[2], V. Hofmann[2], T.J. Re[2], D. Boll[2], M. Benz[2]; [1]*Turin/IT*, [2]*Basle/CH (aurelio.cosentino@gmail.com)*

Purpose: The purpose of this study was to evaluate the comparability of virtual unenhanced (VUE) attenuation values derived from a novel technique for single-source twin-beam dual-energy CT using a split-filter (tbDECT; two equal parts of gold and tin) and a dual-source dual-energy CT (dsDECT).
Methods and Materials: A total of 126 patients were retrospectively analysed. Each patient underwent an abdomino-pelvic CT on a tbDECT and a second-generation dsDECT scanner (SOMATOM Definition Edge and Flash, Siemens, Germany). Virtual unenhanced images were reconstructed off of venous phase series using commercially available software (Syngo.via, Siemens, Germany). Attenuation values of the liver, spleen, kidneys, blood, fat and muscle were recorded. Disagreement of VUE attenuation values >10HU between the two scans was defined as inadequate.
Results: The intrapatient interscanner analysis showed significant differences between VUE attenuation values derived from tbDECT and dsDECT ($p<0.01$) in 6 of 7 organs. The percentage of patients with differences in VUE attenuation values >10HU between tbDECT and dsDECT ranged between 15% (left kidney) and 62% (spleen).
Conclusion: This study showed significant differences in VUE attenuation values derived from different dual-energy techniques (tbDECT vs dsDECT) in the same patient. Thus, to ensure reliable VUE attenuation measurements, it is advisable to perform patient follow-up studies using the same dual-energy technology.

Diffusion-weighted magnetic resonance imaging in uveal melanomas: validation of early chemotherapeutic monitoring of targeted therapy

N. Guberina, S. Bauer, H. Richly, M. Scheulen, A. Wetter; *Essen/DE (nika.guberina@uk-essen.de)*

Purpose: The aim of this study was to explore the feasibility of diffusion-weighted magnetic resonance imaging (MRI) sequences (DW-MRI) as a non-invasive technique for monitoring of therapeutic response to targeted therapy in patients with metastatic uveal melanoma.
Methods and Materials: In retrospective analysis the chemotherapeutic response to targeted therapy was evaluated in 47 patients with metastatic uveal melanoma using diffusion-weighted MRI (DW-MRI) and ADC maps at 1.5T MRI [b=100,500,1000s/mm2]. The apparent diffusion coefficient (ADC) was assessed in metastatic liver lesions prior to therapy [w0] as well as two [w2] and eight weeks [w8] after therapy initiation. The examination protocol included fat-saturated, dynamic T1- and T2-weighted sequences. Correlation with clinical response was performed. Responders were defined as stable-disease. The results were analysed using the analysis of variance (ANOVA) and the paired-sample t-test.
Results: The apparent diffusion coefficient measured by DW-MRI increased in hepatic lesions which showed no tumour progress under targeted therapy (w8 $p8<0.05$). Lesions with no therapeutic response revealed a decrease of ADC within w8 (w8 $p8<0.02$). Furthermore, ratio of ADC0/ADC2 and ADC0/ADC8 between patients with stable-disease and non-responders proved to be significant (w2 $p2<0.05$; w8 $p8=0.006$). Baseline ADC values showed no significant relationship to therapeutic response.
Conclusion: Notably, the results illustrate that DW-MRI allows a non-invasive monitoring of therapeutic response to targeted therapy in patients with metastatic uveal melanoma at an early stage of therapy. An early monitoring of therapeutic response is crucial to determine whether the therapy benefits outweigh the risks associated to treatment toxicity of targeted therapy.

B-0837 10:54

MRI liver adenoma subtyping in animal models of glycogenosis type Ia

F. Rosa, L. Basso, R. Resaz, L. Secondini, I. Verardo, F. Grillo, V. Prono, A. Eva, C. Neumaier; *Genoa/IT (francescarosa892@gmail.com)*

Purpose: Hepatocellular adenomas (HCA) are benign tumours and their major complication is malignant transformation to hepatocellular carcinoma (HCC). Among various subtypes of HCA, β-catenin-activated (βHCA) have a greater risk of malignant transformation. In preclinical studies dedicated MRI protocols suitable to characterize and monitor liver lesions are requested to allow research on their oncogenesis and progression. The aim of this study is to validate a new MRI protocol for HCA subtyping to distinguish low-risk from high-risk tumours.
Methods and Materials: An experimental animal model of glycogen storage disease 1a in which HCC and different types of HCA represent late and severe complications has been previously designed. The experiments were carried out on a 3T scanner performing T2-weighted imaging and T1 spoiled gradient echo-weighted imaging before and after administration of gadobenate dimeglumine. A total of 40 mice were studied for focal lesions detection and a group of 15 was monitored every 4 weeks for 3 months to evaluate lesion growth. Mice were sacrificed after last MRI and lesions were classified using immunohistochemistry.
Results: Our protocol was able to detect liver lesions with a minimum diameter of 1 mm. MRI identified 4 different patterns after contrast administration (isointense, hyperintense, hypointense lesions and lesions with a peripheral contrast enhancement) which corresponded to different HCA subtypes.
Conclusion: βHCA displayed MRI features (hyperintensity on T2WI and hypointensity after contrast administration) clearly distinguishable from those exhibited by other subtypes, indicating that MRI is a reliable method to identify high-risk HCA.

B-0838 11:02

The role of visceral and subcutaneous adipose tissue measurements and their ratio by MRI in subjects with prediabetes, diabetes and healthy controls from a general population

C. Storz[1], S.D. Heber[1], S. Rosplecz[2], J. Machann[1], K. Nikolaou[1], R. Lorbeer[3], A. Peters[2], C.L. Schlett[4], F. Bamberg[1]; [1]*Tübingen/DE*, [2]*Neuherberg/DE*, [3]*Munich/DE*, [4]*Heidelberg/DE (corinna.storz@med.uni-tuebingen.de)*

Purpose: Different adipose tissue compartments are associated with metabolic risk. The aim of this study was to study the relationship of visceral and subcutaneous adipose tissue (VAT and SAT, respectively) by magnetic resonance imaging (MRI) and their ratio in subjects with impaired glucose metabolism from the general population.
Methods and Materials: Subjects from a population-based cohort with established prediabetes, diabetes and healthy controls without prior cardiovascular diseases underwent 3 Tesla MRI. VAT and SAT were quantified from isotropic VIBE-Dixon as total volume and area on a single slice, and their ratio was calculated. Clinical covariates and cardiovascular risk factors were assessed in a standardized fashion. Univariate and adjusted analyses were carried out to determine group differences.
Results: Among 384 subjects (age: 56.2 ± 9.2 years, 58.1% male), volumetric and single-slice VAT, SAT and VAT/SAT ratio measurements were strongly correlated (all $>r=0.89$). Similarly, VAT/SAT_{volume} ratio was strongly correlated with VAT_{volume} but not with SAT_{volume} ($r=0.72$ and $r=-0.21$, respectively). Significant higher levels of VAT_{volume}, SAT_{volume} and VAT/SAT_{volume} ratio were found in subjects with impaired glucose metabolism (all $p\leq0.01$). After adjustment for potential cardiovascular confounders, VAT_{volume} and

VAT/SAT_{volume} ratio remained significantly higher in subjects with impaired glucose metabolism (all <0.02), whereas the association for SAT_{volume} attenuated. In addition, there was a decreasing effect of glycemic status on VAT/SAT_{volume} ratio with increasing body mass index and waist circumference.
Conclusion: VAT_{volume} and VAT/SAT_{volume} ratio are associated with impaired glucose metabolism, independent of cardiovascular risk factors, with a decreasing effect of VAT/SAT_{volume} ratio in obese subjects.

B-0839 11:10

Non-invasive preoperative quantification of pancreatic fibrosis and lipomatosis: correlation of magnetisation transfer imaging and multi-gradient echo MRI with histopathology

K. Schawkat, D. Eshmuminov, D. Lenggenhager, K. Endhardt, B. Vrugt, A. Boss, H. Petrowsky, P.-.A. Clavien, C.S. Reiner; *Zurich/CH (khoschy.schawkat@usz.ch)*

Purpose: To investigate the correlation of magnetization transfer (MT) imaging and multi-gradient-echo magnetic resonance imaging (MRI) with histopathology to quantify pancreatic fibrosis and lipomatosis in patients prior to pancreatoduodenectomy.
Methods and Materials: 24 patients (age, 68±8ys, 16 males) prospectively underwent quantitative MT imaging with a 2D gradient-echo sequence and multi-gradient-echo imaging on a 3T MRI one day prior to pancreatoduodenectomy due to pancreatic adenocarcinoma (n=14), duodenal adenocarcinoma (n=6), neuroendocrine tumor (n=3) or IPMN (n=1). MT-ratio (MTR) and proton density fat fraction (PDFF) were measured in pancreatic tail (PT) and at the resection margin (RM). Pancreatic fibrosis was graded as mild, moderate or severe (F1-3), lipomatosis was graded as 0-10%, 11-30%, and >30% fat deposition (L1-3) on histopathology. Mann-Whitney-*U*-test and Spearman's correlation was used.
Results: Patients with advanced pancreatic fibrosis (F3) showed a significant higher MTR compared to the F1-group at the RM and PT (38±4 vs. 32.3±1.6, p=.018 and 39.7±5.5 vs.31.2±1.7, p=.001). Spearman's correlation coefficient of MTR and fibrosis grade was r=.532 for RM (p=.011) and r=.554 for PT (p=.008). Pancreatic parenchyma with advanced fat deposition (L2-3) showed significantly higher PDFF compared to lipomatosis grade L1 (RM: p=.002 and PT: p=.001). PDFF of pancreatic parenchyma showed a moderate and significant correlation with histopathological lipomatosis grade (RM: r=.668 and PT: r=.707, p=.000). MTR was significantly higher in pancreatic tumor compared to pancreatic parenchyma (44±5.5 vs. 37.4±5.4, p=.000).
Conclusion: Multiparameteric MRI of the pancreas including MTR and PDFF maps may yield quantitative information to preoperatively quantify pancreatic fibrosis and lipomatosis noninvasively.

B-0840 11:18

Conventional liver fat quantification MRI vs complex chemical shift-encoded MRI in an oncologic population

G. Corrias[1], S. Eskreis-Winkler[1], S. Krebs[1], J. Zheng[1], L. Saba[2], L. Mannelli[1]; [1]*New York, NY/US*, [2]*Monserrato/IT (corriasgmd@gmail.com)*

Purpose: MRI is the most accurate imaging technique in diagnosing steatosis. It can also be used to quantify hepatic fat content. There are two main ways in which steatosis can be quantified with MRI: conventional IOP and proton density fat fraction (PDFF). The aim of this study is to compare IOP with an innovative type of PDFF, called IDEAL-IQ, in quantifying fat fraction in an oncological population.
Methods and Materials: A total of 50 consecutive patients were included in the study. Two radiologists reviewed the images and placed 3 elliptic ROIs of 10 mm of diameter in the liver. Intraclass correlation coefficient (ICC) was estimated to evaluate agreement on fat fraction between conventional MRI and IDEAL, as well as between 2 readers. Exact Wilcoxon signed rank test was used to compare iron level and fat fraction between conventional MRI and IDEAL, in all patients, patients with normal iron level, and patients with above normal iron level.
Results: The agreement on fat fraction using conventional MRI was poor (ICC=0.372). The agreement on iron level and IDEAL IQ fat fraction was excellent (ICC=0.935). A statistical difference was demonstrated in fat fraction estimation in low iron group between the fat fractions calculated by IDEAL-IQ and IOP (p<0,001 for reader 1 and 2).
Conclusion: Our results show that fat fraction calculated from IDEAL-IQ maps and from T1-weightened-in-and-out-of-phase (IOP) imaging are significantly different in a population without pathologic liver iron levels. IDEAL IQ had an excellent inter-reader agreement.

B-0841 11:26

Ability to diagnose disorders of liver haemodynamics in conditions of biliary hypertension with perfusion computed tomography

V. Malakhanov, P.V. Seliverstov; *Irkutsk/RU (malakhanow@mail.ru)*

Purpose: The possibility of detection of haemodynamic disorders of the liver in patients with obstructive jaundice syndrome.
Methods and Materials: The study included 37 patients (median 59 years). Duration of jaundice from 3 days to 1 month from the onset of the disease. Patients according to the classification by V. D. Fedorov (2000) were divided into three groups: mild(n = 14), moderate(n = 12) and severe (n = 11). Used Ultravist-370 (50 ml), the infusion rate 5.5 ml/s. Evaluated: arterial liver perfusion (ALP), portal liver perfusion (PLP) . The total liver perfusion (TLP) were calculated by summing up blood (ALP) and portal perfusion (PLP).
Results: In patients with mild, decrease PLP to 15.0%, increase ALP up to 10.0%, TLP is not reduced. In patients with a medium degree of reduced PLP to 40.0%, ALP is increased to 80.0% of TLP is reduced from 15 to 30.0%. In patients with a severe degree there is a decrease in PLP to of 73.0%, with an increase in ALP to 26.0%, TLP was reduced by more than 50.0%.
Conclusion: CT perfusion can be used as a method of assessing haemodynamic instability in the liver in patients with biliary hypertension to assess the severity of liver failure. The obtained information will allow you to properly optimise the treatment of patients.

B-0842 11:34

Comparison of stiffness values of peripheral and central liver tissues with MR elastography in patients with primary sclerosing cholangitis

D. Kuru Öz, E. Peker, M. Kul, A. Erden; *Ankara/TR (digdem_k@hotmail.com)*

Purpose: In primary sclerosing cholangitis (PSC), peripheral vascular and / or lymphatic drainage disturbances resulting from periductal inflammation of peripheral bile ducts are seen as peripheral subcapsular triangular hyperintense areas in T2-weighted images. In the progressive phase, fibrosis may develop in this tissue of impaired perfusion. This study aims to compare the tissue stiffness values of liver peripheral and central segments with MR elastography based on T2 signal differences in liver parenchyma in patients with PSC.
Methods and Materials: A total of 10 patients with PSC were included in this study (5 males, 5 females, mean age 50.6 years, median age 49 years (range 38-59)). The stiffness values of the 1/3 peripheral section and the remaining central section of the liver were measured on confidence map of MR elastography (1.5 Tesla MR system). The 'Wilcoxon signed rank test' was used to compare the peripheral and central measurements determined as mean kPa.
Results: The median stiffness values were 4.3 kPa and 3.35 kPa in peripheral and central sections, respectively. Significant difference between the peripheral and central tissue stiffness values was detected (p=0.008).
Conclusion: In PSC, tissue stiffness in the periphery of the liver is greater than in the central. This finding is consistent with the observation that ductal dilatation, periductal inflammation and fibrosis are predominantly seen at the periphery.

B-0843 11:42

Portal hypertension associated with oxaliplatin administration: incidence and natural history

M. Di Martino, K. Koryukova, C. Catalano; *Rome/IT (micdimartino@hotmail.it)*

Purpose: To establish incidence and clinical manifestations of non-cirrhotic portal hypertension in patients affected by gastrointestinal neoplasm treated with oxaliplatin.
Methods and Materials: This is a retrospective single-center study. From a database of 570 patients we considered eligible for the study 94 patients with GI tract neoplasm (57 colon, 28 rectum, 5 stomach, 4 other) who underwent chemotherapy (mean duration therapy 5.7 months) according to specific selective criteria. Two expert radiologists in liver imaging reviewed in consensus three computed tomography examinations (baseline, at the end of therapy and 6 months after the end of therapy) looking for features of portal hypertension (ascites and varices) and measuring portal vein and spleen parameters (long axis, area and volume). T Student's test and χ^2 Person were used for statistical analysis.
Results: Mean long-axis diameter of portal vein and spleen and spleen volume were significantly higher at the end of therapy (p=.0009; p < .0001; p < .0001, respectively). At the end of therapy, two patients developed varices (2.1%), ten cases of portal vein increase in size (10.6%) and 26 cases of splenomegaly (28%) were reported. Seven patients reported both splenomegaly and portal vein enlargement. After six months the end of therapy, in 4 patients signs of portal hypertension disappeared.
Conclusion: Patients who undergo chemotherapy with oxaliplatin should be also observed for portal hypertension and its evolution.

B-0844 11:50

Learning from our errors: what are the common clinically important errors that radiologists repeatedly make in the UK's largest teaching hospital and how can we best address them?

A. Koo, J.T. Smith; *Leeds/UK (andrew.koo@doctors.org.uk)*

Purpose: To review the attendance, activity and outcomes of 5 years of Radiology departmental educational/discrepancy meetings in our hospital. This is a meeting attended by sub-speciality radiologists, radiographers, nurses, support staff and managers.
To review the clinically important cases and categorise them in an attempt to identify recurring patterns of errors (or educational themes). To identify how many of these themes could be addressed by a more positive and less pejorative method of presenting cases rather than simply reviewing people's "errors".
Methods and Materials: All the attendance records and cases discussed in the 30 consecutive meetings from November 2011 under a single chairman were reviewed retrospectively. Cases had been selected by team members who had noticed a discrepancy / educational case and were presented anonymously.
Results: Mean consultant attendance per meeting was 29 and 69% attended at least 3 meetings per year (Royal College of Radiology recommendation). 628 cases were reviewed. 98% consultants in the department had contributed at least one case over 5 years. 7 common themes were identified; missed lung cancers, missed fractures and their mimics, missed incidental cancers, incorrect cancer staging, incorrect characterisation of disease, missed clinically significant non-cancer diagnoses and uncommon but clinically important disease processes with image-specific signs. Good spots could be identified to illustrate each of these seven common themes.
Conclusion: The fact that many errors in our department fell into several common themes could facilitate rolling audits and targeted teaching. "Good spots" address these themes in a more positive way than "errors".
Author Disclosures:
J.T. Smith: Author; The authors would like to acknowledge Catherine Parchment Smith in helping write and edit our abstract.

Diffusion-weighted MR-volumetry and high-resolution MR-volumetry association with lymphovascular invasion and N-stages in resectable rectal cancer

H. Li, G.W. Chen, X.-.L. Chen; *Chengdu/CN (522696619@qq.com)*

Purpose: To determine whether diffusion-weighted imaging (DWI)-volumetry and high-resolution T2-weighted imaging (T2WI) MR-volumetry could predict lymphovascular invasion (LVI) and N-stages in resectable rectal cancer.
Methods and Materials: 50 consecutive patients with rectal cancer who underwent radical surgery in 1 week after DWI and high-resolution T2WI were retrospectively identified. Gross tumour volume (GTV) was evaluated on DWI and high-resolution T2WI. Univariate and multivariate analyses were performed to determine whether GTV could predict LVI and lymph node metastasis (LNM). Mann-Whitney U test was performed to compare GTV among N-stages. Cut-offs of GTV were investigated using area under the receiver operating characteristic curve (AUC) analysis for predicting LVI and N-stages.
Results: DWI-GTV and T2WI-GTV increased with LVI (r=0.750 and 0.710, P<0.0001, respectively) and increasing of N stage (r=0.780 and 0.755, P<0.0001, respectively). Univariate analysis showed DWI-GTV and T2WI-GTV could predict LVI (P<0.0001). Multivariate analyses indicated only DWI-GTV as an independent risk factor of LVI (P=0.005, odds ratio=1.207) and LNM (P=0.005, odds ratio=1.420). The Mann-Whitney U test showed DWI-GTV and T2WI-GTV could distinguish N0 from N1, N0 from N1-2, N0-1 from N2 (P<0.0001). DWI-GTV could predict LVI (cut-off 11.05cm^3; AUC 0.899), and distinguish N0 from N1 (cut-off 10.86cm^3; AUC 0.865), N0 from N1-2 (cut-off 10.46cm^3; AUC 0.934), N0-1 from N2 (cut-off 17.7cm^3; AUC 0.932). T2WI-GTV could predict LVI (cut-off 13.74cm^3; AUC 0.877), and distinguish N0 from N1 (cut-off 12.25cm^3; AUC 0.827), N0 from N1-2 (cut-off 13.36cm^3; AUC 0.911), N0-1 from N2 (cut-off 20.43cm^3; AUC 0.927).
Conclusion: High-resolution T2WI-GTV and DWI-GTV of resectable rectal cancer were correlated well with the LVI and LNM, but the latter is a potentially more promising non-invasive technique that can help predict the preoperative LVI and distinguishing N-stages.

Could perfusion heterogeneity assessed at DCE-MRI predict rectal cancer sensitivity to chemoradiotherapy?

A. Di Chiara, A. Palmisano, A. Esposito, P. Rancoita, P. Passoni, A. Del Maschio, F. De Cobelli; *Milan/IT*

Purpose: To evaluate whether the rectal cancer's perfusion heterogeneity prior to chemoradioterapy (CRT) evaluated using histogram analysis of DCE-MRI quantitative parameters can predict response to treatment.
Methods and Materials: Twenty-one patients with histologically proven rectal adenocarcinoma underwent DCE-MRI before CRT. Tumour volumes were drawn on Ktrans and Ve maps using T2W-images as reference and 25th, 50th, 75th percentile, mean, standard deviation, skewness and kurtosis calculated. After CRT, all patients underwent surgery and, according with histopatological Rödel's tumour regression grade (TRG), patients were classified in poor responder "non-GR" (TRG 0,1,2) and good responders "GR" (TRG3-4). Mann-Whitney's test was used to compared measurement between GR and non-GR and ROC curves to identify parameters predictive of response. All p-values were adjusted for multiple comparisons using the Bonferroni's correction.
Results: 16 (76%) patients resulted GR and 5 (24%) non-GR. Skewness and kurtosis of Ve resulted significantly higher in non-GR (4.886±1.320 and 36.402±24.486, respectively) than in GR (1.809±1.280, p=0.003 and 6.268±8.130, p= 0.011). Ve skewness < 3.635 was able to predict GR with an AUC of 0.988, sensitivity 93.8%, specificity 80% and accuracy 90.5%. Ve kurtosis < 21.095 was able to predict response with an AUC of 0.963, sensitivity 93.8%, specificity 80% and accuracy 90.5%.Other parameters showed no significant differences, and were not predictive of response.
Conclusion: Ve skewness and kurtosis seem promising in the prediction of rectal cancer's response to CRT.

B-0848 10:46

Radiomics analysis for preoperative prediction of lymph node metastasis in patients with rectal cancer

H. Liu, C. Zhang, J. Li, D. Wang; *Shanghai/CN (liuhuanhuan0117@163.com)*

Purpose: To investigate the value of radiomics analysis for preoperative prediction of lymph node metastasis in patients with rectal cancer.
Methods and Materials: A total of 183 patients with histopathologically confirmed rectal cancer who underwent high-resolution MR imaging without chemoradiotherapy were divided into the primary cohort (n=128) and the validation cohort (n=55). Radiomics features were extracted from oblique axial T2-weighted images of each patient. The independent two-sample t test, Kruskal-Wallis test, and Pearson correlation analysis were used for feature selection. A radiomics signature was built and multivariable logistic regression analysis was used to develop the radiomics model including radiomics features and independent clinico-radiologic risk factors. The performance of the radiomics model was assessed by its calibration, discrimination, and clinical usefulness.
Results: A total of 385 radiomic features were extracted from each patient, and 6 radiomics features were selected for the radiomics signature. The radiomics model included radiomics signature, MR-reported lymph node status, and carcinoembryonic antigen (CEA) level. The model showed good discrimination and moderate calibration in the primary cohort and validation cohort, with a C-index of 0.842 (95% confidence interval (CI), 0.770-0.914) and 0.722 (95% CI, 0.643-0.884), respectively. Decision curve analysis confirmed the clinical utility of the radiomics model.
Conclusion: We developed a radiomics model based on the MR radiomics features in combination with independent clinico-radiologic risk factors. The model could be helpful for predicting the lymph node metastasis in patients with rectal cancer.

B-0849 10:54

Locally advanced rectal cancer: the value of whole-tumour histogram-based texture analysis of baseline ADC map in predicting tumour response to neoadjuvant chemoradiotherapy

I. Yang, B. Wu; *Chengdu/CN (lqyang95@163.com)*

Purpose: To determine the diagnostic performance of ADC map before treatment in predicting pathological complete response (pCR) after neoadjuvant chemoradiotherapy (nCRT) in patients with locally advanced rectal cancer (LARC) using whole-tumour histogram-based texture analysis.
Methods and Materials: 26 patients with LARC who completed nCRT and surgery were enrolled retrospectively. Histopathologic tumour regression grade was the reference standard. Whole-tumour ROIs were manually drawn twice (two weeks interval) on pre-CRT ADC maps performed with the same imaging unit (b=0, 600, 1000 s/mm^2) by one radiologist. Intraclass correlation coefficient

(ICC) was calculated to evaluate intraobserver variability. Independent t test was used to compare histogram-based texture parameters between two groups. Receiver operating characteristic (ROC) analysis was performed to evaluate their diagnostic performance..
Results: For both measurements the standard deviation, variance, entropy, quantile 75%, 90% and 95% of whole-tumour pre-CRT ADC values were significantly lower in pCR group (P=0.001-0.046). And the uniformity and energy were higher (P=0.007-0.027). Since the intraobserver agreement was good between two measurements (ICC, 0.850-0.957), the first-time data were used to following analyses. Respective AUCs of quantile 75%, 90% and 95% values when determining pCR were 0.739, 0.770, and 0.806, with the optimal cut-off point of 1.04×10^{-3} (sensitivity=86.7%, specificity=63.6%), 1.204×10^{-3} (sensitivity=86.7%, specificity=63.6%), and 1.339×10^{-3} mm^2/s(sensitivity=86.7%, specificity=72.7%), respectively.
Conclusion: The pCR group appeared less heterogeneous on pre-CRT ADC map and had lower high percentile ADC values than non-pCR group. Whole-tumour histogram-based texture analysis of pre-CRT ADC map could effectively predict pCR after neoadjuvant CRT in LARC patients.

B-0850 11:02

T2-weighted signal intensity to predict complete and good response after neoadjuvant chemoradiation therapy in patients with rectal cancer
R.A.P. Dijkhoff; *Maastricht/NL (rebeccadijkhoff@hotmail.com)*

Purpose: To determine whether T2-weighted signal intensity (T2W-SI) can predict complete and good response after neoadjuvant chemoradiation(CRT) in patients with rectal cancer.
Methods and Materials: 171 consecutive patients with rectal cancer treated with neoadjuvant CRT underwent MRI before and 8-10 weeks post-CRT. The primary tumour and remnant after CRT were manually delineated on T2W-MRI. Histogram analyses were performed on these volumes of interest with pyradiomics. Extracted parameters were mean, median, SD, range, minimum, maximum T2W-SI before and after CRT. Change between pre- and post-CRT T2W-SI parameters was calculated. Heterogeneity of T2W-SI was assessed by the coefficient of variance (CoV=SD/mean). T2W-SI parameters were compared between complete (CR; ypT0), good responders (GR; ypT0-1) and non-responders (NR; ypT2-4). Reference standard was either surgery or a wait-and-see programme with at least 2years of recurrence-free follow-up.
Results: 36/135 patients had a CR and 49/171 a GR. Maximum SI (941.62 vs 1149.63, p=0.028), heterogeneity of the SI (0.265 vs 0.291, p=0.017) and SI range (828.56 vs 1074.52, p=0.009) at primary staging were significantly lower in CR than in NR. Minimum SI at primary staging was significantly higher in both CR (113.06 vs 75.10, p=0.017) and GR (117.02 vs 69.46, p=0.001) compared to NR. The mean difference in SI between primary and restaging was larger in both CR and GR compared to NR, although not statistically significant in the CR patients (CR: -14257 vs NR: -105.44, p=0.114 and GR: 176.83 vs NR: -87.72, p=0.001).
Conclusion: The pre-CRT T2W-SI is significantly higher in CR and GR with a larger decrease in mean SI after CRT. These parameters could be a potential non-invasive marker for predicting complete/good response in patients with rectal cancer before and after CRT.

B-0851 11:10

Predictive value of functional imaging markers derived from PET/CT and diffusion-weighted MRI in response assessment of rectal cancer treatment
S. Drago, C. Talei Franzesi, S. Lombardi, A. Casiraghi, L. Guerra, S. Sironi, D. Ippolito; *Monza/IT (silvia.drago@hotmail.it)*

Purpose: To assess the clinical diagnostic value of functional imaging for tumor response prediction in rectal cancer, combining quantitative parameters of ADC and SUV max before and after chemo-radiation therapy, with tumor regression grade at histology
Methods and Materials: Forty-five patients with biopsy rectal adenocarcinoma were enrolled in this study. All patients underwent whole body 18-FDG-PET/CT scan and pelvic MRI examination before (PET1, MR1) and after neoadjuvant chemo-radiation therapy(PET2, MR2). MRI was performed on 1,5T magnet(Philips,Achieva), adding DWI sequences (b-value 0 and 1000 mm^2/sec)to the standard protocol. On PET/CT the SUVmax of rectal lesions was calculated in PET1 and PET2.The different SUVmax(ΔSUV) and ADC(ΔADC) values, between baseline and pre-surgical scan, were assessed and correlated with pathologic tumor regression grade (Mandard's criteria;TRG 1=complete regression,TRG5=no regression)
Results: Twenty-nine tumors (68%) showed complete or subtotal regression (TRG1-2) at histology and classified as responders; 16 tumors (32%) were classified as non-responders (TRG3-5). The mean values of SUV max in PET1 were higher than in PET2 (p<0.001), whereas mean ADC values were lower in MR1 than MR2 (p<0.001). The best predictors for TRG response were SUV2 (threshold 4.4) and ADC2 ($1.28x10^{-3}mm^2/s$). Moreover, combining the median quantitative values in a single analysis, the PPV for different response groups related to TRG system, showed an overall AUC of 96%, higher than DWI(88.2%) or SUVmax(93.3%)
Conclusion: In era of PET/MRI scanner, combining DWI value and PET/CT could be the most feasible method to evaluate tumor response in rectal cancer, with accuracy values higher than other imaging techniques

B-0852 11:18

Texture analysis of magnetic resonance imaging in differential diagnosis of rectal tumours
M. Huang; *Zhengzhou/CN (huangmengna1127@163.com)*

Purpose: To analyse magnetic resonance images of rectal villous tubular adenoma and T1-T2 rectal adenocarcinoma, and evaluate the texture characteristics of two kinds of rectal tumours by "nearest neighbour algorithm".
Methods and Materials: From March 2014 to January 2017, 30 patients with rectal villous tubular adenoma and 43 patients with T1-T2 rectal adenocarcinoma in our hospital were retrospectively analysed; texture analysis was performed on the ROIs of two types of tumours.
Results: Totally 24 texture parameters were extracted based on statistical methods, of which 14 parameters had statistically significant difference between the two kinds of data sets (P<0.05). The sensitivity, specificity and accuracy of "nearest neighbour algorithm" of texture parameters of rectal villous tubular adenoma and T1-T2 rectal adenocarcinoma were 79.87±7.55%, 53.89±10.16% and 69.24±5.52%, respectively.
Conclusion: Texture analysis can extract more features for the differential diagnosis of rectal villous tubular adenoma and T1-T2 rectal adenocarcinoma, which would be conducive to the development of clinical treatment and provide a new method for the differential diagnosis of rectal tumours.

B-0853 11:26

Whole tumour texture analysis based on ADC maps as quantitative imaging biomarker in patients with locally advanced rectal cancer "responders" to neoadjuvant chemoradiotherapy
A. Grassi, A. Cirigliano, S. Carbone, M. Biondi, V. Nardone, L. Pirtoli, L. Volterrani; *Siena/IT (andrea.grassi14@alice.it)*

Purpose: To evaluate the predictivity of Texture Analysis (TA) parameters extrapolated by the whole tumour analysis on ADC maps in tumoural response and recurrence in patients whit locally advanced rectal cancer (LARC) treated with neoadjuvant chemoradiotherapy (CRT).
Methods and Materials: We retrospectively analysed 35 pre-CRT MR imaging examinations. After complete surgical resection, only 23 patients with tumour regression grade (TRG) 1-2, considered "responders" according to Mandard TRG, were finally enrolled. Texture features (mean, standard deviation, skewness, kurtosis, entropy and uniformity) were assessed using a filtration-histogram tecnique and were independently correlated, by univariate and multivariate analysis, with TRG and the onset of metastasis. ROC curve analysis was performed and DFS was assessed with Kaplan-Meier method.
Results: Nine patients showed TRG1 (pathological complete response: pCR) and fourteen TRG2 whereas six patients (one TRG1, five TRG2) developed metastatic disease. Kurtosis was significantly lower in TRG1 in comparison with TRG2 (p= 0,016) and significantly higher in patient who had recurrence from those who did not have metastasis (p=0,013). The optimal cut off values were ≤3,5 (78% sensitivity, 86% specificity in predicting pCR) and ≥4,6 (67% sensitivity, 100% specificity in predicting metastatic disease) respectively.
Conclusion: Texture ADC Kurtosis is seems to be a promising parameter in discriminating both rectal cancer responsiveness to CRT and tumoural aggressiveness (metastatic risk). Further investigations are needed to confirm usefulness TA kurtosis in custumised menagement of patients with LARC.

B-0854 11:34

Accurate localization of rectal cancer on preoperative magnetic resonance imaging: a prospective study using an anal verge marker
Y. Han, B. Park, M. Kim, D. Sung, N. Han, K. Sim, S. Cho; *Seoul/KR (yeonny0714@naver.com)*

Purpose: To determine an approach for rectal cancer localization using MRI, with the anal verge as a landmark.
Methods and Materials: Fifty patients scheduled for MRI evaluation of rectal cancer were evaluated. Two markers were attached to the anal verge at 6 and 12 o'clock positions. On sagittal T2WI, the distance between the lowest margin of cancer and upper tangent of the two markers was measured by two radiologists in 6 different ways, and compared with that obtained using rigid sigmoidoscopy. The intraclass correlation coefficient (ICC) was used for the correlation verification. Precise localization of the anal verge was evaluated based on the anal verge markers.
Results: Among 6 different measurment methods, the "direct centre" method showed the highest correlation with rigid sigmoidoscopy (ICC = 0.81) and good interobserver correlation (ICC = 0.98). This method measures the linear distance between the centre of the line segment abutting the lowest margin of the tumour and perpendicular to the longitudinal axis of the rectum, and the

upper tangent of the anal verge markers, on mid-sagittal T2WI. The anal verge identified by the marker was located within a range of -1.4 ~1.5 cm (mean -0.24 cm) from the lowest margin of the external sphincter.
Conclusion: The "direct centre" method is an accurate and relatively easy way for tumour localization using preoperative rectal MRI. The anal verge is located between 1.4 cm above and 1.5 cm below the lowest margin of the external sphincter and is usually in the upper portion of the lowest margin of the external sphincter.

B-0855 11:42

Predictive factors of recurrence at MR examination performed before and after preoperative chemoradiotherapy in patients with rectal cancer: a retrospective study

F. Prampolini, S. Taschini, A. Pecchi, F. Sani, F. Gelsomino, A. Spallanzani, S. Kaleci, P. Torricelli; *Modena/IT (prampolini.francesco@tiscali.it)*

Purpose: To evaluate whether MRI performed before and after neoadjuvant chemoradiotherapy (NACRT) could predict the risk of recurrence in patients with rectal cancer.
Methods and Materials: This study included 87 patients with rectal cancer who had undergone pre- and post-NACRT local staging MRI, with dedicated protocol, between 2005 and 2016. Two radiologists independently reviewed all MR examinations retrospectively and assessed the T-stage, nodal involvement (>5 mm), distance from mesorectal fascia and extramural venous invasion (EMVI scoring system 0-4). Correlation between these parameters and patients' risk of recurrence was evaluated with statistical analysis.
Results: In our analysis all four assessed parameters correlated significantly with the risk of recurrence (*P* value range 0.002-0.026) when evaluated in MRI performed after NACRT, but not in MRI performed before NACRT. The specific analysis of EMVI score (0-4) showed a statistically significant correlation with recurrence only when evaluated at MRI post-NACRT, while extramural venous invasion, if considered as present or absent, regardless of its score, correlated significantly with the risk of recurrence also in pre-NACRT MR examination (P= 0.011).
Conclusion: MRI performed after NACRT has a significant value in predicting the risk of recurrence in patients with rectal cancer. EMVI strongly correlated with the risk of recurrence and its presence in pre-NACRT MRI should be considered as an early predictive factor of disease relapse.

Outcomes of endovascular treatment for acute large vessel ischaemic stroke more than 6 hours after symptom onset

R. Motyer[1,1], H. Kok[2], H. Asadi[3], A. O'Hare[1], P. Brennan[1], P. Sarah[1], S. Looby[1], P. Nicholson[1], J. Thornton[1]; [1]*Dublin/IE*, [2]*London/UK*, [3]*Melbourne, Victoria/AU (ronanmotyer@gmail.com)*

Purpose: Benefit from endovascular thrombectomy (EVT) for large vessel occlusion (LVO) acute ischaemic stroke (AIS) is well demonstrated. Furthermore, emerging evidence supports efficacy in appropriately selected patients treated beyond current recommendations of 6 hours. We evaluated clinical outcomes in patients undergoing late EVT at our institution.
Methods and Materials: Retrospective review of prospectively collected clinical database on 355 patients who underwent EVT for LVO AIS. Data collected consisted of patient demographics, radiological findings and outcome details. Outcomes, including 90-day functional status, recanalisation, symptomatic intracranial haemorrhage (sICH) and 90-day mortality, for patients undergoing EVT <6 hours, >6 hours and >7.3 hours were compared.
Results: 355 patients underwent EVT for LVO AIS at our institution during the review period, with 74 (21%) patients treated >6 hours from symptom onset. Successful recanalisation was achieved in 285 (80%) patients, with 228 (81%) achieving a mTICI ≥2b in <6 hour group, and 57 (77%) in >6 hour group (p=0.429). 90-day functional independence (mRS 0-2) was achieved in 162 (46%) patients, with 130 (46%) achieving a mRS of 0-2 in <6 hour group, and 32 (43%) in >6 hour group (p=0.643). No significant differences were found in rates of sICH or 90-day mortality. No significant differences in functional independence, recanalisation rates, sICH, or mortality were identified in patients treated with EVT >7.3 hours compared to <7.3 hours.
Conclusion: In appropriately selected patients, EVT >6 hours was associated with comparable outcomes to those treated <6 hours. These data support a physiological approach to patient selection.

B-0857 10:38

Endovascular thrombectomy beyond 12 hours of stroke onset: a stroke network's experience of late intervention

R. Motyer, J. Thornton, S. Power, P. Brennan, A. O'Hare, S. Looby, D. Williams, B. Moynihan, S. Murphy; *Dublin/IE (ronanmotyer@gmail.com)*

Purpose: The benefit of late endovascular thrombectomy (EVT) in correctly selected patients presenting with large vessel occlusion acute ischaemic stroke has been demonstrated, with positive outcomes achieved up to 24 hours from symptom onset. As a tertiary stroke service, we reviewed our outcomes in cases of EVT performed >12 hours from symptom onset.
Methods and Materials: Retrospective review of prospectively maintained database of all EVT cases performed for management of AIS with LVO of the anterior circulation at our institution. Patients were evaluated using ASPECTS on non-contrast CT brain and collateral grade on multiphase CT angiogram (mCTA) to aid selection for intervention. Data, including patient demographics, neuroimaging findings, procedural details, recanalization rates and 90-day functional outcomes, from all EVT cases performed >12 hours was collected.
Results: Of the 542 consecutive EVT cases reviewed, 25 (4.6%) were performed >12 hours from symptom onset. Median age was 69 (IQR, 55-80), median NIHSS on presentation 14 (IQR, 11-18.5), median ASPECTS was 8 (IQR, 8-9) and moderate-good cerebral collateral status in 96% of patients (n=24). Median time to groin puncture was 880 minutes (IQR, 753.5-977.5), with a rate of successful recanalization (mTICI 2b-3) of 88% (n=22). The rate of 90-day functional independence (mRS 0-2) was 52% (n=13). There were no cases of symptomatic intracranial haemorrhage and 90-day mortality rate was 12% (n=3).
Conclusion: With careful patient selection, guided by ASPECTS and collateral status, EVT may be performed safely and effectively, with good functional outcomes achieved in patients with delayed presentation acute ischaemic stroke.

B-0858 10:46

Acute ischaemic stroke due to tandem occlusions of the internal carotid artery: results of endovascular recanalisation and clinical outcome

M. Voormolen, T. Van der Zijden, O. D'Archambeau, L. Yperzeele, P. Vanacker, I. Baar, M. Muto, T. Menovsky, P.M. Parizel; *Antwerp/BE (maurits.voormolen@uza.be)*

Purpose: Tandem occlusion of internal carotid artery (ICA) is defined as proximal ICA (near) occlusion combined with distal (embolic) occlusion of ICA and/or middle cerebral artery (MCA). We assessed endovascular recanalisations and clinical outcome in acute ischaemic stroke (AIS) patients due to ICA tandem occlusions.
Methods and Materials: We evaluated immediate angiographic results and prospective clinical outcomes of 19 consecutive patients with tandem ICA occlusions, treated with mechanical thrombectomy (MT) between January 2014 and July 2017, involving 15 men and 4 women, with a median age of 69 years (range 52-87). They comprised 15% of total anterior circulation stroke recanalisations in this period. Thirteen patients had left ICA occlusion (68%). Fifteen patients (79%) received intravenous thrombolysis before endovascular recanalisation.
Results: Successful recanalisation (TICI 2b/3) was seen in 14 patients (74%) and no recanalisation (TICI 0) in three patients (16%). Median procedure time was 65 minutes (range 20-120). Median number of passages was one (range 0-5). In 7 patients (37%) balloon angioplasty of ICA was performed; 1 carotid stent was placed (5%). Median NIHSS was 19 (range 9-29) at admission and 13 (range 2-30) at discharge. Only six patients (32%) had favorable clinical outcome at 3 months (mRS≤2); 9 patients (47%) had major cerebral infarcts, 6 patients died (32%).
Conclusion: In our series, endovascular recanalisation of tandem ICA occlusions in patients with acute ischaemic stroke showed high rates of successful recanalisation, but unfavorable clinical outcomes. Further studies are needed to determine which patients might benefit from endovascular recanalisation.

B-0859 10:54

Bronchial artery embolisation: tuberculosis patients with haemoptysis

K. Muhammad, I.A. Lutfi; *Karachi/PK (dr.khairmuhammad@gmail.com)*

Purpose: The goal of this study is to present our experience of bronchial artery embolization for the treatment of life threatening haemoptysis in patients with pulmonary tuberculosis. This study focuses on overall clinical success rate of this procedure and its cost effectiveness.
Methods and Materials: Our study is based on four year retrospective cross-sectional data from March 2013 to Feb 2017. In our study, fifty patients underwent bronchial artery embolization for the treatment of life threatening

haemoptysis secondary to pulmonary tuberculosis. These patients were referred to radiology department from pulmonary clinics/ emergency. As a part of our departmental protocol, CT aortogram/pulmonary angiogram was performed on almost every patient to evaluate the bleeding bronchial artery for embolization.
Results: We found out in our study bronchial artery embolization was successful in forty eight patients (96 %) and followed up till six months. Recurrence occurred in four (8%) patients after six months in whom there developed new lung cavity or recanalization of artery in previous lesion. In two patients (4%) embolization procedure was abandoned due to tortuous course of bronchial artery. Out of total fifty patients, some of our patient developed complications such as chest pain in fifteen patients (30%) and one patient (2%) developed lower limb weakness (spinal cord related complication). However, there was no mortality due to this procedure in our study.
Conclusion: Bronchial artery embolization is life saving procedure for patient with haemoptysis with no procedure related mortality in our study and cost effective compared to surgery.

B-0860 11:02

Pulmonary arterial occlusion treatment in patients with haemoptysis: a 32-case single-centre study

Z.C. Charline, M. Jaffro; *Toulouse/FR (charline.zadro@gmail.com)*

Purpose: Pulmonary arterial bleeding is a rare cause of haemoptysis, which requires a specific endovascular treatment. Herein, we report the feasibility and effectiveness of pulmonary artery occlusion treatment (PAOT) in our centre.
Methods and Materials: Thirty-two patients treated by PAOT between January 2010 and May 2017 in Toulouse Rangueil University Hospital were retrospectively included. We performed a thoracic angio scan for each patient looking for an argument pointing to a pulmonary arterial origin (PAO) of the bleeding.
Results: Nineteen patients (59 %) had a neoplasia and seven (22%) an active infectious disease. Signs contradicting to a PAO were irregularities (88%) and occlusion (31%) of the pulmonary artery, a lung parenchyma necrosis (59%) and pseudoaneurysms (44%). We used steel coils in 23 cases (72%) and plugs in 12 (38%). The feasibility of PAOT was 100% and the clinical efficacy, defined by early and sustained interruption of bleeding for 1 month, was 78% with a recurrence rate at the last follow-up of 31%. Seven patients had recurrence in the first month, and three later with additional embolisations (5) or surgeries (2). Only one patient with active infection experienced recurrence. Twenty-five patients (78%) had received an exclusive PAOT and 7 (22%) a combined occlusion of pulmonary and bronchial or systemic non-bronchial arteries. There was no significant difference between the two interventions concerning recurrence or survival.
Conclusion: PAOT by steel coils or/and plug is feasible and efficacious with little recurrence in the long term.

B-0861 11:10

Renal artery embolisation for vascular lesions following Nephron-sparing surgery: a five-year experience

E. Amodeo, A. Contegiacomo, N. Attempati, A. Paladini, C. Di Stasi, R. Manfredi; *Rome/IT (enriamo@gmail.com)*

Purpose: Indications to Nephron-Sparing Surgery (NSS) are extending overtime, resulting in improved renal function and parenchymal preservation. On the other hand, NSS is burdened by potentially life-threatening vascular lesions (NSS-VL). Renal Artery Embolization (RAE) is emerging as a mini-invasive alternative to surgery for NSS-VL management. This observational retrospective study describes our experience in the treatment of NSS-VL.
Methods and Materials: Thirty-six patients, from January 2012 to December 2016, with a NSS-VL diagnosed on Computed Tomography Angiography (CTA) before RAE were retrospectively enrolled. Type (pseudo-aneurysm; arteriovenous fistulas; active bleeding) and site (proximal; segmental; distal) of NSS-VL were assessed on CTA images and confirmed during RAE procedure. Technical (intra-procedural VL exclusion) and clinical (patient clinical stability >5 days) success, type of embolic agents (Coils; Glue; Polyvinyl-alcohol particles, PVA; Absorbable Gelatine Sponge, AGS) and intra/ peri-procedural complications were assessed by clinical charts and radiological reports analysis.
Results: Patients had 24/36 (66,6%) pseudo-aneurysms, 6/36 (16,7%) arteriovenous fistulas and 6/36 (16,7%) active bleeding. RAE was performed with Glue (25/3; 69,4%), PVA (6/36; 16,7%), Coils (5/36; 13,9%), AGS (3/36; 8,3%) or a combination of materials (7/36; 19,4%). Technical and clinical success was achieved in 36/36 (100%) and 33/36 (91,7%) patients, respectively. Glue migration occurred in 1/36 (2,8%) patient and was managed with intra-procedural fragmentation with angioplasty balloon. 3/36 (8,3%) patients encountered post-procedural bleeding successfully re-treated with RAE.
Conclusion: RAE is a feasible, effective and safe, mini-invasive alternative to surgery in NSS-VL management.

Alternative techniques in splenic artery embolisation in blunt splenic trauma

M. Citone, F. Mondaini, C. Raspanti, G. Gabbani, E. Casamassima, G. Falcone, F. Fanelli; *Florence/IT (michele.citone@gmail.com)*

Purpose: Splenic artery embolisation(SAE) has been increasingly employed as adjunctive tool in non operative management (NOM) in blunt splenic trauma(BST). Despite high technical success, controversies still exist on technique and materials employed, being coils the most utilised tool. We report our experience with Amplatzer Vascular Plug (AVP) and Onyx in splenic artery embolisation for trauma.
Methods and Materials: Between 2015 and 2017, 11 patients, 7 male,(mean age 47yo range 16-67) received SAE treatment as part of NOM for isolated BST with embolic agent different from coils. Indication to treatment was grounded on contrast blush or active bleeding (AB) or AAST injury score >3 on CECT In 6 patient proximal embolisation with AVP (20-30%oversized) for injury grade >III without active bleeding (AB) was performed while in 5 patients distal SAE with Onyx 34 was performed for AB and (4pts) or extensive laceration(1pt). All procedures were performed under local anesthesia while deep sedation was required for the onyx group.
Results: Technical success (intended as bleeding cessation or splenic artery occlusion) was achieved in 100%. Embolisation was achieved in less than 1min. No migration of embolic agent was observed. None of the patients required splenectomy. No major complication or re-bleeding were reported. No evidence of abscess or major infarction was observed at CT scan performed within 48h.
Conclusion: SAE with AVP or Onyx is a safe and effective procedure in splenic artery embolisation for blunt splenic trauma alternative to traditional coils.

B-0863 11:26

Management of acute occlusion of the superior mesenteric artery by local thrombolysis (multidisciplinary approach)

M.M.A.H. ElShafey, A. Elgendi; *Alexandria/EG (mohamedeshafei@yahoo.com)*

Purpose: To evaluate the effectiveness of endovascular local thrombolysis management in acute superior mesenteric artery (SMA) occlusion as alternative or neo-adjunctive treatment modality to surgery in a multidisciplinary approach strategy.
Methods and Materials: The study was conducted on 12 patients presented by acute abdomen in the emergency department and diagnosed by CT as acute superior mesenteric artery occlusion. In all cases the main stem of the SMA was involved. The median time from admission to attempted endovascular revascularisation was 6-12 hours except for one case (36h). Superselective catheterisation of the SMA was done using Cobra 5fr catheter for control angiogram and a hydrophilic guidewire was introduced passing the occlusive thrombus or embolus and an initial bolus dose of rt-PA or streptokinase was injected, after that exchanged the Cobra catheter by Simmond' catheter for infusion over 12-24 hours. Re-checking the flow after the infusion period was done before removal of the catheter. Close monitoring of the patient was done by multidisciplinary team.
Results: Successful revascularisation of the SMA was achieved in all patients. Only one patient needed further open laparotomy and bowel resection. No significant post-procedure bleeding was reported in any of the cases. One month follow up was done.
Conclusion: Local thrombolysis for acute SMA occlusion is a minimally invasive procedure that can be effective as alternative treatment in selected group of patients without peritonitis. Early intervention (golden time) is the key for better results.

B-0864 11:34

Endovascular treatment of haemodialysis arteriovenous fistula with vessel preparation and drug-coated balloon angioplasty: a single-centre study

J. Lucev, S. Breznik, D. Dinevski, R. Ekart, M. Rupreht; *Maribor/SI (jernej.lucev@gmail.com)*

Purpose: To evaluate the effect of PTA of haemodialysis fistulas utilizing drug-coated balloons with plain balloon vessel preparation (VP DCB).
Methods and Materials: From 2012 to 2015, 31 patients (16 men; mean age 62.81+/-17.2 years) with failing arteriovenous fistula were treated. All stenoses were dilated with regular high-pressure PTA balloons. After achieving angiographic success (<10% residual stenosis), drug-coated balloons were used for drug administration. Observation period was 6, 12 and 24 months. Results were compared with plain balloon PTA performed from 2006 to 2011 (31 patients; 15 men; mean age 67.03+/-8.44 years). Target lesion primary patency, primary-assisted patency and secondary patency were compared. T test, Mann-Whitney U test, Fisher's exact test, Kaplan-Meier survival curve and

log-rank test were used for statistical analysis. The significance was set at 0.05.
Results: Target lesion primary patency for VP DCB and plain balloon group was significantly different at 6 months (90.3% vs 61.3%; p=0.016), 12 (77.4% vs 29%; p=0.000) as well as 24 months (45.2% vs 16.1%; p=0.026). Kaplan-Meier survival curve also showed significant difference for target lesion primary patency (534.2 vs 315.7 days; p=0.000). Target lesion primary assisted patency could not be compared because both groups were too different. However, only 38.7% of patients in VP DCB group were treated twice or more vs 80.6% in plain balloon group (p=0.002). There were no significant differences in target lesion secondary patency.
Conclusion: VP DCB PTA decreases the rate of reinterventions and increases target lesion primary patency during the first 24 months.

B-0865 11:42

Lysis-assisted balloon (LAB) thrombectomy - a method for declotting thrombosed arteriovenous dialysis grafts: results from a retrospective analysis of 241 endovascular procedures
P. Kitrou[1], P. Papadimatos[1], K. Katsanos[1], S.C. Spiliopoulos[2], N. Christeas[1], D. Karnabatidis[1]; [1]*Patras/GR*, [2]*Athens/GR (panoskitrou@gmail.com)*

Purpose: To retrospectively investigate the results of a percutaneous lysis-assisted balloon (LAB) thrombectomy procedure for the treatment of thrombosed arteriovenous dialysis grafts (AVGs).
Methods and Materials: Within 5 years (January 2012 to Decmber 2016), 291 declotting procedures were performed for the treatment of thrombosed dialysis arteriovenous fistulas and grafts. Data were available for 129 patients (75 men, 58.1%) with an AVG, undergoing 241 procedures [1.87procedures/patient (1-10)]. Procedure includes initial lysis with 5mg recombinant tissue plasminogen activator followed by thrombectomy with a high pressure balloon for thrombus maceration using "facing sheaths" technique. 61 patients had ≥2 declotting procedures. In 80 cases (80/241; 33.2%) a stent graft (SG) was used for treatment of persistent stenosis. Main primary outcome measures were clinical success and postintervention assisted primary patency (PAPP). Secondary outcome measures included procedural complications and investigation of independent factors that could influence circuit survival.
Results: Median PAPP was 434 days according to Kaplan Meier survival analysis. Clinical success was 96.26%. In 6 cases (6/241, 2.49%) declotting failed and a catheter was placed. There were 16 minor (16/241, 6.64%) and no major complications. There was no significant difference in circuit survival regardless of SG use (No SG 406 days vs. SG 349 days; p=0.24). There was a significant difference in favor of the 2nd declotting compared to the 1st in 61 patients (1st: 162 days vs. 2nd: 447 days; p<0.0001).
Conclusion: LAB thrombectomy resulted in high circuit survival rates with increased technical success and minimum complications without the use of thrombectomy devices.

B-0866 11:50

Cumulative patency rate of forearm vs upper arm arteriovenous dialysis fistulae
A. Almehmi, V. Narasimha Krishna, A.M. Abdel Aal; *Birmingham, AL/US (aalmehmi@uabmc.edu)*

Purpose: Both upper arm (UA) and forearm (FA) arteriovenous fistulas (AVF) are utilised as a permanent hemodialysis access. The aim of this study was to compare the cumulative patency rate of FA-AVFs and UA-AVFs and to explore the predictors of access survival.
Methods and Materials: We retrospectively analysed 286 hemodialysis patients who underwent AVF creation at our institution between January 2005 and December 2015. Cumulative access patency was defined as the time from access creation to permanent failure, regardless of the number of interventions required to maintain long-term patency for dialysis. The cumulative patency rate was calculated in UA-AVF and FA-AVF groups using Kaplan- Meier survival methods and log-rank tests. Backward stepwise Cox regression model was utilised to determine predictors of hemodialysis access survival.
Results: The total number of patients included in the UA-AVF and FA-AVF groups were 121 and 165 cases, respectively. Baseline characteristics included: 39% were females; 88% were blacks; 50% were diabetics; 96% and 28% of patients had hypertension and congestive heart failure, respectively. Cumulative patency rate of UA-AVF and FA-AVF during the follow up time was 74% and 59%, respectively (p=0.008). In multivariate analysis of AVF survival, we found that hemodialysis access failure was higher in FA-AVF than UA-AVF (HR: 1.97 [1.28-3.06]; p=0.002). Further, female gender was associated with increased AVF failure (HR: 1.58 [1.05-2.37]; p=0.03).
Conclusion: FA-AVFs have a lower cumulative patency rate as compared to UA-AVFs. Further, UA-AVFs and male gender are associated with a better hemodialysis access survival.

Artificial intelligence applied on the national lung screening trial dataset: a radiomics study
S. Martin, J. Hofmeister, S. Burgermeister, C.D. Becker, X. Montet; *Geneva/CH (steve.martin@hcuge.ch)*

Purpose: To investigate the added value of radiomics applied on the National Lung Screening Trial (NLST) dataset in estimating solitary pulmonary nodule malignancy risk compared to the PanCan model.
Methods and Materials: Lung adenocarcinoma (n=227) and squamous cell carcinoma (n=94) with a long axis greater than 8 mm obtained from the NLST dataset were included and matched with benign lung nodules (n=299). Features extraction (n=124671) was performed using an open-source python package after automatic segmentation of the 620 lung nodules from low-dose unenhanced computer tomography (CT). Benign versus malignant classification based on radiomics and clinical data was achieved via features selection, dimension reduction (using principal component analysis), and classification (using a support vector machine classifier). The demographic data, part of the NLST dataset and combined to the extracted features from the CT images for the radiomics analysis, were also evaluated solely according to the PanCan model. Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) of the radiomics were calculated based on the histological diagnostic given in the NLST dataset. The diagnostic performances of the two models were compared on their area under the receiver operating characteristic curve (AUC) analysis.
Results: Radiomics model: sensitivity 96.9%, specificity 93.3%, PPV 93.9%, NPV 96.6%, AUC: 0.983. PanCan model: AUC: 0.797.
Conclusion: Artificial intelligence and data mining in chest CT raise the diagnostic confidence higher than any other models in the field of non-invasive characterisation of lung nodules.

B-0868 10:47

Lung nodule risk stratification using Deep Learning on the complete US National Lung Screening Trial dataset
C. Arteta, L. Pickup, P. Novotny, Z. Sandford, J. Brabec, D. Dufek, J. Kunst, J. Declerck, T. Kadir; *Oxford/UK*

Purpose: Correct classification of screen or incidentally detected indeterminate pulmonary nodules is essential to avoid excessive follow-up. Prior work on limited datasets has shown the potential of computer aided risk stratification but validation on large datasets is required prior to use as a rule-out test. For the first time, we demonstrate validation of a Deep Learning risk stratification system on the complete US National Lung Screening Trial (NLST) dataset.
Methods and Materials: The NLST dataset was manually curated such that each reported nodule and cancer was located and diagnostically characterised. Training and testing sets were built from the full set of patients with solid/mixed nodules of 6mm and above (6132). A Convolutional Neural Network (CNN) was trained with four-fold cross-validation, withholding approximately 370 nodules (class-balanced) in each test set. Performance was evaluated using Area-Under-the-ROC analysis and also the fraction of benign nodules correctly rejected at 0%, 1% and 2% of misclassified malignant nodules (FNR). Similar analysis was performed using nodule size as a classifier.
Results: Using the CNN, Benign Rejection Fraction (min, variance) at 0%, 1%, 2% FNR was 19% (14%, 8%), 32% (16%, 12%), 37% (18%, 13%) respectively. Using size, benign rejection fraction values were 0% at all threshold. AUC for the CNN and size was 0.87 and 0.82 respectively.
Conclusion: Using the CNN, a significant proportion of patients with benign nodules can be correctly identified while keeping the rate of missed cancers at extremely low, thereby avoiding unnecessary follow-up.

Automatic prediction of emphysema extent in low-dose CT by deep learning

G. Bortsova[1], S.N. Ørting[2], F. Dubost[1], I. Katramados[3], L. Hogeweg[3], M.M. Wille[4], L.H. Thomsen[4], M. De Bruijne[1]; [1]*Rotterdam/NL*, [2]*Copenhagen/DK*, [3]*Groningen/NL*, [4]*Hellerup/DK (gerdabortsova@gmail.com)*

Purpose: Emphysema is commonly quantified using CT densitometry measures, which however correlate only moderately with visual assessment of emphysema extent according to trained observers. We propose a deep learning approach to automatically quantify emphysema extent based on its CT patterns rather than on density alone, mimicking visual assessment.
Methods and Materials: Two low-dose CT scans (baseline and 5th annual follow-up) were acquired at full inspiration from 1934 participants of the Danish Lung Cancer Screening Trial (inclusion criteria: age 50-70, at least 20 pack-years of smoking and FEV_1 of at least 30% of predicted). Two observers independently scored emphysema extent from 0 (no emphysema) to 5 (75-100% of lung affected) in the upper, middle and lower lung regions. We trained our algorithm on scans of 993 subjects and evaluated it on 941 subjects.
Results: Agreement between automated and expert's assessment of emphysema presence was good (area under the ROC curve 0.89, accuracy 90.4% - similar to interobserver agreement of 91%). The intraclass correlation coefficient was 0.757 (Pearson: 0.823) for emphysema extent scoring and 0.835 (Pearson: 0.852) between the observers. The Pearson correlation of the expert's scores and densitometry based on -950HU threshold was 0.436. Only in 1.5% of the scans the predicted score was more than one category off.
Conclusion: Our emphysema quantification method's performance is promising. This method may replace time-consuming visual assessment in large-scale studies and, eventually, in clinical practice.

B-0871 11:03

Fully automated segmentation of pulmonary fibrosis using different software tools

A. Giannakis[1], T. Norajitra[1], L. Kehler[1], J. Dinkel[2], O. Weinheimer[1], C. van Lunteren[1], M. Kreuter[1], K. Maier-Hein[1], C. Heussel[1]; [1]*Heidelberg/DE*, [2]*Munich/DE (a-giannakis@hotmail.com)*

Purpose: Evaluation of software tools for segmentation of fibrotic pulmonary parenchyma will strengthen the role of multidetector CT as biomarker of disease extent, evolution, and response to therapy in patients with pulmonary fibrosis.
Methods and Materials: 418 non-enhanced thin section MDCT of 127 patients with idiopathic pulmonary fibrosis and 78 MDCT of 78 healthy individuals were analysed through three fully automated, completely different software tools: YACTA, LUFIT, and IMBIO. The agreement between YACTA and LUFIT on segmented lung volume, 80th (reflecting fibrosis) and 40th (reflecting ground glass opacity) percentile of lung density histogram was analysed using Bland-Altman plots. The fibrosis and ground glass opacity segmented by IMBIO (lung texture analysis software tool) were included in specific regression analyses.
Results: In the IPF-group, LUFIT performed better than YACTA by segmenting more lung volume (mean difference 242 ml, 95% limits of agreement -54 to 539 ml), as well as quantifying higher 80th (76 HU, -6 to 158 HU) and 40th percentile (9 HU, -73 to 90 HU). No relevant differences were revealed in the control group. The 80th/40th percentile as quantified by LUFIT showed positive correlation with the percentage of fibrosis/ground glass opacity calculated by IMBIO (r= 0.784/r=0.918).
Conclusion: In terms of segmentation of pulmonary fibrosis, LUFIT as shape model-based segmentation software tool is superior to YACTA, which works based on threshold, because the density of severe fibrosis is similar to that of the surrounding soft tissues. Therefore, LUFIT may serve as a valid tool in the quantification of pulmonary fibrosis, since this disease mainly affects the subpleural space.

Clinical validation of a deep learning algorithm for quantification of the idiopathic pulmonary fibrosis pattern

T.R. Nimmada[1], P. Rao[1], P.S. Sanghavi[1], V. Venugopal[2], P. Warier[1], Z. Udwadia[1], B. Jankharia[1]; [1]*Mumbai/IN*, [2]*New Delhi/IN (pooja.rao@qure.ai)*

Purpose: Radiologists are currently ill equipped to precisely estimate disease burden and track the progression of idiopathic pulmonary fibrosis (IPF). Development of an automated method for IPF segmentation is challenging, due to the complexity of the fibrosis pattern and degree of variation between patients. Deep neural networks are machine learning algorithms that overcome these challenges. We describe the development and validation of a novel deep learning method to quantify the IPF pattern.
Methods and Materials: We used high-resolution chest CT scans from 23 patients with IPF as training data. The fibrosis pattern was marked out on 60 slices per scan. Annotated scans, with 6 additional normal scans were used to train a convolutional neural network to outline the IPF disease pattern. Segmentation accuracy was measured using Dice score. For each patient, percentage of lungs affected by IPF was calculated. An independent set of 50 scans was used for clinical validation. Disease volume was independently estimated by 2 thoracic radiologists blinded to the algorithm estimate. Algorithm-derived estimates were correlated with radiologist estimates of disease volume.
Results: A 3-dimensional neural network architecture coupled with 2-dimensional post-processing of each slice produced the most accurate segmentation, with a Dice score of 0.77. The correlation between algorithm-derived disease volume estimate and average radiologist estimates was 0.92. Inter-radiologist correlation was 0.89. Radiologist estimates of disease volume varied by 5.5% (range 0-15%).
Conclusion: We demonstrate that a deep neural network, trained using expert-annotated images, can accurately quantify the percentage of lung volume affected by IPF.

Risk assessment of lung cancer development in Idiopathic Pulmonary Fibrosis (IPF) patients using quantitative HRCT analysis

D. Falsaperla[1], S.E. Torrisi[1], A. Torcitto[1], G. Russo[2], A. Stefano[2], A. Vancheri[1], A. Basile[1], C. Vancheri[1], S. Palmucci[1]; [1]*Catania/IT*, [2]*Cefalù/IT (danielefalsaperla@gmail.com)*

Purpose: To investigate the diagnostic accuracy of Kurtosis, High Attenuation Area (HAA) and Fibrotic Area (FA) HRCT indexes in risk assessment of lung cancer development in patients with Idiopathic Pulmonary Fibrosis (IPF).
Methods and Materials: 42 IPF patients were retrospectively analysed; patients were divided into subjects that developed lung cancer (Group A n=9) and patients without lung cancer development (Group B n=33). HRCT and pulmonary function tests were reviewed; the extent of fibrotic disease was quantified on HRCT using Kurtosis, HAA and FA. For group A, measurements were obtained from HRCT acquired before cancer development - medially performed 26 months after IPF diagnosis; for group B, we analysed HRCT acquired medially 18 months from IPF diagnosis. HRCT indexes, FVC and DLCO values were compared between groups using Mann-Whitney U-test.
Results: No difference was recorded for FVC and DLCO values. No statistical difference was found among groups for median values of Kurtosis (3.76 versus 4.26), HAA (27.85 versus 23.16) and FA (15.77 versus 13.89). ROC analysis for prediction of lung cancer development using a threshold value of Kurtosis index ≤5.31 showed sensibility of 100% and specificity of 24.2%; for FA index, using a threshold value >26.375, ROC analysis obtained sensibility of 66.7% and specificity of 69.7%. For HAA index, a threshold value >14.59 reported sensitivity and specificity of 77.8% and 60.6%.
Conclusion: Kurtosis, FA and HAA provide limited diagnostic accuracy in risk assessment of cancer development in IPF patients; FA and HAA showed the best sensitivity/specificity ratio in predicting lung cancer.

B-0874 11:27

Radiomics signature for non-small cell lung cancer recurrence risk prediction after surgery: quantitative analysis of the tumour and peritumoural lung parenchyma on presurgical MDCT

T. Akinci D'Antonoli, A. Farchione, J. Lenkowicz, M. Chiappetta, G. Cicchetti, A.R. Larici, V. Valentini, L. Bonomo, R. Manfredi; *Rome/IT (drtugba@hotmail.com)*

Purpose: To estimate recurrence risk after surgery in non-small cell lung cancer (NSCLC) patients by employing a prediction model with radiomics signature (RS) and clinical parameters.
Methods and Materials: 124 NSCLC patients (stages I to IIIA) who received surgery (2008-2013) at our hospital were retrospectively enrolled. Tumour recurrence (TR), local recurrence (LR) and distant metastasis (DM) was diagnosed on follow-up imaging (3-5 years). The region of interests (ROI) for the tumour (GTV), the peritumoural lung parenchyma 2 cm around the tumour (PTV) and the involved lobe (LB) were semiautomatically contoured. 90 features (statistical, morphological, textural) were extracted from each ROI with an in-house developed software (Moddicom). RS was computed with the best-performed radiomics model's coefficients for each outcome (features selection: "fscaret" and step-wise selection on the top 10 features; model selection: highest AUC in 10-fold cross-validation), then significant clinical features (Cox regression analysis: tumour-node-metastasis stage [TNMS], histology, age, smoking status and gender) were added. Predictive nomograms were created at 1-, 2-, 3-year survival.
Results: Median time-to-recurrence was 44 months; 25 patients developed LR, 31 patients developed DM. For TR and DM outcomes GTV+PTV (AUC 0.750 for both), for LR outcome GTV (AUC 0.731) were found to be the best performed models; adding TNMS improved all models' performance (TR, DM, LR: AUC 0.760, 0.759, 0.750, respectively). The nomogram with RS and TNMS discriminated high-risk better than TNMS alone.
Conclusion: Utilizing radiomics on pre-treatment MDCT images, extracting peritumoural and intratumoural radiomics features could be a useful tool to stratify NSCLC patients at different recurrence risk and to define a personalised treatment.

Lung adenocarcinoma radiogenomics predicts clinical outcome

A. Leonardi, A. Napoli, R. Scipione, M. Anzidei, S. Dababou, C. Catalano; *Rome/IT (andrea.leonardi1988@gmail.com)*

Purpose: To statistically correlate CT features, quantitative texture analysis (QTA), epidermal growth factor receptor (EGFR) mutations and clinical outcome in patients with lung adenocarcinoma.
Methods and Materials: We retrospectively enrolled eighty-one patients affected by lung adenocarcinoma to evaluate conventional CT features and assess QT analysis. Correlations between CT features, QTA, EGFR mutations and clinical outcome were determined through univariate analysis, unpaired Student t test, chi-square and Mann-Whitney tests. A multiple logistic regression analysis and Receiver Operating Characteristics (ROC) curve analysis versus death and EGFR status was performed for CT features and QTA.
Results: EGFR mutation was detected in 31/81 tumors (38.3%). EGFR mutation demonstrated a correlation with emphysema ($p<0.0001$) and a positive association with necrosis ($p=0.017$). At multivariate analysis air-bronchogram and locoregional infiltration were proved to be positively and negatively associated with EGFR-mutated status ($p=0.0304$ and $p=0.0018$ respectively). No significant correlation was observed between the conventional CT features and overall survival. Mean, SD and skewness were found to have a significant correlation with EGFR mutation ($p=0.0001$; $p=0.0001$; $p=0.0459$). The only parameter correlated with the event of death was entropy ($r=0.2708$; $p=0.0329$).
Conclusion: CT and QTA features of lung adenocarcinoma demonstrated a significant relationship with EGFR mutations and clinical outcome.

B-0876 11:43

Can texture analysis predict non small cell lung cancer recurrence after surgery ?

R.S.R. Lopes do Rosario, N. Michoux, V. Lacroix, B. Ghaye; *Brussels/BE (ritar1@hotmail.com)*

Purpose: To predict the aggressiveness of NSCLC (in terms of recurrence) using morphology and texture analysis on a pre-surgical CT.
Methods and Materials: This retrospective study included 46 consecutive patients with NSCLC (T1 or T2N0M0) treated by surgery. A preoperative acquisition obtained using the same reconstruction parameters on the same CTscanner was used to extract tumor morphological properties, to assess intra-tumoral texture parameters from the *Grey Level Co-occurrence and Run-Length matrices.* Eight patients presented with tumor recurrence during a mean follow-up of 4.5years after surgery. Different predictive models either based on individual parameters or on a small set of parameters embedded in a logistic regression were reconstructed. Receiver operating characteristic analysis was performed to assess the predictive performance of these models.Then, the best multiparametric models were submitted to a *leave-one-patient-out-cross-validation (LOOCV).*
Results: Individual morphological parameters Surface Area and Aspect Ratio displayed a good performance in identifying patients with tumor recurrence (Area: Se=88%, Sp=88%, AUC=0.86, Aspect Ratio: Se=88%, Sp=60%, AUC=0.73). After LOOCV, models based on 4 texture parameters (Homogeneity, Sum Variance, Grey-Level Nonuniformity, Run Percentage) or on (Sum Average, Grey-Level Nonuniformity, Run Percentage, Short Run Low Grey-Level Emphasis) displayed a very good performance in identifying patients with tumor recurrence (Se=100%, Sp=91%, Acc=91% for both models).
Conclusion: These preliminary results confirm the growing evidence that lung cancers have texture features related to their tumoral aggressiveness. Combining morphological and texture parameters may allow improved tumor recurrence prediction. Further work is required to understand how to optimally implement texture analysis of these CT images.

Diagnostic accuracy of primary macronodular adrenal hyperplasia on CT: a quantitative and qualitative study

S.M. Ando, F.M. Coelho, P.C. Viana, L.G. Gomes, M.B.V. Fragoso, F.I. Yamauchi; *São Paulo/BR (sabrina.ando78@gmail.com)*

Purpose: To determine the accuracy of computed tomography (CT) in diagnosis of primary macronodular adrenal hyperplasia (PMAH).
Methods and Materials: This retrospective IRB approved study included 122 patients divided into 4 groups: PMAH (n=9), congenital adrenal hyperplasia (CAH) (n=21), primary hyperaldosteronism (PH) (n=52) and control group (CG) (n=40). CT images were evaluated by two blinded observers, who subjectively classified adrenals as definitive or not for PMAH, based on bilateral adrenal enlargement with nodules. Measurements of adrenal body and limbs width and length in axial plane were also recorded.
Results: Sensitivity, specificity, positive and negative predictive values for subjective analysis were 89%, 95%, 57% and 99% for observer 1 and 89%, 91%, 44% and 99% for observer 2. The interobserver agreement was 0.99 by kappa statistics. All measurements demonstrated significant difference between PMAH and others groups ($p<0.05$ ANOVA). Mean body, medial and lateral limbs width and adrenal length measurements in right and left adrenals were respectively on PMAH 1.5, 0.9, 0.8 and 4.9 cm and 1.7, 1.0, 1.3 and 4.9 cm. On CG, 0.6, 0.3, 0.3 and 3.5 cm and 0.7, 0.5, 0.4 and 3.6 cm. On CAH and PH, 0.8, 0.5, 0.5 and 4.0 cm and 0.9, 0.6, 0.5 and 4.1 cm. The cut off ≥ 1.5 cm of right body width had 100% of specificity and 55.5% of sensitivity for the diagnosis of PMAH.
Conclusion: Qualitative CT features have high accuracy for diagnosis of PMAH. Quantitative analysis may also be useful in indeterminate cases with high specificity.

B-0878 10:38

Hollowed adrenal gland sign in patients of septic shock: prevalence, CT appearance and consequence

Q. Xie, H. Wang, J. Guan; *Guangzhou/CN (usefulkey0077@hotmail.com)*

Purpose: To investigate the prevalence, CT appearance and consequences of hollowed adrenal gland sign in septic shock patients.
Methods and Materials: From September 2014 to May 2017, there were 152 consecutive patients with septic shock in ICU (mean 60.6 years; range 19-89 years; 95 males, 57 females). All the patients received dual-phase contrast-enhanced CT scan in one week after diagnosis. CT findings and clinical records were reviewed retrospectively. Single factor analysis was performed. The hollowed adrenal gland sign was defined as: (1) diffuse enlargement of bilateral adrenal gland; (2) in arterial phase, the central area of adrenal gland shows much lower attenuation; (3) in venous phase, the central "hollowed" area shows further enhancement and is similar to the peripheral area.

Results: All the patients showed various degrees of and diffuse enlargement in bilateral adrenal gland. 52 patients (52/152) showed hollowed adrenal gland sign (positive group) while the remaining 100 patients were negative. The prevalence of hollowed adrenal gland sign in septic shock patients was 34.2% and finally 43 patients died from MODS (82.7%, 43/52). In negative group, 50 patients finally died from MODS (50.0%, 50/102). There was significant difference between two groups (P<0.01). The result of single factor analysis showed that the hollowed adrenal gland sign was an independent factor to predict prognosis (death) for septic shock patients.
Conclusion: Hollowed adrenal gland sign is common on CT in septic shock patients and predicts a dim prognosis.

B-0879 10:46

Histogram analysis of adrenal lesions with a single measurement: feasibility and incremental value for diagnosing adenomas

T.O. Rocha[1], T.C.V. Albuquerque[1], J.C. Nather[1], C.S. Garrido[1], J. Elias Jr[1], S. Tucci Jr[1], Z. Wang[2], A.C. Westphalen[2], V.F. Muglia[1]; [1]*Ribeirao Preto/BR*, [2]*San Francisco, CA/US (talescva@gmail.com)*

Purpose: Our purpose was to assess if histogram analysis of adrenal lesions, from a single measurement of mean and standard deviation (SD), using threshold of 10% of negative voxels can replace voxel counting while keeping diagnostic accuracy.
Methods and Materials: In a four-year period, 308 consecutive patients had 325 adrenal lesions diagnosed on CT exams. After exclusions, 91 patients (108 lesions), 20 malignant and 88 adenomas (confirmed by histology or follow-up) were enrolled. Two observers retrospectively measured size, mean attenuation, SD and generate histogram. The voxel distribution was assessed for normality. The 10th percentile was calculated from voxel counting (P10obs) and estimated from the formula: P10est = mean - (1.282 x SD). Diagnostic accuracy of mean attenuation and histogram analysis using P10obs and P10est were compared.
Results: 74 patients had 88 adenomas and 17 patients had 20 malignant lesions, 7 adrenocortical carcinomas, 13 metastasis. 93.1% of histograms had a normal distribution. The correlation among P10obs and P10est was perfect, r=0.9827 (reader 1) and 0.9843 (reader 2) (p<0.00001 for both). For both readers, sensitivity, specificity of the mean attenuation analysis was 65.9% (55.0-75.7%) and 100.0% (83.2-100%), and for P10obs and P10est was the same, for both observers, 87.5% (78.7-93.6%) and 95% (75.1-99.8%), respectively. The increment in sensitivity was significant (p<0.0001), while the drop of specificity was not (p=0.15).
Conclusion: The majority of voxels histograms from adrenal lesions follows normal distribution allowing an estimation using mean and SD. The accuracy of histogram was superior to mean attenuation analysis, either using P10est or P10obs.

B-0880 10:54

CT numbers of kidneys in virtual noncontrast images acquired from dual-source dual-energy dynamic CT of kidney: comparison with standard noncontrast CT

Y.-M. Lin; *Taipei/TW (garbato@gmail.com)*

Purpose: To compare virtual noncontrast (VNC) images derived from dynamic dual-source, dual-energy CT (dsDECT) of kidney with standard noncontrast (SNC) images, and determine the optimal phase for generating virtual noncontrast images.
Methods and Materials: Twenty-nine men and sixteen women underwent dynamic dsDECT (100/Sn140kVp) of kidney that included noncontrast, corticomedullary (CMP), nephrographic (NP), and excretory phases (EP). CT numbers were measured in the cortex and medulla. Image noise was measured on SNC and VNC images. Expected dose saving by removing the SNC phase was calculated.
Results: The difference in mean attenuation between SNC and VNC images was ≤ 4 HU. VNC attenuation values of the cortex in the CMP and medulla in the NP did not significantly differ from SNC values. VNC attenuation of the cortex was higher than that of the medulla in the CMP ($p < 0.05$), while there was no significant difference in NP. In the EP, inadequate iodine subtraction was obvious in the urinary collecting system. Image noise was significantly greater in SNC images ($p < 0.001$). Mean radiation dose reduction achievable by removing the SNC phase was 12.3% ± 0.9%.
Conclusion: VNC images from dynamic dsDECT of kidney were similar to SNC images, with greater attenuation variability. We recommend the NP as the optimal phase for creating VNC images in dynamic dsDECT of kidney.

B-0881 11:02

Optimal energy level for renal lesion detection and characterisation on virtual monoenergetic images

C. Schabel[1,2], F. Vernuccio[3], J. Ramirez Girlando[4], K. Nikolaou[1], D. Marin[2]; [1]*Tübingen/DE*, [2]*Durham, NC/US*, [3]*Palermo/IT*, [4]*Malvern, PA/US (christoph.schabel@med.uni-tuebingen.de)*

Purpose: Dual energy-reconstructed virtual monoenergetic images (VMIs) can yield more stable CT numbers and improved image quality compared to conventional single energy CT imaging. The aim of our study was to investigate the best VMI energy for the detection and characterization of renal lesions.
Methods and Materials: This retrospective, HIPAA-compliant study was IRB approved, with a waiver of informed consent. Between June 2012 and July 2016, a total of 194 renal lesions (62 solid, 132 cystic) underwent unenhanced single-energy and enhanced dual-energy CT during the nephrographic phase. VMI datasets were created from 70 to 100 keV. Lesion enhancement was measured by calculating the difference in attenuation (ΔHU) between the contrast-enhanced VMI and unenhanced single-energy images. Receiver-operating-characteristics were determined.
Results: The area-under-the-curve (AUC) was highest at 70keV (0.96) and decreased significantly with higher energies (0.94 at 80keV[$P = 0.004$]; 0.86 at 90 keV[$P < 0.0001$], and 0.79 at 100keV[$P < 0.0001$]). Number of missed minimally-enhancing solid renal lesion was lowest at 70keV(13/62) and increased with higher energies (19/62 at 80keV, 25/62 at 90keV, and 29/62 at 100keV) using a threshold of 15HU lesion enhancement. However, 12 of the 132 confirmed renal cysts were incorrectly classified at 70 keV VMI due to spurious levels of enhancement, compared to 5, 3, and 7 false positive cases at 80, 90, and 100keV, respectively.
Conclusion: Our study demonstrated that VMI at 70 keV may represent the optimal energy level for renal lesion detection and characterization.

Diffusion weighted magnetic resonance imaging in assessment of parenchymal damage in chronic kidney disease

K. Sulkowska, P. Palczewski, A. Furmanczyk-Zawiska, A. Perkowska-Ptasinska, W. Szeszkowski, M. Durlik, M. Golebiowski; *Warsaw/PL (k.sulkowska@outlook.com)*

Purpose: The aim of our study was to evaluate the feasibility of using diffusion weighted magnetic resonance imaging (DW-MRI) for noninvasive assessment of pathologic changes in CKD.
Methods and Materials: Thirty-four patients in different stages of CKD were examined on a 1.5 T MR unit. The examination consisted of morphologic sequences and respiratory triggered multislice diffusion-weighted echo-planar sequence with 10 b values. Diffusion parameters were calculated with the use of mono- (total apparent diffusion coefficient, ADC_T) and biexponential model (pure diffusion coefficient-D and perfusion fraction-Fp). In 31 patients, ultrasound guided biopsy was performed in less than 30 days from MRI (18 ± 4 days). Histopathological assessment was performed by an experienced nephropathologist who separately scored changes in glomeruli and tubulo-interstitium. Pearson's correlation coefficients (PCCs) were calculated by bivariate correlation to investigate relationship between diffusion parameters and histopathological assessment of renal damage. P-value<0.05 indicated statistical significance.
Results: We observed a moderate negative correlation between D and the percentage of glomeruli with focal global sclerosis (PCC -0.52, p=0.003). D also reversely correlated with combined parameters reflecting chronic changes in glomeruli (PCC -0.48, p=0,006) and tubulo-interstitium (PCC -0.47, p=0,007). ADC_T showed significant negative correlation only with interstitial infiltrations (PCC- 0.44, p=0,013). Fp showed very high standard variation and no significant correlation with histopathological assessment.
Conclusion: DWI-MR allows for a noninvasive assessment of parenchymal damage and glomerular loss in CKD. Using biexponential fitting of DW-signal is advantageous over monoexponential fitting owing to the elimination of negative influence of Fp on obtained results.

B-0883 11:18

Towards renal metabolic imaging of fatty kidney

I. Dekkers[1], P. de Heer[2], A.P.J. de Vries[1], H.J. Lamb[1]; [1]*Leiden/NL*, [2]*Amsterdam/NL (I.A.Dekkers@lumc.nl)*

Purpose: Elevated renal triglyceride content (fatty kidney) is a potential biomarker for obesity-related renal disease. However, non-invasive measurement techniques for the assessment of renal triglyceride content (TG) are currently limited. Here we report the results of the technical development of

renal metabolic imaging for the quantification of renal TG using proton-magnetic resonance spectroscopy (1H-MRS).
Methods and Materials: Renal metabolic imaging was performed in healthy human volunteers using a 3T MRI. Quantitative intra- and inter-examination single-voxel point resolved spectroscopy (PRESS) spectra were obtained in healthy human renal parenchyma using 1H-MRS with respiratory motion triggering. In total, 23 healthy participants (mean age 30.1±13.4 years, mean BMI 22.8±5.2 kg/m²) underwent 1H-MR spectroscopy, of which 19 participants underwent intra-examination reproducibility and 9 participants underwent inter-examination reproducibility. Renal TG content was calculated via in-house-developed post-processing script and corresponding reproducibility was determined using Pearson's correlation and Bland-Altman analysis.
Results: Overall mean renal TG content was 0.19±0.12% (range 0.07 to 1.02%). There were no significant differences between first TG% and repeated measurements (p=0.96 for intra-examination; p=0.75 for inter-examination). Both intra-examination (r=0.91) and inter-examination (r=0.73) measurements were highly correlated with first TG measurements. Intra-examination and inter-examination limits of agreement of renal log TG% were, respectively [-1.36%, +0.34%] and [-0.77%, +0.62%].
Conclusion: Renal proton MR spectroscopy is a reproducible technique for measuring renal triglyceride content non-invasively. This technique can be applied in future studies to further investigate the development of obesity-related renal disease.

B-0884 11:26

DKI of microstructural alterations in the kidneys of patients with hyperuricemia

X. Cai, Z. Chen; *Guangzhou/CN (caixran@jnu.edu.cn)*

Purpose: To evaluate the feasibility of diffusion kurtosis imaging (DKI) for early detection of renal microstructural alterations in patients with hyperuricemia.
Methods and Materials: A total of 75 subjects including 25 asymptomatic hyperuricemia (AH) patients, 25 gouty arthritis (GA) patients and 25 age- and sex-matched healthy volunteers were enrolled in this study. MR examinations were performed on a 3T MR scanner. DKI data were acquired to derive axial, radial, and mean kurtosis, as well as fractional anisotropy (FA), axial, radial, and mean diffusivity for comparisons among the 3 groups. Also, they were correlated with estimated glomerular filtration rate (eGFR).
Results: Mean MK and Kr values in the renal cortex and medulla significantly increased from control subjects to the AH and GA patients ($p < 0.05$). GA patients showed statistically greater cortical and medullary Ka values as compared with the other two groups ($p < 0.05$). Mean medullary FA value significantly decreased across the three groups ($p < 0.05$). The mean MD and Da values in the cortex and medulla and Dr value in the medulla were found to be significantly different between GA patients and control subjects ($p < 0.05$). No correlation was found between any DKI parameters with eGFR.
Conclusion: DKI demonstrates comparably stronger potential than diffusion tensor imaging in terms of early detection of renal cortex and medulla changes in patients with hyperuricemia. MK and Kr may be more sensitive to detect early-stage injury.

B-0885 11:34

Can renal artery resistive index predict disease activity in lupus nephritis?

S.M. Mehana; *Alexandria/EG (sayedmehana9@gmail.com)*

Purpose: To evaluate the predictive value of Doppler renal resistance index (RRI) in comparison with disease activity score, serologic and biology parameters in lupus nephritis.
Methods and Materials: The study included 43patients with SLE fulfilling the Systematic Lupus International Collaborating Clinics Classification 2012 Criteria; group I included 33 patients with lupus nephritis, group II included 10 SLE patients without lupus nephritis and group III included 10 healthy subjects as control group.Determination of the activity and chronicity indices performed according to the scheme of the International Society of Nephrology/Renal Pathology Society (ISN/RPS) 2003 classification of lupus nephritis.
Results: • The mean value of Doppler-Based RRI in the healthy group is significantly lower than the lupus nephritis and SLE patients who showed also a significant difference. • The mean age of those who had resistive index of 0.7 and above was significantly higher than those below 0.7.. The same pattern was observed for blood urea, creatinine and renal biopsy chronicity index. • The Area under the ROC curve (AUC) of Doppler-Based Renal Resistive index as a marker of renal biopsy chronicity index was 0.769 (95% confidence interval). • A renal resistive index of 0.70 threshold is better than 0.65 cut-off to predict renal biopsy chronicity index • No significant correlation was found between renal resistive index and activity index in renal biopsy.
Conclusion: Renal resistive index can be used as a non invasive reliable marker of chronicity in cases of lupus nephritis.

B-0886 11:42

Deep learning for automated MRI-based cyst load determination in PKD patients

M. Gattoni, A. Hartenstein, E. Siewert, T. Denecke, B. Hamm, D. Geisel, T. Penzkofer; *Berlin/DE*

Purpose: Quantification and follow-up of cyst load in polycystic kidney disease (PKD) patients through radiological imaging can be arduous to perform, especially in MRI. We applied deep learning to facilitate this task.
Methods and Materials: We collected 51 datasets of patients with polycystic kidney disease, standardized imaging and good image quality. Manual segmentation of the liver and liver cysts was performed on T2 Imaging. The data were divided into cases for training, for validation and for independent testing. A deep learning network was trained using the DeepMedic 3D-CNN platform. The results were compared to manual threshold segmentation of the same dataset using the DICE coefficient for segmentation similarity.
Results: Average cyst load in the datasets was 42.4 ± 21.7 percent in livers with a volume of 3404 ± 1705ml. DICE similarity coefficients were 0.84 ± 0.07 between manual and deep learning segmentations and 0.80 ± 0.10 between thresholding and manual segmentation (p=0.038). Typical segmentation times in PKD patients are 30+ min for manual segmentation, compared to ~5min for threshold segmentation and less than a minute (24.9 ± 14,6s) for the deep learning segmentation.
Conclusion: Automated liver cyst load measurement using a deep learning approach can be performed using a 3D-CNN approach on a single MRI sequence. Application of this method could lead to markedly reduced assessment time enabling consistent follow-up and potentially abbreviated MRI protocols for PKD patients.

An integrated CAD system of DWI MRI and laboratory biomarkers in the diagnosis of kidney transplant dysfunction

M. Shehata[1], M.E. Abou El-Ghar[2], T. El-Diasty[2], A. EL-Baz[3]; [1]*Iousivelle, KY/US*, [2]*Mansoura/EG*, [3]*Louisville, KY/US (maboelghar@yahoo.com)*

Purpose: Accurate non-invasive assessment of kidney transplant dysfunction (KTDF) is crucial for the identification of proper treatment. Therefore, we introduce a novel fully automated computer-aided diagnostic (CAD) system for KTDF assessment using 4D (3D + b-value) DW-MRI data integrated with laboratory-based biomarkers.
Methods and Materials: The proposed CAD system integrates both clinical-(e.g. SPCr and CrCl) and image-based biomarkers. To extract the latter, our CAD system aligns the DW-MRI data to handle motion effects and then segments kidney from surrounding tissues, after that, estimates ADCs to construct the discriminatory features for transplant status classification, finally, image and clinical biomarkers are fused together to assess transplant status by cascading two stages of deep learning-based classifiers. The first stage distinguishes non-rejection (NR) from rejection and its mimics; the second stage classifies this rejection and its mimics as early rejection (ER) or other kidney diseases (OD) (e.g. acute tubular injury, etc.).
Results: DW-MRI datasets have been collected from 58 biopsy-proven cohort. All subjects, NR (16), ER (37), and OD (5), were assessed with SPCr laboratory values. Approximately, 50 coronal DW-MR images were acquired to cover the whole kidney before any biopsy procedure using a GE 1.5T scanner at different b values. Using leave-one-subject-out experiments, our CAD system achieved a 95% accuracy (sensitivity = 95% and specificity = 94%) between NR and rejection and its mimics, and a 95% accuracy between ER and OD transplants.
Conclusion: Our initial diagnostic results hold promise of the proposed CAD system as a reliable, inexpensive, and noninvasive diagnostic tool.

A 2 minute, ultra-fast wholebody PET/CT enabled by digital photon counting PET detector technology

M.I. Knopp[1], C.L. Wright[1], K. Binzel[1], F.L. Giesel[2], J. Zhang[1], P. Maniawski[3], M.V. Knopp[1]; [1]*Columbus, OH/US*, [2]*Heidelberg/DE*, [3]*Cleveland, OH/US*
(knopp.29@osu.edu)

Purpose: To assess the clinical feasibility of a 10x reduction in whole body PET acquisition time with comparable diagnostic and quantitative characteristics to current clinical PET acquisition enabled by digital photon counting PET (dPET).
Methods and Materials: Thirty-eight patients scheduled for FDG whole body PET/CT were imaged using three separate acquisitions as part of intra-individual comparison study with a pre-commercial release dPET/CT (Vereos) and cPET/CT (Gemini). Standard cPET imaging was performed at ~75 min p.i. of ~ 450 MBq FDG with investigational dPET imaged at ~55 min p.i. The first dPET acquisition was performed using 90s/bed position, immediately followed by a 9s/bed position acquisition lead to average table times of ~15 and ~2 min and compared with 90s/bed position cPET. The 9s/bed dPET were reconstructed using a previously optimised methodology. All other aspects of image acquisition were kept identical. Three blinded reviewers evaluated the data sets regarding visual characteristics, diagnostic confidence and semi-quantitative readouts.
Results: Visual assessment scores were significant higher for 90s/bed dPET whole body ($p<.01$) with no significant difference between 9s/bed dPET and 90s/bed cPET. Quantitatively, the 9s/bed dPET presented slightly increased background noise, however there was no impact on diagnostic confidence or SUV measures.
Conclusion: Next generation digital photon counting detector technology enabled a radical reduction in wholebody acquisition time with comparable diagnostic confidence and quantitative precision to current generation cPET acquisitions taking 10 times longer. This allows for new PET workflow concepts, improved patient comfort, minimised patient motion and whole-body pseudo dynamic imaging of tracer uptake.
Author Disclosures:

Practice-based evidence for clinical benefit of PET/CT - results of the first oncologic PET/CT registry in Germany

C. Pfannenberg, L. Wang, B. Gückel, S. Gatidis, S.-.C. Olthof, M. Reimold, C. La Fougère, K. Nikolaou, P. Martus; *Tuebingen/DE*
(christina.pfannenberg@med.uni-tuebingen.de)

Purpose: To evaluate the impact of PET/CT on clinical management based on a prospective data registry. The registry was developed to meet the requirements for PET/CT coverage by health insurance.
Methods and Materials: We evaluated a prospective patient cohort having a non-investigational PET/CT at one university center from 4/2013 till 08/2016. The registry collected questionnaire data from requesting physicians on intended patient management before and after PET/CT. 4504 patients with 5939 PET/CT examinations were enrolled in the registry, including evaluable data from 3724 patients with 4754 studies. The impact of PET/CT was assessed across various cancers for different indications and categories of non-treatment (watching, additional imaging, biopsy) and treatment.
Results: The most frequent PET/CT indication was cancer staging (60.5%). Melanoma, lung, lymphoma, NET and prostate cancers accounted for 70% of cases. Overall, PET/CT was associated with a 36.9% change (OR 4.4; 95% CI, 3.8-5.0) in decision to treat or not to treat, including 30.4% change to treatment from non-treatment. The frequencies of changes ranged from 46.0% for melanomas to 28.3% for head and neck cancers. The impact of PET/CT was highest in reducing demands for additional imaging which decreased from 50.9% to 5.8%. Pre-PET/CT planned invasive biopsy could be avoided in 73.3% of cases. When the intended management was treatment, the therapeutic goal (curative vs.palliative) changed after PET/CT in 21.6% of cases.
Conclusion: The data of this large representative registry confirmed that physicians often change their intended management on the basis of PET/CT consistent across different cancer types.

B-0890 10:46

Patients' perception of radiologists in a oncologic imaging department

C. Giaconi, F. Cerimele, A. Bulleri, C. Basile Fasolo, E. Neri; *Pisa/IT*
(radiodiagnostica3.aoup@gmail.com)

Purpose: To analyse the patients' perception of the radiologist role in a oncologic imaging Department.
Methods and Materials: Between June and July 2017, two surveys have been addressed to 400 patients admitted to a Oncologic Imaging Department. The "Entry" survey was handed out to patients waiting for their turn in the radiology unit and included questions related to the environment and reception workflow. The “Exit” survey, instead, was given at the end of the examination to patients waiting for their report or that were just about to leave the department. It included questions related to the visibility of radiologist, to the clarity of medical consultation, the perception of the different professional roles (radiologist and radiographer).
Results: Ninety percent (369/400) of patients declared that the Radiologist did not clearly introduced himself to the patient, but were satisfied by the quality of consultation in the entry and exit phases. Eighty-four patients who had ultrasound, that were asked to rate the helpfulness and kindness of the radiologist, responded very satisfied in 68 cases (80.25%) satisfied in 10 (11.9%), somewhat satisfied in 6. Most patients (294/400; 93.04%) recognized that the diagnosis was carried out by the radiologist, but 13 patients (4.11%) answered “the technician” and 9 (2.85%) “the machine”.
Conclusion: The survey demonstrate that the vast majority of patients have a correct perception of the radiologists' roles in the imaging department. However such well recognized value of the radiologist seems to be less balanced by an appropriate doctor to patient communication.

B-0891 10:54

How to structure the attendance of radiologists to oncologic multidisciplinary team meetings

C. Giaconi, F. Cerri, C. Arena, A. Bulleri, E. Neri; *Pisa/IT*
(claudiagiaconi@tiscali.it)

Purpose: In XX University Hospital there is a strong demand of attendance of radiologists to oncologic multidisciplinary teams (MDTs). The aim of the study is to analyse the additional workload of radiologists attending MDTs.
Methods and Materials: The oncologic imaging Unit of the xx University Hospital fulfill the imaging requests of the Oncologic Unit with 8 board certified radiologists. Each staff member is committed to perform US, CT and MRI on a 38 hours x week working time.However, in the last 3 years a strong demand of attendance of radiologists to MDTs has been raised by the Oncology Department, on a weekly basis, for the following cancer types (GI tract, head and neck, melanoma, pediatric, lymphoma, prostate, gynecology). Radiology staff commitments and workload has been re-scheduled accordingly.
Results: The mean weekly workload increase by each radiology staff was 7 hours (+20%). The time allocated by each radiologist to participate MDTs included 3 hours for MDTs preparation (prior review of patient's images, and clinical information) and 4 hours mean attendance.The workload increase was not compensated by a reduction in imaging acquisition and reporting time.
Conclusion: Attendance of radiologists to MDTs is mandatory for the management of oncologic patients, and represents a value-based professional role. However, the time allocated to prepare and attend MDTs is not accounted as indicator of radiologists workload and performance.

B-0892 11:02

Open access prescription in oncologic imaging: one-year trial

F. Cerri, C. Giaconi, C. Arena, A. Bulleri, E. Neri; *Pisa/IT*
(claudiagiaconi@tiscali.it)

Purpose: To implement an open access prescription system (Pleiade) to allow order entries from the Oncologic to the Imaging Unit in a Academic Hospital.
Methods and Materials: In the last 3-years the oncologic imaging demand in XX University Hospital raised rapidly, with specific request of Total Body CT for primary staging and follow-up in various cancer groups; the Oncologic Imaging Unit could not itself fulfill the entire CT request. Therefore since January 2017 a so called "open access" hospital information system, called "Pleiade", was implemented, allowing the electronic prescription of CT exams from the Oncologic to the Imaging Department on a 365 day scheduled agenda, that included 54 patients slots per week. A clinical decision support system is not yet implemented.
Results: To date the agenda is fully booked since December 2017, with 218 patients scheduled per month. A retrospective analysis of a 6 months activity that included 1308 patients, showed that the vast majority of CT (1110/1308 patients; 84%) was performed with the clinical indication of oncologic follow-up. Therefore the strong demand of CT exams for the follow-up impacted on the availability of primary staging slots.

Conclusion: The Pleiade system unburdened the administrative workload of the oncologic imaging Department. However the open access to the imaging schedule, and the absence of appropriateness criteria, generated a significant prescription of follow-up CT, that impacted on the availability of primary staging CT.

B-0893 11:10

Integrated versus separate reporting of FDG-PET/CT and MRI for abdominal malignancies: effect on diagnostic confidence and staging outcomes

L.A. Min[1,2], W. Vogel[1], M.J. Lahaye[1], M. Maas[1], M. Donswijk[1], E. Vegt[1], R.G.H. Beets-Tan[1,2], D.M. Lambregts[1]; [1]*Amsterdam/NL*, [2]*Maastricht/NL (l.min@nki.nl)*

Purpose: Increasing numbers of patients receive multimodality imaging (FDG-PET/CT and MRI) to stage abdominal malignancies, with potential implications for optimal image interpretation. This study evaluates effects of integrated reporting of FDG-PET/CT and abdominal MRI on diagnostic confidence and staging outcomes.
Methods and Materials: 149 cases where abdominal MRI and FDG-PET/CT were performed within a 14-day interval were retrospectively included. Original MRI and PET reports were retrieved from the hospital database and reported findings (per lesion; total 1228) translated into a 5-point confidence score (1=definitely benign to 5=definitely malignant). Teams of 2 readers (radiologist + nuclear physician) together performed integrated re-assessment of the images, blinded for the initial reports.
Results: Integrated re-assessment led to discrepant findings in ≥1 lesions compared with either the original FDG-PET/CT or MRI reports in 62/149 cases, which would have had no clinical impact in 26 (17.4%), minor impact in 17 (11.4%) and potential major impact in 19 (12.8%). On a per lesion basis, the integrated approach resulted in increased/decreased diagnostic confidence in 8.7%/6.2% compared to the initial FDG-PET/CT and 11.5%/11.0% compared to the initial MRI reports. Inconclusive (confidence 3) scores were comparable: 8.3% (FDG-PET/CT) and 8.1% (MRI) for the initial reports vs 6.9% for the integrated approach.
Conclusion: Integrated assessment of FDG-PET/CT and MRI by a nuclear physician and radiologist together leads to discrepant findings compared to separate imaging assessment in a substantial number of cases, which could have potential major clinical impact in 12.8%. Impact on overall diagnostic confidence and number of inconclusive outcomes appears to be limited.

B-0894 11:18

New insights for spectral CT imaging in staging of patients with hypervascularised abdominal tumours

G. Böning[1], S. Adelt[1], U. Fehrenbach[1], J. Kahn[1], F. Feldhaus[1], M.H. Maurer[2], D.M. Renz[3], B. Hamm[1], F. Streitparth[1]; [1]*Berlin/DE*, [2]*Berne/CH*, [3]*Jena/DE*

Purpose: In oncologic imaging, spectral CT based parameters of iodine concentration and spectral slope over virtual mono-energetic levels may deliver information superior to standard CT. Aim of this study was to analyse potential differences of spectral CT parameters in hypervascularised abdominal tumours to improve lesion characterisation.
Methods and Materials: 111 patients with hypervascularised abdominal tumours were included. We analysed 77 cases with neuroendocrine tumours/ carcinomas (NET/NEC), 18 cases with hepatocellular carcinoma (HCC) and 16 cases with renal cell carcinoma (RCC). Patients underwent a standardised multiphase abdominal CT with spectral mode arterial phase. We analysed iodine concentrations of the tumours, the increase slope of mean HU in tumors between 40keV and 140keV as well as the applied dose.
Results: The iodine concentrations of the tumours were 2.5±1.5mg/cm^3 (NET/NEC), 2.2±0.7mg/cm^3 (HCC) and 3.8±1.8mg/cm^3 (RCC). The increases slope of mean HU in tumours between 40keV and 140keV were 2 (NET/NEC), 1.8 (HCC) and 3 (RCC). In a subgroup of 41 patients (26 NET/NEC, 9 HCC, 6 RCC) with strong tumour hypervascularisation the mean HU values at 40 keV were significantly ($p < 0.001$) different between RCC (421±167 HU) and HCC/NET (245±70 HU/266±140 HU). The mean $CTDI_{vol}$ of the spectral mode arterial phase was 9.6±4mGy and 9.9±4.3mGy/9.9±4.6mGy for portal venous and hepatic venous phases.
Conclusion: Spectral CT based parameters are promising to deliver additional information for characterisation of hypervascularised abdominal tumours at dose levels comparable to standard CT. To determine whether they can be used in clinical routine potential confounding factors should be analysed.

B-0896 11:26

Application of 80-kVp scan and raw data-based iterative reconstruction for reduced iodine load PET/CT in an oncological setting: a win-win technique

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: To evaluate the image quality, radiation dose, and renal safety of contrast medium (CM)-reduced abdominal-pelvic CT combining 80 kVp and advanced Iterative Reconstruction (IR) in patients with renal dysfunction being worked up or followed up in an oncological setting.
Methods and Materials: The study included 30 patients with renal dysfunction (estimated glomerular filtration rate [eGFR] lt 45 mL/min/1.73 m^2) who underwent PET/CT with low dose of contrast medium (Iodixanol 320, 360 mgI/kg, 80 kVp, IR). 30 other patients without renal dysfunction (eGFR gt 60 mL/min/1.73 m^2) who underwent standard PET/CT (120 kVp, filtered-back projection) with normal contrast dose (Iodixanol 320, 600 mgI/kg) were included as controls. The following image criteria were compared - CT attenuation, image noise, and contrast-to-noise ratio (CNR). Size-specific dose estimate (SSDE) and renal function 1-3 months after CT were measured.
Results: The SSDE and iodine load of the 80-kVp protocol were 30% and 45%, respectively, lower than of the 120-kVp protocol (p lt0.01). CT attenuation and CNR of solid viscera and vessels in 80-kVp images were better than those of 120-kVp images (plt0.05). There were no significant differences in quantitative or qualitative image noise or subjective overall quality (p>0.05). No significant contrast induced renal parenchymal injury was observed.
Conclusion: 80-kVp scans combined with advanced Iterative Reconstruction result in 40-50% reduction in radiation dose and 40% iodine load with no compromise on diagnostic image quality. At the same time risk of contrast induced renal damage was also reduced.

B-0897 11:34

Improved image quality of whole body low-dose CT study combined with iterative model reconstruction algorithms for follow-up of oncologic patients

I. Salemi[1], D. Ippolito[1], C.R. Talei Franzesi[1], C. Maino[1], C. Cangiotti[1], S. Sironi[2]; [1]*Monza/IT*, [2]*Bergamo/IT (i.salemi1@campus.unimib.it)*

Purpose: To compare radiation dose and image quality of low-dose CT protocol combined with iterative model reconstruction algorithm (IMR) with standard-dose approach combined with hybrid-iterative reconstruction algorithm (iDose) for follow-up of oncologic patients.
Methods and Materials: Seventy-three patients with known oncological diseases who underwent, during their clinical follow-up, both low-dose CT, performed on 256-row scanner (iCT Elite, Philips) with 100 kV and automated mAs modulation (depending on patient weight), and standard-dose CT, performed on 256-row scanner with 120 kV and automated mAs modulation, were enrolled. Images were reconstructed with IMR algorithm for low-dose CT examination and iDose algorithm for standard-dose CT examination. We evaluated density values and signal-to-noise ratio (SNR), along with image noise, dose parameters and diagnostic quality with 5-point scale.
Results: Noise of images expressed as SD values, measured in liver and spleen, was significantly lower in IMR images (liver 10,98 vs 14,05, p<0,001) whereas SNR was statistically higher (9,03 vs 8,47) compared to iDose reconstructions. Volumetric-Computed-Tomographic-Dose-Index (CTDIvol) and Dose-Length-Product (DLP) were significantly lower in IMR compared to iDose reconstructions (DLP 491,48 vs 856,92 mGy*cm, p<0,001), with overall dose reduction of 42,6%. Qualitative analysis did not reveal significant differences in diagnostic quality (p=0,04).
Conclusion: Automatic tube-current modulation combined with IMR algorithm and low kV setting allows dose reduction (42,6%) in whole body CT imaging without loss of diagnostic quality, thus representing a useful diagnostic approach in reducing dose exposure in oncologic patients who underwent several follow-up studies.

B-0898 11:42

Slowly injected unsplited bolus protocol for the reduction of contrast medium (CM) and mean radiation dose exposure (SUPREME Protocol)

A. Contegiacomo, N. Attempati, E. Amodeo, D. Coppolino, A. Cina, R. Manfredi; *Rome/IT (andrea.contegiacomo@policlinicogemelli.it)*

Purpose: To validate SUPREME protocol in terms of vascular/parenchymal enhancement, image quality, contrast medium (CM) administration and radiation exposure (RE), in oncological patients.
Methods and Materials: SUPREME Protocol was adopted for prospective examination of 40 consecutive patients with a previous standard protocol CT examination, performed in our institution. SUPREME protocol: patient weight: >70/<70 kg; CM volume: 130/120; CM injection-rate: 2/1,8 mL/s; Saline solution volume: 60/50 mL; Saline solution injection-rate: 3 mL/s; Acquisition delay: 80s; body surface: thorax-abdomen. Two radiologists in consensus compared SUPREME Protocol examinations with both immediately previous

and next follow-up CT examinations of the same patient performing: images qualitative (0/3=poor/excellent) and quantitative (Hounsfield Units sampling at aorta, great vessels and liver/spleen parenchyma) assessment; CM administration and RE comparison between the two protocols. Statistical analysis was performed with T-student test and Cohen's k coefficient.
Results: The agreement between the two protocols for the images qualitative assessment was good (k-Cohen>0.6) for the two radiologists in consensus. No quantitative differences were observed between the two protocols with only a better enhancement of the inferior mesenteric artery in the standard protocol (p<.05). A global 15% of CM volume and 37.8% of dose exposition reduction was observed in the SUPREME protocol with respect to standard protocol (p<.05).
Conclusion: SUPREME Protocol is a valid tool in oncological parients, for CM administration and RE reduction, providing the same image quality of standard protocol.

Metal artefact reduction in computed tomography (Smart MAR): improvement of image quality and diagnostic confidence in patients with metallic dental implants
F. Feldhaus[1], G. Böning[1], U. Fehrenbach[1], J. Kahn[1], M.H. Maurer[2], D.M. Renz[3], B. Hamm[1], F. Streitparth[1]; [1]*Berlin/DE*, [2]*Berne/CH*, [3]*Jena/DE*
(felix.feldhaus@charite.de)

Purpose: To determine whether the metal artefact reduction tool - a three-stage, projection-based, postprocessing algorithm - improves subjective and objective image quality and diagnostic confidence in patients with dental artefacts.
Methods and Materials: 100 consecutive patients with nonremovable oral implants or dental fillings were included. Indications were oropharyngeal tumours. CT scans were performed on a single-source, 64-row multislice CT scanner (MS-CT, Evolution, GE Healthcare). CT raw data were postprocessed using Smart MAR. Image quality of Smart MAR-based reconstruction series was evaluated both quantitatively (5 ROIs) and qualitatively (two independent raters) and compared to standard reconstructions. Dose was analysed in terms of dose-length-products (DLP) and computed tomography dose indices (CTDIvol).
Results: In Smart MAR reconstructions, both attenuation and noise were significantly reduced in areas adjacent to implants and in more distant areas (all p<0.001) compared to standard reconstructions. There was statistically significant improvement in signal-to-noise ratio (SNR; p=0.001) and contrast-to-noise ratio (CNR; p=0.001). Smart MAR significantly improved visualization of tumour (detected in 36 of 100 patients, 36%) and representative oropharyngeal tissue (p<0.001). In 8 of 36 patients (22%), tumour was only detected in reconstructed series using Smart MAR. The mean DLP of the entire scan was 506.8mGy*cm; average CTDIvol was 5.5mGy for oropharyngeal region.
Conclusion: Smart MAR significantly improved both objective and subjective image quality of oropharyngeal CT scans even in the presence of severe artefacts, resulting in higher diagnostic confidence. Allowing automated imaging postprocessing without increasing radiation exposure compared to standard CT scans, Smart MAR appears to be well suitable for clinical routine.

Next generation imaging of head and neck cancer using dual-layer spectral CT
F. Lohöfer, G. Kaissis, F. Köster, M. Rasper, I. Einspieler, C. Gerngross, A. Fichter, E.J. Rummeny, R. Braren; *Munich/DE*

Purpose: The aim of this study was to evaluate the performance of dual-layer spectral CT (DLSCT) in the detection and staging of head and neck cancer (HNC) compared to conventional contrast enhanced CT (CECT).
Methods and Materials: 39 patients with histopathologically proven diagnosis of HNC were examined with a DLSCT scanner and retrospectively analyzed. A 50-patient healthy control group was used. Images were acquired in the portal venous phase. Monoenergetic 40kV-equivalent (*MonoE40*) images and iodine maps were compared to CECT images. Diagnostic confidence for tumor identification and margin detection was rated independently by 4 experienced observers. The steepness of the Hounsfield Unit (HU)-increase at the tumor margin was analyzed. External carotid artery branch image reconstructions were performed and their contrast compared to conventional arterial phase imaging.
Results: *MonoE40* images were superior to CECT images in tumor detection and margin delineation. *MonoE40* showed significantly higher attenuation differences between tumor and healthy tissue compared to conventional CT images (p<0.0001) The HU-increase at the boundary of the tumor was significantly steeper in *MonoE40* images compared to conventional CT images (p<0.0001). Iodine uptake in the tumor was significantly higher compared to healthy tissue (p<0.0001). *MonoE40* images allowed depiction of the external carotid artery and its branches in the portal venous phase.
Conclusion: DLSCT enables improved detection of primary and recurrent HNC as well as quantification of tumor iodine uptake. Improved contrast between tumor and background compared to CECT provides diagnostic confidence concerning tumor margin detection and vessel identification, which can facilitate surgical planning.

B-0901 10:46

Staging of head and neck cancer by dual energy CT: comparison of dual and single source dual energy
M. Wiesmüller, W. Wüst, M.S. May, M. Uder; *Erlangen/DE*
(marco.wiesmueller@uk-erlangen.de)

Purpose: Aim of this study was to compare image quality of third-generation Single-Source Dual-Energy CT (SS-DECT) with third-generation Dual-Source dual energy CT (DS-DECT) in staging examinations of head and neck cancer.
Methods and Materials: 102 patients with histologically proven head and neck cancer were prospectively randomized to undergo radiation dose matched SS-DECT (n=51, 120 kV, split filter technique, 384 ref. mAs) or DS-DECT (n=51, 80/Sn150 kV, tube A 100/ tube B 67 ref. mAs) for tumor staging. Inline weighted average images (WAI) and virtual monoenergetic images (VMI) for two different low energies (40 and 60 keV) were reconstructed. Objective image quality was evaluated as dose normalized contrast to noise ratio (CNRD) and subjective image quality was rated on a 5-point Likert-scale.
Results: In both groups highest CNRD for vessel and tumor attenuation was obtained on 40 keV VMI. CNRD for tumor attenuation was comparable between SS-DECT and DS-DECT while CNRD for vessel attenuation was on average 1.4 times higher with DS-DECT for low energies (40 and 60 keV). Overall subjective image quality in the SS-DECT group was highest on the WAI followed by 40 keV and 60 keV. Subjective image quality was significantly better with DS-DECT.
Conclusion: In SS-DECT as well as DS-DECT highest overall image quality in head and neck imaging can be obtained with a combination of WAI and low keV reconstructions. DS-DECT is superior to SS-DECT in terms of subjective image quality and vessel attenuation, but comparable for tumor attenuation.

B-0902 10:54

Oral cavity cancer staging by CT for the new TNM-8: using an extrapolated measurement to evaluate the depth of invasion
J.M.M.M. Santos, A. Mourão de Abreu, M.R.T. Garcia, L. Franceschi, L.L. Matos, C.J. Silva, E.M.M. Gebrim, R.L.E. Gomes; *São Paulo/BR*
(joao_ssa@hotmail.com)

Purpose: To retrospectively compare computed tomography oral cavity primary cancer staging, comparing the 7th and 8th edition of TNM, based on an imaging extrapolated measurement of the new pathological depth of invasion criteria.
Methods and Materials: The records of 100 patients with oral cavity primary cancer operated in our institution from 2009 to 2015 were reviewed retrospectively. Pathological and imaging tumor and nodal staging were reclassified according to 8th edition of TNM (TNM-8), and correlated to the previous TNM-7. TNM-8 changes implemented extranodal extension and depth of invasion (DOI), which was based on the pathological specimen measure from the level of outer line of the closest adjacent normal mucosa to the deepest point of the tumor. Here, we proposed a post-contrast CT extrapolation of the pathological DOI criteria using the measure from the transition line between lesion and adjacent normal mucosa to the deepest point of the tumor (extrapolated depth).
Results: Among T1 or T2 patients, there was a discrepancy between 7th and 8th TNM staging in 70%. Of these, 67 (95.8%) were up-staged (p < 0.0001). The nodal factor was up-staged in 10% of the patients. Locoregional recurrence-free survival and oral cavity cancer-specific survival prediction of TNM-8 was significantly more accurate (p < 0.0001).
Conclusion: Compared with the 7th edition, TNM-8 provides valuable results regarding tumor and nodal staging. Post-contrast CT is a great tool to analyze the depth of the lesion and perform the correct staging, provided that the measurements are made in the right way.

B-0903 11:02

Does performing staging MRI for lateral tongue tumours after biopsy of the primary tumour overestimate tumour dimensions and staging?

B. Dhillon, D. Pawaroo; *Norwich/UK (baljeet.dhillon@doctors.org.uk)*

Purpose: Tumour (T) staging of oral cavity carcinoma is dependent upon the maximal dimension of the tumour. The majority of the staging MRIs for lateral tongue tumours in our institution are performed after the biopsy of the primary tumour. It can be difficult to discern whether the abnormal T2 high signal and contrast enhancement at the primary tumour site is due to malignancy or whether part of it may be due to the biopsy. This makes T staging of the tumour difficult. It is important for the surgeons to have accurate T staging particularly the thickness of the tumour to ensure the correct operation is carried out for complete excision.
Methods and Materials: 35 patient who underwent hemiglossectomy for lateral tongue carcinoma were identified. Tumour dimensions on T2-weighted MRI and contrast-enhanced MRI were measured in AP and lateral planes. Corresponding tumour measurements from histology reports of the surgical specimen were compiled. Paired t test was used to compare the MRI and histological measurements.
Results: All patients had biopsy before staging MRI. Paired t test showed no significant difference between the MRI and histologic measurements (p=0.3978 for AP dimension, p=0.4364 for lateral dimension). Only 3 cases (of 35) had their T-staging downstaged based on histology post-operatively. 6 cases actually had their T-staging upstaged based on histology post-operatively.
Conclusion: Performing MRI post-biopsy does not significantly increase the tumour measurements and hence does not affect the tumour staging preoperatively.

B-0904 11:10

Assessment of mandibular involvement by oral cavity and oropharyngeal squamous cell carcinoma: CT scan and MRI evaluation

R.K.N. Solanki, I.N. Patel; *Ahmedabad/IN (solankirn@yahoo.co.in)*

Purpose: To identify CT and MRI findings to predict mandibular involvement by oral cavity and oropharyngeal squamous cell carcinoma.To establish MRI as a superior modality to CT scan for mandibular involvement.
Methods and Materials: MR and CT images in 36 patients with SCC of the oral cavity(Ca buccal mucosa, retromolar trigone, gingivobuccal sulcus, floor of mouth) were evaluated for the presence and extent of mandibular cortex, bone marrow invasion and inferior alveolar canal involvement. The results were correlated with histopathologic findings. Using a multidetector spiral CT scanner & 1.5 T MRI in all patients with T1 WI, T2WI and fat suppressed images were obtained
Results: We analyzed location of tumor on lower alveolus, tumor within 1 cm of mandible, sensory distribution of inferior alveolar nerve and identified periosteal striping like subperiosteal reaction, cortical expansion and pathologic fracture as predictor of bone invasion. CT scan detects mandibular invasion grossly, missing it in 27% cases and is also associated with pitfalls of dental amalgam artifact. T1 WI, T2 WI and contrast- enhanced T1-weighted images are of highest value detection of involvement of bone marrow , inferior alveolar canal and soft tissue extent.Detection of tumour signal replacing the hypointense cortical rim was considered the main MRI finding
Conclusion: MRI is now commonly considered the modality of choice for bony involvement ,extension to retromolar trigone, alveolar ridge and inferior alveolar canal invasion with additional information about recurrent or residual disease in oral cavity and oropharyngeal squamous cell carcinoma, even more sensitive than CT scan.

B-0905 11:18

Automatic adaptive iterative metal artifact reduction

A.F. Halaweish[1], B. Schmidt[2], K. Grant[1], T. Flohr[2], C. Hofmann[2]; [1]*Malvern, PA/US*, [2]*Forchheim/DE*

Purpose: Current metal artifact reduction (MAR) algorithms either present the user with a list of application specific presets, resulting in varying image impressions based on usage, or forgo the flexibility for simplicity and provide one processing option regardless of scenario. The objective of this work is to evaluate the performance of an automatic-adaptive MAR algorithm, aimed at automating the metal detection and artifact reduction processing and eliminating end result variability.
Methods and Materials: Building upon the currently implemented iterative MAR (IMAR) algorithm, automatic IMAR incorporates an automated online adaption of MAR parameters into the post-processing pipeline. This is accomplished through slice-by-slice adaption of the parameters based on image and sinogram metrics. In addition to the adaptive parameterisation, dedicated z-filtering and sinogram mixing improvements facilitate the incorporation of a more accurate sinogram restoration, by preserving as much of the original information as possible. Finally, an adaptive high-frequency streak reduction solution is incorporated into the workflow. To give the user additional flexibility, rather than relying on predetermined application specific presets, strength of artifact reduction was incorporated as an option for processing.
Results: Automatic IMAR processed images from Head and Neck, Thoracic, Abdominal and MSK specific scans demonstrated excellent image quality and significantly reduced streak artifacts through the imaged region of interest, when compared to their WFBP and traditional IMAR processed equivalents.
Conclusion: The automation of the metal artifact reduction process, through adaptive parameter selection and improved metal artifact reduction efforts, facilitates an application which specifically tailors image quality with minimal user interaction.

B-0906 11:26

Virtual monoenergetic images can reduce metal artefacts caused by dental implants in computed tomography

N. Grosse Hokamp[1,2], K.R. Laukamp[1], S. Lennartz[1], D. Zopfs[1], D. Maintz[1], J. Borggrefe[1]; [1]*Cologne/DE*, [2]*Cleveland, OH/US (nils.grosse-hokamp@uk-koeln.de)*

Purpose: To compare the extent of metal artefact reduction by use of high-keV virtual monoenergetic images (VMI) from spectral detector computed tomography (SDCT).
Methods and Materials: 40 consecutive patients with dental implants were included in this retrospective, IRB-approved study. All examinations were performed using a SDCT (IQon, Philips Healthcare). Images were reconstructed as conventional images (CI) and as VMI in a range of 40-200 keV (10 keV increment). Quantitative image analysis was performed ROI-based by measurement of attenuation (HU) and standard deviation (SD) in most pronounced hypo- and hyperdense artefact, fat and soft tissue with presence of artefacts. Qualitatively, extent of artefact reduction, assessment of soft palate and cheeks were rated on 5-point Likert scales by 2 radiologists. Statistically data were assessed using ANOVA and Wilcoxon test with correction for multiple comparisons; interrater agreement was determined by intraclass correlation coefficient (ICC).
Results: The hypo- and hyperattenuating artefacts showed an increase and decrease of HU values in high-keV VMI (CI/ VMI_{200keV}: -218.7/-174.4 HU, p=0.1; and 309.8/119.2, p≤0.05, respectively). Artefacts in the fat, as depicted by image noise did also decrease in high-keV VMI (CI/VMI_{200keV}: 23.9/16.4, p≤0.05). Qualitatively, hyperdense artefacts were decreased significantly in VMI≥100keV (e.g. VMI_{200keV}/CI: 3(1-5)/2(1-3), p≤0.05). Arieface reduction resulted in improved assessment of the soft palate and cheeks (e.g. VMI_{200keV}/CI: 3(1-5)/2(1-4) and 3(1-5)/2(1-5), p≤0.05). Overall interrater agreement was good (ICC=0.78).
Conclusion: VMI as provided by SDCT allow for reduction of artefacts caused by dental implants and improves diagnostic assessment of soft tissue.

B-0907 11:34

Diagnostic accuracy of FDG-PET and contrast-enhanced CT in patients with head and neck cancer of unknown primary origin

D. de Haan[1,2], A. van der Hoorn[2], H.E. Westerlaan[2]; [1]*Almelo/NL*, [2]*Groningen/NL (ddhaan@gmail.com)*

Purpose: To assess the diagnostic accuracy of FDG-PET and contrast-enhanced CT in patients with a malignant cervical lymph node of unknown primary origin. We propose that additional imaging techniques could improve the diagnostic accuracy in these patients.
Methods and Materials: We retrospectively analysed 48 patients who presented with a malignant cervical lymph node, without presence of a clinically apparent primary tumour. Patients underwent an total body FDG-PET scan or total body FDG-PET combined with a contrast-enhanced CT-scan of the head and neck. The imaging studies were correlated with biopsy or surgical pathology results of the suspected primary tumour if detected in clinical follow-up.
Results: FDG-PET detected a primary tumour in 21 out of 48 patients (44%), while contrast-enhanced CT detected a primary tumour in 13 patients (29%). 3 patients had a negative FDG-PET and a positive CT, and 9 patients had a positive FDG-PET and a negative CT. The combined sensitivity of FDG-PET and CT was 50%. Out of 23 patients with negative imaging (50%), 13 had a confirmed site of primary tumour during treatment and follow-up (27%), confirming malignancy in 34 patients (71%). In 14 patients, no primary site was confirmed (29%).
Conclusion: Patients with cancer of unknown primary often have negative findings on oncologic imaging workup. A primary site may be detected during follow-up. We demonstrate the diagnostic accuracy of FDG-PET and contrast-enhanced CT-scan. Adding other imaging modalities might also improve the sensitivity of initial imaging.

B-0908 11:42

Can MR textural analysis improve detection of extracapsular nodal spread in patients with oral cavity cancer?

R. Frood, E.Y.A. Palkhi, M. Barnfield, R. Prestwich, S. Vaidyanathan, A. Scarsbrook; *Leeds/UK (russell.frood@doctors.org.uk)*

Purpose: To explore the utility of MR texture analysis (MRTA) for detection of extracapsular nodal spread (ECS) in oral cavity squamous cell carcinoma (SCC).
Methods and Materials: 115 patients with node-positive oral cavity SCC treated surgically between 2008 and 2016 who received radiotherapy in a single centre were evaluated; 45 patients (39%) had pathological evidence of ECS. Two experienced radiologists independently reviewed baseline MRI blinded to histology. Presence/absence of MR features associated with ECS were agreed in consensus. Region of interests (ROI) encompassing the largest node on T2 and post-contrast T1-weighted images were defined. First-order texture parameters (entropy, skewness and kurtosis) were extracted using proprietary software (TexRAD) with fine, medium and coarse filters. Sensitivity, specificity and positive and negative predictive values (PPV and NPV) of MR predictors of ECS were compared with histology as the gold standard. Areas under the curve (AUC) calculated by receiver operating characteristics (ROC) analysis and optimal threshold was calculated for texture parameters.
Results: Sensitivity, specificity, PPV and NPV (%) for MR predictors were: flare sign (38%, 95%, 86%, 66%); irregular capsular contour (69%, 45%, 42%, 63%); local infiltration (31%, 92%, 77%, 63%); nodal necrosis (72%, 41%, 49%, 65%). Nodal entropy had a statistically significant correlation with ECS on both MR sequences independent of filtration level; the most significant being medium filtration T1 nodal entropy (p =0.001), AUC = 0.70, with a threshold > 5.26.
Conclusion: First-order MRTA may improve ECS prediction in oral cavity SCC.

B-0909 11:50

Comparison of local shim coils and slice-specific integrated shimming in EPI-based DWI of the head and neck region

S. Walter[1], M. Notohamiprodjo[1], M. Keil[2], K. Nikolaou[1], P. Martirosian[1], S. Gatidis[1]; [1]*Tübingen/DE*, [2]*Erlangen/DE (sven.walter@uni-tuebingen.de)*

Purpose: Echo-planar (EPI) diffusion weighted imaging is a widely used MR method for (non-)oncological diseases because of its short acquisition-time and defiance against motion induced phase errors. Nevertheless, static field inhomogeneities cause artefacts at higher field strengths in the head/neck region. The purpose was to assess the implementation of additional shim coils into the head/neck surface coil to homogenize the magnetic field, thus improving image quality, compared to single-shot and slice-specific integrated dynamic shimming EPI.
Methods and Materials: sEPI, iEPI and sEPI with additional shim coils (cEPI) of the head/neck region was performed in 10 healthy volunteers (6 male, mean age: 29±4 years) on a clinical 3 Tesla MR-scanner (MAGNETOM Vida, Siemens). Additionally, B0 field maps were acquired using T1w GRE sequence. Assessment of image quality, geometric distortions, ghosting artefacts and signal loss was performed visually by two radiologists in consensus on a 4-point-scale (1 = best possible outcome). Apparent diffusion coefficients (ADC) were compared using ROIs in the spinal fluid, spinal cord and the trapezius muscle.
Results: Additional shim coils showed improved homogenization of the static field, foremost of the lower, posterior neck. Image quality, geometric distortions, signal loss and fat saturation were reduced in iEPI and cEPI. Mean ADC values showed no significant differences in all three compartments; sEPI: 3507, 793 and 1663, iEPI: 3722, 797 and 1765, cEPI: 3597, 839 and 1690.
Conclusion: Additional shim coils in the surface coils of the head/neck showed improved overall image quality compared to sEPI and comparable results to iEPI.

Malignant breast lesions typing with diffusion tensor imaging: could fractional anisotropy considered a preoperative 'imaging biomarker'?

F. Pipan[1], P. Clauser[2], C. Zuiani[1], T.H. Helbich[2], P.A.T. Baltzer[2]; [1]*Udine/IT*, [2]*Vienna/AT (francesca.pipan@gmail.com)*

Purpose: To assess the relationship between apparent diffusion coefficient (ADC) and fractional anisotropy (FA) derived from diffusion tensor imaging (DTI) and breast cancer biomarkers Estrogen Receptor (ER), proliferation index Ki67 and human epidermal growth factor receptor2 (HER-2).
Methods and Materials: The Ethics Committee approved this retrospective study. 359 consecutive patients performed 3T MRI with an additional DTI sequence. Included in our analysis were 154 patients (mean age 54 years, range 26-87) with 159 new diagnosed histologically verified malignant lesions. The ADC and FA values were retrospectively measured using a region of interest positioned in the suspicious lesion. Immunohistochemical analysis with evaluation of ER (>11% ER+, ≤11% ER-), Ki67 (>14% Ki67+, ≤14% Ki67-) and HER-2 was performed on the biopsy specimens according to current standards. Mann-Whitney U-test and receiver operating characteristics (ROC) analysis were applied.
Results: FA values were higher in ER+ (0.152±0.004; ER- 0.117±0.006 p<0.05) and lower in Ki67+ (0.138±0.004; Ki67- 0.164±0.009, p<0.05). There were no significant differences in ADC in ER+/ER- (p=0.22) and Ki67+/Ki67- (p=0.47) or ADC and FA values in HER2+/HER2- (p=0.88 and p=0.36, respectively). The area under the ROC curve showed two cut off values: FA>0.17 (identification of 34.7% of ER+, specificity 90.9%) and FA<0.10 (identification of 23.3% of Ki67+, specificity 94.19%).
Conclusion: FA were significantly higher in ER+ and lower in Ki67+ tumours. FA seems to be more reliable than ADC in characterizing malignant breast lesions. FA could be used as a preoperative "imaging biomarker" and considered an additional tool for therapeutic planning.

B-0911 10:47

Breast lesion detection and characterisation with MRI: intra-individual comparison of gadoterate meglumine and gadobenate dimeglumine at 3 Tesla

P. Clauser[1], T.H. Helbich[1], P. Kapetas[1], K. Pinker[2], M. Bernathova[1], P.A.T. Baltzer[1]; [1]*Vienna/AT*, [2]*New York, NY/US*
(paola.clauser@meduniwien.ac.at)

Purpose: To compare a halved dose of the high-relaxivity contrast agent gadobenate dimeglumine, 0.075 mmol/kg, with a two-fold higher dose of gadoterate meglumine, 0.15 mmol/kg, for breast lesion detection and characterization on contrast-enhanced MRI at 3 Tesla.
Methods and Materials: Eligible for this IRB-approved prospective, randomized, intra-individual comparative study were patients with imaging abnormalities (BI-RADS 0, 4 or 5) on conventional imaging. Each patient underwent two examinations, 24-72h apart, one with gadobenate and the other with gadoterate administered in randomized order. Examinations were performed at 3T using identical sequence and timing parameters including high spatiotemporal resolution dynamic-CE, T2w-TSE, STIR-T2w and DWI. Histopathology was the standard of reference. Three blinded, off-site readers evaluated the examinations using BIRADS. Detection, sensitivity, specificity, and accuracy were calculated per-lesion and per-region and compared by univariate and multivariate analysis.
Results: 109 patients were recruited. Five were excluded due to technical problems or lack of reference standard leaving 104 women with 142 histologically verified lesions (109 malignant, 33 benign) for evaluation. The detection with gadobenate (84.5-88.7%) was not inferior to gadoterate (84.5%-90.8%), P>0.165. At per-region analysis, gadobenate demonstrated higher specificity (96.4%-98.7% vs. 92.6-97.3%, P<0.007) and accuracy (96.3-97.8% vs. 93.6-96.1%, P≤0.001), for all three readers. Gadobenate allowed a reduction in false positives of up to 58%. Multivariate analysis demonstrated a reader-independent superior accuracy with gadobenate.

Conclusion: Halved dose of gadobenate (0.075, mmol/kg) is not inferior to a two-fold higher dose of gadoterate (0.15 mmol/kg) for lesion detection. Gadobenate allows improved lesion characterization with an increased specificity and accuracy.

A formalised clinical decision rule applied to breast MRI: can we rule-out malignancy in lesions presenting as suspicious mammographic microcalcifications?

J. Al Mohanna[1], F. Pipan[2], P. Clauser[3], A. Bumberger[3], A. Stöttinger[3], P. Kapetas[3], C. Zuiani[2], T.H. Helbich[3], P.A.T. Baltzer[3]; [1]*Riyadh/SA*, [2]*Udine/IT*, [3]*Vienna/AT (dr.jalilah@hotmail.com)*

Purpose: To investigate whether a clinical decision rule (the Kaiser score, formerly *Tree* flowchart) applied to breast MRI in patients with lesions presenting as suspicious mammographic microcalcifications can rule-out malignancy.
Methods and Materials: IRB-approved retrospective single-center study. 150 consecutive patients (mean age 52 years, range 24-85) undergoing breast MRI (protocol in accordance with EUSOBI/EUSOMA recommendations) for lesions presenting as suspicious mammographic microcalcifications (BI-RADS 4) were investigated. Breast MRI were interpreted by two independent readers that localized the area of microcalcifications in the MRI images and applied the Kaiser score. In short, this rule consists of a formalized flow chart that guides the reader through a 3-step diagnostic process. A resulting score indicates the probability of malignancy ranging from 1 (minimal) to 11 (maximal). A cut-off of ≤4 was suggested to avoid unnecessary biopsies. Each reader's results were tested against the reference standard (vacuum-assisted breast biopsy) using Receiver Operating Characteristics (ROC) analysis.
Results: Histopathology revealed 96 malignant and 54 benign lesions (malignancy rate 64%). Areas under the ROC curves (AUC) were measured: 0.810 (95%-CI: 0.738-0.869), R1 and 0.779 (95%-CI: 0.704-0.842), R2. Both readers AUC´s did not differ (P=0.479). At a cut-off of >4, sensitivity was 97.9% (R1) and 100% (R2). Applying this cut-off could have reduced unnecessary biopsies by 50% (95%-CI: 36.1-63.9%) for R1 and 22.2% (95%-CI: 12.0-35.6%).
Conclusion: The formalized Kaiser score applied to breast MRI in patients with lesions presenting as suspicious mammographic microcalcifications can rule-out malignancy, allowing a potential reduction of unnecessary biopsies by 22.2-50%.

B-0913 11:03

Selecting treatment options in patients with ductal carcinoma in situ (DCIS) using MRI

A. ter Braak, P.W. Plaisier, M. Menke-Pluijmers, P.J. Westenend; *Dordrecht/NL (bpmterbraak@yahoo.com)*

Purpose: Ductal carcinoma in situ (DCIS) is diagnosed in a needle biopsy. In 20-25% of the patients underestimation occurs, i.e. invasive breast cancer is detected in the surgical specimen. In patients with invasive cancer, nodal staging is performed by sentinel node biopsy. Patients without invasive cancer could be candidates for active surveillance. MRI is sensitive in detecting invasive cancer and thus could be helpful in selecting patients with a biopsy diagnosis DCIS for one of these options.
Methods and Materials: Prospective observational study in which MRI was offered to all subsequent patients with a biopsy DCIS diagnosis in addition to standard diagnosis and treatment between april 2012 and march 2017.
Results: 157 of 228 (69%) subsequent patients with DCIS were included. Biopsies were performed using a 9G needle. 71 patients were not included, mainly because patients declined participation. Five patients, two of which were included, were not operated. The underestimate rate both in included and not included patients was 25%, thus excluding selection bias. The positive predictive value of MRI for detecting invasion was 0.57 (26 of 46 patients) .The negative predictive value of MRI was 0.90 (98 of 109 patients). Sensitivity and specificity for detecting invasive cancer on MRI were 0.70 and 0.83.
Conclusion: In patients with DCIS diagnosed by needle biopsy, negative MRI could reliably identify patients without invasive cancer. MRI could be used to select patients with DCIS for active surveillance. However, MRI can not reliably predict the presence of invasive cancer in patients with DCIS.

B-0914 11:11

Contribution of preoperative breast MRI study to pure DCIS

E. Horvath, C. Darrás Ismael, C. Silva, E. Castillo, M.A. Pinochet, C. Galleguillos, E. Droguett, M. Villalon, F. Pizzolon; *Santiago/CL (darrascarla@gmail.com)*

Purpose: To evaluate the usefulness of preoperative MRI study in patients with pure ductal carcinoma in situ (DCIS).
Methods and Materials: IRB approved a retrospective, descriptive observational study of a series of cases. Patients with breast cancer operated between January 2015 and March 2017 were reviewed and pure DCISs with mammography (Mx), ultrasound (US) and preoperative MRI available in PACS were selected. Bland-Altman test was used to describe the size concordance considering the histopathology of the surgical specimen as the reference standard. The MRI contribution was classified into 4 groups. Group 1: MRI provided the same information as conventional studies. Group 2: improved the description of tumour size without changing the surgical approach. Group 3: generated unnecessary procedures. Group 4: correctly changed the surgical management.
Results: Of 467 cancers operated, 77 (16.5%) were DCIS, 41 (53.2%) pure and 36 with microinvasion (46.8%). Thirty-three patients met inclusion criteria. Thw average age was 52.78 ± 12.55 years. The detectability of the lesions was 90.9%, 30.3% and 74.2% for the Mx, US and MRI, respectively. Concordance index of tumour size: MRI=73.3%, US=70% and Mx=58.1%. MRI contribution in preoperative staging: Group 1=18 cases (58%), Group 2= 3 cases (9.7%), Group 3=0 and Group 4=2 cases (6.5%).
Conclusion: Undoubtedly, Mx is the main method of detection of pure DCIS. However, MRI proved to be the best technique to evaluate tumour size, allowing better preoperative staging than conventional studies in 15% of the cases, and even to correctly change surgical management in 6%.

B-0915 11:19

Is it worth to perform preoperative MRI after the combination of digital mammography, digital breast tomosynthesis and US?

I. González de la Huebra Rodríguez, A. García Baizán, M. Calvo Imirizaldu, A. Ezponda Casajús, P. Bartolomé, A. Quilez, A.M. Elizalde Pérez, L.J. Pina Insausti; *Pamplona/ES (igonzalez.6@unav.es)*

Purpose: To compare the sensitivity (ST) of preoperative breast MRI and the combination digital mammography (DM) + tomosynthesis (DBT) + US in all cancers and in specific subtypes.
Methods and Materials: We reviewed the records of 280 breast cancers in 192 women, diagnosed between October 2011 and September 2016. All of the patients underwent DM, DBT, US and MRI. This was designed as a lesion-by-lesion study. The lesions were classified according to the BI-RADS categories (1-3 were considered negative, while 4-5 positive). The gold standard was the surgical specimen. We compared the sensitivities of the different combinations DM+DBT+US vs DM+DBT+US+MRI using a McNemar test (SPSS 20.0).
Results: 280 breast cancers (32 ductal carcinomas in situ, 210 invasive ductal carcinomas, 38 invasive lobular carcinomas) were reviewed in 192 patients. Among the 248 invasive cancers, 207 were luminal (129 luminal A, 78 luminal B) and 41 were non-luminal (32 triple negative and 9 pure Her2). The ST for the combination DM+DBT+US was 86.4% while the ST for MRI was 94.3% (p<0.001). For DCIS the ST were, respectively, 82.3% vs 85.3% (p=1), for IDC the ST were 87.9% vs 96.2% (p<0.001), for ILC the ST were 81.6% vs 92.1% (p=0.219). Regarding the immunohistochemical patterns, for luminal cancers the ST was 85.8% vs 94.6% (p<0.001) and for non-luminal cancers 92.7% vs 97.6% (p=0.5).
Conclusion: According to our data, the addition of breast MRI significantly increased the sensitivity of the combination DM+DBT+US for all cancers, except for DCIS, invasive lobular cancers and non-luminal cancers.

B-0916 11:27

The incremental value of preoperative MRI for evaluation of extent of disease in IDC vs ILC

T. Alster, E. Carmon, B. Maly, T. Sella; *Jerusalem/IL (tamarse@hadassah.org.il)*

Purpose: ILC is more commonly multifocal/multicentric compared to IDC, with a high discordance rate between imaging and pathology. However, most studies were conducted before the era of breast MRI. The purpose of this study was to assess the incremental value of pre-operative breast MRI over mammography (MG) and US in depicting the accurate extent of disease in IDC compared to ILC.
Methods and Materials: Retrospective analysis of pre-operative MG, US and MRI was performed in 239 patients with either IDC (n=193) or ILC (n=46). Images were evaluated for solitary, multifocal or multicentric disease and compared for concordance with post-surgical pathology. Discordance was documented as either overestimation or underestimation. Two tailed paired T and Fischer's exact tests were used for analysis.

Results: Multifocality was present on pathology in 35% and 61% of patients with IDC and ILC ($p<0.05$) and multicentricity in 23% and 42% respectively ($p=0.84$). For IDC, concordance with pathology for all modalities was similar (65-76%). In ILC, MRI was more commonly concordant than MG and US (89%, 44%, 49% for multifocality ($p<0.05$) and 80%, 63%, 71% for multicentricity ($p=0.3$)). Among discordant cases, underestimation was significantly more common for MG and US. MRI equally overestimated multifocal and multicentric disease in IDC (21 and 22%), but very rarely overestimated multifocal disease in ILC (2%).
Conclusion: The added benefit of MRI for evaluation of extent of disease is greater in ILC than IDC. Demonstrating an 80-90% concordance rate with pathology, ILC should be regarded as a relative indication for pre-operative MRI.

B-0917 11:35

The role of MRI in predicting irradical surgery and local recurrence after breast conserving surgery in T3 breast cancer patients after neoadjuvant chemotherapy

I. Ioan[1,2], J. van Urk[2], D.K. Schouten[2], M.E. van der Noordaa[2], M. Vrancken Peeters[2], R.G.H. Beets-Tan[2], G. Winter-Warnars[2], C. Loo[2]; [1]*San Donato Milanese/IT*, [2]*Amsterdam/NL (ileana.ioan@libero.it)*

Purpose: To investigate the role of MRI in predicting irradical surgery and local recurrence (LRR) after breast conserving surgery (BCS) in patients with extensive breast cancer (>5 cm) treated with neoadjuvant chemotherapy (NAC).
Methods and Materials: Dynamic Contrast Enhanced MR images of 45 patients with T3 breast cancer, treated with NAC and BCS were retrospectively reviewed. Morphology, size, enhancement kinetics were assessed before and after NAC and the accuracy of MRI to predict pathological CR (pCR). Clinical, surgical and histological information after NAC and during long term follow up was obtained.
Results: Median follow up was 4.6 years (min 0.8y - max10.2y). Seventeen (38%) patients had positive margins after BCS. Of these, only seven (15%) had mastectomy, two (4%) had re-excision and eight (18%) had more extensive radiotherapy. There were no local recurrences. Two patients died of distant metastasis. Clinical Complete Response (cCR) on MRI was achieved in 24 (53%) patients and pCR in only 14 (31%). Sensitivity, specificity, NPV and PPV of MRI to predict pCR was: 55%, 71%, 42% and 81%. The risk of irradical surgery was equal for patients with 37% (9/24) and without 38% (8/21) cCR on MRI after NAC. The risk of irradical BCS was higher in patients with non mass enhancement on MRI before NAC 45% (11/24) or ILC 60% (6/10) than in mass enhancement 28% (6/21) or IDC 34% (12/35).
Conclusion: Non mass enhancement on MRI before neoadjuvant chemotherapy is associated with higher risk of irradical breast conserving surgery in T3 breast cancer.

B-0918 11:43

Accuracy of breast magnetic resonance imaging compared to mammography in the preoperative detection and measurement of pure ductal carcinoma in situ

H. Preibsch, J. Beckmann, G. Blumenstock, A. Staebler, B. Wietek, K. Nikolaou, B. Wiesinger; *Tübingen/DE (Heike.Preibsch@med.uni-tuebingen.de)*

Purpose: Ductal carcinoma in situ (DCIS) hinders detection by imaging methods due to multifocal appearance and discontinuous growth. Preoperative determination of its extent is therefore challenging. Aim of this study was to investigate the additional benefit of breast magnetic resonance imaging (MRI) to mammography (MG) in the diagnosis of DCIS according to size and grading.
Methods and Materials: Retrospective analysis of 295 patients with biopsy-proven, pure DCIS. Mean patient age was 57.0 years (27-87 years). In 41.7% (123/295) MRI was performed additional to MG. Mammographic breast density, benign breast parenchymal enhancement (BPE), tumour size and grading were analyzed.
Results: Mean tumour size of DCIS was 35.3mm. DCIS was occult on MG in 14.6% (43/295) and on MRI in 1.6% (2/123). Size was underestimated by 4.6mm (mean) mammographically. Regarding breast density MG overestimated tumour size by 16mm (median) in density a, was exact in density b and underestimated by 5.5 and 8mm in density c and d, respectively. DCIS was high grade in 46.8% (138/295), intermediate grade in 41.1% (122/295) and low grade in 11.9% (35/295). MG was exact regarding tumour size in low grade DCIS, underestimated intermediate grade by 1mm (median) and high grade by 10.5mm (median). MRI overestimated low grade DCIS by 1mm (median), was exact regarding intermediate grade and underestimated low grade by 1mm (median). BPE did not significantly influence tumour detection and measurement.
Conclusion: MRI outperforms MG in the detection and size estimation of DCIS with a benefit for surgical planning and reduction of positive margin rates.

B-0919 11:51

Non-mass enhancement in breast-MRI: which BI-RADS descriptors for distribution and internal enhancement patterns have the highest likelihood of malignancy?

M. Lunkiewicz[1], S. Forte[2], B.K. Freiwald[1], G. Singer[1], R.A. Kubik-Huch[1]; [1]*Baden/CH*, [2]*Basle/CH (magdalena.lunkiewicz@ksb.ch)*

Purpose: The purpose of this study was to evaluate the positive predictive values for malignancy of non mass enhancement (NME) descriptors, using the revised BI-RADS Atlas (5th Edition), with focus on clustered ring internal enhancement pattern.
Methods and Materials: We reviewed Breast MRIs of patients on which an MRI-guided VAB-Biopsy had been performed between 2012 and 2016. All studies were independently reevaluated by two experienced radiologists, blinded to the histopathological results. Distribution modifiers and pattern of internal enhancement was recorded. Consensus was reached by involving a third radiologist. The findings were correlated with the histopathological results.
Results: 142 women were included. 72 biopsied lesions were assessed as NME.Pathology results for NME included 53 (73.6%) benign lesions and 19 (26.4 %) malignant lesions.Among all internal enhancement patterns, clustered ring enhancement (7/14, PPV 50%) and clumped enhancement (7/30, PPV 23.3 %) had the highest malignancy rate.Among all distribution patterns, segmental distribution (5/9, PPV 55.6 %) and linear distribution (5/20, PPV 25%) had the highest malignancy rate.The combination of segmental distribution and clustered ring internal enhancement pattern had the highest malignancy rate (4/6, PPV 66,7 %).The overall interobserver agreement rate for distribution modifiers was 0.67 and 0.69 (CI 95%) for internal enhancement pattern. The biggest discrepancy occurred between focal distribution of non mass enhancement vs mass lesions.Interreader agreement was lowest for the segmental distribution and clumped internal enhancement pattern.
Conclusion: Using the revised 5h edition of BI-RADS Atlas, clustered ring internal enhancement pattern and segmental distribution had the highest PPV for malignancy.

Covert brain ischaemia and its impact on cognition in the Polish population: preliminary results of the PURE - mind (Prospective Urban and Rural Epidemiological) cohort study

J. Jacków, A. Zimny, P. Podgórski, M. Sasiadek, D. Szczesniak, J. Rymaszewska, K. Połtyn-Zaradna, K. Zatońska, A. Szuba; *Wroclaw/PL (jagodajackow@yahoo.pl)*

Purpose: Assessment of incidence of covert brain ischaemia and its impact on cognition in the Polish population as a part of Polish and international PURE-mind (Prospective Urban and Rural Epidemiological) cohort study after one year of the project.
Methods and Materials: The study group consisted of 249 subjects (mean age:56.1 yrs range:42-66 yrs, F/M:155/94, urban/rural:197/52). All participants were examined using international PURE-mind protocols including questionnaires about their life-style, laboratory blood tests and psychological assessment measured with Montreal Cognitive Assessment (MOCA) followed by structural brain MRI. Axial T2-, PD-weighted, FLAIR and DWI images were used to assess the number of white matter hyperintensities (WMHs) and SWI for microbleeds. Imaging findings were correlated with cardiovascular risk factors and cognitive state.
Results: WMHs were found in 97/249 (38.9%) subjects (mean number:16.1, range:1-89). No large territorial infarcts and microbleeds were found. 176/249 (70.6%) participants showed normal cognitive state while 73/249 (29.4%) revealed mild cognitive impairment (MCI). There was a significant positive correlation between WMHs and age ($p<0.05$). There were no correlations among WMHs and gender, weight, urban/rural living environment, contact with heavy metals, smoking, alcohol consumption, hypertension, diabetes, myocardial ischaemia and cognitive impairment ($p>0.05$). 61/176 (34.6%) normal and 36/73 (49.3%) MCI subjects showed similar amount of WMHs (mean number:15.0, range:1-73; mean number:14.0, range:1-89, respectively).

Conclusion: Incidence of WMHs is strongly related to age, less dependent on their life-style or accompanying diseases. WMHs have no important impact on cognitive state in the relatively young screened population.

B-0921 10:47

Clinical and MRI characteristics of patients with pontine hyperintense lesions in a series of ischaemic strokes

M. Majer, S. Colombani, M. Mejdoubi; *Fort De France/FR*

Purpose: Pontine hyperintense lesions (PHL) are sometimes detected on brain Magnetic Resonance Imaging (MRI) in asymptomatic patients. They are therefore considered a form of small vessel disease (SVD) with possibly the same pathophysiology as white matter hyperintensities (WMH). Because this imaging sign is rarely seen in the general population, the aim of our study was to investigate the relationship between PHL and clinical/MRI data in a series of stroke patients.
Methods and Materials: Patients' medical history was obtained regarding age, gender, the presence of arterial hypertension, diabetes mellitus, hypercholesterolemia, coronary heart disease, atrial fibrillation, peripheral arterial obstructive disease, current smoking and alcohol consumption. WMH grade, presence of microbleeds, infarcts type and PHL presence were reported after MRI analysis. Potential predictors of PHL presence were investigated using logistic regression modelling.
Results: PHL were found in 110 (20.6%) of the 534 prospectively included stroke patients. In univariate analysis, a significant association was demonstrated between PHL and age (p< 0.0001), female gender (p=0.04), microbleeds (p< 0.0001), high WMH grade (Fazekas classification 2-3; p= 0.0001), hypertension (p = 0.02) and diabetes (p = 0.03). In multivariate analysis, only age ≥60 years (OR [95% CI]: 3.44 [1.17-10.15], p< 0.025), female gender (OR [95% CI]: 1.78 [1.11-2.87], p= 0.0175), microbleeds (OR [95% CI]: 1.97 [1.18-3.30], p= 0.0098) and high WMH grade (OR [95% CI]: 7.54 [4.17-13.62], p<0.0001) remained independently associated with PHL.
Conclusion: Several clinical and imaging factors are independent predictors of PHL presence in stroke patients. To our knowledge, significant association between PHL occurrence and microbleeds has never been reported before. This might suggest that SVD is the principle pathophysiologic process in PHL. We suggest that PHL be considered as a subgrade in the Fazekas classification.

B-0922 10:55

Collateral filling velocity predicts malignant oedema development in acute ischaemic stroke

M.F. Froelich, P. Reidler, M.P. Fabritius, L. Rotkopf, F. Schuler, W.H. Sommer, K.M. Thierfelder, W.G. Kunz; *Munich/DE*

Purpose: To assess the predictive value of collateral filling velocity on malignant edema development (MED) in acute ischemic stroke.
Methods and Materials: Subjects were selected from a cohort of 1,845 consecutive patients with suspected ischemic stroke who underwent CT including whole-brain CT perfusion. Inclusion criteria were: (1) isolated pre-bifurcation M1 segment occlusion, and (2) available follow-up imaging within 72 hours. Time to peak (TTP) enhancement was measured distal to the occlusion in the M2 segment branches in the Sylvian fissure. Collateral filling velocity was defined as the difference in TTP enhancement between the ischemic and non-ischemic hemisphere. MED was defined as development of midline shift of ≥5 mm in follow-up imaging. Multivariable binary logistic regression analysis was performed to adjust for clinical and imaging parameters.
Results: Ninety-nine patients (56.6% female, mean age 73 years) were included. 18 patients (18.2%) suffered from MED. Longer TTP enhancement was significantly associated with MED (odds ratio [OR]=1.627; 95% confidence interval [CI], 1.044-2.536; p=0.032). Lower values of the Alberta Stroke Program Early CT Score (OR=0.370; 95% CI, 0.152-0.898; p=0,028) were also associated with MED. The analysis was further adjusted for intravenous thrombolysis treatment, neurological deficit on admission based on the National Institutes of Health Stroke Scale, and the volume of cerebral blood flow-cerebral blood volume mismatch, which were not associated with MED (all p>0.05).
Conclusion: Slower collateral filling velocity independently predicts malignant edema development in acute large-vessel occlusion stroke. As an objective, threshold-independent quantitative parameter, it may allow standardized risk prediction in acute stroke imaging.

B-0923 11:03

Collateral scores and perfusion parameters for outcome prediction in acute ischaemic stroke: how many scans are needed?

K. Schregel, I. Tsogkas, D. Behme, C. Peter, I. Maier, J. Liman, M. Knauth, M.-N. Psychogios; *Göttingen/DE (katharina.schregel@med.uni-goettingen.de)*

Purpose: Collateral circulation is an important determinant for outcome in endovascularly treated patients with acute ischaemic stroke (AIS). Several collateral scores to support triage and outcome prediction exist. We applied different scoring systems on single- and multi-phase CTA (sp-/mpCTA) and compared them to CT perfusion (CTP) to identify the best method for collateral evaluation in AIS.
Methods and Materials: A total of 102 patients with AIS due to large vessel occlusion (LVO) in the anterior circulation who underwent multimodal CT imaging and who were treated endovascularly were included. Collateral status was assessed on spCTA and on mpCTA derived from CTP using four different scoring systems and compared to CTP parameters.
Results: Collateral scores correlated well with each other and with CTP (p<0.01 for each). Collateral scores stratified by extent of perfusion deficit were significantly different between groups (p<0.01 for each). Stepwise logistic regression showed that probability of a favorable outcome was highest, when patients were not hypertensive, had high baseline ASPECTS and good collaterals on spCTA (OR 5.82, 1.53 and 1.47, respectively; 95% CI 1.83-18.51, 1.03-2.27 and 1.11-1.94, respectively). In ROC analysis, a spCTA collateral score discriminated best between favorable and unfavorable outcome and was equal to CTP parameters.
Conclusion: Collateral status evaluated on spCTA may suffice for outcome prediction and decision making in AIS patients, potentially obviating further imaging modalities like mpCTA or CTP.

The utility of CAD software in acute stroke protocol workflow for automatic evaluation of infarct core size

D. Juskanic, A. Petrovicova, S. Holly; *Nitra/SK (juskanic@gmail.com)*

Purpose: Triaging acute stroke patients for appropriate treatment is often carried out in a high-pressure setting, which is a potential source of interpretative variability. Use of decision supportive tools appears to be promising in reducing interpretation and management errors. Without prior systematic use of ASPECTS, we describe the single centre experience while implementing the CAD software during night shifts.
Methods and Materials: During two months study period, all 95 patients with suspected stroke referred during night shifts were examined under standard CT stroke protocol with subsequent automatic post-processing using the CAD tool e-ASPECTS (Brainomix, Oxford, UK). In patients with ICA or MCA strokes, logistic regression was used to evaluate the relationship between entry variables and treatment decisions. The correlation between ASPECTS with mRS on discharge was performed.
Results: The greatest influence on treatment decision had entry NIHSS (p 0.01), ASPECTS was not significant (p 0.294). In the treatment group, none of the patients had ASPECTS lower than 7, median ASPECTS was 9 (interquartile range [IQR] 8-9). In patients with no specific treatment, median ASPECTS was 10 (interquartile range [IQR] 9-10). Moderate correlation between ASPECTS and mRS on discharge was found (r 0.518).
Conclusion: In the treatment group, where no other contraindications were present, ASPECTS played more of an external role in validating decisions made during standard routine protocol. Conversely, in the subset of patients outside the 4.5-hour window or patients with wake-up stroke, ASPECTS could potentially serve as a factor favoring revascularization, or as a quantitative alternative for CT perfusion.

B-0925 11:19

Voxel-based lesion symptom mapping of NIHSS scores in patients with acute media infarction

J. Jesser[1], B. Dinse[1], J. Baldo[2], A. Arévalo[3], M. Bendszus[1], K. Schlamp[1]; [1]*Heidelberg/DE*, [2]*Martinez, CA/US*, [3]*São Paulo/BR*
(Jesser.Jessica@gmail.com)

Purpose: The aim of this study was to find key areas in the brain that cause a severe clinical situation when damaged in patients with an acute infarction of the middle cerebral artery.
Methods and Materials: In retrospect we identified 126 patients with acute media infarction. Inclusion criteria: symptom onset <24h before MRI, no mismatch between stroke lesion in diffusion- and perfusion-weighted imaging (DWI vs. PWI) in the MRI session, accessible NIHSS records ("National Institute of Health Stroke Scale"). The NIHSS is used for quantification of stroke severity. The stroke lesion was manually traced in the DWI-sequence and normalized to standard space. VLSM-analysis ("voxel-based lesion symptom mapping"): In the process a t-test is conducted in every voxel using the lesioned versus non-lesioned voxel as independent variable and the total NIHSS score (at the time of the MRI) as dependent variable.
Results: We found three highly significant clusters (p<0,001) associated with high NIHSS scores in acute media infarction. These clusters are localised in the left brain hemisphere: subcortical in the supramarginal gyrus, in the corona radiata where the corticospinal tract and the arcuate fascicle cross and below the basal ganglia in the inferior frontooccipital fascicle.

Conclusion: The areas associated with high NIHSS scores in acute media infarction are involved in functions like language, visual attention and movement. We think that these areas are important for integrating several functions and therefore cause a dramatic clinical situation even when only a small volume of brain tissue is damaged.

B-0927 11:27

Clinical outcome after mechanical thrombectomy in diabetic patients with major ischaemic stroke of the anterior cerebral circulation

J. Borggrefe[1], B.K. Glück[1], C. Kabbasch[1], O. Onur[1], N. Abdullayev[1], V. Maus[1], G.R. Fink[1], A. Mpotsaris[2]; [1]*Cologne/DE*, [2]*Aachen/DE*
(Jan.Borggrefe@uk-koeln.de)

Purpose: Diabetic patients (DP) with acute ischaemic stroke (AIS) show a poorer outcome than non-diabetic patients (NDP). This study provides a comprehensive analysis of factors associated with unfavourable outcome in DP receiving MT for AIS of the anterior circulation.
Methods and Materials: This monocentric study includes 317 consecutive patients receiving MT for AIS in the terminal internal carotid artery and/or middle cerebral artery, including 46 DP. The study included pretreatment stroke CT with perfusion and collateral status, comprehensive treatment data, pre-existing comorbidities, laboratory parameters, and medication. Neurological status was assessed at baseline (NIHSS/mRS) and after 90 days (mRS 90).
Results: Compared to NDP, DP showed a significantly poorer outcome (mRS90 >2) ($p<0.05$). Collateralization and infarct core size did not differ between groups while the penumbra was significantly smaller in DP than in NDP ($p<0.05$). The poorer mRS 90 outcome (mRS90 > 2) in DP was associated with poor collaterals ($p=0.01$) and hyperglycemia on admission (aHG) ($p<0.05$). Shorter time to recanalization (TTR) was associated with favourable mRS 90 in the NDP group ($p<0.001$) but not in DP ($p=0.49$). In univariate logistic regression, following parameters were significantly associated with mRS 90: diabetes, aHG, TTR, and the NIHSS ($p<0.05$ each). In multivariate analyses and partition regression models DP with admission hyperglycemia (≥ 132 mg/dl) and older age (≥ 66 years) showed a particularly poor outcome.
Conclusion: The main factors for a less favourable outcome of DP after MT are admission hyperglycemia, age, NIHSS, and prolonged times to recanalization.

B-0928 11:35

MRI morphometry of the corpus callosum in patients with small vessel diseases of the brain

D. Bazhenova, V.E. Sinitsyn, R.N. Konovalov; *Moscow/RU*
(bazhenova.darya@gmail.com)

Purpose: The purpose of this study was to compare the area of corpus callosum (CC) segments in healthy subjects and patients with small vessel disease of the brain (SVDB) using MRI morphometry.
Methods and Materials: Three groups of subjects (N = 109, 29-83 years, 42 male) took part in the study: 1st group - hypertensive microangiopathy (n=73), 2nd - cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) (n=9), 3rd - healthy volunteers (n=27). Subjects underwent MRI of the brain and neuropsychological assessment. The areas of CC and each of 7 segments were calculated using the MultiVox software (Fig.1).
Results: The areas of the 1st, the 6th, the 7th segments, and the total area of CC in patients with hypertensive microangiopathy were significantly less than in the control group and CADASIL ($p<0.005$). The severity of cognitive impairment of the examined individuals positively correlated with the area of the 1st, the 2nd segments and the total area of CC ($p<0.05$). The grade of the cerebrospinal space expansion correlated inversely with the areas of the 1st, the 2nd, and the 6th CC segments ($p<0.05$).
Conclusion: The study discovered differences in the area of the CC and some of its segments between studied groups. The severity of cognitive impairment correlated with a volume decrease in the anterior part of CC. The expansion of cerebrospinal space volume in patients with SVDB was associated with decrease of the grey and white matter volume, including CC. Morphometry of CC can be used as a biomarker of SVDB.

B-0929 11:43

The aspect of intracranial haemorrhage of cranial CT at the moment of admission is useful to predict the clinical and radiological evolution

S. Bonilla, E. Pascual Goni; *Barcelona/ES (santibonilla22@gmail.com)*

Purpose: To determine which neuroradiology signs were able to predict the growth (HG), the early neurological impairment and the functional prediction.
Methods and Materials: Retrospective study of consecutive patients diagnosed with spontaneous intracraneal hemorrage [IHC] (2013-2016). The study includes the patients with craneal CT < 6 hours and exclution criteria. Two blind assessors analyzed the form, density, presence of intralesional hipodensities, swirl-sign, blend-sign & black hole in basal CT. Interobserver variability for each sign (Cohen's kappa) was analyzed. Clinical and radiological variables associated to growth, DNP (decrease of the scale of Glasgow (GCS) of >1p and/or NIHSS ≥4p increase) and functional prediction at 3 months were evaluated through univariate and multivariate analysis.
Results: 98 out of 313 patients fulfilled criteria. The irregular form frequency, heterogeneous density, presence of hipodensities, "swirl-sign", "blend-sign" and "black hole" were 57%, 32%, 51%, 36%, 9% and 34% respectively. Interobserver concordancy was good for all of them (K>6). The growth was observed in 42% of cases. The growth was associated regardless the form and the presence of hopidensities. The DNP was associated regardless the GCS at the admission, the form and the swirl-sign. The functional prediction was associated regardless the form.
Conclusion: The morphological characteristics of intracranial haemorrhage (IHC) in the craneal CT at the admission predict the risk of growth, the early neurological impairment and the functional prediction. The analysis of the form of the haemorrhage in our patients was the sign of the best predictive power of the clinical & radiological evolution.

Whole tumour histogram analysis of T2-weighted, diffusion-weighted, and postcontrast T1-weighted images in medulloblastoma: assessment risk of recurrence

Q. Lv; *Zhengzhou/CN (478071645@qq.com)*

Purpose: To explore the value of MRI whole-tumour histogram in the risk assessment of medulloblastoma recurrence.
Methods and Materials: Retrospective analysis of 32 patients which were pathologically confirmed medulloblastoma. These patients were divided into two groups, which were defined as the recurrent group and the non-recurrent group. Using the software Mazda, whole-tumour regions of interest were drawn on all slices of diffusion-weighted, T2-weighted, and postcontrast T1-weighted images to obtain histogram parameters, including the average value, variance, skewness, kurtosis, perc.01%, perc.10%, perc.50%, perc.90% and perc.99%. The histogram parameters were analysed statistically to find out the characteristics of the significant differences between the two groups. Next, we drew the ROC curve to assess diagnostic efficiency in medulloblastoma recurrence.
Results: The variance, the kurtosis derived from precontrast T1-weighted images have the statistical significance ($P<0.05$). The variance showed the sensitivity and the specificity of the risk of medulloblastoma recurrence were 81.36% and 60.0%, respectively; the kurtosis were 86.7% and 62.5%. The variance and the 99th percentiles derived from T2-weighted images have the statistical significance ($P<0.05$). The sensitivity and the specificity were 66.7%, 87.2% and 66.7%, 76.5%, respectively. However, there is no difference of parameters between two groups in the ADC ($P>0.5$).
Conclusion: MRI whole-tumour histogram analysis can be used as an important supplementary method to assess the risk of medulloblastoma recurrence. The variance derived from T2-weighted images has the potential to be the most significant parameter for assessing the risk of medulloblastoma recurrence.

The role of diffusion weighted imaging for the differentiation of malignant and benign peripheral nerve sheath tumours

L. Well[1], K.I. Geier[1], M. Kaul[1], L. Späth[1], T. Derlin[2], J. Herrmann[1], G. Adam[1], J. Salamon[1]; [1]*Hamburg/DE*, [2]*Hannover/DE (l.well@uke.de)*

Purpose: To evaluate the role of diffusion-weighted-imaging (DWI) for the differentiation of malignant and benign peripheral nerve sheath tumours (MPNST/BPNST) in patients with Neurifibromatosis 1 using intravoxel incoherent motion (IVIM) and standard apparent diffusion coefficient (ADC) models.
Methods and Materials: Prospectively, n=26 patients with neurofibromatosis 1 were subjected to magnetic resonance imaging; n=67 tumours (n=12 MPNST / n=55 BPNST). Imaging was performed at 3T, acquired sequences were T2w with and without fat-saturation, 3D-T1w and DWI. Eleven b-values (0-800 s/mm²) were fitted with a biexponential model to extract perfusion fraction f, diffusion coefficient D and pseudo-diffusion coefficient D*. Additionally, the

apparent diffusion coefficient (ADC) was calculated. ROIs were manually drawn in the center and periphery of tumours to determine signal intensities. Seven morphological features were selected for visual differentiation. Mann-Whitney-U, Fisher's exact test and receiver operating characteristic (ROC) analyses were performed.
Results: Signal intensities of MPNST were significantly different from BPNST in IVIM (mean f: 21022 vs 13608 p=0.0028; mean D*: 971613 vs 1756326 p<0.0001) and ADC (mean 1232182 vs 2108616; p<0.0001). Signal intensities between center and periphery of tumours were significantly different for the perfusion fraction in BPNST but not in MPNST (p=0.0171; all other p>0.05). ROC showed good levels of sensitivity and specificity for ADC and D* (Sensitivity vs specificity: ADC 91.67%vs98.18%, AUC 0.9833; D* 91.67%vs90.91%, AUC 0.9318). Morphological features were applicable for identification of MPNST (all p<0.05).
Conclusion: Diffusion weighted imaging allows identification of MPNST in patients with Neurofibromatosis 1 with high levels of sensitivity and specificity.

B-0933 10:46

Relaxation-compensated multi-pool CEST signal at 7T MRI of glioblastomas is dependent on the anatomic localisation

C. Dreher[1], J. Windschuh[1], F. Sahm[1], P. Bachert[1], M. Ladd[1], M. Zaiss[2], H.-P. Schlemmer[1], A. Radbruch[1], D. Paech[1]; [1]*Heidelberg/DE*, [2]*Tübingen/DE (c.dreher@dkfz-heidelberg.de)*

Purpose: To investigate the localization dependence of relaxation-compensated multi-pool Chemical-Exchange-Saturation-Transfer (CEST) MRI at 7T and histopathological parameters in newly diagnosed untreated WHO IV° glioma patients.
Methods and Materials: Twenty patients with newly diagnosed WHO IV° gliomas were prospectively included in this study and investigated at a 7T whole-body scanner (Siemens Healthcare, Erlangen, Germany). Mean CEST signal intensities (Nuclear-Overhauser-Effect(NOE), Amide-Proton-Transfer(APT), Downfield_NOE-suppressed APT(DNS_APT)), ADC parameters and histopathological parameters of the tumor volumes were evaluated with regard to extension, localization (brain hemisphere and lobe) and contact to the subventricular zone using non-parametric Mann-Whitney tests, ANOVA on ranks test and Spearman correlation.
Results: Mean CEST APT&DNS_APT signal intensities (0,156±0,118 & 0,137±0,116) were significantly increased in right vs. left hemisphere glioblastomas (0,072±0,014 & 0,048±0,014), (p=0,044 and 0,010). Mean ADC parameter were significantly decreased in right vs. left hemisphere glioblastomas (1,04*10^7±0,08*10^7 vs. 1,18*10^7±0,12*10^7) (p=0,046). Mean CEST NOE signal intensity didn't differ significantly between both hemispheres, but was significantly increased in case of subventricular zone contact (0,101±0,015 vs. 0,118±0,015) (p=0,037). The lobe localization and extension of the tumor had no significant effect on CEST and ADC signals. CEST APT&DNS_APT and ADC signal intensities did significantly correlate (-0,67 and -0,56) (p<0,01), but not CEST NOE and ADC parameters. Histopathological parameters were not significantly different with regard to different localizations.
Conclusion: Relaxation-compensated multi-pool CEST MRI signal depends on the anatomic localization. Amide CEST and ADC are positively correlating - NOE parameters are solemly different with regard to subventricular zone contact, possibly showing complementary information to Amide CEST and ADC.

B-0934 10:54

Metabolic imaging of tumours employing dynamic ^{17}O MRI: initial results in glioma patients

D. Paech, N. Behl, R. Umathum, M. Ladd, H.-P. Schlemmer, A. Nagel, S. Niesporek; *Heidelberg/DE (d.paech@dkfz.de)*

Purpose: To investigate cerebral metabolic rate of oxygen consumption ($CMRO_2$) in brain tumours employing dynamic ^{17}O magnetic resonance imaging (^{17}O-MRI).
Methods and Materials: In this ongoing IRB approved study one untreated glioma patient (male, 26 y.-o. astrocytoma WHO grade II) was included. ^{17}O MRI was conducted at a 7 Tesla whole-body scanner (Siemens Healthcare, Erlangen, Germany) with a nominal spatial resolution of $(7.5mm)^3$ employing a density-adapted radial sequence with Golden Angle acquisition scheme. 3.8±0.1L of 70%-enriched ^{17}O gas were administered using a remotely controllable closed circuit breathing system. High-resolution T1 MPRAGE $(0.6mm)^3$ and T2 TSE $(0.4x0.4x0.5mm)^3$ sequences were additionally acquired and used for tumour and normal brain segmentation. Post-procecessing of ^{17}O-MRI data was conducted with a partial volume correction algorithm to account for spilling-effects at low resolution. Signal intensities in the investigated volumes were compared using the Wilcoxon rank-sum tests.
Results: ^{17}O-MRI MRI revealed significantly decreased $CMRO_2$ in tumour tissue (0.59-0.66±0.16 µmol/g/min) compared to contralateral normal appearing brain tissue (1.10-1.22±0.08 µmol/g/min) (p<0.01). Further, $CMRO_2$ was significantly increased in gray matter (2.34-2.58±0.20 µmol/g/min) compared to white matter tissue (0.56-0.62±0.06 µmol/g/min) (p<0.01).
Conclusion: ^{17}O-MRI may provide new insights into tumour metabolism through the localised quantification of the cerebral metabolic rate of oxygen consumption. Our results agree with the Warburg-effect describing decreased $CMRO_2$ of tumours due to the shift in glucose metabolism from oxidative phosphorylation to lactate production for energy generation.

B-0935 11:02

Histogram analysis of apparent diffusion coefficient maps for distinguishing lateral ventricle central neurocytoma from ependymoma

W. Wang, J. Cheng, Y. Zhang; *Zhengzhou/CN (weijianwang520@163.com)*

Purpose: We explored the role of histogram analysis of apparent diffusion coefficient (ADC) maps for discriminating lateral ventricle central neurocytoma from ependymoma.
Methods and Materials: We retrospectively evaluated findings in 35 patients with lateral ventricle central neurocytoma and 20 patients with ependymoma who underwent diffusion-weighted imaging (b = 0,800 s/mm(2)) at 3T with acquisition of corresponding ADC maps. We derived histogram data from regions of interest drawn on all slices of the ADC maps in which tumor was visualized, including areas of necrosis and hemorrhage in the tumor. We used the t test to evaluate the capacity of histogram parameters (variance, kurtosis,1th,10th percentiles) to discriminate central neurocytoma from ependymoma and analyzed the receiver operating characteristic (ROC) curve to determine the optimum threshold value for each parameter and its corresponding sensitivity and specificity.
Results: Lateral ventricle central neurocytoma demonstrated significantly lower variance, kurtosis,1th,10th percentiles than ependymoma($P < 0.05$). ROC curve analysis of the variance yielded the best area under the ROC curve (AUC; 0.83), sensitivity of 80%, and specificity of 82%, with a cutoff value of 2012.
Conclusion: Histogram analysis of ADC maps might be helpful for discriminating lateral ventricle central neurocytoma from ependymoma.

B-0936 11:10

Nedd4-1 expression promotes tumour progession in gliomas and relationship between nedd4-1 expressions and DKI features in gliomas

X. Cheng, J. Cheng; *Zhengzhou/CN (chengxiaoyaz@163.com)*

Purpose: The aim of this study was to investigate whether Nedd4-1 is present in glioma and to evaluate the correlation of Nedd4-1 expression with the progression, prognosis and DKI manifestation of the disease.
Methods and Materials: 60 patients with gliomas, who underwent preoperative DKI at 3 T after written informed consent. Normalized mean kurtosis (MKn) and mean diffusivity (MDn) metrics from DKI were assessed in these patients. Immunohistochemistry and western blot were used to investigate the expression of Nedd4-1 protein in these patients.
Results: Immunohistochemistry levels and western blotting analysis discovered that the expression of Nedd4-1 was increased with WHO grade($P<0.05$). In addition,a non-parametric analysis revealed that the attenuated Nedd4-1 expression was significantly correlated with a large tumour diameter ($P<0.05$),frequent intra-tumour necrosis ($P<0.05$),and that high expression of Nedd4-1 is closely consistent with poor prognosis of glioma. MKn was significantly higher(but MDn decreased) in higher glioblastoma(0.56 ± 0.11) than in primary glioblastoma (0.38 ± 0.10, $p < 0.05$). Significant correlations were found between nedd4-1 and MKn ($r = 0.623$, $P < 0.001$); as well as for MDn ($r=-0.418$, $P < 0.05$). In contrast, FA had no obvious correlation with nedd4-1 ($r = 0.065$, $P = 0.603$).
Conclusion: Our results provide convincing evidence that the expression of Nedd4-1 is up-regulated in human gliomas. The glioma patients with higher Nedd4-1 expression have a worse prognosis. Considering the diagnostic and prognostic significance of these molecular markers, MK appears to be a promising in vivo biomarker for glioma.

B-0937 11:18

Visually AcceSAble Rembrandt Image (VASARI) assessment features predict GBM recurrence patterns

D. Xuesong, W. Zhang; *Chongqing/CN (duxs1966@126.com)*

Purpose: To estimate Visually AcceSAble Rembrandt Image (VASARI)assessment features in predicting GBM recurrence patterns.
Methods and Materials: Sixty-five patients who suffered from GBM recurrence were included. Pre-surgery MRI and survival data were collected retrospectively. Semantic features were extracted using the VASARI feature-set criteria by three experienced neuro-radiologists independently. Recurrence patterns defined as "local" and "distant" with enhanced T_1WI at the time recurrence was proven. Survival analysis was done using the Kaplan-Meier analysis.
Results: Patients' recurrence was proven either by pathology or by the RANO criteria. Patient number of "local" was 49 (71.1%), while "distant" was 16

(28.9%). Clinical data such as age, Ki-67 and KPS showed no significant differences in the two groups. Semantic feature based on VASARI set indicated that tumour necrosis (F7), definition of the non-enhancing (F13), cortical involvement (F20), extent of resection of enhancing tumour (F26) and extent resection of nCET (F27) showed significant difference in unique recurrence patterns. Results revealed PFS was much longer when tumour necrosis ratio was low and patients suffered cortical involvement survived a shorter PFS and so it did in F26 and F27 subgroups.
Conclusion: VASARI features could predict GBM recurrence patterns and these features were associated with patients' PFS.

B-0938 11:26

Using multiple linear regression to investigate IDH1 gene mutation in glioma by joint application of DCE-MRI and DSC-MRI
W. Xu[1], J. Wen[2], Y. Li[2]; [1]*Shanghai, SH /CN*, [2]*Shanghai/CN*
(xuweixingzi@163.com)

Purpose: To explore whether quantitative analysis of DCE-MRI and DSC-MRI could detect IDH1 gene status in glioma.
Methods and Materials: Patients (Dec. 2014-Oct. 2016) underwent DCE-MRI and DSC-MRI. The associations between each parameters and IDH1 gene status were analyzed by independent sample t test. The effective parameters were analyzed by multiple linear regression to calculate the prediction accuracy (PA).
Results: 57 LGG (43 IDH1 mutation type vs 14 IDH1 wild type) and 71 HGG cases (12 IDH1 mutation type vs 43 IDH1 wild type) underwent DCE-MRI. 56 LGG (45 IDH1 mutant type vs 11 IDH1 wild type) and 74 HGG cases (14 IDH1 mutant type vs 60 IDH1 wild type) had DSC-MRI. 120 patients took both scanning. All cases were pathologically confirmed. In LGG group, the K_{ep}, K^{trans}, TTP, Ve, rCBV, rCBF had statistical difference between IDH1 mutant and wild type ($P<0.05$). AUC was 0.945, 0.904, 0.934, 0.827, 0.818 and 0.79, respectively. Combined rCBV, K_{ep} and K^{trans} obtained PA as high as 96.4%, OR= 9.22. Model: $y=19.11-0.89\ rCBV - 60.6\ K_{ep} + 11.22\ K^{tran}$. The K_{ep}, K^{trans}, Ve, MAXSlope, AUC, rCBV and rCBF had significant associations with IDH1 status in HGG ($P<0.05$). AUC was 0.838, 0.816, 0.827, 0.832, 0.862, 0.826 and 0.774, respectively. Combined rCBV, K_{ep} and K^{trans} obtained 90.5% IDH1 PA, OR=42.34. Model: $y=2.44-0.43\ rCBV - 5.05\ K_{ep} - 4.93\ K^{trans}$.
Conclusion: Combined use of DCE-MRI and DSC-MRI could benefit the judgement of IDH1 gene mutation in glioma.

B-0939 11:34

Evaluation of the apparent diffusion coefficient in patients with recurrent glioblastoma under treatment with bevacizumab with radiographic pseudoresponse
T.A. Auer, F. Marini, M. Renovanz, M.A. Brockmann, Y. Tanyildizi; *Mainz/DE*

Purpose: Response assessment in neuro-oncology criteria (RANO) are used to assess response to first-line treatment of glioblastoma (GBM). Differentiation between response and pseudoresponse under treatment with bevacizumab (BVZ) remains challenging. This study evaluates ADC changes in patients with radiographic pseudoresponse under treatment with (BVZ).
Methods and Materials: Patients (n=40) with recurrent GBM under treatment with BVZ underwent MRI before, two and four months after treatment with BVZ. In patients with radiological pseudoresponse (n=11), ADC analyses were performed. Areas with T1 contrast enhancement (CE) decrease and FLAIR signal decrease were manually selected and compared with size and position-matched healthy contralateral brain parenchyma.
Results: Histogram-based ADC (10^{-6} x mm^2/s) of these patients decreased significantly ($p < 0.005$) from baseline MRI (T1-CE, FLAIR: 1124.9±160.3, 1098.4±226.2, respectively) to 2 months (781.3±110.7, 783.3±103.3) and remained stable during 4 months (777.0±138.5, 784.4±155.4, all mean±SD), despite progressive disease. Mean ADC values of the healthy contralateral brain tissue remained stable ($p > 0.05$) (ADC values: baseline: 786.2±110.7, 2 months: 781.1±76.2, 4 months: 804.1±86.2).
Conclusion: Treatment of GBM with BVZ leads to a decrease of ADC values in areas of pre-treatment T1-CE/FLAIR signal hyperintensity to levels of comparable with normal brain tissue. ADC values remained normal, even when progressive tumour growth was reported.

B-0940 11:42

The predictive capacity of DWI vs perfusion imaging in response assessment of brain metastases following stereotactic radiosurgery
P. Arcuri[1], S. Roccia[1], G. Fodero[1], R. Mole'[1], A. Destito[1], C. Bertucci[2], D. Lagana'[1]; [1]*Catanzaro/IT*, [2]*London/UK (arppaolo@alice.it)*

Purpose: The purpose of this study was to compare the predictive capacity of the apparent diffusion coefficient (ADC) with perfusion imaging distinguishing tumour recurrence or progression from treatment effects in brain metastasis, following stereotactic radiosurgery (SRS).
Methods and Materials: We retrospectively reviewed 32 brain metastases from 24 patients treated with SRS (3x10 Gy), imaged at baseline, one month and three months post-treatment using DWI and perfusion imaging. At one year post-treatment or last available follow-up MRI, volume criteria determined final tumour response status. Gd-DTPA was injected intravenously at a rate of 4 mL/s . To assess differences in tumour blood volume during radiotherapy and among patients, all CBV maps were normalized to CBV values in the contralateral NAWM (rCBV). Youden's index test was used for statistical analysis to define optimal thresholds that distinguished responders from non-responders as well as sensitivity and specificity.
Results: Sensitivity of an increase in the ADC ratio to make an early (1 month) prediction of tumour control was 81.7% and specificity was 86.5%. When using rADC values of metastases measured in the follow-up of 3 months, sensitivity and specificity were 83.5 and 70.7%, respectively. Progressive lesions showed a significant reduction in rCBV values at the 1-month follow-up with a sensitivity and specificity of 85.3% and 80.0%. At the 3-month follow-up, sensitivity and specificity were 83.5 and 70.7%, respectively.
Conclusion: An increased rADC values and a significant reduction in rCBV values at the 1-month follow-up are indicators of good tumour control, and reflect the beneficial effect of SRS.

Simulation-based training for radiology professionals in the management of acute emergencies following contrast media reactions
R. Taoussi, Z. Qechchar, M. Fehdi, M. Mouhaoui, N. Touil, O. Kacimi, N. Chikhaoui, G. Lembarki; *Casablanca/MA*

Purpose: The purpose of our study was to assess the effectiveness of simulation-based medical education in the management of radiological emergencies among Radiologists and technicians and to compare this teaching method to the traditional theoritical clinical education.
Methods and Materials: Our study was a prospective, observational, single-centered study including the radiologist and technicians of Casablanca Ibn Rochd University Hospital including Professors in Radiology. The study undertaken in five phases: First a pre-test followed by a theoritical and practical training on emergencies following the administration of iodinating contrast medias, then the students were separated in two groups, one undergoing the medical simulation training and one that doesn't, and then a post-test concerning the two groups.
Results: 40 professionals were enrolled in the study: 20 (Group 1) benefited from the medical simulation and 20 (Group 2) who didn't. The pre-test results were comparable between the two groups (6,05/20 ± 2,68 for groupe 1 versus 5,88/20 ± 2,52 for group 2). The post test results were better for group 1 (18,83/20 ± 1,27 versus 17,13/20 ± 2,01 for group 2, $p<0,0001$). The average satisfaction rate was 8,79/10 ± 2,17. The results of the satisfaction survey were in favor of the effectiveness of simulation-base medical teaching in the improvement of the theoritical knowlede (100%) as well as the medical reasoning when faced with a Radiological emercency (100%).
Conclusion: This study emphasis the benefit of simulation-based medical teaching and learning as an innovating teaching tool in front of Radiology emergencies.

B-0942 10:47

Clinical impact of iterative model reconstruction algorithm in a department of emergency radiology in a large series of patients
A. Pecorelli[1], D. Ippolito[1], A. de Vito[1], S. Lombardi[1], L. Riva[2], C. Talei Franzesi[1], S. Sironi[3]; [1]*Monza/IT*, [2]*Missaglia/IT*, [3]*Bergamo/IT*
(pecorelli.anna@gmail.com)

Purpose: To compare the radiation dose exposure of low dose Computed Tomography (CT) examinations using iterative model reconstruction (IMR) algorithm with standard CT equipment in an Emergency Radiology Department (ERD), with trauma center.
Methods and Materials: We reviewed more than 7000 CT scan examinations performed wit new 256row CT scan (iCT Elite, Phlips) combined with new IMR algorithm, in several anatomical district (i.e.: brain, thorax, abdomen and whole body) in patients referred to our ERD with different clinical emergency settings

(trauma, embolism, vascular disease). For each exam we analyzed the CT dose index (CTDI, expressed in mGray) and the dose length product (DLP, expressed in mGray.cm) and compared with dose of our previously CT scan equipment.
Results: The means values of CTDI were lower with IMR compared with our previous CT equipment: brain 59.3 vs 42.4 (-29%), thorax 8.8 vs 5.6 (-36%), abdomen 17.7 vs 6.3 (-64%) and whole body 16.8 vs 12.4 (-26%).In the same way the totals DLP were lower with IMR compared with standard CT: brain 949.2 vs 794.7 (-17%), thorax 324.3 vs 242.5 (-25%), abdomen 911.0 vs 361.5 (-60%) and whole body 1118.0 vs 893.0 (-20%).
Conclusion: The radiation dose can be significantly reduced using LDCT with IMR algorithm instead standard CECT for the diagnostic evaluation of patients admitted in an ERD.

B-0943 10:55

Age dependency of the Wells Score for pulmonary embolism
S. Nagel, I. Steffen, T. Elgeti; *Berlin/DE (sebastian.nagel@charite.de)*

Purpose: To evaluate a possible age dependency of the classic Wells Score (WS) in patients with suspected pulmonary embolism (PE).
Methods and Materials: 1000 consecutive patients from our emergency department were included into this IRB approved retrospective study. WSs were re-calculated from electronic patient records. CT-pulmonary angiography (CTPA) served as standard of reference for the diagnosis of PE. Logistic regression models and receiver operating characteristic (ROC) curves were used to analyze the effect of patient age, D-Dimer, WS and INR on PE. Best cut-off values in ROC analyses were determined using Youden-Index.
Results: Pulmonary embolism was present in 25.6% of cases. Univariate ROC analysis showed a significant effect of D-Dimer (AUC=0.8; p<0.001) and WS (AUC=0.78, p<0.001) . The multivariate logistic regression model showed a significant association of PE with D-Dimer (p<0.001), WS (p<0.001) and INR (p<0.05) whereas patient age showed a tendency to significance (p=0.070). A significant interaction was observed for WS and patient age (p=0.006). ROC analysis of the multivariate logistic regression model predictor revealed an AUC of 0.84 (p<0.001) with a sensitivity of 79.4% and a specificity of 73.5% for the best cut-off value.
Conclusion: The results of this exploratory study show a significant interaction of the patients' age and the Wells Score for the diagnosis of PE. This may indicate the use of age dependent cut-off values for WS to undertake CTPA.

B-0944 11:03

Ruling out acute kidney injury (AKI) with "admission" reno-caval ultrasound (ARCUS) examination
N. Attempati, A. Contegiacomo, E. Amodeo, M. Barone, A. Cina, R. Manfredi; *Rome/IT (nicoatt89@gmail.com)*

Purpose: Acute Kidney Injury (AKI) requires fast and effective diagnostic workup, but no tools are available for ruling out all possible aetiologies (pre-renal/renal/post-renal) at one time. This study aims to evaluate whether examination of Inferior Cava Vein (IVC) collapsibility (hydration index) and hydronephrosis (obstruction index), with the integration of doppler Resistivity Index (RI), as first diagnostic tool (ARCUS), allows AKI aetiology identification.
Methods and Materials: from January 2016 to July 2017, ARCUS examination was prospectively performed on 30 patients with sudden oligo-anuria or estimated Glomerular Filtration Rate (eGFR) reduction. Maximal inspiration IVC collapse >50% was considered suggestive of pre-renal AKI and presence of hydronephrosis suggestive of post-renal AKI; in all the other cases RI >0.70 was considered diagnostic for renal AKI. ARCUS examination outcome was compared with final medical diagnosis to assess tool specificity and sensitivity.
Results: 17/30 patients had IVC collapse >50%, with 85,7% specificity and 93,7% sensitivity for pre-renal AKI; hydronephrosis was observed in 10/30 patients, with a 100% specificity and sensitivity for post-renal AKI. In 3/30 patients RI evaluation was performed: 2 patients had RI >0.70 and 1 <0.70 (pre-renal AKI), with a sensitivity and specificity of 50% and 100% respectively for Renal AKI.
Conclusion: our pilot study suggests that ARCUS examination is a very good tool for AKI initial and rapid evaluation, with excellent specificity and good sensitivity.

B-0945 11:11

When ultrasound is not enough: predicting downstream utilisation of CT after ultrasound in patients with acute abdomen
K. Rippel, D. Ordu, L.-P. Rollandi, T. Kleffel, C. Scheurig-Muenkler, T. Kröncke, F. Schwarz; *Augsburg/DE (Katharina.Rippel@klinikum-augsburg.de)*

Purpose: To analyse whether markers of systemic inflammation predict the utilisation of additional CT after ultrasound in ED patients presenting with acute abdominal pain.
Methods and Materials: We analyzed 506 patients who presented to the ED over a three-month period with acute abdominal pain and were referred for an ultrasound examination of the abdomen. We analysed electronic health records for prior medical history and laboratory tests of systemic inflammation (WBCC and CRP) at the time of presentation. Furthermore, all abdominal CT scans performed within a 36-hour window following the ultrasound exam were registered. Receiver-Operating-Characteristic(ROC) statistics were used to analyse the predictive value of CRP and WBCC for additional utilisation of CT. We performed subgroup analyses for patients without recent hospital admission and with known malignancy.
Results: 71 patients were excluded due to various reasons. Of the remaining 435 patients, 65(15%) underwent additional abdominal CT. Differences in WBCC and CRP between patients who underwent CT vs. those who did not were highly significant (WBCC: 12.4 [9.2;17.6] vs. 9.6 [7.5;12.9]; CRP: 8.2 [0.93;20.4] vs. 1.1 [0.28;6.0], both p's<0.01). On ROC analysis, WBCC and CRP had similar moderate predictive values for subsequent utilisation of additional CT (AUC:0.69±0.04 vs. 0.66±0.04,p=0.66). Predictive values were highest in the subgroup of patients without hospital admission in the preceding 12 months (AUC:0.89± 0.06 vs. 0.75±0.05, p=0.06).
Conclusion: Across all patients presenting with acute abdomen, CRP and WBCC has moderate predictive value for subsequent CT utilisation after ultrasound. However, in patients without recent hospital admission, predictive value is excellent.

B-0946 11:19

How accurate are we and how can we get better in diagnosing acute appendicitis by unenhanced multidetector computed tomography: a large meta-analysis and literature review
A. Mishra, R. AlSaady, S. Patel, S.A. Mahemood, T.S. Abdulla, A.A.W. Hussain; *Doha/QA (dranujmish@yahoo.com)*

Purpose: To analyse CT criteria and determine best CT parameter(s) for diagnosing acute appendicitis.
Methods and Materials: Retrospective analysis of patients diagnosed with acute appendicitis was done. 800 patients underwent unenhanced abdominal CT(UACT) within 24-48 hours of onset of acute pain, were analysed (male 563 (70.4%); female 237 (29.6%); mean age 36 years; range 5-86 years). UACT assessment of appendix was based on: appendix diameter, periappendiceal inflammatory fat-stranding (PIFS), fluid collection, free air and appendicolith.
Results: Appendiceal diameter correlated to the inflammation of the appendix (p=0.001) with sensitivity (Sn)=94.4%, specificity (Sp)=90.3%, negative predictive value (NPV)=93.2% and positive predictive value (PPV)=91.6%. 767 (95.9%) patients had appendiceal diameter ≥7 mm, of which 43(5.6%) did not have histopathological diagnosis of acute appendicitis. The patients with acute appendicitis had a mean appendiceal diameter of 8.5 mm (range 6-16; SD 2.7) whereas patients with normal appendix had mean appendix diameter of 4.1 mm (range 2-6; SD 0.8). There was correlation between CT criteria for presence of PIFS, fluid, appendicolith and inflammation of the appendix (p=0.01). In patients with normal appendix, mild-to-moderate PIFS was noted in 16 (48.5%) and severe PIFS in 10 (30.3%) patients. In patients with acute appendicitis, PIFS was observed in 682 (85.3%) patients with Sn=96.2%, Sp=87.4%, NPV=92.8% and PPV=89.6%. None of the patients with normal appendix had appendicolith whereas 309 (38.6%) with acute appendicitis demonstrated appendicolith with Sn=96.1%, Sp=78.2%, NPV=76.7%, PPV=74.3%. 17(2.1%) had periappendiceal fluid. 6(0.8%) had extraluminal air around the appendix out of which 1 (5.9%) did not have histopathological perforation. Combining appendiceal diameter and PIFS yielded Sn=98.4%, Sp=99.8%, NPV=94.5% and PPV=99.2%.
Conclusion: Appendiceal diameter ≥ 7 mm and PIFS have high sensitivity but relatively lower specificity individually, but when combined together has almost 100% specificity with 99.2% positive predictive value.

B-0947 11:27

Comparing diagnostic performance of ultra-low-dose CT compared to abdominal plain films
J. Lee[1], S. Bruni[1], S. Kennedy[1], V. Swami[1], E. Chen[1], R. Menezes[1], D. Borrego[2], C. Lee[2], P. Rogalla[1]; [1]*Toronto, ON/CA*, [2]*Rockville, MD/US (ljhjohn.lee@mail.utoronto.ca)*

Purpose: To determine relative diagnostic performance of ultra-low-dose CT (ULD-CT) and abdominal plain films (APF) with regard to sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) in the emergency setting.
Methods and Materials: As per new institutional protocol, all patients with acute abdominal pain who would be referred to APF were automatically converted to ULD-CT. Target exposure values were set to achieve 1 mSv equivalent exposure to a standard 75 kg individual. Our study examined 196 consecutive ULD-CT ordered since initiation of the new protocol and 196 consecutive APF from the emergency department prior to inception of new protocol over a period of 9 weeks. Final diagnosis was compared to the gold standard diagnosis comprising of lab values, clinical notes, additional imaging tests, endoscopy, and surgery. Each patient was followed up for a minimum of one month.

Results: There were no statistical difference between age (63.3 vs 60.8, p=0.5) and gender (49% vs 51% male, p=0.7) between ULD-CT and APF groups. When comparing ULD-CT to APF, sensitivity (0.86 vs 0.40, p<0.01), specificity (0.98 vs 0.81, p=0.02), PPV (0.94 vs 0.50, p<0.01) and NPV (0.92 vs 0.74, p=0.02) were higher for ULD-CT.
Conclusion: ULD-CT has statistically higher sensitivity, specificity, PPV and NPV compared to APF. ULD-CT has the potential to replace APF by delivering significantly better diagnostic information despite a radiation dose profile comparable with conventional APF. This is the largest study to date comparing the diagnostic performance of ULD-CT compared to APF.

B-0948 11:35

CT signs of bowel necrosis in CL-SBO
C. Rondenet[1], I. Millet[2], L. Corno[1], I. Boulay Coletta[1], P. Taourel[2], M. Zins[1]; [1]*Paris/FR*, [2]*Montpellier/FR*

Purpose: To identify computed tomography (CT) findings associated with bowel necrosis in patients with surgically confirmed strangulating closed-loop small-bowel obstruction (CL-SBO) due to adhesions or internal hernia.
Methods and Materials: This retrospective study was approved by our institutional review board and informed consent was waived. To identify specific signs of bowel necrosis, two gastrointestinal radiologists performed blinded, independent, retrospective reviews of 41 CT studies from consecutive patients who had CL-SBO due to adhesions or internal hernias and who underwent surgery within 48 h. Based on surgical and pathological findings, patients were classified as having reversible ischaemia or histologically documented necrosis. Univariate statistical analyses were performed to assess associations between CT signs and bowel necrosis. K statistics were computed to assess interobserver agreement.
Results: We included 25 (61%) women and 16 (39%) men with a median age of 79 years. Bowel necrosis was found in 25/41 (61%) patients and ischaemic but viable bowel in 16/41 (39%) patients. Increased unenhanced bowel-wall attenuation was the only CT finding significantly associated with bowel necrosis (*P*=0.0002). This sign had 58% (95%CI, 37-78) sensitivity and 100% (95% CI, 79-100) specificity for necrosis. Interobserver agreement was fair (0.59; 95%CI, 0.37-0.82).
Conclusion: Increased unenhanced bowel-wall attenuation is specific of bowel necrosis and should lead to prompt laparotomy for bowel resection.

B-0949 11:43

Contribution of ultra low-dose CT in extremities trauma
F. Snene, T. Addala, J. Greffier, P. Viala, J.P. Beregi, A. Larbi; *Nîmes/FR (snenefehmi@gmail.com)*

Purpose: To evaluate the diagnostic power of ultra-low-dose CT (ULD-CT) of the extremities (wirst/hand or ankle/foot) compared to the X-ray in emergency room.
Methods and Materials: An ULD acquisition without contrast medium injection as well as an X-ray of the injured extremitie were performed in 76 patients consulting the emergency department of our institution from March to August 2017.Raw data were reconstructed with Sinogram-Affirmed-Iterative-Reconstruction (SAFIRE, Siemens) with soft tissue (I30f) and bone (I70f) reconstructions kernel. The subjective analysis (image quality, diagnostic quality, characterization of the lesions with confidence level) was performed by double blind reading (1 senior and 1 junior radiologist). The diagnostic performance of the ULD-CT and X-ray were compared.
Results: Effective dose for ULD-CT were lower than the recommandations of the IRSN 2012(National Institute for Radiation Protection and Nuclear Safety).Kappa Cohen test agreement among the two observers for the evaluation of traumatic lesions was substantial, ranging from 0.8 to 0.95.The analysis of data showed the absence of inferiority of the ULD-CT in the detection of traumatic lesions comparatively to the X-ray. The ULD-CT showed its superiority in the characterization of associated anomalies (p<0.05)Readers recorded a significantly high score of diagnostic confidence level for ULD-CT compared to X-ray (p<0.05)
Conclusion: ULD-CT with iterative reconstructions allowed a reliable study of extremities trauma patients with an equivalent or lower irradiation dose than plain X-ray.Reproducibility is independent of the level of experience of the readers.

B-0950 11:51

Diagnostic performance of quiescent interval single-shot (QISS) non-contrast MRA at 3 Tesla for the diagnosis of acute lower limb ischaemia
Y. Ragab[1], A. Al Marakby[1], H.M. Hamza[2], A. Hasanin[1]; [1]*Cairo/EG*, [2]*London/UK (yragab61@hotmail.com)*

Purpose: To assess the diagnostic performance and limitations of ECG-gated non-contrast-enhanced quiescent interval single-shot (QISS) magnetic resonance angiography at a magnetic field strength of 3 Tesla in patients with acute peripheral arterial occlusive disease (PAOD).
Methods and Materials: 29 patients with manifestations of acute lower limb ischaemia, referred for lower limb gadolinium-based contrast enhanced magnetic resonance angiography (MRA) were included. Imaging was performed on a 3T whole-body MR. Non-contrast MRA series using QISS technique were initially performed. Image quality and stenoses diameters were compared to contrast-enhanced MRA (CE-MRA) as standard of reference. Two blinded readers rated the image quality and the degree of stenosis for both ECG-gated QISS and CE-MRA in 26 predefined arterial vessel segments on 5-point Likert scales.
Results: Compared with CE-MRA, QISS MRA technique showed high sensitivity (93%), specificity (95%), positive (95.1%), and negative predictive value (96%) for the detection of significant (≥50%) stenosis or occlusion. Interreader agreement for stenosis and occlusion assessment of both QISS and CE-MRA was excellent (κ-values of 0.94 and 0.95, respectively). As compared to CR-MRA, image quality of QISS was significantly lower for the distal aorta, the femoral and iliac arteries (each with p<0.01), while no significant difference was found in the popliteal (p=0.07) and lower leg arteries (p=0.9).
Conclusion: Non-contrast QISS MRA has been shown to be technically comparable to CE-MRA in the assessment of femoropoliteal and leg arteries; however, it has limitations during evaluation of the lower aorta and iliac arteries.

Inferior glenohumeral vertical distance: a novel radiographic marker better suited for detection of rotator cuff tears involving the infraspinatus tendon
M. Alfaqih, S. Soni, S. Flacke, Y. Andrabi, D. Elentuck, R. French; *Burlington, MA/US (mohammad.alfaqih@lahey.org)*

Purpose: Evaluate the association between the radiographically determined inferior glenohumeral vertical distance (IGHVD) and rotator cuff tears (RCT) involving infraspinatus (IS) tendon and compare the sensitivity and specificity of acromiohumeral distance (AHD) and IGHVD for RCT involving IS tendon.
Methods and Materials: 140 patients with MRI proven full thickness rotator cuff tear were included after they met the inclusion and exclusion criteria. Patients were divided into two groups, group A: RCT involving full or partial IS tears, and group B: RCT not involving IS. Radiographs were analysed blinded to MRI findings. IGHVD determined by measuring vertical distance from anatomical neck to inferior glenoid level in anteroposterior (AP) view; distance of more than 2mm was considered positive. AHD was assessed by measuring vertical interval between inferior border of acromion process and humeral head in (AP) view; distance less than 7 mm was considered positive.
Results: Group A included 89 patients and Group B involved 51 patients. A strong association was found between IGHVD and rotator cuff tears involving infraspinatus tendon (p < 0.001). IGHVD was found to have increased sensitivity, PPV and NPV (66%, 92%, 60%, respectively) compared to AHD (20%, 85%, 40%, respectively). The specificity of both was comparable (90% for IGHVD and 94% for AHD).
Conclusion: There is a strong association between radiographically determined IGHVD and infraspinatus tear and is more sensitive than AHD.

Imaging of aponeurotic expansion of supraspinatus tendon by 3.0 T MRI and its association with biceps brachii long head, supraspinatus and subscapularis tendon pathologies
Z. Akkaya, H. Bas, D. Oztuna, G. sahin; *Ankara/TR (zehraakkaya@gmail.com)*

Purpose: The purpose of this study was to identify the prevalence of the aponeurotic expansion of the supraspinatus tendon (SSa) by 3.0 T MRI and to search for possible associations with the pathologies of the supraspinatus (SS), biceps brachii long head (BB) and subscapularis (Sub) tendons.
Methods and Materials: A total of 154 patients and 157 shoulders (3 cases with bilateral examinations) between the ages of 18 and 45 years, examined by 3.0 T scanner between July 2011 and March 2017, were re-examined for the presence of SSa. When present, it was further categorised according to its

size. The exclusion criteria were history of shoulder trauma, surgery, deformity, inflammatory arthropathy, end-stage rotator cuff disease, major systemic illness, and technically inadequate imaging. The pathologies of BB, SS and Sub tendons were evaluated separately and using Mann- Whitney U and Kruskall- Wallis tests tendon pathologies were compared to SSa types
Results: A total of 82 male and 72 female cases with a mean age of 34 (±8.2) were included. There were 126 cases (80.3%) without a visible SSa and the incidence of BB pathologies in this group was significantly lower than the other types where a visible SSa was noted ($p<0.05$). No significant correlations were found between pathologies of SS and Sub and SSa types. For pathologies of all three tendons, age was found to be a significant variable ($p<0.01$).
Conclusion: BB tendon pathologies were significantly more common in cases with SSa which might indicate a risk factor on its own.

B-0953 10:46

Reliability of strain elastography in the supraspinatus tendon
K. Brage; *Odense M/DK (kabr2@ucl.dk)*

Purpose: Sonoelastography (SEL) is used to measure tissue elasticity, and individual studies show good reliability; however, this study investigates the reliability of SEL, when used in the supraspinatus tendon. The aim of this study was to test the intra-examiner reliability of a novel SEL protocol for supraspinatus tendon elasticity in participants with supraspinatus tendinosis diagnosed with MRI and in asymptomatic participants.
Methods and Materials: Ten participants with no shoulder complaints and 10 participants with supraspinatus tendinosis were examined independently by the project leader (KB). GE LOGIQ S7 fitted with a quasi-static strain imaging software was used to create elastograms as ratios between the supraspinatus tendon and reference regions of muscle (deltoid), and a gel pad, respectively. Elastograms were also evaluated qualitatively according to the structure (homogeneous, relatively homogenous, and heterogeneous), the colour (blue, blue with 1-25% green, blue with 26-50% green, green with 1-25% blue, and green), and the number of lesions was counted.
Results: The intra-class correlation (ICC 2.3) of measurements with the reference of muscle was excellent 0.92 (95%CI: 0.80-0.97), as well as for the gel pad 0.87 (95%CI: 0.67-0.95) and number of lesions 0.98 (95%CI: 0.96-0.99). Moderate kappa (k) was found for estimation of colour (k = 0.58) and structure (k = 0.60).
Conclusion: Intra-rater reliability was moderate to excellent when a standardized procedure was applied for measuring tissue stiffness in the supraspinatus tendon. Future studies should test inter-rater reliability in addition to validation against conventional ultrasound and MRI.

B-0954 10:54

Evaluation of tendinopathy of the long head of the biceps tendon by strain and shear wave elastography
M.H. Sahan, M. Inal, V. Burulday, T. Kultur; *Kirikkale/TR (vedoctor@hotmail.com)*

Purpose: The purpose of this study was to investigate strain (SE) and shear wave elastography (SWE) characteristics of the long head of the biceps tendon (LHBT) tendinopathies in comparison with magnetic resonance imaging (MRI).
Methods and Materials: Twenty patients with a diagnosis of tendinopathy and twenty healthy subjects with a normal LHBT in MRI were enrolled. A total of 40 shoulders were examined prospectively by SE and SWE. LHBT SE color mapping was divided into four types in accordance with elasticity designs: type I predominantly blue (hardest tissue), type II predominantly blue-green (hard tissue), type III predominantly green (intermediate tissue), type IV predominantly green-yellow-red (soft tissue). Quantitative measurements of LHBT hardness with SWE were analyzed in kilopascals (kPa).
Results: SE images from the tendinopathy group: transverse: type I (24%), type II (50%), type III (25%): longitudinal: type I (15%), type II (75%), type III (10%); control group images: transverse: type II (10%), type III (55%), type IV (35%), longitudinal: type II (10%), type III (55%), type IV (35%). SWE values: transverse: 38.32±7.2 kPa, 18.6±3.1 kPa and longitudinal: 39.42±7.4 kPa, 20.62±4.6. There was a statistically significant difference in terms of elasticity patterns between the tendinopathy and control groups ($p<0.001$). The receiver operating characteristic curve analysis was perfect and a cut-off value of tranverse, 25.8 kPa, longitudinal, 24.6 kPa shear had very high sensitivity and specificity for tendinopathy.
Conclusion: SE and SWE may be useful diagnostic tools for LHBT tendinopathy when considering usability, cost effectiveness and patient preference compared to MRI.

B-0955 11:02

How, when, why in magnetic resonance arthrography: an international survey by the European Society of Musculoskeletal Radiology
D. Albano[1], C. Messina[2], A. Tagliafico[3], L.M. Sconfienza[2]; [1]*Palermo/IT*, [2]*Milan/IT*, [3]*Genoa/IT (albanodomenico@me.com)*

Purpose: To perform an online survey among all members of the European Society of Musculoskeletal Radiology (ESSR) to understand how, when, and why magnetic resonance arthrography (MRA) is used in clinical practice.
Methods and Materials: We administered an online survey to all 1,550 members of the ESSR about the use of MRA in clinical practice asking ten different questions. Subgroup analysis was performed between general and orthopaedic hospitals. Mann-Whitney *U* and X^2 statistics were used.
Results: A total of 148 answers were included in our analysis, representing 9.5% (148/1,550) of ESSR members. A median of 3,000 (25^{th}-75^{th} percentiles: 1,567.5 - 5,324.5) musculoskeletal MR examinations per single institution were performed in 2016 and a mean of 125.5 MRAs (50.75 - 249). Ratio between MRA and musculoskeletal MR was 4.7% (1.6%-9.0%). Using MRA, the most investigated joint was the shoulder followed by the hip. The most common indications were the evaluation of instability, labrum, and rotator cuff. Fluoroscopy represented the preferred guidance to inject joints in 61.0% of cases. A self-prepared mixture of gadolinium and saline solution is preferred in general hospitals, while pre-diluted gadolinium-based syringes are mainly used in orthopaedic hospitals ($P=.010$). The number of MRA performed at orthopaedic hospitals (284; 83.75-449.50) was significantly higher ($P=.006$) than that performed at general hospitals (115.50; 44.75-234.25).
Conclusion: One out of twenty MR examinations is a MRA, with higher prevalence in orthopaedic hospitals. The shoulder and the hip are the most investigated joints. Instability and labrum are the most common reasons to perform MRA.

B-0956 11:10

The diagnostic accuracy of diffusion-weighted imaging for the detection of partial-thickness rotator cuff tears
O. Mansour, G. Jafarinosar; *Tehran/IR (mansour.omid@yahoo.com)*

Purpose: The aim of our study was to investigate the accuracy of DWI sequence in diagnosis of partial thickness tears of rotator cuff tendon in compare with routine sequences.
Methods and Materials: We collected the data of 60 patients who referred to our imaging centre for shoulder MRI. Imaging was performed with a 1.5 Tesla MRI unit (Ingenia CX , Philips medical systems). The following imaging protocol was used: coronal oblique T2W TSE (TR/TE 3200/90ms), thickness 3.5mm, coronal oblique T1W TSE (TR/TE 460/16ms), thickness 3.5mm, coronal, sagittal and axial PD fat suppressed (TR/TE 1800/24ms), thickness 3.5mm. All sequences were acquired with a fov 16cm and matrix size 256x228. DWI sequence (b factors 0 and 600s/mm^2) was performed in coronal oblique plane (TR/TE 3200/60ms), thickness 3.5mm, fov 20cm, matrix size 128x128. Of 60 patients, 32 patients underwent shoulder arthroscopy within 3 months after MR examination. Two radiologists reviewed MRI studies.
Results: Imaging findings at MRI studies and arthroscopic results were compared in 22 of 32 patients were diagnosed with partial thickness tears in arthroscopy. The results showed DWI sequence was superior to routine sequences in diagnosing partial thickness tears of rotator cuff.
Conclusion: According to the results of our study, DWI sequence plays a effective role to diagnose the partial thickness tears of rotator cuff than routine sequences (DWI accuracy 88%, routine sequences accuracy 76%).

B-0957 11:18

Ultrasound imaging of muscle contraction of the tibialis anterior in patients with facioscapulohumeral dystrophy
K. Gijsbertse[1], R. Goselink[1], S. Lassche[1], M. Nillesen[1], A. Sprengers[1], N. Verdonschot[1,2], N. van Alfen[1], C.L. de Korte[1]; [1]*Nijmegen/NL*, [2]*Enschede/NL (kaj.gijsbertse@radboudumc.nl)*

Purpose: The pathophysiological mechanisms leading to muscle weakness in most neuromuscular disorders are not completely understood. Dynamic ultrasound imaging in combination with a speckle tracking method is introduced to visualize and quantify muscle deformation.
Methods and Materials: Ultrasound image sequences were acquired from 16 legs (4 patients with facioscapulohumeral dystrophy (FSHD) and 4 healthy controls) during voluntary contractions of the tibialis anterior muscle. A cross correlation method was applied to estimate muscle tissue deformation from the ultrasound images. The resulting deformation patterns were compared with muscle ultrasound echo intensity analysis (a measure of fat infiltration and dystrophy) and clinical outcome measures.
Results: Ultrasound speckle tracking revealed a distinctively different tissue motion patterns between patients with peroneal weakness and healthy controls. Patients with severe peroneal weakness showed a homogeneous displacement pattern of the tibialis anterior with small motion of the central

aponeurosis (2.1 ± 1.0 mm), contrary to healthy subjects that showed a large non-uniform displacement (9.7 ± 1.8 mm), increasing form the periphery of the muscle to the central aponeurosis. Furthermore, the difference in muscle deformation patterns of patients shows good agreement with clinical measures (e.g. decrease in force generation) and ultrasound echo intensity analysis.
Conclusion: This work provides a tool to quantify muscle motion and evidence of changing functional behaviour of the affected muscles in FSHD patients. The quantitative characterization of muscle contraction provides new insights into the way pathologic muscle tissue deforms, leading to a better understanding of the underlying mechanisms related to weakness in muscle disease.

B-0958 11:26

Adhesive capsultis of the shoulder: a new ultrasound-guided and rehabilitation multidisciplinary treatment protocol to restore shoulder girdle kinesis

G. Ferrero, V. Amico, F. Lacelli, E. Fabbro, N. Perrone, G. Serafini;
Pietra Ligure/IT (giulio.ferrero@gmail.com)

Purpose: To examine the effectiveness in short and medium terms of a new multidisciplinary treatment protocol (ultrasound guided and rehabilitative) of adhesive capsulitis of the shoulder (AC).
Methods and Materials: 12 patients with clinical diagnosis of AC were treated with a protocol including ultrasound-guided capsular hydrodistension, intra-articular steroid and hyaluronic acid (HA) injection, suprascapular and axillary nerves US-guided block and physiokinesitherapy (PKT) within two hours. Intensive PKT was then administered for 20 sessions. Evaluation was made before and after the first treatment, at the fifth, tenth and twentieth session using Constant-Murley scale and measuring ROM. The results were compared with a control group of 15 patients treated without nerve block. T test was used to evaluate differences in Constant-Murley scale and ROM before and after treatment.
Results: Prompt ROM improvement (P<0,001) was observed after the first treatment session in both groups, with better C-M score and ROM values in patients who underwent nerve block. In both groups, a gradual and constant ROM recovery was observed.
Conclusion: The study demonstrates that the proposed treatment can be effective, with better results compared to conventional treatment both in terms of ROM recovery and pain. AC can be treated with a multidisciplinary approach to obtain a shorter recovery time and better clinical results.

B-0959 11:34

US-guided percutaneous double needle lavage in the treatment calcific tendinopathy of therotator cuff performed with or without US-guided block of the suprascapular nerve

D. Maiettini, R. Torre, S. Mosca, A. Rebonato; *Perugia/IT (danielemaiettini@gmail.com)*

Purpose: To compare the outcome of ultrasound-guided percutaneous double needle irrigation (US-PICT) in the treatment of calcific tendinopathy of the rotator cuff performed with or without ultrasound-guided block of the suprascapular nerve in terms of pain control and shoulder mobility.
Methods and Materials: We retrospectively enrolled 47 patients treated with US-PICT during 2015 and 2016 diagnosed with calcific tendinitis of the rotator cuff. Twenty-seven patients were treated with US-PICT alone while the remaining 20 were treated after the ultrasound-guided block of the suprascapular nerve of the same shoulder, using Lidocaine. The Visual Analogy Scale (VAS) and the Constant score were assessed before and immediately after the procedure and at 7 days, one and three months.
Results: Overall patients the VAS and Costant scores showed a significant improvement after the procedure, during the follow-up (p<0.0001). The block group showed a significant reduction of the VAS immediately after the procedure with respect to the non-block group (mean values 4,4 vs 5,6) (p=0.01). At one week, one and three month follow-up there was no significant difference between groups considering VAS score (p>0.05). Constant score values didn't show any statistical difference during follow up between the block and non-block group. No major or minor complication were encountered.
Conclusion: Ultrasound-guided percutaneous double needle irrigation in the treatment calcific tendinopathy confirmed to be effective both considering pain control and shoulder recovery. Ultrasound-guided block of the suprascapular nerve is effective in peri-procedure pain control while doesn't improve shoulder mobility recovery.

B-0960 11:42

Another breach in the wall: efficacy of sodium hexametaphosphate (SHMP) solution vs simple saline in percutaneous treatment of calcific tendonitis of the shoulder: 6-months follow-up

S. Mariani[1], F. Bruno[1], S. Quarchioni[2], E. Cannizzaro[1], C. Gianneramo[1], F. Arrigoni[1], L. Zugaro[1], A. Barile[1], C. Masciocchi[1]; [1]*L'Aquila/IT*, [2]*Teramo/IT (mari.silvia@hotmail.it)*

Purpose: Calcific tendinitis of the shoulder is a common cause of pain and articular disability. The aim of our study was to evaluate the efficacy of percutaneous US-guided lavage in treatment of calcific tendinitis using a sodium hexametaphosphate(SHMP) solution(0.5%), in comparison with the same technique using simple saline.
Methods and Materials: We evaluated 32 symptomatic patients with calfic tendinitis of the rotator cuff . Patients were randomly divided into 2 groups and treated by percutaneous fragmentation and lavage using SHMP (Group1, 16 patients) or simple saline (Group2, 16 patients). In all patients, clinical and instrumental evaluation morphologic changes were assessed before and 2 weeks, 1 month and 6 months after treatment. Imaging evaluation included conventional radiography and ultrasound, while clinical follow-up was performed using Constant Shoulder Score for functional improvement and VAS Score for pain.
Results: In Group 1, 11 patients showed almost complete dissolution of calcifications (68,75%), while the remaining 5 just partial dissolution (31,25%); of these, 3 (60%) showed subtotal dissolution after 1 month. In Group 2, 9 patients (56,25%) showed almost complete dissolution and partial in the remaining 7(43,75%) (p≤0.05), of these 1 patient (14,29%) showed subtotal dissolution after 1 month. VAS and Constant Score showed a significant improvement in 100% of patients in both groups (p≤0.05) after 4 weeks and 6 months.
Conclusion: The use of SHMP showed superior results compared to the treatment with simple saline solution especially in single session treatment and short-term follow-up. After 6 months in fact, both groups showed matched results.

B-0961 11:50

Improvement of image quality and diagnostic confidence using Smart MAR - a projection-based CT protocol in patients with orthopaedic metallic implants in hip and shoulder

F. Feldhaus, G. Böning, U. Fehrenbach, J. Kahn, B. Hamm, F. Streitparth;
Berlin/DE (felix.feldhaus@charite.de)

Purpose: To determine whether the metal artifact reduction tool - a three-stage, projection-based, postprocessing algorithm - improves subjective and objective image quality and diagnostic confidence in patients with orthopaedic implants.
Methods and Materials: 20 patients with orthopaedic screws/replacement of hip or shoulder were included. CT scans were performed on a single-source, 64-row multislice CT scanner (MSCT, Evolution, GE Healthcare). CT raw data were postprocessed using Smart MAR. Image quality of standard and Smart-MAR-based reconstruction series was evaluated both quantitatively (in ROIs) and qualitatively (two independent raters) and compared to standard reconstructions. Dose was analyzed in dose-length products (DLP) and computed tomography dose indices (CTDIvol).
Results: Smart MAR reconstructions of shoulder and hip (each n=10) showed significantly reduced attenuation and noise of regions adjacent to metallic implants (all $p</= 0.005$). Smart MAR improved subjective visualization of adjacent trabecular and cortical bone and adjacent soft tissue (all p<0.02). Subjective diagnostic confidence was also improved in hip (p=0.01) and shoulder region (p=0.02). There was no significant improvement in signal-to-noise ratio (SNR; p<0.72). Mean DLP of hip region was 515,7 SD 192,2 HU (shoulder: 295,6 SD 144,0), mean CDTIvol 13,5 SD 4,6 (shoulder 13,7 SD 6,4).
Conclusion: Smart MAR significantly improved image quality of hip and shoulder CT scans even in the presence of severe artifacts, resulting in higher diagnostic confidence. Especially for the evaluation of periprosthetic tissues of the hip and shoulder, this automated postprocessing technique appears to be well suitable for clinical routine without increasing radiation exposure compared to standard CT scans.

Reduction of contrast agent using virtual monochrome image in haemodynamics aortic phantom

F. Washizuka, T. Kitamura, T. Hatakeyama, H. Nakano; *Tokyo/JP (fuyuki.washizuka@med.toho-u.ac.jp)*

Purpose: It is possible to reduce the contrast agent in the fixed type phantom using virtual monochrome images (VMI). Consider whether reduction of the amount of contrast agent is possible even using haemodynamic aortic phantom.
Methods and Materials: Using the CT scanner (Somatom Definition Flash; Siemens Healthcare), haemodynamic phantom was scanned in the dual energy scan (80-Sn140kV). The kernel used for image reconstruction is "B30". Injection condition was 24mgI/kg/s (assuming a weight of 60 kg, 370mgI/ml syringe, and 10-second injection). After that the contrast agent was reduced by 10% and scanned. The reconstructed images are 54 keV, 57 keV, 60 keV, 63 keV, 66 keV, 69 keV, and 72 keV and MIX images. Contrast to noise ratio (CNR) and shape reproducibility was calculated, and visual evaluation was performed.
Results: The CNR was highest at around 66 keV, and CT value was increased at lower keV. Using VMI (66keV), if the CNR is made equivalent, the contrast agent can be reduced by 20% and equivalent images can be obtained. Considering the noise of the background and using further low keV, the CT value increases, it is possible to reduce 40% of the contrast agent.
Conclusion: Using VMI in not only fixed phantom but also haemodynamic phantom, we could reduce contrast agent by up to 40%.

B-0963 10:30

Development and reliability of an ultrasound protocol to evaluate quadriceps muscle mass and diaphragm structure: a pilot study

A. André[1], J. Pinto[2], D. Oliveira[2], C. Aguiar[2], S. De Francesco[2], A. Oliveira[2], A. Marques[2], P. Martins[2]; [1]*Coimbra/PT*, [2]*Aveiro/PT (alexandra.andre@estescoimbra.pt)*

Purpose: This study aimed to evaluate the intra and inter-operator reliability of an ultrasound (US) protocol, to assess quadriceps muscle mass and diaphragm structure in healthy people, for future monitoring of patients with respiratory disease.
Methods and Materials: Twelve volunteers (6♀, 31.8±10.6 years; BMI=23.4±3.7 kg/m2) participated. An US equipment (Logiq P6 PRO, GE) with a multifrequency linear probe (11L) was used. Three measures of Quadriceps (Q_{TK}) and Rectus Femoris thickness (RF_{TK}), RF cross sectional area (RF_{Area}), bilateral diaphragmatic thickness at maximal inspiration ($D_{TK}I$) and at end expiration ($D_{TK}E$) were obtained by one operator. Six volunteers were randomly evaluated by two operators. Mann Whitney test was used to assess differences between inspiration and expiration and the right and left hemi-diaphragm. The Intraclass Correlation Coefficient ($ICC_{2,1}$) was used to explore reliability.
Results: Mean RF_{TK} were 1.72cm, 8.19cm^2 for RF_{Area} and 3.23cm for Q_{TK}. Significant differences were found between $D_{TK}I$ and $D_{TK}E$ both at right (0.31±0,17cm vs 0.23±0.19cm, p=0.01) and left hemi-diaphragm (0.37±0.18cm vs 0.24±0.14cm, p=0.01). No significant differences between the right and left hemi-diaphragms were observed during inspiration or expiration. Intra and inter-operator reliability were all Excellent: $D_{TK}E$ (intra: $ICC_{2,1}$=0.977; inter: $ICC_{2,1}$=0.822), $D_{TK}I$ (intra: $ICC_{2,1}$=,0.903; inter: $ICC_{2,1}$=0.805), Q_{TK} (intra: $ICC_{2,1}$=0.976; inter: $ICC_{2,1}$=0,940), RF_{Area} (intra: $ICC_{2,1}$=0.973; inter: $ICC_{2,1}$=0.981) and RF_{TK} (intra: $ICC_{2,1}$=0.998 ; inter: $ICC_{2,1}$=0.762).
Conclusion: Results showed the feasibility and reliability of this US protocol in healthy people. One single measurement by one operator seems to be adequate. Bilateral diaphragmatic measurements might not be necessary in respiratory patient's evaluation

B-0964 10:38

Orbital ultrasound evaluation of the optic nerve sheath diameter

H.I.M.G. Ferraz[1], R.A. Santos[2]; [1]*Peso da Régua/PT*, [2]*Coimbra/PT (helenaimgferraz@gmail.com)*

Purpose: The human eye is one of the most complex organs in our body. The fact that the eye is a liquid-filled superficial structure allows an optimal appreciation of the ocular structures on ultrasound. There has been an increase in the use of this modality in the evaluation of the diameter of the optic nerve sheath (ONSD). To purpose of the study is to analyse the reproducibility of the ONSD diameter measures, to characterise the ONSD by ultrasound, to verify the existence of correlation with body mass index (BMI), blood pressure (BP) and glucose values.
Methods and Materials: 370 ultrasound images of ONSD were collected from 84 individuals, divided into 2 groups. The ICC was obtained to evaluate the reproducibility of the ultrasound measurements. The BMI, BP and glucose values were also collected from all subjects. The correlation of data was also evaluated with the Pearson test and the Student's T test for independent samples.
Results: The ONSD ICC values showed satisfactory reproducibility (0.73). BMI and age showed a positive correlation with BP ($p<0.05$). No significant differences were found between the group with pathology (myopia, astigmatism or hypermetropia) and without.
Conclusion: Ultrasonography showed a satisfactory reproducibility to assess the ONSD and could help with new ocular disease evaluation.

B-0965 10:46

Effects of smoking on carotid artery structures and haemodynamics: role of the radiographer in ultrasound assessment

D.M.B. Simão, L.P. Ribeiro, A.F. Abrantes, J.P. Pinheiro, R.P. Almeida, A.Q. Brito, S. Rodrigues; *Faro/PT (diogo_simao93@hotmail.com)*

Purpose: Currently, tobacco is a behaviour associated with the appearance of several pathologies, such as atherosclerosis or stroke and qualified radiographers in sonography field should be able do detect premature vascular changes due to smoking. The goal of this study was to assess and compare structural and haemodynamic parameters on carotid arteries in smokers and non-smokers by ultrasound.
Methods and Materials: Several parameters on the carotid artery were evaluated by a trained radiographer: intima-media thickness (IMT), peak systolic velocity (PSV) and end-diastolic velocity (EDV). Measurements were performed using a sample of 103 volunteer participants (52 non-smokers and 51 smokers) aged between 20 and 40 years. B-mode images were acquired in longitudinal and transverse sections of the common carotid arteries. Inclusion criteria contains healthy participants with unknown diseases. The smokers group was divided into four different categories depending on the number of cigarettes smoked by day.
Results: It were observed higher mean values for all of the structural and haemodynamic parameters in the smokers group (IMT=0,706mm; PSV=104,94cm/s and DV=30,20cm/s) comparing with non-smokers (IMT=0,512mm; PSV=72,47cm/s and DV=19,29cm/s). Also, the female smokers group presents higher values when compared with the male smokers group (x=0,758 vs x=0,652, respectively).
Conclusion: The data from this study suggest that smoking has negative effects on carotid artery structure and haemodynamics. Therefore, smoking is a risk factor for alterations in carotid artery haemodynamics and female smokers are more likely to develop vasculares changes. Radiographers can play a key role in the detection of pathophysiological changes in a preventive perspective.

B-0966 10:54

Abdominal and lumbar muscle evaluation by ultrasound

R.A.M. Santos, R. Barreiro; *Coimbra/PT (rutemartinssantos@gmail.com)*

Purpose: The aim of this study is to characterize the muscular ultrasound of two postural muscles (rectus abdominis and lumbar multifidus) in healthy individuals and in individuals with postural alterations (namely hyperlordosis).
Methods and Materials: 30 young adults were submitted to an ultrasound evaluation of the rectus abdominis and multifidus lumbar muscles in rest and contraction and an angle measurement of the lumbar spine through a photometry equipment. They were divided into groups: one of control and other with non-congenital posture. The sample was composed of 11 participants with postural deviations and 19 without. 360 images were analysed with Image J software to obtain muscle thickness and echo-intensity values from the two muscles in two conditions and the angle of the lumbar spine was calculated also for all participants.
Results: There were significant differences between rest and contraction on muscle thickness and echo intensity of both muscles. There were no significant differences between the two groups of participants and there was no correlation between the angle and the ultrasound measurements.
Conclusion: The postural deviations do not influence the ultrasound characteristics of the studied muscles. However, more studies must be performed to analyse the relation between the lumbar and abdominal muscles and the postural changes.

B-0967 11:02

Vastus lateralis stiffness assessed by SSI elastography

R.A. Santos[1], P. Armada-da-Silva[2]; [1]*Coimbra/PT*, [2]*Lisbon/PT*
(rutemartinssantos@gmail.com)

Purpose: To assess changes in VL's shear modulus with knee position and after a session of maximal isometric and isokinetic Conc and Ecc contraction and to analyse the relationship between VL's shear elasticity and submaximal knee extension torque with supersonic shear wave imaging (SSI).
Methods and Materials: Sixteen subjects were submitted to acute changes in VL's stiffness associated with passive stretching, performance of short but intense contractile activity, and muscle isometric contractions that were investigated by means of SSI.
Results: The results demonstrated an acute increase of around 10% in VL's shear modulus as a result of performing maximal isometric, concentric, and eccentric contractions. The shear modulus of the VL also increased when the knee moved from 10^{o} to 50^{o} and then to 90^{o} flexion. Finally, a linear relationship between the shear modulus and the level of isometric muscle contraction was observed.
Conclusion: SSI proved to be a good method to investigate muscle mechanical property changes associated with muscle function. These results emphasise the value of an objective and quantifiable muscle US evaluation for studying muscle adaptation to exercise training and muscle function, in general.

B-0968 11:10

Use of ultrasound for diagnosis of schistosomiasis mansoni

H.M.K. Masha; *Nairobi/KE (hildakadzo@yahoo.com)*

Purpose: To establish the role of ultrasound in the diagnosis of Schistosoma mansoni.
Methods and Materials: Ultrasound was used to scan a group of 400 individuals in obtaining sonographic grading.The study was done in an area called Nzoila in Kenya and included adults and children both males and females.The age range considered for the study was 8-45 years.Characteristic sonographic features of schistosoma to be observed were periportal fibrosis noted along the long axis of the intrahepatic portal veins. Scanning along central and peripheral bifurcation points of the portal veins produced branching pattern of high echogenicity. From this sonographic pattern, grading was done as follows; A- Normal, B-Early peripheral fibrosis, C-Clear cut pipestems and rounded density bands, D-Central fibrosis of main portal vein and gallbladder wall thickening, E-Advanced stages of fibrosis forming patches on the liver parenchyma, F-extreme advanced fibrosis extending to the liver surface, distorting its shape, XYZ other pathology not schisto related.Wall thickness of the portal veins was measured. Other sonographic abnormalities were noted (splenomegaly, oesophageal and splenic varices and ascites). A portable ultrasound machine with curvey linear probe was used. Portable generator, warm gel, Pinter with glossy printing paper and recording material.
Results: The grading observed were as follows; pattern B-65% ,C-5.4%, E-1.5%,F-4.6%, X Y Z- 0.7%It was also noted that advanced sonographic abnormalities seen in children differed significantly from those of adults.
Conclusion: Ultrasound is an ideal tool for classification of liver fibrosis in schistosomiasis and can also be used in a country control programme.

B-0969 11:26

Point of care creatinine testing: a feasibility study in an outpatient CT setting

B. Snaith[1,2], M.A. Harris[1], B. Shinkins[3], M. Jordaan[1], A. Lewington[3], M. Messenger[3], N. Spencer[1]; [1]*Wakefield/UK*, [2]*Bradford/UK*, [3]*Leeds/UK*
(bev.snaith@midyorks.nhs.uk)

Purpose: There remains controversy around the relationship between iodinated contrast media and contrast-induced acute kidney injury (CI-AKI), but international guidance endorses renal function screening. Point of care (PoC) testing may reduce inefficiencies, improve patient safety and optimise capacity, but evaluation of their implementation within this context is limited.
Methods and Materials: Following ethical approval, this feasibility study was performed across two UK hospital sites. A PoC creatinine analyser was added as an adjunct to the standard laboratory blood test. Patients having contrast-enhanced CT consented to a risk screening questionnaire and two samples of blood for PoC and laboratory analysis for evaluation of serum creatinine (SCr) and estimated glomerular filtration rate (eGFR). Follow-up testing 48-72 hours post-contrast was also offered. The analytical performance and clinical concordance of PoC was assessed.
Results: 300 patients were recruited with a mean age of 65 years (range 23-91). Pre-scan blood test timing varied (mean 3.7 weeks; range 0- 59.6); however, four patients had bloods available despite fail-safe procedures. Three patients had an unexpected drop in eGFR; all indicated acute illness. Screening questionnaire responses showed a statistically significant relationship between reduced eGFR and renal (p=0.010) or cardiac (p=0.032) problems. At follow-up, five patients (5/102; 4.9%) registered CI-AKI (≥25% increase in SCr). Positive and negative bias was seen with the PoC device, with mean bias close to zero.
Conclusion: PoC technology exhibits acceptable clinical performance. The implementation of a risk screening questionnaire partnered with PoC technology may streamline services and enable direct access to imaging; however, multi-centre evaluation is required.

B-0970 11:34

Implementation of a multi-phase contrast injection: single-pass acquisition trauma CT protocol

D.J. Biddle, S. Freeman, A. Barker, C. Walker, R. Higgins, S. Upponi;
Cambridge/UK (david.biddle@nhs.net)

Purpose: Can the radiation dose for trauma CT be reduced utilising a multiphase contrast injection, single-pass acquisition, whilst maintaining the overall image quality?
Methods and Materials: 50 consecutive trauma CTs using the established two-pass protocol were retrospectively analysed (arterial thoracoabdominal imaging and portal venous abdominopelvic imaging). Retrospective analysis was also made of 50 consecutive trauma CTs utilising the new single-pass, multiphase injection protocol (mixed arterial and venous phase of chest, abdomen and pelvis). Patients were imaged on a Siemens Definition AS+ 128 slice scanner. Both trauma protocols were triggered using a region-of-interest (ROI) placed over the descending thoracic aorta. Hounsfield unit measurements were obtained with a ROI drawn over the main pulmonary artery, descending thoracic aorta and portal vein. Two consultant radiologists assessed the overall quality of the studies, rating the studies as diagnostic or non-diagnostic, and evaluating contrast density. Splenic enhancement was specifically assessed as a marker of solid organ enhancement. Radiation dose was compared.
Results: The single-pass cohort had significant dose reduction compared with the two-pass method (DLP 935.60 vs 1849.58 mGycm; p=0.0000000005506), and a lower kV (p = 0.0029). Pulmonary artery enhancement was comparable (p = 0.401), whilst the aortic and portal vein attenuation was significantly higher in the single-pass cohort. Both cohorts had excellent diagnostic quality: 100% in two-pass method and 98% in single-pass method. Both cohorts maintained diagnostic splenic attenuation (100%).
Conclusion: The single-pass, multiphase technique significantly reduces the radiation dose in trauma patients, compared with the established technique, whilst maintaining diagnostic accuracy.

B-0971 11:42

CT hepatic contrast enhancement adjusted for body type versus lean body weight

T. von der Fehr, V. Hjelle, J.M. Erdal, T. Helle, A.P. Parkar; *Bergen/NO*
(janne.erdal@gmail.com)

Purpose: The optimal contrast enhancement for detection of liver lesions on CT is 50 HU. We aimed to study if switching from administered contrast amount based on body type to a lean body weight (LBW) calculator (according to Hume) could improve the quality of hepatic contrast enhancement (HCE).
Methods and Materials: The age, gender, height and weight, contrast amount, flow rate and tube voltage (kV) of 200 consecutive patients who underwent the same CT protocol were recorded. The first 100 patients (group A) were administered contrast amount (80-100-120 ml) according to their body type (normal-overweight-muscular). The next 100 patients (group B) were administered contrast according to their LBW (0.75 g Iodine/kgLBW). As delay was fixed at 70s and all other parametres remained constant, flow rate varied in group B. CT density (HU) on the first smart-prep image and post-contrast were measured on the same slice and anatomic area. Density increase ≤49 HU was considered "inadequate".
Results: After image review, 183 patients were included (group A= 95, group B=88). Inadequate HCE scans fell between group A (29;31%) and group B (16;18%), but not significantly (X_2, p=0.053). Age, gender, body weight and flow rate did not significantly affect HCE. kV significantly affected HCE, with 91% adequate scans with 100 kV and 61% with 120 kV (X_2, p<0.001). LBW >60 kg significantly affected kV (p=0.006) and HCE (p=0.004).
Conclusion: The LBW calculator only slightly, but not significantly, improved HCE. Increasing LBW warrants imaging at 120 kV to achieve acceptable image quality, but also reduces the iodine attenuation. Future optimisation process must address improving HCE in patients with LBW>60 kg.

B-0972 11:50

Optimisation of contrast delivery using quantitative and qualitative analysis in a clinical based CTPA setting

C. McKay, S. Maguire, P. Gilligan, C. Walsh, J. Matthews, S.J. Eustace;
Dublin/IE (ce.mckay5@gmail.com)

Purpose: Current practice in our hospital involves bolus tracking with subjective manual cessation of contrast administration for CT Pulmonary Angiography. This has implications for contrast usage in certain vulnerable patient cohorts. The purpose of the study was to assess the effect of varying the volume of contrast administered on the enhancement of the pulmonary arteries.
Methods and Materials: CTPA (n=100) images from a dual tube definition scanner (Siemens, Erlangen) were evaluated using objective and subjective parameters. The average Hounsfield units were assessed in the pulmonary artery at central, segmental and subsegmental levels. The clinical analysis was based on the experienced radiologists' reports which include a commentary on image quality including the level of contrast opacification of the pulmonary arteries.
Results: There was a significant variation in the volumes of contrast administered for CTPA exams (Range 35-90 ml of Optiray 350 (Guerbet, France), Median: 66 ml, Mode :90 ml). Contrast enhancement of the pulmonary arteries were maintained above the set threshold of 210 Hounsfield units even at low contrast volumes. All exams in the cohort were considered sufficient for diagnosis, however 7% were noted as suboptimal in the clinical reports. A lower KVp setting was found to improve vascular enhancement.
Conclusion: It is possible to deliver adequate CTPA images with lower contrast volumes in a clinical setting and a protocol of a maximum volume of 70 ml is proposed.

T1 based myocardial tissue characterisation in healthy volunteers: reference values for novel parameters of tissue dispersion

S. Rueppel, S. Lyschik, M.C. Halfmann, S. Benz, J. Eichstädt, C. Düber, K.-F. Kreitner, T. Emrich, F. Hahn; *Mainz/DE*

Purpose: Data on reference values of healthy adults concerning novel markers of myocardial tissue heterogeneity based on T1 Maps does actually not exist. We aim to provide these reference values for analysis of myocardial tissue heterogeneity to strengthen this approach for clinical use.
Methods and Materials: In this study, 55 carefully chosen healthy volunteers, matched in age and sex, underwent CMR imaging at 3 Tesla (Magnetom Skyra®, Siemens Healthineers). We evaluated Modified Look-Locker inversion recovery (MOLLI) based T1 Maps by using a dedicated software (CVI42, Circle®) after accurate elimination of artifacts. Beside established parameters like mean segmental und global T1 values, parameters of myocardial tissue dispersion as maximum and minimum T1 (max and minT1), dynamic range (dyn), standard deviation (SD) and mean absolute deviation (MAD) of mean T1 and SD were calculated.
Results: The measurements lead to the following values (median and interquartile range): Global T1 1190 ms (1148 ms/ 1217 ms), SD 85,2 ms (70.9 ms/ 98,7 ms), MADT1 25,3 ms (16,7 ms/ 35,5 ms), MADSD 12,8 ms (9,6 ms/ 21,0 ms), minT1 931 ms (864 ms/ 1013 ms), maxT1 1710 ms (1595 ms/ 1810 ms) and Dyn 777 ms (696 ms / 928 ms).
Conclusion: To our knowledge, our study provides first reference values for novel markers of myocardial tissue heterogeneity in healthy adults. Further studies are needed to establish this approach for clinical use.

B-0974 10:38

Novel T1 map parameters of tissue heterogeneity are not influenced by age and gender in healthy volunteers

S. Lyschik, S. Rueppel, S. Benz, M.C. Halfmann, J. Eichstädt, C. Düber, K.-F. Kreitner, T. Emrich, F. Hahn; *Mainz/DE*

Purpose: Data concerning the influence of gender and age on myocardial T1-values is controversial or not existing, especially for novel parameters of tissue heterogeneity. Our aim is to perform analyses of influencing factors on established and novel parameters of myocardial tissue characterization.
Methods and Materials: 55 cardiovascular magnetic resonance examinations were performed at 3T (Magnetom Skyra®, Siemens Healthineers) in carefully chosen healthy volunteers. A dedicated software (CVI42, Circle®) analysed the produced T1 Maps. Tissue heterogeneity parameters were calculated and included analysis of dispersion like mean and standard deviation (SD), dynamic range and mean absolute deviation (MAD) of mean T1-values and their SD. These values were subsequently tested for influencing factors like age, sex and their combination using an analysis of variance (ANOVA). Post-hoc testing using the Bonferroni correction was performed for subgroup analyses.
Results: Established parameters like median T1 were influenced by gender (p=.001), but not by age (p=.777). Myocardial dispersion parameters, e.g. MAD or dynamic range showed no statistically significant differences with regard to age and gender (p=.559 and .665 respectively p=.416 and .105). The combination of both factors did not reveal a significant influence.
Conclusion: Published data on the influence of age and gender on established T1-Map parameters in healthy volunteers is controversial. These controversies could be caused by selection bias, differences in sequence types or post-processing software. Sophisticated post-processing analysis of myocardial tissue heterogeneity are not influenced by age and gender and could be beneficial to establish myocardial tissue characterization as a method for clinical use.

B-0975 10:46

Artefacts in myocardial mapping

C. Eilers, J. Eichstädt, K.-H. Schmidt, C. Düber, T. Emrich, K.-F. Kreitner;
Mainz/DE (tilman.emrich@gmail.com)

Purpose: Cardiac magnetic resonance (CMR) imaging in general and myocardial mapping in particular provide valuable insights into the structure of myocardial tissue and help in discriminating healthy from diseased myocardium. However, artefacts and insufficient motion correction remain an existing but rarely addressed problem in CMR mapping imaging.
Methods and Materials: In this study, 66 patients with miscellaneous heart diseases and 80 healthy volunteers underwent T1 and T2 myocardial mapping at 3T. All maps were evaluated with regard to frequency of artefacts. The type of artefacts and the involved myocardial segments according to American Heart Association (AHA) classification were recorded. Furthermore, we evaluated in how far the artefact prevented clinical evaluation of the involved segment. The artefacts were classified as: chemical shift artefacts, off-resonance artefacts, susceptibility artefacts, partial volume artefacts and artefacts due to insufficient motion correction.
Results: In native T1- and T2-mapping, artefacts occurred in 7% of the myocardial segments, 6% had to be excluded from further analysis. Most common artefacts were off-resonance and susceptibility artefacts. Myocardial segments most often affected by artefacts were located inferolateral, anteroseptal and apical. There was no statistical significant difference in the amount, type and distribution of artefacts between T1 and T2 mapping and between the mapping of healthy volunteers and patients.
Conclusion: The frequency of artefacts in T1 and T2 mapping prevented further analysis in 6% of segments. The distribution of artefacts among segments is not random. Instead, it follows the same recurring pattern in patients and healthy volunteers and in both T1 and T2 mapping.

B-0976 10:54

Myocardial T1 and T2 mapping in severe aortic stenosis: novel insights into the pathophysiology of myocardial remodelling

A. Fehrmann Efferoth, M. Treutlein, T. Rudolph, V. Rudolph, K. Weiss, D. Giese, A. Bunck, D. Maintz, B. Baessler; *Cologne/DE (anafehrmann@googlemail.com)*

Purpose: Severe aortic stenosis (AS) is known to be associated with substantial myocardial remodelling, leading to diffuse myocardial fibrosis (DMF). The purpose of the present study was to combine native T1 and T2 mapping in a comprehensive cardiac magnetic resonance (CMR) examination to characterize myocardial tissue changes in the setting of severe AS.
Methods and Materials: 26 prospectively selected patients with severe AS and 17 healthy controls underwent CMR imaging on a clinical 3T scanner. The CMR protocol included a native modified Look-Locker T1-mapping and a gradient-spin-echo T2-mapping sequence in three short-axis slices and one long-axis view. After segmentation, myocardial T1 and T2 values were averaged over the entire myocardium.
Results: Global native myocardial T1 was significantly increased in AS patients when compared with controls (1305±39 vs 1272±21 ms, p=.005). Similarly, mean myocardial T2 was significantly elevated in AS patients (51±4 vs 46±2 ms, p<.001) and showed a strong correlation with native T1 (r=.60, p<.001). An overlap was observed between T1 values of both groups, whereas T2 times discriminated nearly perfectly between the two groups (area under the curve: 0.76 for T1, 0.87 for T2).

Conclusion: Patients with severe AS exhibit significantly elevated native myocardial T1 times, which has previously been shown to correlate with the amount of myocardial collagen. The present study is the first to show that native T1 and T2 values are both significantly elevated and correlated in AS patients, pointing towards a potential role of oedematous/inflammatory processes in the pathophysiology of myocardial remodelling associated with AS.

Myocardial tissue characterisation by cardiac magnetic resonance imaging in left ventricular non-compaction: new insights with T1 mapping and extracellular volume quantification

J.A.B. Araújo-Filho, A.N. Assuncao-Jr, M.D. Tavares de Melo, R.N. Dantas Jr, C.H. Nomura, J.R. Parga Filho; *São Paulo/BR (ariaraujocg@hotmail.com)*

Purpose: This study aimed to characterize myocardial T1 mapping and extracellular volume (ECV) fraction by cardiovascular magnetic resonance (CMR), and investigate how these biomarkers relate to left ventricular ejection fraction (LVEF) and ventricular arrhythmias (VA) in patients with left ventricular non-compaction (LVNC).
Methods and Materials: We prospectively recruited 36 patients with LVNC and 18 controls to perform a cardiovascular magnetic resonance (CMR) with T1 mapping from July 2013 to September 2016. ECV was quantified in LV segments without late gadolinium enhancement (LGE) areas to investigate diffuse myocardial fibrosis. Differences in CMR parameters between patients and controls were assessed using t test or Wilcoxon rank-sum test, and a linear regression model was built for LVEF to test the association with ECV and clinical characteristics.
Results: Patients with LVNC had higher native T1 (1024±43ms vs. 995±22ms, p=0.01) and expanded ECV (28.0±4.5% vs. 23.5±2.2%, p<0.001) compared to controls. ECV was independently associated with LVEF (β=-1.3, p=0.003). Moreover, among patients without LGE, VA were associated with higher ECV (27.7% with VA vs 25.8% without VA, p=0.002).
Conclusion: In LVNC patients, tissue characterization by T1 mapping suggests an extracellular expansion in myocardium without LGE, which was associated with myocardial dysfunction and VA, possibly related to diffuse myocardial fibrosis. These findings lend support to the potential role of T1 mapping in refining LVNC risk stratification.

B-0978 11:10

ECV mapping without HCT: comparison between two different synthetic ECV-calculation methods and clinical applicability

L. Bottoni[1], E. Gavazzi[1], M. Ravanelli[1], M. Zanirato[2], A. Greiser[2], D. Farina[1], R. Maroldi[1]; [1]*Brescia/IT*, [2]*Erlangen/DE (luca.bottoni87@hotmail.com)*

Purpose: To assess the accuracy and clinical applicability of two different synthetic-ECV mapping methods.
Methods and Materials: 47 consecutive cardiac MRI scans were performed applying three different ECV mapping techniques: 8/47 patients were discarded for poor image quality. In 15/39 automated ECV mapping (Siemens, Germany), incorporating the Hct measured in lab. This method was set as the reference standard. In 24/39 cases was applied automated synthetic ECV mapping (with software-calculated Hct) (Siemens, Germany). In all patients in-house calculated ECV was performed applying the formula [(1-Hct)(1/□myocardium-1/□blood)] with Hct=[0,88-(T1blood/3240)]. Image were analysed placing ROIs on blood pool and myocardium, rigidly in the same position in all cases.
Results: The software-calculated Hct was compared with the lab-measured Hct in 17 cases: software-calculated Hct was significantly higher (p=.0089). The in-house calculated Hct was compared with the lab-measured Hct in 29 cases: no significant difference was seen. However, no statistically relevant difference between the ECV measured with automated-ECV, synthetic-ECV and in-house calculated ECV was found.
Conclusion: Synthetic-ECV mapping bases it measurement on a software-calculated Hct which is significantly different from real, whereas in-house calculation offers a more reliable estimate. However, the ECV values measured with three techniques show no statistical difference. Synthetic-ECV mapping is a clinically applicable alternative in cases when lab-measured Hct is unavailable.

B-0979 11:18

Diagnostic potential of texture analysis applied on cardiac magnetic resonance T1 and T2 mapping in patients with biopsy-proven chronic myocarditis

B. Baessler[1], C. Lücke[2], K. Klingel[3], R. Kandolf[3], G. Schuler[2], D. Maintz[1], M. Gutberlet[2], H. Thiele[2], P. Lurz[2]; [1]*Cologne/DE*, [2]*Leipzig/DE*, [3]*Tubingen/DE (bettina.baessler@uk-koeln.de)*

Purpose: To apply texture analysis (TA) for the first time on T1 and T2-maps derived from cardiac magnetic resonance (CMR) T1 and T2 mapping and to test its diagnostic performance in patients with "DCM-like" chronic myocarditis.
Methods and Materials: Fourty patients with clinical chronic heart failure (EF<50%, symptom duration >14 days) and suspicion for underlying chronic myocarditis were prospectively included. Patients underwent biventricular endomyocardial biopsy (EMB), cardiac catheterization and CMR imaging at 1.5T including native T1 and T2-mapping as well as standard Lake Louise criteria (LLC). TA was applied on T1 and T2-maps using a freely available software package by drawing a region of interest encompassing the entire myocardium. Step-wise dimension reduction and texture feature selection was performed for selecting texture features enabling the diagnosis of DCM-like chronic myocarditis, using EMB as the reference standard.
Results: Mean symptom duration was 121±164 days and mean EF was 26±11%. EMB confirmed the presence of myocarditis in 26 patients (EMB+), whereas 14 patients had no signs of inflammation (EMB-). Similar to standard LLC, mean myocardial T1 and T2 demonstrated poor diagnostic performance in receiver operating curve (ROC) analyses (area under the curve [AUC]: 0.52 for LLC, 0.54 for T1 and T2, respectively). The combination of two texture features derived from T2 maps, T2_Kurtosis and T2_SumEntrp, yielded a superior diagnostic performance with an AUC of 0.75 and a sensitivity/specificity of 77/71%.
Conclusion: TA is feasible when being applied on myocardial T1 and T2-maps and delivers interesting novel parameters for the diagnosis of chronic myocarditis.

B-0980 11:26

Texture analysis of myocardial infarction of CT: impact of iterative reconstruction

M. Mannil, J. von Spiczak, U. Mühlematter, A. Thanabalasingam, R. Manka, H. Alkadhi; *Zurich/CH (Manoj.Mannil@usz.ch)*

Purpose: To compare machine learning-based texture analysis (TA) with subjective visual diagnosis of myocardial infarction (MI) in CT of the heart, and to evaluate the impact of iterative reconstruction (IR) on the results.
Methods and Materials: Ten patients with confirmed chronic MI and twenty controls with no cardiac abnormality underwent the same contrast-enhanced ECG-gated cardiac CT protocol. Images were reconstructed with filtered back projection (FBP) and advanced modelled IR at strength levels 3-5. Subjective diagnosis of MI was made by two independent, blinded readers. Classification of MI was performed using machine-learning based decision tree models for the entire dataset and after splitting into training and test data to avoid over-fitting.
Results: Subjective visual analysis for diagnosis of MI showed excellent intrareader (kappa:0.93) and poor interreader agreement (kappa:0.3), with variable performance at different reconstruction types. TA showed similarly high performances for all image reconstructions (correct classifications 94-97%, areas-under-the-curve 0.94-0.99). After splitting into training and test data, overall lower performances were observed with best results for IR level 5 (correct classifications 73%, area-under-the-curve 0.65).
Conclusion: As compared to subjective visual image analysis, machine learning-based TA enables objective and reproducible diagnosis of MI in CT with high accuracy, showing best results at highest IR levels.

B-0981 11:34

Texture analysis and machine learning for detecting myocardial infarction in non-contrast low-dose CT

M. Mannil, J. von Spiczak, R. Manka, H. Alkadhi; *Zurich/CH (Manoj.Mannil@usz.ch)*

Purpose: To test whether texture analysis (TA) and machine learning enable the detection of myocardial infarction (MI) on non-contrast enhanced low radiation dose cardiac computed tomography (CCT) images.
Methods and Materials: In this IRB-approved retrospective study, we included non-contrast enhanced electrocardiography-gated low radiation dose CCT image data (effective dose 0.5mSv) acquired for the purpose of calcium scoring of 27 patients with acute MI, 30 patients with chronic MI, and in 30 subjects without cardiac abnormality (hereafter termed *controls*). TA of the left ventricle was performed using free-hand regions-of-interest and texture features were classified twice. Model I: controls vs. acute MI vs. chronic MI; Model II: controls vs. acute and chronic MI. For both classifications, five commonly used machine learning classifiers were used: decision tree C4.5

(J48), k-nearest neighbors (k-NN), locally weighted learning (LWL), sequential minimal optimization (SMO), and an artificial neural network. Additionally, two blinded, independent readers visually assessed non-contrast CCT images for the presence or absence of MI.
Results: In model I, best classification results were obtained using the k-NN classifier (sensitivity 69%, specificity 85%). In model II, best classification results were found with the LWL classification (sensitivity 86%, specificity 81%) with an area-under-the-curve from receiver operating characteristics analysis of 0.78. In comparison, both readers were not able to identify MI in any of the non-contrast, low radiation dose CCT images.
Conclusion: This study indicates the ability of TA and machine learning for detecting MI on non-contrast low radiation dose CCT images, being not visible for the radiologists' eye.

B-0982 11:42

Myocardial textural analysis and machine learning for differentiating normal myocardium vs chronic infarct on non-contrast CT scan
A.A. Albweady[1], S. Raja[2], S. George[3], M. Alharbi[2], K. Aldossari[2]; [1]*Qassim/SA*, [2]*Riyadh/SA*, [3]*Houston, TX/US (ALBWEADY88@GMAIL.COM)*

Purpose: Prior sparse literature suggests that a couple of soft findings on plain CT such as hypodensity, calcium deposits etc can favor chronic Infarction. Recent developments in Radiomics- texture analysis (TA) and machine learning (ML) can tease out such occult features on medical imaging including CT. We explored if TA and ML can differentiate normal myocardium from prior infarcts.
Methods and Materials: We retrospectively analysed 24 patients(M=18, F=6), having both FDG PET-CT and MPI (cardiac perfusion SPECT) for myocardial viability from 2015 to 2017. Utilising the ground truth (scar Vs. normal myocardium) on the co-registered PET and SPECT transverse slices (matched defect-infarct, mismatch-viable myocardium), we flagged 3 to 4 representative 3D VOI (volume of interest) on each pt. on a dedicated workstation. The voxel level data from the flagged VOI were exported to EXCEL and MATLAB for TA computation.
Results: Utilising a Training subset 50% (no=18), Testing subset 50% (no=18), for developing the predictive model and testing respectively. A prediction classification accuracy of 82%, AUC 0.875 in the training set was achieved with C5.1 decision tree algorithm to classify scar vs. normal myocardium. Using one way ANOVA the single most important feature had a statistically significant p-value of 0.009 in the differentiation of scar Vs normal myocardium.
Conclusion: Texture analysis and machine learning can dissect normal myocardium from chronic infarcts, on non-contrast CT. The novel technique could potentially be used as a screening tool in patients at high risk for unrecognised chronic infarcts.

B-0983 11:50

Initial in vitro comparison of a spectral photon counting CT and a spectral dual-layer CT system for non-invasive evaluation of soft-plaque-restenosis in coronary artery stents
T. Hickethier[1], D. Bar-Ness[2], A. Bunck[1], D. Maintz[1], G. Pahn[3], P. Coulon[4], S.A. Si-mohamed[2], P. Douek[2], M. Sigovan[2]; [1]*Cologne/DE*, [2]*Lyon/FR*, [3]*Hamburg/DE*, [4]*Suresne/FR (tilman.hickethier@uk-koeln.de)*

Purpose: Even when compared to latest spectral-dual-layer-CT-systems (SDLCT) future spectral-photon-counting-detector-CT-systems (SPCCT) promise improved spatial resolution and decreased (stent related) blooming artifacts. We investigated the influence of conventional (Conv) and monoenergetic (MonoE) reconstructions from SDLCT and SPCCT on delineation of soft-plaque-restenosis in coronary stents.
Methods and Materials: Artificial stenosis (~30HU) were implanted into 10 different coronary stents (~3mm) embedded in plastic tubes filled with contrast agent (~400HU). CT data was acquired with a SDLCT (IQon, Philips) and a SPCCT (Prototype, Philips). Sharp kernels were used for reconstructions with Conv and MonoE at 50, 70, 100 and 140keV. Visibility of the stenosis and the remaining lumen was evaluated by 2 readers for each stent and reconstruction using a Likert scale reaching from 1 (image quality impedes lumen assessment) to 5 (stenosis and remaining lumen are clearly visible).
Results: Interrater agreement was very good (kappa=0.9). Stenosis delineation was best in Conv, 50 and 70keV MonoE SPCCT images (median score=5). Differentiation was significantly more difficult in corresponding SDLCT images (median score=3;p<0.01). Despite visibly lower blooming artifacts, 100 and 140keV MonoE images showed significantly poorer results than the corresponding 50keV MonoE images due to reduced contrast enhancement resulting in impaired visualisation of the unaltered lumen (median score=2 for 100keV and 1 for 140keV on both scanners;p<0.01).
Conclusion: Evaluation of soft-plaque-restenosis can be significantly improved by using conventional and low keV MonoE reconstructions of future SPCCT. High keV MonoE reconstructions are not recommended for coronary stent assessment with SPCCT or SDLCT due to impeded stenosis delineation.

To evaluate the role of 68Ga DOTA NOC receptor PET CT in detection of unknown primary neuroendocrine tumours
S.M. Shaikh; *Hyderabad/IN (drsikandar_s@yahoo.co.in)*

Purpose: The aim of our study was to evaluate the role of receptor PET/CT using 68Ga-DOTA-NOC in the detection of undiagnosed primary sites of neuroendocrine tumours (NETs).
Methods and Materials: Overall 29 patients (M:F 15:14, age 55±9 yr) with histopathologically proven NET and unknown primary were included . PET/CT was performed after injection of 100 MBq (46-260 MBq) of 68Ga-DOTA-NOC. The (SUVmax) was calculated and compared with SUVmax in known pancreatic NET (pNET) and ileum/jejunum/duodenum (SI-NET). The results of PET/CT were also correlated with CT alone.
Results: In 17/29 (59%) of patients, 68Ga-DOTA-NOC PET/CT localised the site of the primary: ileum/jejunum (7), pancreas (6), rectum (1), lungs (1) and paraganglioma (2). CT alone (on retrospective analyses) confirmed the findings in 6/29 (20%) patients. The mean SUVmax of identified previously unknown pNET and SI-Net were 15.6 ± 9.8 (range 7.8-34.8) and 8.1± 6.0 (range 4.2-27.8), respectively. SUVmax in patients with previously known pNET and SI-NET were 26.1±14.5 (range 8.7-42.4) and 11.3±3.7 (range 5.6-17.9). The SUVmax of the unknown pNET and SI-NET was significantly lower ($p< 0.05$) as compared with known primary tumour sites. 19% of the patients had high-grade and 81% low-grade NET. In 3/29 patients the primary tumour was subsequently resected (1 pancretic, one ileal and one rectal tumour).
Conclusion: 68Ga- DOTA-NOC PET/CT is highly superior to 111In Octreoscan (17% detection rate for CUP according to the literature) and plays a major role in the management of patients with CUP-NET.

B-0985 10:38

PET/MR of biliary tract malignancies: impact on treatment planning
O.A. Catalano[1], U. Mahmood[1], C. Ferrone[1], L. Blaszkowsky[2], L. Goyal[1], T. Hong[1], C. Catana[3], D. Gervais[1], B.R. Rosen[3]; [1]*Boston, MA/US*, [2]*Newton, MA/US*, [3]*Charlestown, MA/US (onofriocatalano@yahoo.it)*

Purpose: To compare the impact of PET/MR versus PET/CT on treatment planning in biliary malignancies.
Methods and Materials: 18 consecutive patients with biliary malignancies underwent whole-body contrast-enhanced (CE)-FDG-PET/CT, 13 of them underwent CE-FDG-PET/MR and 5 non-CE-FDG-PET/MR. Two readers evaluated PET/CT and PET/MR for local extension, resectability and metastases. Impact of findings on treatment planning was discussed with the referring clinicians.
Results: PET/MR and PET/CT were concordant and correct in 8/18 patients: disclosing metastases in 4 and ruling out metastases and confirming resectability in 4. However, in 1/4 of resectable cases PET/MR demonstrated additional regional lymphadenopathy mandating changes in surgical technique. PET/MR and PET/CT were concordant and incorrect in 1/18 patient, missing peritoneal disease. PET/MR and PET/CT were discordant in 9/18, with PET/MR being correct: PET/MR disclosed metastases missed at PET/CT in 4, diaphragmatic infiltration missed on PET/CT in 1, and interpreted benign findings, confused with metastases on PET/CT, in 4 (inflammatory enlarged non-regional lymph nodes in 1, focal cholangitis in 2, perfusion abnormalities in 1) making them resectable.
Conclusion: PET/MR imaging of biliary malignancies is useful in staging and assessment for resectability. PET/MR did not mis-stage any patient when compared to PET/CT, correctly diagnosed all 9 discordant cases, and mandated changes in treatment plan in 10 cases (p<0.05). PET/MR might represent a valid tool for treatment planning of biliary malignancies.

B-0986 10:46

Implications of 2-hydroxyglutarate in gliomas with IDH1/2 mutations

L. Wang[1,2], Y. Zhang[1], Z. Liu[3,1], H. Mao[2]; [1]*Shenzhen/CN*, [2]*Atlanta, GA/US*, [3]*Nanchang/CN (2718377613@qq.com)*

Purpose: Mutated isocitrate dehydrogenase 1 or 2 (mIDH1/2) occur in 80% of low grade gliomas. Onco-metabolite, R(-)-2-hydroxyglutarate (2HG) is a biomarker for mIDH on molecular classification of tumors and can be detected with magnetic resonance spectroscopy (MRS) for predicting prognosis. To determine whether MRS measurement of 2HG can provide more prognostic and therapeutic information, we investigated the correlations of 2HG level with tumour progressions and other metabolites.
Methods and Materials: 2HG concentrations were measured from tissue specimens of 47 gliomas with mIDH by 2D Correlation Spectroscopy using solid state NMR. All tumours were categorised into three WHO grades. Progression free survival (PFS) of patients with mIDH/wild type (WT) IDH was determined. 2HG levels were compared with WHO grades, PFS, and selected metabolites, such as lactate (Lac), glutamate (Glu) and glutamine (Gln). Non-parametric Mann-Whitney correlation for comparison/Spearman was used for statistical analysis.
Results: 2HG level is elevated in tumours of higher grades. mIDH gliomas has increased PFS compared to those with WT IDH. However, PFS is negatively correlated with 2HG concentration. Metabolite measurements showed that increased 2HG level is related to increases of Glu and Gln, indicating that 2HG may trigger a metabolic shift since Glu/Gln can be converted to a-ketoglutarate, the substrate of mIDH. Furthermore, the levels of Lac and 2HG are found to be positively correlated, possibly due to increase of glucose consumption related to high mutant enzyme activity.
Conclusion: Imaging methods capable of monitoring 2HG level may enable non-invasive and longitudinal assessment of prognosis and treatment responses.

B-0987 10:54

Magnetic resonance spectroscopy of the placenta: a feasibility study

C.M.J. Beaumont, E.H. Whitby; *Sheffield/UK (charlottiebeaumont@gmail.com)*

Purpose: Placental proton magnetic resonance spectroscopy (^{1}H MRS) is a newly emerging technique with the potential to non-invasively assess the function of the placenta in vivo. Previous studies utilising this technique have been limited. This study aimed to investigate whether this tool could be feasible for routine clinical use.
Methods and Materials: In utero-placental MR spectra were obtained from women (n=43) referred for foetal MRI following abnormal ultrasound scans. Participants were of varying gestational age (GA) and exhibited a wide range of foetal pathologies unrelated to placental function. Spectra quality was assessed both qualitatively and quantitatively, with the potential influence of GA and placental Grannum grade (GG) also considered.
Results: Almost 75% of spectra obtained were considered good quality, with substantial agreement between assessors (Fleiss Kappa: K=0.646) and were, therefore, considered suitable for diagnostic interpretation. Neither GA (Anova: P>0.05) nor GG significantly influenced visual spectra quality. Signal-to-noise ratio also appeared unaffected by the GA (regression: P>0.05) and GG (Anova: P>0.05) of participants. Lipid contamination due to foetal movement negatively affected spectra obtained from participants of low GA. No visible trend was observed between GA or GG and spectral metabolites.
Conclusion: In vivo placental ^{1}H MRS is feasible in routine clinical practice and warrants further investigation. The spectra obtained do not appear to be influenced by either the GA or GG in terms of quality or spectral metabolites. Future studies establishing metabolite threshold profiles for conditions, and confirming our conclusions regarding the influence of potential confounding variables would be beneficial.

B-0988 11:02

Imaging glycolytic heterogeneity of HCC in real time using dynamic hyperpolarised magnetic resonance spectroscopy: a personalised medicine approach

G. Kaissis, F. Lohöfer, E. Bliemsrieder, G. Topping, F. Schilling, E.J. Rummeny, M. Schwaiger, R. Braren; *Munich/DE*

Purpose: To demonstrate glycolytic heterogeneity of hepatocellular carcinoma in a homograft model using hyperpolarised ^{13}C-Pyruvate dynamic magnetic resonance spectroscopy (MRS) and response to PARP14 inhibition therapy as in vitro validation.
Methods and Materials: Cell clones were derived from diethyl nitrosamine (DEN)-induced tumors and implanted into the hindquarters of Wistar rats. Dynamic hyperpolarised ^{13}C-Pyruvate-MRS was performed. Real-time conversion of pyruvate to lactate was measured and modelled using a two-compartment model. Results were correlated with IC_{50} values of the corresponding cell lines for PARP14 inhibition in vitro.
Results: Cell clone isolation and reimplantation from DEN-induced HCC was successful. Dynamic MRS provided excellent SNR and showed linear kinetic characteristics for pyruvate to lactate conversion (R^2= 0.98, p<0.001, n=6). Kinetic constants correlated inversely with IC_{50} values of the same cell lines for in vitro PARP14 inhibition (R^2= -0.9384, p=0.0015, n=6).
Conclusion: This is the first study to demonstrate successful cell isolation and reimplantation in the DEN/Wistar model and the first to demonstrate feasibility of dynamic hyperpolarised ^{13}C-Pyruvate-MRS for kinetic modelling of pyruvate-to-lactate conversion for identification of metabolic subgroups. In vitro results correlate with MRS measurements demonstrating higher sensitivity to antiglycolytic therapy in tumors with high lactate production from pyruvate (i.e. higher glycolytic activity). Our approach can be utilised for imaging metabolic heterogeneity of HCC (e.g. differentiating glycolytic vs. nonglycolytic tumors) in the setting of personalised medicine applications as well as pharmacodynamic studies and novel inhibitor development.

B-0989 11:10

The early study of DWI and 1H-MRS in rabbit VX2 transplanted tumours after radiation comparison with pathology changes

Y.-M. Li, D.-D. Lin, Z. Xing, Y. Chuan, X. Xu; *Fuzhou/CN (fjmulym@163.com)*

Purpose: To analyse the role of DWI and 1H-MRS in evaluating the sensitivity of early radiotherapeutic effects by comparing the features of DWI and 1H-MRS with pathology changes in VX2 transplanted tumour.
Methods and Materials: Sixty rabbits were implanted VX2 tumour in unilateral thigh muscle to establish the experimental models. 2 weeks later, the rabbits were randomly divided into 10 groups according to whether accepting the radiation therapy and the different observation time.The groups were performed MR scans include T1WI, T2WI, DWI, and ^{1}H-MRS on 3.0T before radiotherapy and 1,3,5,7days after radiotherapy, respectively. Tumour volume,ADC values, Cho/Cr ratios and Lip/Cr ratios of rabbit VX2 transplanted tumour in radiation group and control group at different observed day were analysed using a factorial design statistical method.
Results: 1. After radiation, ADC values in radiation group increased gradually (P<0.05). 2. Cho peak tended to descend and the Lip peak tended to climb in radiation group. There were statistically changes of Cho/Cr, Lip/Cr ratios in different group and times. 3. The expression of the bax gene in radiation group tended to increase gradually.
Conclusion: DWI and 1H-MRS could detect the internal structure changes of tumour early after radiation in the level of molecule and biochemistry. There were some correlations between the tumour volume, the ADC values, Cho/Cr ratios and Lip/Cr ratios and the expression of bax gene after early radiotherapy, DWI and 1H-MRS may be valuable means in predicting early radiotherapeutic effect.

BAT activity in Type I and Type II diabetes mouse models: multimodal imaging study using 7T MRI and intravital microscopy

C.S.L. Jung, M. Heine, N. Mangels, M. Kaul, G. Adam, H. Ittrich, J. Heeren; *Hamburg/DE*

Purpose: Purpose was to determine metabolic activity of brown adipose tissue (BAT) in type I and type II diabetes mouse models using superparamagnetic iron oxide nanoparticles (SPIO) or quantum dots (QD - for intravital microscopy (IVM)) embedded into triglyceride-rich lipoproteins (TRL).
Methods and Materials: C57BL/6J wild-type mice were either treated iv with Alloxan (Abcam) which is toxic to pancreatic beta cells or received a high fad diet to induce diabetes (type I and II). BAT activity was stimulated using CL316,243, a β3 receptor agonist. MRI at 7T ClinScan (Bruker) was performed before and 20min after iv injection of TRL-SPIOs using a T2*w Multiecho-GRE sequence. IVM analysis was performed for real time imaging of TRL-QD uptake into BAT. To quantify TRL clearance, the fate of radioactively labelled TRLs were analysed under same experimental conditions.
Results: While control mice show a significant signal drop after CL treatment, no signal difference in BAT before and after TRL-SPIO injection was detectable neither for type I nor for type II diabetes mouse model. Real time IVM analyses showed a reduction of TRL-QD uptake in case of diabetes. MRI and IVM results were confirmed quantitative by metabolic studies using radioactive TRL. In both setups diabetes disease leads to a reduction of TRL uptake into BAT.
Conclusion: β3-receptor activation via CL with following acute insulin release lead to BAT activation, which can be visualised *in vivo* by MRI. In case of diabetic disease, the uptake of TRL into BAT is diminished, indicating a loss of BAT activity.

B-0991 11:26

In vivo tracing of superparamagnetic iron oxide-labelled bone marrow mesenchymal stem cells transplanted for traumatic brain injury by susceptibility weighted imaging in a rat model

Y. Zhang; *Zhengzhou/CN (109496417@qq.com)*

Purpose: To label rat bone marrow mesenchymal stem cells (BMSCs) with superparamagnetic iron oxide (SPIO) in vitro, and to monitor the survivorship and location of these labelled BMSCs in a rat model of traumatic brain injury (TBI) by susceptibility weighted imaging (SWI) sequence.
Methods and Materials: BMSCs were cultured in vivo and then labeled with SPIO. The rat TBI model was developed in the left hemisphere following Feeney's method. Twenty-four hours after TBI, we stereotactically transplanted the BMSCs into the region nearby the contusion site. Monitoring of these SPIO-marked BMSCs by SWI was performed at one day, one week and three weeks after implantation.
Results: Numerous BMSCs were successfully labeled with SPIO and positive for Prussian blue staining. Scattered iron particles were observed in the cytoplasm by electron microscopy. MRI of the transplanted sites demonstrated a low signal intensity on every image of SWI sequence.
Conclusion: SWI sequence in vivo can consecutively and noninvasively trace and demonstrate the status and distribution of BMSCs labelled with SPIO in the brain of TBI model rats.

B-0992 11:34

Molecular imaging heterogeneity study of breast tumours as a new diagnosis parameter

M. Herranz[1], P. Ling Ling[2], P. Aguiar[1], W. Liang[2], L. Albaina Latorre[3], M. Juaneda[3], A. Ruibal[1]; [1]*Santiago de Compostela/ES*, [2]*Shanghai/CN*, [3]*A Coruña/ES (michel.herranz.carnero@sergas.es)*

Purpose: The concept of tumour heterogeneity corresponds to different levels of expression, cellularity, hypoxia or other parameters interested in being measured into a single tumour. We describe relationship between tumour heterogeneity concept uses in radiology with PET parameters and if any biological characteristics of the breast tumours have a structure-function correlation.
Methods and Materials: 500 consecutive patients with breast cancer were analysed in a dedicated breast PET. Different parameters have been defined to find a pattern of texture and heterogeneity (TeHe), for this, and following the rules of the radiological descriptions we have described a series of structural templates. A mathematical pattern has been defined for their correlation. Patterns of heterogeneity have been correlated with clinical values of the tumours, such as molecular classification, size, type, histology, progression, relapses, etc.
Results: 7 different patterns divided into 5 large groups of values for TeHe are described, and classified as: 1: homogeneous diffuse, 2: lobular, 3: annular and spindle, 4: eccentric and focused; and 5: speckled. A numerical value has been assigned between 1 and 5 for this classification with 1 being the most homogeneous and 5 being the most heterogeneous. This value is achieved through a mathematical relationship: medSUV/maxSU/[(MedSUV/maxSUV)Qmax/(medSUV/maxSUV)Qmin].
Conclusion: Studies of tumour heterogeneity based on metabolism show us different patterns that correlate with molecular subtypes and predict response to treatments.

Small animal imaging using a clinical PET/CT system: high throughput imaging enabled by next-generation digital PET

M.V. Knopp, K. Briley-Saebo, M.I. Menendez, A. Siva, K. Binzel, J. Zhang; *Columbus, OH/US*

Purpose: Preclinical imaging, particularly of rodents, is a key aspect of development of new molecular imaging approaches. We sought to develop the capability of multi-subject, simultaneous whole-body PET/CT imaging using a next generation, digital PET detector based, clinical PET system.
Methods and Materials: A pre-commercial release, next-generation, digital photon counting clinical PET/CT system (Philips Vereos, dPET) was used. Enabled by the excellent count sensitivity and time of flight timing resolution (325 ps) of the dPET system, we have previously optimized an ultra-high definition reconstruction utilizing a 1 mm^3 voxel size. CT imaging was reconstructed with a 1024x1024 matrix, 0.5 mm voxel length. A mouse hotel that can be variably configured to accommodate up to 6 animals at once was constructed.
Results: Both CT and PET imaging was achievable within a single acquisition volume achieving excellent image quality with an initial acquisition time of 10 minutes. We additionally found that imaging for 3 minutes produced adequate image quality as well. No cross-interference from the multiple beds was observed. While the 6 bed layout appears practical, a higher number of beds is feasible without loss of spatial or quantitative quality from the PET perspective. The CT field of view is limited to about 6 mice if high resolution imaging is required.
Conclusion: Next-generation clinical PET/CT systems can feasibly be used for high throughput, whole-body imaging of rodents, here with 6 animals simultaneously. This approach could benefit large rodent population imaging with efficient radiotracer management, particularly for short lived isotopes.

Preliminary analysis of ultrasound imaging-based thermometry in ex vivo biological tissues

F. Giurazza, G. Frauenfelder, C. Massaroni, G. Galati, A. Picardi, E. Schena, B.B. Beomonte Zobel, S. Silvestri; *Rome/IT (francescogiurazza@hotmail.it)*

Purpose: Real-time monitoring of tissue temperature during percutaneous tumour ablation improves treatment efficacy, leading clinicians to adjustment of treatment settings. This study aims at assessing the feasibility of ultrasound-thermometry during laser ablation of biological tissue using a specific ultrasound imaging techniques based on elastography (ARFI).
Methods and Materials: ARFI uses high-intensity focused ultrasound pulses to generate 'radiation force' in tissue; this causes tissue displacements trackable using correlation-based ultrasound methods: the sensitivity of shear waves velocity is able to detect temperature changes. Experiments were carried out using a Nd:YAG laser (power: 5W) in three ex vivo pig livers. In each organ was placed a thermocouple close to the applicator tip (distance range: 1.5-2.5cm) used to record a reference temperature. Positioning of laser applicator and thermocouple was eco-guided. The organ was scanned by an echography system (Siemens ACUSON-S3000); propagation velocity was measured in a region of interest (ROI) of 1x0.5cm located close to thermocouple, to investigate the influence of tissue temperature on shear wave velocity.
Results: Shear wave velocity has a very low sensitivity to temperature up to 55-60°C, and in all cases velocity is $<5 m \cdot s^{-1}$; for temperature >55-60°C velocity shows a steep increment. The system measures a value "over limit", meaning a velocity $>10 m \cdot s^{-1}$.
Conclusion: Ultrasound thermometry during laser-ablation of biological tissue based on elastography shows an abrupt output change at temperatures >55-60°C. This issue can have a significant clinical impact, considering tumour necrosis when temperature crosses 55°C to define the boundary of the damaged volume.

Gd presence in the brain: impact of daytime and anaesthesia

T. Taoka[1], G. Jost[2], S. Naganawa[1], H. Pietsch[2]; [1]*Nagoya/JP*, [2]*Berlin/DE (ttaoka@med.nagoya-u.ac.jp)*

Purpose: The purpose of the current study is to investigate the influence of the circadian rhythm associated with the glymphatic activity on the presence of gadolinium the rat brain after repeated administration of gadolinium-based contrast agents (GBCA).
Methods and Materials: Twenty-four Han-Wistar rats were divided into four groups: Group 1; morning injection, Group 2; evening injection, Group 3; morning injection under short-duration anaesthesia and Group 4; morning injection under long-duration anaesthesia. Every subject received gadodiamide (1.8mmol/kg x 8 times over 2 weeks). 5 weeks after the last injection the brains were dissected and the Gd concentration in the cerebellum, pons and cerebrum was quantified by inductively coupled plasma mass spectrometry.
Results: In cerebellum, mean Gd concentrations were 3.58, 5.77, 2.95 and 2.51 (nmol/g tissue) in Groups 1, 2, 3 and 4, respectively. Likewise, mean Gd concentrations were 2.86, 5.04, 2.37 and 1.92 (nmol/g) in cerebrum, and 1.63, 1.76, 1.61 and 1.22 (nmol/g) in pons.
Conclusion: In the cerebellum and cerebrum, Gd concentration was highest in the group with evening injection, followed by morning injection, morning injection with short anaesthesia and morning injection with long anaesthesia GBCA administration. As rats are nocturnal animals, glymphatic system is expected to be more active during daytime. The results of this study might be explained by the higher glymphatic clearance following the morning injection, while a reduced glymphatic activity is present after the injection in the evening. Anaesthesia seemed to facilitate the glymphatic clearance of GBCA especially for longer durations.

Quantitative assessment of spatial and temporal gadolinium deposition within the deep brain nuclei

G. Marie, P. Požeg, J. Son Forget, J.P. Maeder, R. Meuli; *Lausanne/CH (guillaume.marie@chuv.ch)*

Purpose: Gadolinium is known to deposit in the deep brain nuclei, but no quantitative study has been done yet. This study aims to quantify the spatial and temporal dissemination of gadolinium in deep brain nuclei after repeated injections of linear GBCA.
Methods and Materials: We analysed retrospectively MRIs from a cohort of 30 patients at CHUV, who received at least 10 injections of non-ionic linear gadodiamide (Omniscan, GE healthcare, Piscataway, New Jersey). We calculated the difference of native T1 mean SI ratios of DN, GP, posterior thalamus, SN, superior colliculus and anterior putamen, to pons, not known to accumulate significantly gadolinium. We analysed the change rates in the SI ratios over the successive GBCA's administrations, using linear mixed effects modelling (Bernal-Rusiel et al., NeuroImage, 2013).
Results: We observed a significant, gradual and differential increase of SI ratios in ROIs after successive injections (P<0.001), suggesting a gradual deposition in space and time where faster profiles of deposition in GP, DN and SN are demonstrated in comparison to superior colliculus, posterior thalamus and anterior putamen.
Conclusion: The deposit may occur gradually in space and time following the first injection of linear GBCAs, as quantitative measures show differential profiles of T1 hypersignals in basal ganglia structures. The different slopes observed in SI ratios may correlate with respective inner iron content of different nuclei and subsequent increased probability of transmetallation reactions with the GBCA ligand and of gadolinium unchelation.

Gadolinium retention in the brain: an MRI relaxometry study comparing linear and macrocyclic types of gadolinium-based agents

Y. Forslin, J. Martola, S. Shams, S. Fredrikson, M. Kristoffersen Wiberg, T. Granberg; *Stockholm/SE (yngve.forslin@ki.se)*

Purpose: Gadolinium retention in the brain after administrations of gadolinium-based contrast agents (GBCA) has recently been demonstrated, predominantly in the dentate nucleus (DN) and globus pallidus (GP). This retention is associated with lasting high T_1-weighted signal and has been consistently shown for linear GBCAs. It is debated if the more stable macrocyclic GBCAs lead to in vivo-detectable alterations of the T_1. We aimed to quantitatively investigate T_1 in relation to linear and macrocyclic GBCA administrations in DN and GP by relaxometry in MS patients.
Methods and Materials: A multi-parametric MRI sequence was used to obtain longitudinal relaxation rates on a 3 T Siemens Magnetom Trio MRI scanner. In 89 consecutively recruited patients with multiple sclerosis (MS), regions of interest were drawn in the DN and GP by a resident in radiology blinded to the clinical information.
Results: Patients without previous exposure to GBCAs and those who had only received macrocyclic GBCA had longer T1 relaxation, in DN and GP, in comparison with those patients who had received >1 linear GBCA (unpaired t test: P=0.036 and P=0.021, respectively). Higher number of administered linear (but not macrocyclic) GBCA was associated with faster T1 relaxation in DN and GP (multiple regression analysis: β=0.32, P=0.006 and β=0.24, P=0.046). These results remained significant after correction for the MS disease duration.
Conclusion: Multiple GBCA administrations lead to shorter relaxation rates in GP and DN. Patients only receiving the macrocyclic type gadoterate meglumine have a longer relaxation rates in comparison with patients who received linear types of GBCA.

Increased signal intensity of dentate nucleus in multiple sclerosis patients with history of higher gadolinium-enhanced MRI scans

H. Naghibi, M. Mohammadzadeh, A. Fallahian, M. Shakiba, P. Sabetrasekh, H. Soroush; *Tehran/IR (mm1361@yahoo.com)*

Purpose: It has been mentioned that there is an increased probability of hyperintensity of dentate nucleus [DN] with more gadolinium [GAD]-enhanced MRI exams. Here, we have assessed this event in a group of multiple sclerosis [MS] patients with history of multiple GAD-enhanced MRI exams.
Methods and Materials: Totally 140 MS patients [mean age: 36.1±9.3 years (19-64); 86% female] with history of multiple GAD-enhanced MRI scans and 21 healthy controls were enrolled. DN hyperintensity was assessed visually in unenhanced T1-weighted MRI; signal intensity ratio [SIR] was calculated by setting region of interests [ROIs] on DN and pons and dividing DN SI into pons SI. Two groups of patients and controls and different patient subgroups [classified based on total number of MRI scans (more than 4 times versus others)] were compared regarding mean SIR and visual hyperintensity.
Results: Totally, 83 patients received contrast more than 4 times [68%]; among them, 26 showed DN hyperintensity [31.3%] while there was not hyperintensity in other patients and controls [both Ps<0.02]. Mean SIR in patients and controls was 1.10±0.07 and 1.04±0.02, respectively [P<0.001]. Mean SIR was 1.14±0.04 in DN hyperintense patients and 1.09±0.07 in other patients [P<0.001]. Mean SIR in patients with higher contrast injection (>4) was 1.12±0.7 while it was 1.06±0.04 in other patients [P<0.001]; after deleting patients with DN hyperintensity, these figures were 1.11±0.08 and 1.06±0.04, respectively [P<0.001]. Correlation coefficient of SIR with contrast injection time was 0.66 [P<0.001].
Conclusion: SI and visual DN hyperintensity are increased in more contrast injections. This could be due to tissue deposition of GAD. The clinical importance of this phenomenon should be assessed in future studies.

B-0999 11:02

USPIO-enhanced MRI study on electroacupuncture alleviating inflammatory response of permanent focal subacute-stage cerebral ischaemia in rats

S. Yang, F. Lu, S. Zhan; *Shanghai/CN*

Purpose: To evaluate the effectiveness of acupuncture on alleviating inflammatory response derived by macrophages recruitment during subacute period after permanent middle cerebral artery occlusion (pMCAO) in rats on enhanced MRI with ultrasmall superparamagnetic particles of iron oxides (USPIO).
Methods and Materials: Thirty-nine SD ischaemia rats with USPIO injection were established including sham-operation group (group A), pMCAO group without acupuncture (group B) and electroacupuncture pMCAO group (group C). Each group was further divided into 3 subgroups on 72h, 5d and 7d after ischaemia modeling. The signal intensity of the darkest area of infarction with corresponding mirror area was measured on T2W images after MR scanning. Then the darkest area of infarction and mirror area on SWI of groups B and C were measured and the ratios were calculated. Correlations between signal intensity ratios of the darkest area on T2W images and proportion of positive iron particles in anti-CD68 macrophages were analysed.
Results: The ratios of darkest area with 7d on T2W images were significantly higher in group C than in group B ($P < 0.05$). The ratios of darkest area with 5d and 7d subgroups were significantly higher in group C than that in group B on SWI ($P < 0.05$).The signal intensity ratios of the darkest area on T2WI were positively correlated with proportion of positive iron particles in anti-CD68 macrophages of 5d ($r = 0.483$, $P = 0.047$) and 7d ($r = 0.525$, $P = 0.033$).
Conclusion: With USPIO-enhanced MRI, we found electroacupuncture could alleviate inflammatory response derived by macrophages recruitment at the subacute stage in pMCAO rats.

B-1000 11:10

MRI perfusion weighted imaging and von Willebrand factor antigen plasmatic levels (VWF:Ag) as predictors of prognosis in grade IV gliomas (GBM)

F.M. Doniselli, G. Marfia, S.E. Navone, L. Guarnaccia, R. Campanella, P. Summers, A. Costa; *Milan/IT (fabio.doniselli@gmail.com)*

Purpose: The prognostic significance of VWF:Ag and dynamic contrast-enhanced (DCE) and dynamic susceptibility contrast (DSC) MRI parameters in brain tumours is unknown. The aim of the study is to investigate the correlation of MRI-perfusion parameters and VWF:Ag with patient prognosis in GBM.
Methods and Materials: We reviewed a series of twenty-six patients with biopsy-proven GBM (males/females 18/8; median age 63 years) who underwent pre-operative DCE-MRI and DSC-MRI. VWF:Ag was analysed from pre-operative collected plasma sample (expressed as IU/dL). We measured the mean and maximum values of DSC-derived relative cerebral blood flow (rCBF) and volume (rCBV), DCE-derived volume transfer constant (K^{trans}), plasma volume (V_p) and reflux rate constant between the fractional volume of the extravascular space and blood plasma (K_{ep}). Non-parametric Mann-Whitney test was used.
Results: The median overall survival was 7 months (interquartile range=5-12).The distribution of vWF:Ag was bimodal, for which the median value (247 IU/dl) was used to separate the patients into two equally sized groups: a low vWF:Ag group (vWF:Ag<248; median=165, IQR=137-201) and a high vWF:Ag group (vWF:Ag>=248; median=410, IQR=329-528). When we compared the two groups, the median follow-up duration was 10 (IR=7-15) and 6 months (IR=3-7.5), respectively (p=0.02). The median K^{trans} values were 0.31 (IR=0.16-0.50) and 0.53 min^{-1} (IR=0.34-1.19), respectively (p=0.02). The median K_{ep}

values were 1.79 (IR=1.23-2.70) and 3.89 min^{-1} (IR=2.42-7.15), respectively (p=0.005). No significant differences in overall survival or correlation with vWF:Ag were found for other parameters.
Conclusion: These findings in a small group of patients suggest a role for VWF:Ag, K^{trans}, and K_{ep} as a prognostic indicator of post-operative survival of patients with GBM.

B-1001 11:18

3D high-resolution post-contrast imaging at 3T for the delineation of enhancing brain tumours: a comparison of three different techniques
L. Danieli[1], D. Distefano[1], E. Prodi[1], E. Ventura[1], G.C. Riccitelli[1], M. Reinert[1], A. Kaelin[1], A. Cianfoni[1,2], E. Pravatà[1]; [1]*Lugano/CH*, [2]*Bern/CH (lucia.danieli@eoc.ch)*

Purpose: To prospectively investigate three different post-contrast 3D-T1-MRI techniques [Magnetization-Prepared-Rapid-Gradient-Echo (MPRAGE), Volumetric-Interpolated-Brain-Examination (VIBE), Sampling-Perfection-with-Application-optimised-Contrasts-using-different-flip-angle-Evolutions (SPACE)] in the assessment of contrast-to-noise-ratio (CNR), total volume (TV) and margins extent delineation (MED) of brain primitive tumours (pT) and metastases potentially amenable to surgical and/or conformal radiotherapy treatment.
Methods and Materials: Fifty contrast-enhancing lesions (38 pT and 12 metastases) were detected in 36 patients using 3T MRI with 1-mm MPRAGE, VIBE and SPACE sequences randomly acquired 5 minutes after 0.1ml/kg administration of gadobutrol. Lesions CNR and TV segmentation were performed by an experienced neuroradiologist using a validated semi-automated tool (SmartBrush, Brainlab) followed by manual refinement. For each combination of sequence pairs, MED mismatch was quantified using subtraction volumetric maps of the segmented lesions. Mann-Whitney and paired-samples Wilcoxon non-parametric tests were used to investigate between-sequences discrepancies in CNR, TV and MED subtraction volumes.
Results: In both pT and metastases, CNR was higher for SPACE compared to VIBE and MPRAGE (p-range<0.001-0.045) and for VIBE compared to MPRAGE (p-range<0.001-0.004). Larger TVs for pT were obtained with SPACE compared to VIBE (p=0.006), and for metastases with SPACE compared to MPRAGE (p=0.012). Discrepancy in MED was also found, with SPACE exceeding both VIBE (p=0.004) and MPRAGE (p=0.01) in pT, and MPRAGE only (p=0.005) in metastases.
Conclusion: We found technique-related differences in the CNR, TV and MED estimates of both brain pT and metastases. The relatively higher CNR seen with SPACE may account for the larger TV and MED. These findings may be relevant for treatment planning and response assessment.

Comparison of arterial spin-labeling and dynamic susceptibility contrast MRI in detecting crossed cerebellar diaschisis in patients after glioma resection
T. Lin, F. Feng, Y. Lv, H. You; *Beijing/CN (jasminelty@163.com)*

Purpose: To compare two clinical most common used methods: arterial spin-labeling (ASL) and dynamic susceptibility contrast (DSC) MRI in detecting CCD in patients after glioma resection.
Methods and Materials: 145 patients with perfusion deficit in one hemisphere after glioma resection and radiotherapy were reviewed. Lesion locations were recorded. Visual qualitative analysis was performed by two neuroradiologists on ASL CBF map. Signal intensity asymmetry of bilateral cerebellar hemisphere was classified into three grades: grade I, isointense; grade II, slightly hypointense; grade III, markedly hypointense. Quantitative analysis by calculating asymmetry index (AI) of bilateral cerebellar hemispheres was performed on all 145 patients on ASL CBF, DSC rCBF and rCBV maps. One-way ANOVA was used to compare differences between the AIs in each method. Chi-squared or Fisher exact test was used for finding correlations between CCD and the locations of supratentorial lesions.
Results: The interrater agreement was excellent (kappa value = 0.852) in qualitative analysis. Thirty-nine (26.9%) patients were CCD positive (27 in grade II and 12 in grade III). Lesions affecting corona radiata (P<0.001), basal ganglia (P<0.001), temporal lobe (P=0.038) and insular lobe (P=0.031) were significantly associated with CCD. The mean AI of ASL CBF (27.59%±8.60%) was significantly larger than that of DSC rCBV (15.27%±12.66%) (P<0.001) and DSC rCBF (10.84%±8.56%) (P<0.001).
Conclusion: ASL is more sensitive than DSC rCBV and rCBF map in detecting CCD among patients after glioma resection. CCD is more likely to be associated with supratentorial lesion involved with corona radiata, basal ganglia, temporal lobe and insular lobe.

MR-perfusion characteristics and PET/CT comparison in patients with gliomas after radiotherapy
A.V. Smirnova[1], O.V. Lukina[2], M. Cherkashin[2], N. Plakhotina[2], A. Tkachev[3], M. Anishkin[1], M. Rukhlenko[1]; [1]*St. Petersburg/RU*, [2]*Saint-Petersburg/RU*, [3]*Volgograd/RU (smirnova_alina@bk.ru)*

Purpose: To evaluate gliomas perfusion changes after radiotherapy in comparison with PET/CT data.
Methods and Materials: In our study 125 gliomas patients treated by different radiation modalities were initially included. 51 were excluded on different stages because they did not survive at month 24. All patients were divided into two groups: group A - gliomas I-IIG (n=21), group B - gliomas III-IVG (n=53). MR-perfusion and PET/CT (methionine) were performed before radiotherapy, and after 6, 12, 18 and 24 months.
Results: In group A initially increase CBV, methionine UI≥2.0; in follow-up 1 high CBV in 93%, UI≤2.2; decrease CBV in 7%, UI≤1.8; in follow-up 2 high CBV in 74%, UI≤2.7; reduction CBV in 26%, UI≤1.8; in follow-up 3 high CBV in 57%, UI≤3.2; in follow-up 4 reduction CBV in 43%, UI≤1.8; in follow-up 5 high CBV in 31%, UI≤4.1; reduction CBV in 69%, UI≤1.6 were detected. In group B initially not increased CBV, methionine UI≤1.5; in follow-up 1 low CBV in 83%, UI≤1.5; in follow-up 2 increase CBV in 17%, UI≤1.7; in follow-up 3 low CBV in 91%, UI≤1.5; increase CBV in 8%, UI≤1.7; in follow-up low CBV in 98%, UI≤1.5; increase CBV in 2%, UI≤1.5; in follow-up 5 low CBV in 100%, UI≤1.5.
Conclusion: Gliomas metabolism and perfusion in first year after radiotherapy characterised by multidirectional changes. Just after 2 years of surveillance we have detected strong CBV and UI reduction. We suggest that future investigations with strong study power will generate evidence for clear differentiation the gliomas relapse and postradiation brain damage.

B-1004 11:42

Can unenhanced brain magnetic resonance imaging be used in routine follow-up of meningiomas to avoid gadolinium deposition in the brain?
F. Kural Rahatli, F. Yildirim Donmez, Ç. Kesim, k. Haberal, H. Turnaoglu, A. Agildere; *Ankara/TR (drkural@hotmail.com)*

Purpose: We speculated that unenhanced brain MRI can be used in routine follow-up of patients with intracranial meningioma to avoid gadolinium deposition in the brain and allow measurement of meningioma dimensions from precontrast T2-weighted images. We investigated whether measurements on pre-contrast T2-weighted images and post-contrast T1-weighted images are correlated.
Methods and Materials: Thirty meningiomas with multiple enhanced brain MRI using linear non-ionic GDBCA (gadoversetamide) were analysed. The dimensions of meningiomas were measured on both axial precontrast T2-weighted images and axial postcontrast T1-weighted images. Signal intensity ratios were calculated for dentate nucleus-to-pons (DN/pons), dentate nucleus-to-cerebellar white matter (DN/cerebellum) and globus pallidus-to-thalamus (GP/thalamus).
Results: Size of six meningiomas increased, as determined from measurements on both axial precontrast T2-weighted images and axial postcontrast T1-weighted images. The signal intensity ratios showed a significant increase (p<0.005) from the first to last brain MRI. The mean DN/pons ratio at first MRI was 1.055±0.38 and 1.149±0.86 at the last MRI. The mean DN/cerebellum ratio at first MRI was 1.068±0.42 and 1.156±0.78 at the last MRI. The mean GP/thalamus ratio at first MRI was 1.077±0.24 and 1.136±058 at the last MRI.
Conclusion: Size of meningiomas in post-contrast axial T1-weighted images was correlation with that in pre-contrast axial T2-weighted images, that is, both showed tumour growth. DN/pons, DN/cerebellum, and GP/thalamus signal intensity ratios increased with multiple administrations of linear non-ionic GBCAs in patients with normal renal function. Gadolinium deposition could be avoided in patients with meningioma using unenhanced brain MRI for follow-up scans.

Perfusion abnormality in posterior inferior cerebellar artery termination of vertebral artery on arterial spin labelling and dynamic susceptibility contrast perfusion MRI
D. Park, T. Kim; *Guri/KR (dwpark@hanyang.ac.kr)*

Purpose: A posterior inferior cerebellar artery (PICA) termination of vertebral artery has been regarded as a normal variation of vertebrobasilar circulation. However, the perfusion condition of PICA territory in the cerebellum has not been evaluated. This study aims to present the perfusion abnormality in PICA termination of vertebral artery (PICA-VA) on arterial spin labeling (ASL) and dynamic susceptibility contrast (DSC) perfusion MRI.
Methods and Materials: Sixteen patients (M:F=8:8, 49-90 years old) who conducted brain MRI including MR angiography, and ASL and DSC perfusion MR studies and are found to have PICA-VA, are evaluated in this study. PICA-

VA are associated with ipsilateral hypoplastic vertebral artery in 14 patients, and bilateral foetal type posterior cerebral artery in 2 patients.
Results: Hypoperfusion in PICA territory is detected on both ASL and time to peak (TTP) map of DSC perfusion MRI in 11 patients (68.7%), on only TTP perfusion MRI in 2 patients (12.5%), on only ASL perfusion MRI in 1 patient (6.3%) and not on both perfusion MRI in 2 patients (12.5%). Any clinical manifestations of vertebrobasilar insufficiency are not accompanied in 2 patients (12.5%).
Conclusion: PICA-VA that is regarded as normal variation, considerably have hypoperfusion in PICA territory of cerebellum. PICA-VA could have the clinical significance, especially in vertebrobasilar insufficiency, so perfusion study such as ASL or DSC perfusion MRI may help to evaluate the clinical status of vertebrobasilar insufficiency.

Spectral detector-computed tomography iodine density thresholds for the detection of vertebral metastases

N. Abdullayev, V. Neuhaus, M. Le Blanc, N. Grosse Hokamp, V. Maus, S. Lennartz, D. Maintz, J. Borggrefe; *Cologne/DE*
(Jan.Borggrefe@uk-koeln.de)

Purpose: To evaluate quantitative iodine density mapping (IDM) from spectral detector computed tomography (SDCT) as a quantitative parameter for the separation of vertebral trabecular bone metastases (BM) and healthy trabecular bone (HTB).
Methods and Materials: This retrospective study includes portal venous SDCT datasets of cancer patients with and without known bone metastasis (n=43 and n=40, respectively). Target lesions as well as non-affected control vertebrae were defined by two radiologists in consensus using follow-up CT imaging, MRI and/or bone scintigraphy. IDM and its standard deviation (SD) were determined based on ROI measurements in BM and HTB of patients with and in HTB of patients without bone metastasis, and various reference tissues/vessels in both. Phantomless bone mineral density (vBMD) measurements of the lumbar spine were conducted.
Results: We found a significant difference between IDM of BM and HTB (mean 5.55±0.98 vs. 3.57±0.96) ($p<0.0001$); however, there was a considerable overlap and a vBMD bias. A trivariate analysis including IDM, the inhomogeneity of the IDM as determined by the SD, and the normalization to the vertebral venous sinus improved the statistical separation of metastasis to a specificity of 100.0% and a sensitivity of 95.4% (AUC 0.98, $p<0.05$ compared to univariate models).
Conclusion: SDCT allows for quantification of iodine in bone lesions which appears promising to serve as a parameter for the detection of bone metastases.

B-1013 08:34

Combining fractal- and entropy-based bone texture analysis for the prediction of osteoarthritis: data from the multicentre osteoarthritis study (MOST)

Z. Bertalan[1], S. Nehrer[2], R. Ljuhar[1], A. Fahrleitner-Pammer[3], D. Ljuhar[1], H.-P. Dimai[3]; [1]*Vienna/AT*, [2]*Krems/AT*, [3]*Graz/AT (rljuhar@gmail.com)*

Purpose: Osteoarthritis (OA) is the leading cause of long-term pain and disabilities associated with musculoskeletal disorders. Effective treatment depends on early detection and quantification of risk. Current disease parameters, like joint space width (JSW), have proven to be insufficient for the prediction of OA. The purpose of the present study was to investigate if combining bone texture analyses with JSW and joint space area (JSA) may improve prediction of OA.
Methods and Materials: Conventional posterior-anterior (PA) knee radiographs were obtained from the multicentre osteoarthritis study (MOST) database. Oriented texture algorithms were developed, using specific machine-learning algorithms. Selected areas used for textural analyses included 4 regions of interest (ROI) in the proximal tibia and one on each condyle of the distal femur. Furthermore, JSW/JSA were assessed using newly developed and fully automated software.
Results: 1092 radiographs obtained from one study centre were screened. 230 women, 344 men met the inclusion criteria, i.e. a Kellgren & Lawrence (KL) score of 0 at baseline. At month 84, 41 female, 79 male patients had developed KL≥1, and 189 female, 265 male patients remained at KL0. Area under the curve (AUC) for incident OA using JSW/JSA/clinical features was 0.67±0.08 for women, 0.61±0.1 for men. In contrast, combining texture, JSW/A and clinical features resulted in significantly improved AUC (0.80±0.07 for women and 0.69±0.1 for men, respectively).
Conclusion: This study provides strong evidence that a combination of textural analyses of plain radiographs together with JSW/A and clinical features is superior to JSW/A and clinical features alone in predicting incident OA.

B-1014 08:38

Delayed gadolinium-enhanced MRI of menisci and cartilage (dGEMRIM/dGEMRIC) in overweight patients with knee osteoarthritis

S. Hangaard[1], H. Gudbergsen[1], C.L. Daugaard[1], H. Bliddal[2], J.D. Nybing[1], V. Casula[3], M.T. Nieminen[3], C.J. Tiderius[4], M. Boesen[2]; [1]*Frederiksberg/DK*, [2]*Copenhagen/DK*, [3]*Oulu/FI*, [4]*Lund/SE (stine.hangaard.01@regionh.dk)*

Purpose: Changes in the menisci are associated with development of knee osteoarthritis (KOA). The aim of this study was to examine the delayed-gadolinium-enhanced-MRI-of-menisci (dGEMRIM) and its relationship with Kellgren-Lawrence grade (KLG) and with articular cartilage dGEMRIC.
Methods and Materials: 86 overweight patients with KOA (mean KLG 3) from the CAROT study had an intra-articular injection of Gd contrast. Four invasion times (50, 350, 650, 1410 ms) dGEMRIC and dGEMRIM were performed in 1.5 T. T1 relaxation time values were calculated for posterior weight-bearing femoral cartilage in the lateral knee compartment, and for the posterior horn of the lateral and medial menisci.
Results: For femoral cartilage (N=86) the mean T1 value was 441ms. The mean T1 value in the lateral menisci (N=85) was 498ms and for the medial menisci (N=62) mean T1 value was 484ms. A positive correlation was found between posterior medial and lateral menisci $R=0.62$ ($p<0.0001$) and a similar trend was seen between lateral femoral cartilage and lateral menisci with $R=0.26$ ($p=0.02$). Comparing the meniscus from the most affected knee compartment to KLG showed trends toward increasing T1 values for KLG 1-3 and a decreasing T1 value for KLG 4.
Conclusion: The positive correlation between lateral and medial menisci indicates parallel degeneration processes in both knee compartments. The correlation between menisci and cartilage suggests concomitant, but different, degeneration in the two tissues in OA. The interpretation of inverse U-shaped relation between meniscal T1 values and KLG is in accordance with findings comparing various degrees of meniscal degeneration with dGEMRIM and proteoglycan content.

B-1015 08:42

Ultrasound of the posterior interosseous nerve in the arcade of Frohse

C. Tulay, S. Aubry, A. Podda, J. Behr; *Besancon/FR*
(wonder_angel15@hotmail.com)

Purpose: To accurately assess the diameter of the posterior interosseous nerve (PIN) as it passes through the arcade of Frohse and to demonstrate that exist a physiological difference in anteroposterior diameter between the upstream, the entry point and downstream of the arcade.
Methods and Materials: Prospective monocentric study of the PIN in 30 healthy volunteers (sex ratio = 1) which have been examined bilaterally by ultrasound with a high frequency probe (18 MHz) in longitudinal section. The anteroposterior diameter of the PIN was measured at the entry point in the arcade of Frohse, 5mm upstream and 5mm downstream.
Results: The anteroposterior diameter of the NIP was 0.833 mm +/- 0.208, 0.6mm +/- 0.173 and 0.486mm +/- 0.131 respectively upstream, at the entry and downstream of the Arcade of Frohse. It significantly decreases by 27.2% between the upstream and entry point (-0.233mm; $p<0.001$), by 16.6% between the entry point and downstream (-0.114mm; $p < 0.001$), and by 39% between the upstream and downstream (0.357mm; $p<0.001$).
Conclusion: There is a physiological decrease in the anteroposterior diameter of the PIN as it passes through the arcade of Frohse, not to be wrongly considered as a compression of the nerve in the arcade.

B-1016 08:46

Safety and efficiency of treatment of partial supraspinatus tendon tear with injection of PRP and HA

C. Lupo[1], A. Meli[2], V. Incarbone[2], N. Casamassima[2], L. Callegari[2]; [1]*Palermo/IT*, [2]*Varese/IT (claudialu@live.it)*

Purpose: Evaluate safety and efficiency of treatment of partial supraspinatus tendon tears with intralesionals injection of autologous platelet-rich plasma (PRP) associated with low molecular weight hyaluronic acid (HA 0.8%) under ultrasound guidance.
Methods and Materials: Between January and September 2016, we selected 84 patients, mean age 57, with a ultrasound diagnosis of partial tear of supraspinatus tendon; 48/84 confirmed with MRI. Before the treatment (T0), all patients were evaluated the pain with the visual analogue scale (VAS). After local ultrasound guided anaesthesia with lidocaine, an injection of glenohumeral joint with a 22G needle with lateral access was given, followed by needling of supraspinatus tendon and subsequent intratendineus injection with 2.5cc of (PRP) and 2cc of (HA0.8%), 3 injections, one every three weeks. The safety of the procedure was considered by the analysis of complications; efficacy was considered by clinical follow-up at six weeks after the procedure and imaging follow-up at six months in 84/84 patients with US and in 35/84 with MRI.

Results: 84/84 patients improved pain with a statistically significant difference (p <0.001) of VAS scale before and after treatment without major complications. 55/84 patients showed some modification of the ultrasound and RM patterns.
Conclusion: Injection of (PRP) with (HA0.8%) is a well-tolerated procedure in treatment of partial the supraspinatus tendon tear with a marked improvement on pain.

B-1017 08:50

Improving the sensitivity of bone mineral density assessment using spectral detector CT

S. van Hedent, K.-H. Su, F. Liang, J.-W. Kuo, D.W. Jordan, B. Eck, P.R. Ros, R. Muzic; *Cleveland, OH/US (svhedent@vub.ac.be)*

Purpose: Bone mineral density (BMD) analysis by Dual-Energy x-ray Absorptiometry (DEXA) is complicated by false negatives due to overlapping densities in the projection area. Spectral Detector CT (SDCT) can overcome these limitations, while providing volumetric information. We investigated its performance for BMD assessment and compared it to DEXA and phantom-less Quantitative CT (QCT).
Methods and Materials: Ten uniform solutions of bone-like material, K_2HPO_4 ranging 0-600 mg/ml, were scanned in an acrylic phantom using the SDCT in four varying clinically relevant scan conditions. Images were processed to estimate the K_2HPO_4 concentrations. A model representing a human lumbar spine (European spine phantom) was scanned and used as calibration for linear regression analysis, so that our method could be retrospectively applied to abdominal SDCT scans of 20 patients who also had a QCT and DEXA. Performance of QCT, DEXA and our SDCT method were compared.
Results: There was excellent correlation (R2 >0.99, p = 0.00) between true and measured K2HPO4 concentrations for all scan conditions. Overall mean measurement error ranged from -11.49 ± 4.70 mg/ml (-2.78 ± 6.01%) to -12.34 ± 6.26 mg/ml (-4.77 ± 3.00%) depending on scan conditions. Using DEXA as gold standard, sensitivity and specificity for detecting decreased BMD in the scanned patients was 100 and 73.3%, and 100 and 40% for SDCT and QCT respectively.
Conclusion: SCDT has excellent sensitivity and high specificity for detecting decreased BMD, allowing its use for opportunistic screening or pre-operative planning.

B-1018 08:54

Virtual bone mineral density imaging with third-generation dual-energy CT for diagnosis of osteoporosis: a preliminary study

L. Wang, G. Shenchu, B. He, J. Chen; *Nantong/CN (wanglin_nt@126.com)*

Purpose: To quantitatively assess the diagnostic value of virtual bone mineral density (VBD) imaging at DECT for osteoporosis (OP).
Methods and Materials: Forty-five patients with vertebral trauma underwent DECT and DXA examinations of the lumbar 1-4. VBD images were derived from three-material decomposition algorithm using post-processing software ('Liver VNC', Syngo Via Dual Energy, Siemens), while the default CT values of fat, soft tissues, iodine and iodine slope were corrected to the yellow marrow, red marrow, calcium and calcium slope which were recommended in another software ('Bone Marrow', Syngo Via Dual Energy). CT attenuation values (VBD_Att), calcium density (VBD_CaD) and fat fraction (VBD_Fat) were measured for quantitative analyses. CT numbers on mixed images (LB_0.5) reconstructed with a merging coefficient 0.5 at DECT were recorded. Bone mineral density and T scores of lumbar measured with DXA served as the gold standard. Pearson correlation analysis was performed to compare DECT and DXA results. Diagnostic performance of VBD imaging was assessed by ROC analysis.
Results: A total of 166 lumbars were evaluated. LB_0.5 and VBD_Att were significantly different between OP and non-OP vertebral bodies (all P<.01). VBD_Att and VBD_CaD both had significant correlations with T scores (all P<.01). However, no significant correlation existed between VBD_Fat and T scores (P=.08). Furthermore, sensitivity and specificity for assessment of OP were 86.00%, 80.17% for VBD_Att and 84.00%, 81.03% for VBD_CaD. Diagnostic performance was significantly higher in VBD_Att and VBD_CaD compared to LB_0.5 (all P<.01).
Conclusion: Dual-energy VBD imaging shows acceptable diagnostic performance for OP in patients with vertebral trauma.

B-1019 08:58

Quantitative MRI of knee articular cartilage in hyperuricemia

X. Cai, X. Liu; *Guangzhou/CN (caixran@jnu.edu.cn)*

Purpose: To identify the changes of knee articular cartilage in patients with gout and with asymptomatic hyperuricemia.
Methods and Materials: Forty-three patients with gouty arthritis, 30 with asymptomatic hyperuricemia and 30 age- and sex-matched controls were included in this study. Multiple-TE FSE sagittal images of the knee were acquired using a 3T MRI scanner. T2 values of the superficial and deep zones of the tibiofemoral and patellofemoral cartilages were analysed in sub-compartmental areas and compared among the three groups. Also, they were correlated with the serum uric acid level in those gout patients without taking any uric-acid-lowering drug.
Results: Cartilage thinning was observed in 13 out of 57 (22.81%) involved knees in patients with the symptomatic gout and 3 out of 36 (8.33%) examined knees with asymptomatic hyperuricemia. Significantly higher T2 values were observed at the superficial and deep zones of the cartilage in the gout patients compared to the normouricemic controls. However, no significant difference was found in T2 values of superficial and deep zones of the cartilage between the asymptomatic hyperuricemia patients and normouricemic controls. Moderate positive correlation was found between the T2 value of superficial zone of the cartilage with serum uric acid level.
Conclusion: Patients with gout demonstrate increased T2 value at the superficial and deep zones of the knee cartilage indicative of early change in cartilage matrix composition. Cartilage thinning also occurs more frequently in those patients. The high serum uric acid level could accelerate the cartilage injuries in gouty patients.

B-1020 09:02

In vivo quantitative 4D-CT analysis of carpal kinematics with radio-scaphoid and luno-capitate angles during radio-ulnar deviation: feasibility and clinical interest

A. Rauch; *Nancy/FR (aym.rauch@gmail.com)*

Purpose: To study the variation of radioscaphoid (RSA) and lunocapitate (LCA) angles during wrist radio-ulnar deviation (RUD) using semi-automatic quantitative 4D-CT in patients with and without scapholunate-ligament tears (SLT).
Methods and Materials: 37 patients with suspected scapholunate instability were prospectively evaluated with 4D-CT and CT-arthrography of the wrist. The study was approved by the local ethics committee and all patients signed an informed consent. Various dynamic parameters (mean, amplitude, maximal angle, standard deviation (SD), angular coefficient of variation (ACV)) describing RSA and LCA variation during wrist RUD were calculated and compared in patients with and without SLT by two readers.
Results: The mean values for RSA and LCA in the control group varied, respectively, from 102.98° ± 7.6° to 104.47° ± 8.89° and 85.92° ± 9.37° to 90.09° ± 10.56° with ACV from 10,78% to 11.03% and 13.49% to 13.52% for readers one and two, respectively. The inter-observer variability was excellent for RSA (ICC = 0.82) and substantial for LCA (ICC= 0.79). LCA amplitude, SD and maximal angle were significantly smaller in SLT group (p varied from 0.0001 to 0.0026), respectively, from 36% to 44%, 37% to 44% and 13% to 19%. RSA amplitude tended to be smaller in SLT group (18% to 27%, p varied from 0.0295 to 0.1328). LCA yielded the best sensitivity for SLT (71-91%) while RSA yielded the best specificity (87-100%).
Conclusion: 4D-CT can quantitatively assess carpal kinematics during RUD which could improve the diagnosis and prognostic evaluation of patients with SLT.

B-1021 09:06

Detection of osseous metastases using dual-energy CT with material decomposition algorithms: phantom development and preliminary clinical validation

H.-C. Huang[1], B.M. Yeh[2], R. Srinivasan[2], Y. Sun[2]; [1]*Taipei City/TW*, [2]*San Francisco, CA/US (hjround@gmail.com)*

Purpose: Meta-analysis studies have shown that the conventional single-energy computed tomography (SECT) has limited ability in detecting subtle bone metastases. The purpose of this study was to use dual-energy CT (DECT) with bone-water material decomposition algorithms to detect nearly isodense bone metastases in phantoms, and to validate its use with retrospective patient DECT scans which were initially read as negative for bone metastases, but later detected by other imaging modalities or at follow-up CT.
Methods and Materials: We constructed 51 semi-anthropomorphic lumbar spine phantoms randomly embedded with 75 simulated tumours (25 mild lytic, 25 isodense, and 25 mild sclerotic). These phantoms were scanned in a rapid-kilovoltage-switching DECT scanner. Two radiologists independently reviewed images from 70 keV virtual monochromatic reconstruction and 4 material decomposition algorithms (hydroxyapatite-water, water-hydroxyapatite, cortical bone-water, water-cortical bone). We recorded reviewer's response regarding the presence of tumours. The sensitivity and specificity of different reconstruction algorithms were evaluated with McNemar test. The tumour conspicuity scores were recorded in 3-point Likert scales and then evaluated by Wilcoxon signed rank test. Finally, we validated our testing algorithms by retrospectively reviewing patients' images in our institution.
Results: Hydroxyapatite-water material decomposition algorithm achieved higher sensitivity in detecting isodense lesions (38% vs 18%, p=0.013) and possessed higher tumour conspicuity score (p<0.0001) as compared to the 70

keV reconstruction in the phantom study. Hydroxyapatite-water algorithm also detected more tumours in the retrospective patients' studies.
Conclusion: DECT with hydroxyapatite-water material decomposition may help detect subtle spine metastases. Further study in prospective clinical scans is warranted.

High diagnostic accuracy of k_{ep} on dynamic contrast-enhanced MRI perfusion in identifying vertebral malignancy

M. Verma, S. Sood, B. Singh, M. Thakur, S. Sharma, S. Sharma; *Shimla/IN (mansiverma1608@gmail.com)*

Purpose: Vertebral lesions are not easily amenable to biopsy due to inherent risks associated with this invasive procedure. There is considerable overlapping of radiologic features of benign and malignant lesions on conventional MRI. We performed this study to evaluate the role of dynamic contrast-enhanced (DCE) MRI perfusion parameters in differentiating malignant from benign lesions.
Methods and Materials: We studied all patients presenting to our hospital with a radiologic evidence of vertebral lesions from July 2016 through June 2017. We performed DCE-MRI of spine on 1.5 T scanner using 3D VIBE sequence after intravenously injecting 0.1mmol/kg body weight of gadopentetate dimeglumine. We used Tofts model to calculate DCE parameters that included K^{trans}, k_{ep}, Ve and iAUC. We compared the means of each perfusion parameters by type of lesion (benign/malignant) at 0.05 significance level and performed ROC curve analysis.
Results: We could confirm histologic/cytologic diagnosis in 35 of the 45 patients recruited. Of these 19 were tubercular and 16 malignant lesions. The mean (±sd) of k_{ep} (min^{-1}) was significantly higher (2.89±3.3) in malignant compared to benign lesions (0.81±0.19), whereas Ve (ml/g) was significantly lower in malignant (0.27±0.13) compared to benign lesions (0.47±0.12) at 0.05 significance level. k_{ep} cut-off of ≥ 1.17 min^{-1} had a sensitivity of 93.8% and specificity of 100% with a diagnostic accuracy of 94.4% in detecting malignant disease.
Conclusion: High k_{ep} is highly suggestive of malignant lesions. We recommend k_{ep} cut-off of ≥ 1.17 min^{-1} that was found to have high diagnostic accuracy in identifying malignant lesions.

B-1023 09:14

Complementary metal artefact reduction of total hip replacements by monoenergetic and O-MAR reconstructions in spectral-detector computed tomography

K.R. Laukamp, S. Lennartz, V. Neuhaus, N. Grosse Hokamp, R. Rau, M. Le Blanc, N. Abdullayev, D. Maintz, J. Borggrefe; *Cologne/DE (kai.laukamp@uk-koeln.de)*

Purpose: This study compares metal artefact (MA) reduction in imaging of total hip replacements (THR) using virtual monoenergetic images (VMI), for MA reduction specialised iterative reconstructions (O-MAR) and conventional images (CI) from spectral-detector computed tomography (SDCT).
Methods and Materials: 27 SDCT datasets of patients carrying THR were included. CI, O-MAR and VMI with different energy levels (60-200keV) were reconstructed from the same scans. MA width was measured. Attenuation (HU), noise (SD) and contrast-to-noise ratio (CNR) were determined in: extinction artefact, adjacent bone, muscle and bladder. Two radiologists assessed artefact reduction and image quality subjectively.
Results: In comparison to CI, VMI (200keV) and O-MAR showed a strong artefact reduction (MA width: CI 29.9±6.8mm, VMI 17.6±13.6mm, p<0.01; O-MAR 16.5±14.9mm, p<0.001; MA density: CI -412.1±204.5HU, VMI -279.7±283.7HU; p<0.01; O-MAR -116.74±105.6HU, p<0.001). In strong artefacts reduction was superior by O-MAR. In moderate artefacts VMI was more effective. O-MAR showed best noise reduction and CNR in bladder and muscle (p<0.05), whereas VMI were superior for depiction of bone (p<0.001). Subjective assessment confirmed that VMI and O-MAR improve artefact reduction and image quality (p<0.001).
Conclusion: O-MAR and VMI (200keV) yielded significant MA reduction. Each showed distinct advantages regarding effectiveness of artefact reduction and assessment of adjacent bone, muscle and pelvic organs.

B-1024 09:18

Ultra-high field 7 Tesla MRI and biomechanical investigation of vertebral bone microarchitecture

D. Guenoun, A. Foure, M. Pithioux, S. Guis, T. Le Corroller, V. Pauly, P. Chabrand, P. Champsaur, D. Bendahan; *Marseille/FR (daphne.guenoun@ap-hm.fr)*

Purpose: to investigate bone microarchitecture parameters of human ex-vivo vertebrae using ultra-high field 7Tesla MRI (7T MRI).
Methods and Materials: Twenty four vertebrae (L2, L3, and L4) from eight cadavers were studied using 7T MRI. Their Bone mineral densities (BMD) were investigated using dual energy x-ray absorptiometry. Then, all specimens underwent mechanical compression tests to failure. The failure load (in Newton) and constraint (in megapascal) were measured. Bone volume fraction (BV/TV), trabecular thickness (Tb.Th), and trabecular spacing (Tb.Sp) were measured in MRI using a digital topological analysis (Bone J). Measurements were recorded by two observators to characterize the interrater reliability. Statistical analyses were performed using SPSS. Correlations between variables were analyzed using Spearman correlations and stepwise regression. A p value of 0.05 was considered as significant.
Results: the inter-rater reliability for bone microarchitecture parameters quantification was very good. The failure load and constraint measured during the compression tests were significantly correlated with BV/TV, Tb.Sp and BMD while Tb.Th was correlated with constraint only (p<0.05). Stepwise regression with backward elimination demonstrated that combining BV/TV and BMD improved the relationship with the constraints from an adjusted r^2 =0.384 for BMD alone to an adjusted r^2=0.414 for BMD+BV/TV.
Conclusion: we demonstrated for the first time that the variables characterizing the vertebral bone microarchitecture in 7T MRI were significantly correlated with biomechanical parameters. In addition, we illustrated that combining BMD and 7T MR, trabecular bone analysis provided additional information regarding vertebral bone strength in comparison with DXA alone.

B-1025 09:22

Postoperative evaluation of a arthroscopic coracoid bone block surgery with CT-Scan.

O. Andreani[1], P. Gendre[2], C. Dekimpe[1], A. Rudel[1], N. Amoretti[1], P. Boileau[1]; [1]*Nice/FR*, [2]*Cagnes sur Mer/FR (andreani.olivier@gmail.com)*

Purpose: To know and use the criteria of good positioning and bone consolidation of a coracoid bone block. To evaluate the results in terms of positioning and bone consolidation of an arthroscopic technique of Latarjet coracoid bone block.
Methods and Materials: A retrospective monocentric study of 161 patients who underwent a Latarjet coracoid bone block surgery under arthroscopy by a senior operator for management of anterior chronic shoulder instability. All patients were monitored at 15 days and 6 months by CT-scan. The positioning of the stop was evaluated in the horizontal and vertical plane. Bone consolidation was evaluated at 6 months.
Results: The bone block was sub-equatorial in 151 (93%) patients, equatorial in 9 (5%) and supra-equatorial in 2 (1%). The bone block was flush in 153 patients (94%), overflowing in 8 (4.5%) and medial in 1 patient (0.5%). At 6 months postoperative, complete bone consolidation was obtained in 147 patients (90.5%). 14 (9%) had a bone block pseudarthrosis, one a fractured of the bone block, one a complete lysis and one a bone block migration. The clinical prognostic factor of lack of consolidation was smoking. Five patients had recurrent instability.
Conclusion: CT-scan is an easy and reproducible tool for postoperative osseous evaluation of Latarjet arthroscopic surgery.This technique gives good results in terms of positioning and consolidation of the coracoid bone block.

B-1026 09:26

Volumetric bone mineral density assessment of the lumbar spine using a novel phantomless dual-energy CT postprocessing algorithm in comparison to dual x-ray absorptiometry

C. Booz[1], P.C. Hofmann[2], M. Sedlmair[2], T. Flohr[2], B. Schmidt[2], S.S. Martin[1], D. Leithner[1], T.J. Vogl[1], J.L. Wichmann[1]; [1]*Frankfurt a. Main/DE*, [2]*Forchheim/DE (boozchristian@gmail.com)*

Purpose: Current techniques for the evaluation of bone mineral density (BMD) commonly require phantom calibration. The purpose of this study was to evaluate a novel algorithm for phantomless in vivo dual-energy computed tomography (DECT)-based volumetric assessment of BMD of the lumbar spine in comparison to dual x-ray absorptiometry (DXA).
Methods and Materials: This retrospective study was approved by the institutional review board. The requirement to obtain informed consent was waived. Data from clinically indicated DECT and DXA examinations within 2 months of 47 patients were evaluated. Using a novel automated dedicated postprocessing algorithm for DECT, the trabecular bone of lumbar vertebrae L1-L4 was analysed after five volumes of interest on different slices had been

manually defined for each vertebral body. Pearson product-moment correlation, Bland-Altman plot and further regression analyses were calculated for statistical analysis.
Results: A total of 186 lumbar vertebrae in 47 patients (24 male, 23 female) were analysed. Mean BMD of L1-L4 determined by DXA was 0.986 g/cm², and 20 patients (42.6%) showed an osteoporotic BMD according to guidelines of the World Health Organisation. Average DECT-based BMD of L1-L4 was 88.68 mg/cm³. According to CT guidelines of the American College of Radiology DECT measurements identified seventeen patients (36%) with an osteoporotic BMD. Statistical analysis showed a moderate correlation between volumetric and areal BMD values based on DECT and DXA with a Pearson's product-moment correlation coefficient of r=0.421.
Conclusion: A novel DECT-based postprocessing algorithm allows for phantomless volumetric BMD assessment of the trabecular bone of lumbar vertebrae.

Learning curve of an ultrasound-guided percutaneous release of carpal tunnel: a cadaveric study
O. Andreani, C. Dekimpe, C.-P. Raffaelli, N. Amoretti; *Nice/FR (andreani.olivier@gmail.com)*

Purpose: The aim of our study was to evaluate the feasibility and the learning curve of an ultrasound-guided percutaneous carpal tunnel release.
Methods and Materials: 14 carpal tunnel releases were carried out, on un-embalmed cadavers, 7 by a senior and 7 by a junior radiologist. Sonographic evaluation, with 18 MHz probe, was first performed to detect the anatomical variant and length of the retinaculum. After hydrodissection by Xylocaine of the carpal tunnel, we used an Acufex knife (2,5 mm; Smith and Nephew®) to cut the retinaculum, under ultrasonographic guidance. We evaluated the time (from the first injection of Xylocaine until the knife was taken off); success of the procedure: complete release of retinaculum and absence of complication (lesion of the median nerve and its branch, especially the thenar motor branch, or vascular structure, especially the arterial palmar arch), checked by dissection after procedure; and size of cutaneous incision.
Results: The mean time of the procedure was 14 minutes. (11 min senior versus 17 min junior). The section was complete at the 4th procedure for the senior and at the 5th procedure for the junior radiologist. No lesion of the median nerve or vascular structure was observed. The release was incomplete in 7 firsts' wrists, due to an incomplete section of the distal retinaculum (lack of 10 mm on average). Several passages were associated with more frequent complete section. The mean size of the incision was 3 mm.
Conclusion: We observed a rapid learning curve of carpal tunnel release with ultrasound guidance, for a senior or junior radiologist, without difference in the term of success. This procedure seems to be safe, reproducible and minimally invasive.

B-1028 09:34

The accuracy of ultrasound with and without sonoelastography in the diagnosis of partial-thickness rotator cuff tears with MDCT arthrography and arthroscopic verification
V.E. Gazhonova, M. Emelianenko, M. Onishchenko; *Moscow/RU (vx969@yandex.ru)*

Purpose: To compare the diagnostic accuracy of conventional US and sonoelastography (SE) for the diagnosis of partial-thickness rotator cuff tears (RCTs) with MDCT-arthrography and arthroscopic correlation.
Methods and Materials: 50 shoulders with suspected partial RCT based on MRI or US findings were assessed with conventional US and SE. SE images were evaluated by reviewers using experimentally proven colour grading system (grade 2, red colour - RCT, grade 1, green - tendonitis, grade 0, blue - normal). Strain ratios (SR) in the affected region of the tendon were calculated in comparison to the deltoid muscle. MDCT arthrography and arthroscopy were used as reference methods for verification.
Results: Using conventional US, 75% (24 of 32) of the partial RCTs were found correctly. Using SE, 28 RC tendons were categorised as grade 2, 15 as grade 1, and 7 as grade 0. SR in RCT regions <1.2 was in 30 shoulders, and SR >1.2 in 20 patients. Evaluation of interobserver reliability of the SE findings showed "almost perfect agreement" with a weighted kappa coefficient of 0.83 for colour SE grades. By comparing SE with the reference methods, colour grading system had a positive correlation (r=0.84, p=<0.001), and SR values <1.2 were characteristic for RCT with positive correlation (r=0.93, p=<0.001). In diagnosing a partial RCT, SE was more sensitive than conventional US (p<0.05).
Conclusion: SE using colour grading scale and quantification of SR values in the affected tendon's regions is a more sensitive and specific technique for diagnosing partial-thickness RCT than conventional US.

B-1029 09:38

Iterative reconstruction improves image quality in virtual non-calcium images of the spine for the detection of bone marrow edema in patients with vertebral compression fractures
N. Engelhard[1], K.-G. Hermann[1], M. Fuchs[1], M. Pumberger[1], M. Putzier[1], J. Mews[2], B. Hamm[1], T. Diekhoff[1]; [1]*Berlin/DE*, [2]*Neuss/DE (nils.engelhard@charite.de)*

Purpose: Dual-energy computed tomography (DECT) allows detection of bone marrow edema (BME) after vertebral compression fractures using virtual non-calcium imaging (VNCa). The aim of this study was to evaluate, which reconstruction offers the best image quality.
Methods and Materials: 18 patients over 50 years of age with available CT raw-data were retrospectively included. DECT was performed on a single-source machine (80/135 kVp sequential volume acquisition) and reconstructed using filtered back projection (FBP) and iterative reconstructions (IR) with three different iteration levels (IR1-IR3). VNCa images were generated using a raw-data (RD) and an image-data (ID) based software. Target vertebras (TV) with fracture and BME in STIR sequence and normal appearing reference vertebras (RV) were defined. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. Intervertebral ratio (IVR) served as measurement for the detectability of BME. Friedmann-Test with multiple comparisons was applied.
Results: 39 TV and 18 RV were included. RD showed significantly inferior SNR (p = 0.0001-0.0003) compared to ID. CNR differences were only significant for FBP vs IR3 (p = 0.002). In ID, IR gradually improved SNR values, however, differences were only significant for FBP vs IR3 (p = 0.005). For CNR there was no significant difference. IVR improved with increasing iteration levels, however, differences were only significant for the comparison to FBP (p = 0.03-0.0008). We found no differences of IVR comparing RD and ID.
Conclusion: IR improved the image quality and detectability of BME in DECT. The ID was superior to the RD based approach.

T2 relaxometry of cartilage and meniscus and semi-quantitative assessment of the knee using DESS: a 5-minute MRI scan
S. Eijgenraam[1], A. Chaudhari[2], G. Gold[2], M. Reijman[1], E. Oei[1], B. Hargreaves[2]; [1]*Rotterdam/NL*, [2]*Stanford, CA/US (s.eijgenraam@erasmusmc.nl)*

Purpose: Quantitative MRI measures such as T2 relaxation times of cartilage and meniscus, and semi-quantitative assessments such as MRI Osteoarthritis (OA) Knee Score (MOAKS), are commonly used to track spatial and temporal changes of knee-OA. Acquiring these biomarkers currently requires multiple MR sequences, resulting in long acquisition-times. We evaluated the double-echo steady-state (DESS) sequence with an acquisition-time of only five minutes for simultaneous T2 relaxometry of cartilage and meniscus, and MOAKS scoring, in patients with no, mild and moderate knee-OA.
Methods and Materials: 54 patients (20, 18 and 16 with Kellgren-Lawrence (KL) grades 0, 2, and 3 resp.) were scanned using DESS and a clinical multisequence knee-protocol. MOAKS was performed with only DESS (with multiplanar reformatting). Mean T2-values of cartilage and meniscus were calculated on single slices. Statistical testing between KL-groups was performed using Students T-Tests. Correlation between T2-values and MOAKS was assessed using linear regression analysis.
Results: Mean T2-values in cartilage, obtained with DESS, were 37.7 ± 4.1, 44 ± 8 and 50.8 ± 8.4 ms for KL0, KL2 and KL3 resp. (p < 0.001). In menisci, mean T2-values of 15.4 ± 3.3, 18 ± 3.3 and 21 ± 6.4 ms were found for KL0, KL2 and KL3 resp. (p < 0.001). T2-values showed a good correlation with corresponding MOAKS-cartilage findings (r = 0.61, p = 0.002).
Conclusion: Simultaneous quantitative T2 and morphological assessment of cartilage and meniscus with a 5-minute DESS-sequence show consistent outcomes with increasing stages of degeneration, making this sequence a promising tool for OA research.

B-1031 09:46

Correlation of body mass index with paraspinal muscle fatty degeneration in non-diabetic patients with lumbar spinal canal stenosis: results from 685 patients

S. Winklhofer[1], J. Burgstaller[1], U. Held[1], T. Finkenstaedt[1], F. Del Grande[2], G. Andreisek[3], J. Steurer[1], N. Bolog[4]; [1]*Zurich/CH*, [2]*Lugano/CH*, [3]*Münsterlingen/CH*, [4]*Munchenstein/CH (Sebastian.Winklhofer@usz.ch)*

Purpose: Purpose of this study was to investigate the correlation between lumbar muscle fatty degeneration assessed by magnetic resonance imaging (MRI) and body mass index (BMI) in a large non-diabetic patient group with lumbar spinal stenosis (LSS).
Methods and Materials: MRI images of 685 patients (52% female, mean age 74 years, interquartile range 67 - 80 years) with LSS were analysed in this institutional review board-approved study. Muscle degeneration was assessed by two independent readers on axial T2 weighted images using a modified 5-grades Goutallier classification. Th correlation between muscle degeneration and BMI was calculated using the non-parametric Spearman coefficient test.
Results: The following distribution of muscle degeneration was found in the 685 patients: grade 0: 136 (20%), grade 1: 265 (39%), grade 2: 220 (32%), grade 3: 41 (6%), grade 4: 23 (3%). The mean BMI was 26.6 kg/m^2, interquartile range 23.8 to 29.7. Correlation analysis between BMI and the muscle stage degeneration in 5 ordinal categories was 0.060 for female patients ($p = 0.26$), 0.148 for male patients ($p = 0.007$), and 0.067 for all patients ($p = 0.08$).
Conclusion: The weak correlation between BMI and the degree of muscle degeneration indicates that overweight might not be an important potential source of paraspinal muscle degeneration in non-diabetic patients with LSS.

Diffusion tensor imaging in idiopathic normal-pressure hydrocephalus: clinical and CSF flowmetry correlations

I. Grazzini, G. Cuneo, F. Redi, C. Caccialupi, K. Sammartano, C. Ciccotosto; *Arezzo/IT (irene.grazzini@gmail.com)*

Purpose: Diffusion tensor imaging (DTI) is a non-invasive magnetic resonance (MR) technique that provides information about the orientation and the anisotropy of the white matter tracts, and may delineate microstructural changes in cerebral white matter. We analysed DTI quantitative parameters in idiopathic normal-pressure hydrocephalus (INPH) patients and investigated the relationship between DTI findings and clinical scores and CSF flow velocity.
Methods and Materials: 15 consecutive patients with INPH and Evans Index >0.3 and 15 age-matched controls underwent MR CSF flowmetry and DTI using a 1.5T system. Fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD) and radial diffusivity (RD) values were calculated using a region-of-interest (ROI) atlas-based tract mapping in 9 cerebral areas and compared among the two groups. In addition, for INPH patients, DTI parameters were correlated to clinical scores (Mini-Mental State Examination (MMSE) and Frontal Assessment Battery (FAB)) and CSF flow velocity.
Results: Mean FA was significantly lower in the INPH group than in the control group for the forceps minor; the INPH group had significantly higher mean AD for the genu of the corpus callosum ($p<0.05$). We did not find significant correlation between the DTI parameters and CSF flow velocity and MMSE, whilst we observed a negative correlation between forceps minor FA and FAB.
Conclusion: Our findings suggest that DTI will provide a non-invasive biomarker of white matter changes in patients with INPH. Moreover, DTI may offer a prognostic tool, over CSF flow velocity, to help identify INPH patients who may benefit from surgical intervention.

A survey for neuroimaging harmonization needs for large-scale neurodegenerative biomarker studies

J. Jovicich[1], F. Barkhof[2,3], C. Babiloni[4], K. Herholz[5], B.N. van Berckel[2], C. Mulert[6], G. Frisoni[7,8], SRA-NED JPND Working Group[1]; [1]*Mattarello/IT*, [2]*Amsterdam/NL*, [3]*London/UK*, [4]*Rome/IT*, [5]*Manchester/UK*, [6]*Hamburg/DE*, [7]*Brescia/IT*, [8]*Geneva/CH (jorge.jovicich@unitn.it)*

Purpose: The European Joint Programme on Neurodegenerative Disease Research committed to our working group SRA-NED (http://www.sraned.org/) the survey of the international community for identifying (1) current barriers for a harmonized use of MRI/PET/EEG biomarkers of neurodegenerative diseases and (2) community-driven solutions to overcome them.
Methods and Materials: A 10-minute survey was developed to gather information from relevant communities (neuroimaging consortia, industry, and more than 30 international researcher and medical associations). The survey evaluated high-level barriers to participate in multicentric studies, biomarkers to be prioritized and current challenges for modality-specific harmonization issues.
Results: 459 participants completed the survey (MRI 53.6%, EEG 30.3%, and PETSPECT 16.1%). Participants represented a strong multidisciplinary community, dominated by research and academia including industry and clinical settings (Europe 75%, North and South America 20%, and Asia, Oceania and Africa 5%). In all modalities (MRI/PET/EEG), more than 60% of the participants reported significant difficulties for including neuroimaging markers in multicentric clinical studies, indicating barriers for each neuroimaging modality. Survey participants converged to specific requests about support needs for a more productive use of MRI/PET/EEG biomarkers. Results allowed making concrete suggestions for potential solutions, inspiring a roadmap for the future investments of international sponsors for clinical trials in the neurodegenerative diseases.
Conclusion: To our knowledge, this survey represents the largest in the clinical neuroimaging community in the field of neurodegenerative diseases. The results support a strategic research agenda of future investments to exploit the potential of the MRI/PET/EEG biomarkers in large multicentric studies in neurodegenerative diseases.

B-1034 10:55

Subcortical nuclei in Alzheimer's disease: a volumetric and diffusion kurtosis imaging study

M.-L. Wang, W. Li; *Shanghai/CN (doctor-mingliang@sjtu.edu.cn)*

Purpose: To investigate the volumetric and DKI parameter changes of subcortical nuclei in AD, and their relationship with cognitive function.
Methods and Materials: A total of 17 mild AD patients, 15 moderate to severe AD patients, and 16 controls underwent examinations of neuropsychological tests, MRI scans. Volume, mean kurtosis (MK), mean diffusivity (MD), and fractional anisotropy (FA) were measured in subcortical nuclei including the hippocampus, thalamus, caudate, putamen, pallidum, and amygdala. MRI parameters were compared among groups. Correlation analysis was performed between subcortical nuclei volume, DKI parameters, and MMSE score.
Results: Significant volume reduction was seen in left hippocampus in mild AD, and bilateral hippocampus, thalamus, putamen, left caudate and right amygdala in moderate to severe AD ($P<0.05$). Increased MD values were observed in left hippocampus, left amygdala and right caudate in mild AD, and bilateral hippocampus and right amygdala in moderate to severe AD ($P<0.05$). Decreased MK values were observed only in bilateral hippocampus in moderate to severe AD ($P<0.05$). No group significances were found in FA value. MMSE score was positively correlated with volume of bilateral hippocampus, thalamus, and putamen, and MK value of left hippocampus ($P<0.05$). A negative correlation was found between MMSE score and MD value of bilateral hippocampus and left amygdala ($P<0.05$).
Conclusion: Mild AD mainly has microscopic subcortical changes revealed by increased MD value, and moderate to severe AD mainly has macroscopic subcortical changes revealed by volume reduction. MK is more sensitive in the late AD than mild AD.

B-1035 11:03

Structural and functional changes in resting brain activity in neurodegeneration according to VBM and rsfMRI comparison

E. Seliverstova, Y. Seliverstov, M. Krotenkova, R. Konovalov, A.N. Sergeeva, S. Illarioshkin, S. Morozova; *Moscow/RU*

Purpose: To study structural and functional pattern in resting brain network (default mode network) in early stages Parkinson's disease (PD) comparing to healthy controls by voxel-based MRI (VBM) and resting-state fMRI (rsfMRI) data analysis.
Methods and Materials: We have exanimated and compared 3 independent groups. Forty patients with PD in early steps in pharmacological treatment and

newly diagnosed and 22 healthy volunteers were investigated and underwent 1.5 T T1-MPR, rsfMRI scanning for VBMand rsfMRI data acquisition. All participants were right-handed.
Results: In group of newly diagnosed PD patients we observed significant (p<0,005) greater volume of right precuneus (part of DMN) comparing to patients in pharmacological treatmentand healthy volunteers. We perform the ROC-test with estimation of sensitivity and specificity of right precuneus changes with receipt of threshold values of this index. Comparing rsfMRI data and volume changes in precuneus in group of newly diagnosed PD patients we observed direct correlation: than higher volume of precuneus that greater area of spontaneous neuronalactivity in left anterior prefrontal cortex.
Conclusion: Our findings may be part of functional cortical reorganization with functional connectivity changes between brain regions and indicate about compensatory hypertrophy ofprecuneus as compensatory mechanisms of neuroplasticity phenomena in early stages of PD with sensitivity (77,8 %) and specificity (76,5%) probably achieve to beginning PD and be anadditional early marker of neurodegeneration.

B-1036 11:11

Determining leader nodes in dementia networks
Y. Yazicioglu[1], K. Pinker[2], A. Tahmassebi[3], A. Meyer-Baese[3,4];
[1]*Boston, MA/US*, [2]*Vienna/AT*, [3]*Tallahassee, FL/US*, [4]*Maastricht/NL*
(ameyerbaese@fsu.edu)

Purpose: Fusing modern network theory and control strategies yields a novel transformational paradigm in dementia research. One research direction is determining the leader nodes in disease networks that can be directly manipulated via external inputs to influence the overall network trajectory and simulate the disease progression.
Methods and Materials: We examine 249 subjects with FDG-PET and T1-weighted MRI images consisting of 68 control, 111 mild cognitive impairment (MCI) and 70 Alzheimer's disease (AD). We consider only 42 out of the 116 from the AAL in the frontal, parietal, occipital and temporal lobes. Different from previous work on controllability of disease networks, we determine the disease leader nodes by relying only on the network's structure, particularly the graph distances between the nodes, and not on the existing connection weights.
Results: We show that there is a common leader node in structural and functional brain networks reflecting the changes from controls over MCI to AD. For functional data, we see one leader node in the frontal lobe present in all three networks and a decreasing number of leader nodes from controls to AD. The same situation is observed for structural data with one node in the temporal lobe, however there are more nodes in common between controls/MCI and MCI/AD.
Conclusion: We have established a new method to determine the leader nodes that can be directly manipulated to change the trajectory of the dementia networks. Implicitly, we can gain an understanding of dementia evolution and the subsequent development of therapeutic solutions.

B-1037 11:19

Differential functional connectivity changes of subregions of the dorsal premotor cortex in healthy ageing
B. Sigl[1], C. Jockwitz[2], S. Eickhoff[2], F. Hofstaedter[2], C. Rubbert[1], K. Amunts[2], S. Caspers[2], B. Turowski[1], J. Caspers[1]; [1]*Düsseldorf/DE*, [2]*Jülich/DE*
(benjamin.sigl@med.uni-duesseldorf.de)

Purpose: The dorsal premotor cortex (PMd) is the interface between the motor and higher cognitive networks and shows several structural and functional changes in healthy ageing as well as in various neurodegenerative diseases such as Parkinson's disease. Here, we investigate the resting-state functional connectivity (RSFC) and age effects of the PMd with respect to three recently identified cytoarchitectonic subregions (6d1-3).
Methods and Materials: Resting-state fMRI of 848 healthy adults from the population-based cohort study 1000BRAINS was analysed (age=55-88 years, mean-age=67.22 years; 459 males; 3T-MRI). Cytoarchitectonic maximum probability maps of PMd areas served as seed regions for RSFC analyses. After preprocessing of fMRI data using SPM, voxel-wise whole-brain RSFC was assessed for each seed and correlated with age (p<0.05, cluster-level FWE corrected).
Results: All PMd areas of both sides showed connectivity decline with left anterior insula (AI) with increasing age. Area-specific connectivity loss was found for the right area 6d1 in the bilateral primary motor cortex , for the left area 6d2 in the inferior parietal lobule, for the right area 6d2 in the right dorsolateral prefrontal cortex (dlPFC), and for the left area 6d3 in the left ventral premotor cortex. An age-dependent increased connectivity was found for bilateral area 6d3 in the sensorimotor areas on both sides.
Conclusion: PMd subregions show divergent RSFC changes during ageing, which support their functional diversity. Connectivity loss with the motor cortex, dlPFC and AI could explain the decline in sensorimotor and cognitive abilities in older age. Increase of area 6d3's RSFC with sensorimotor areas might hint at compensatory mechanisms regarding its interface function within the motor system.

B-1038 11:27

Automatic quantification of enlarged perivascular spaces on brain MRI
F. Dubost[1], H.H. Adams[1], G. Bortsova[1], M. Ikram[1], W.J. Niessen[1,2], M.W. Vernooij[1], M. De Bruijne[1,3]; [1]*Rotterdam/NL*, [2]*Delft/NL*, [3]*Copenhagen/DK*
(floriandubost1@gmail.com)

Purpose: Enlarged perivascular spaces (EPVS) are an emerging biomarker for cerebral small vessel disease. An automatic quantification of EPVS is introduced, as manual scoring of EPVS is a tedious and error-prone task.
Methods and Materials: T2-weighted MR images (voxel size 0.49 x 0.49 x 0.8mm^3) were acquired from 2000 subjects (mean age 74 years, range 60-90) from a population-based study. An experienced rater (2 years experience) counted the number of EPVS on a single slice in the centrum semiovale and basal ganglia and on the whole volume in hippocampi and midbrain. A deep learning algorithm, based on convolutional network regression, was developed to reproduce the visual scoring. The algorithm was trained on 1600 and evaluated on 400 MRI scans. Intraclass correlation coefficients (ICCs) were computed to assess agreement between automatic and visual scores and we compared to inter-rater (105 scans) and intra-rater (85 scans) reliabilities.
Results: The ICC between visual and automatic scores was 0.87 (+/- 0.02) for centrum semiovale, 0.80 (+/- 0.02) for basal ganglia, 0.81 (+/- 0.03) for hippocampi and 0.62 for midbrain (+/- 0.04). Except for the midbrain, these values were equal to or higher than inter-rater reliability (ICCs 0.80, 0.62, 0.82 and 0.75, respectively), and intra-rater reliability (0.88, 0.80, 0.85 and 0.82, respectively).
Conclusion: The automatic scoring of EPVS shows good agreement with visual scoring, at the level of intrarater agreement for the centrum semiovale, basal ganglia and hippocampi. This method can facilitate quantitative EPVS analysis in large clinical studies.

B-1039 11:35

Dementia imaging in Europe: results from the European Society for Neuroradiology (ESNR) Diagnostic Subcommittee Survey
M.W. Vernooij[1], S. Haller[2], G. Frisoni[3], F. Pizzini[4], T.A. Yousry[5], N. Bargalló Alabart[6], M. Smits[1], R. Schmidt[7], F. Barkhof[8]; [1]*Rotterdam/NL*, [2]*Geneva/CH*, [3]*Brescia/IT*, [4]*Verona/IT*, [5]*London/UK*, [6]*Barcelona/ES*, [7]*Graz/AT*, [8]*Amsterdam/NL (m.vernooij@erasmusmc.nl)*

Purpose: The purpose of this survey was to assess current practices throughout Europe, with respect to standardised imaging, evaluation and reporting of brain imaging in clinical practice of patients suspected of dementia.
Methods and Materials: Survey invitations were emailed to ESNR members (n=1662) and known associates (n=6400). The questionnaire featured 45 individual items, divided into multiple choice, single best choice and free text answers. Information was gathered on personal practice, imaging technique and protocol, scan rating and reporting and communication with clinicians.
Results: 193 individuals from unique institutes (28 European countries) had responded by 1 July 2017. Of these, 75% were neuroradiologists, 12% general radiologists, 11% (neuro)radiologists in training. 38% of responding centres perform > 5 scans/week for suspected dementia (48% 1-5 scans). MRI is primarily used in 72% of centres, 25% use primarily CT. >90% of centres acquire a combination of T2w, FLAIR, non-contrast T1w, DWI and T2*w sequences. 75% of centres use visual rating scales in reporting, primarily Fazekas and medial temporal atrophy scale. 32% of respondents note they are not fully confident in using rating scales. Only 23% of centres extract volumetric information from dementia scans. A minority of centres (28%) uses structured reports.
Conclusion: Results show homogeneity in imaging modality and protocol, but more heterogeneity in application of volumetric processing and structured reporting and communication. Though likely subject to selection bias, this survey yields valuable information on current practices in dementia imaging, and forms the basis for future recommendations.

B-1040 11:43

Sulcal-based morphometry for the diagnosis of normal-pressure hydrocephalus in patients with ventriculomegaly
G. Kuchcinski, C. Jacquiez, M. Baroncini, J. Dumont, C. Delmaire, L. Defebvre, J.-P. Pruvo, X. Leclerc; *Lille/FR (gregkuch@msn.com)*

Purpose: To determine the diagnostic accuracy of automated sulcal morphometry to differentiate patients with idiopathic normal-pressure hydrocephalus (iNPH) from patients with ventriculomegaly secondary to other conditions in comparison to standard visual rating scales.
Methods and Materials: The local institutional ethics review board approved the study. Written informed consent was obtained from all patients. Thirty-one consecutive patients with iNPH, 35 with vascular dementia, 23 with chronic noncommunicating hydrocephalus and 24 healthy controls prospectively underwent a 3T MR examination. Sulcal opening of ten sulci of interest throughout the brain convexity was measured using an automated surface-based approach from the 3D T1-weighted images. High-convexity tightness

and lateral sulcus dilatation were independently evaluated by 2 observers using visual rating scales. The interobserver reliability was calculated with linear weighted kappa and intraclass correlation coefficient for visual rating scales and sulcal opening, respectively. ROC curve analysis determined the best parameter to identify iNPH patients.
Results: Automated sulcal morphometry achieved a higher reproducibility and diagnostic accuracy than visual rating scales ($P<0.05$). The best parameter to discriminate iNPH from other conditions was the ratio between opening lateral sulcus opening and intraparietal sulcus opening (AUC=0.85 [95%CI=0.74-0.95] and 0.87 [95%CI=0.74-0.96] for the left and right hemisphere, respectively). A cut-off value>1.25/1.20 in the left/right hemisphere provided a sensitivity of 81%/84% and a specificity of 89%/84%.
Conclusion: Automated sulcal morphometry is a suitable method to analyse the modifications of the subarachnoid spaces of iNPH patients and may help the radiologist to discriminate iNPH from ventriculomegaly secondary to brain atrophy or noncommunicating hydrocephalus.

B-1041 11:51

3D detection of cellular neurodegeneration in Alzheimer's disease via multi-scale x-ray phase-contrast micro- and nano-CT
G.E. Barbone[1], P. Di Pietro[2], M. Eckermann[1], A. Mittone[3], A. Bravin[3], P. Romanelli[4], G. Battaglia[2], P. Coan[5]; [1]*Garching/DE*, [2]*Pozzilli/IT*, [3]*Grenoble/FR*, [4]*Milan/IT*, [5]*Großhadern/DE*
(Giacomo.Barbone@physik.uni-muenchen.de)

Purpose: Experimental x-ray phase-contrast CT (PCI-CT) provides soft-tissue sensitivity without application of stains or contrast agents. Most interestingly, this technique can visualize nervous tissue structure at multiple scales, from full-organ anatomy to single cells without the need for sample dissection. We thus choose PCI-CT for the analysis of AD pathology in the brain of 3xTgAD mice, an experimental model of AD expressing three mutant alleles, *Psen1*, *APP* and *tau,* and displaying both amyloid-β plaque and tangle pathologies.
Methods and Materials: Multi-scale 3D images of brain samples extracted from wild-type mice (n=6) and 3xTgAD mice (n=6, all at 13 months of age) were obtained by synchrotron PCI-CT. We used 17-30 keV x-rays and sCMOS-sensor PCO camera, and switched between optics systems with voxel sizes from 3^3 µm³ to 0.1^3 µm³.
Results: Full-organ 3-micron brain CTs showed the PCI's sensitivity to microscopic amyloid deposits within both hippocampal and cortical cell layers. Moreover, localized 0.3 µm CTs detect single neuronal cells, intra-neuronal aggregates, and extracellular deposits. We observed both healthy and altered pyramidal neurons and recognized them alongside agglomerates. Image contrast allows quantification of aggregate load and of cell layers-specific plaque size 3D distributions. Last, sub-cellular structures (cone-shaped soma, circular high-density nuclei) are visible at 0.1^3 µm³.
Conclusion: PCI-CT detects amyloid plaques in aged healthy and diseased 3xTgAD mice, and provides unique 3D mappings of neuronal tissues, their surrounding angio-structures, and of single neurons down to the nanometer scale. PCI-CT thus provides a novel high-resolution 3D virtual histology technique for *postmortem* neuroimaging of neurodegenerative diseases.

Preliminary results of DWI sequences in detecting arterial wall inflammation in patients with giant cell arteritis
A. Napolitano, G. Ironi, E. Tombetti, E. Incerti, S. Leoni, M. Picchio, L. Gianolli, L. Dagna, F. De Cobelli; *Milan/IT (napolitano.angela@hsr.it)*

Purpose: The usefulness of techniques of vessel wall imaging is still debated and novel tools are required. We aimed to verify if MRI diffusion-weighted imaging can provide a novel characterisation of vasculitic lesions.
Methods and Materials: T1 weighted, T2-weighted STIR and DWI (b0 -b600) MRI sequences were performed to evaluate the aorta and its primary branches in 5 GCA patients with a recent positive FDG-PET examination. From a clinical point of view, two patients were classified as “active”, while three as “grumbling”. The same sequences were performed in 5 healthy subjects, as controls.
Results: All five patients showed arterial wall hyperintensity in STIR (median arterial-to-muscle ratio 4.1, range 3.6-5.1) and DWI b-600 images, with restricted arterial wall diffusivity in the ADC maps (median ADC 2.3, range 1.6 - 3.3). Conversely, in the healthy control group no abnormalities in the aortic wall were found with STIR sequences (median T2 ratio 1.8, range 1.1-2.2 , p=0.016), as well as no high signal was detectable in DWI. Considering individual arteries of the GCA patients, the ADC values correlated both with wall thickness (r 0.607, p=0.016) and the arterial-to-muscle ratio at the STIR sequences (r 0.709, p=0.015), while did not correlate with SUV (r 0.065, p=0.819).
Conclusion: Vessel wall characterisation by DWI is feasible in GCA and can reveal ongoing wall oedema in patients with grumbling disease. DWI might thus help define the activity status of patients. Further studies are warranted to better define the role of DWI imaging in GCA.

B-1043 10:38

Ultrasound biomicroscopy in the diagnosis of giant cell arteritis
C.-P. Raffaelli, A. Hombreux, N. Tieulie, S. Lassalle, N. Azulay, P. Giordana; *Nice/FR (raffaelli.c@chu-nice.fr)*

Purpose: The purpose of this study was to evaluate the value of ultrasound biomicroscopy (UBM) in the diagnosis of giant cell arteritis (GCA).
Methods and Materials: 19 patients with classical clinical criterias of GCA were included. Both temporal arteries were explored using an ultra-high frequency transducer (Vevo MD, Visualsonics, 70 MHz) providing an axial resolution of 20 µm. Wall artery analysis relayed on : (i) Wall thickness and ratio wall thickness/artery diameter. (ii) Characteristic GCA features as intima hyperplasia. All the patients underwent a temporal artery biopsy (TAB) as a gold standard with histologic and biomicroscopic correlations.
Results: The feasibility of UBM was complete in all the patients. 11 patients were diagnosed with GCA by TAB. The UBM wall thickness ratio(p = 0,001) and intimal hyperplasia (p = 0,001)were highly correlated with GCA. A wall thickness cut-off (210 µm) had an accuracy of 100%.
Conclusion: The UBM seems a new and promising device for early diagnosis and monitoring of GCA, requiring further studies.

B-1044 10:46

Dynamic 4D CT angiography (DCTA) of the lower extremities with a 256-slice CT
N. Buls[1], Y. De Brucker[1], H. Devos[2], D. Aerden[3], G. Van Gompel[1], P.T. Boonen[3], K. Nieboer[1], J. de Mey[3]; [1]*Brussels/BE*, [2]*Wemmel/BE*, [3]*Jette/BE (nico.buls@uzbrussel.be)*

Purpose: To investigate the benefit of additional dynamic 4D CT series (DCTA) on the lower extremities in the evaluation of patients suspected with periphery arterial disease (PAD).
Methods and Materials: Seventeen patients received a dynamic sequence next to their runoff CTA. Acquisition was performed on a 256-slice CT (GE Healthcare) with following scan protocol: 18x repeated series at the level of the calves at 2s interphase delay and 160mm collimation. The CTA injection protocol was: 90mL contrast and 40mL saline, the dynamic sequence used 50mL contrast and 40mL saline. Two readers rated following items on a four point Likert scale: arterial enhancement; stenosis assessment; diagnostic confidence; vessel calcification; venous overlay. Enhancement (HU) was

measured in major vessels from time enhancement curves. Effective radiation dose was also estimated.
Results: A total of 102 vessels were analyzed. Enhancement was considered better with DCTA (66% of vessels) than CTA (44%) and vessels with insufficient enhancement dropped from 24% to 8%. Optimal diagnostic confidence increased from 31% to 58% with DCTA. The DCTA information changed stenosis assessment in 25% of the cases. Venous overlay was higher with DCTA (15%) than CTA (6%). Interreader variability was moderate (kappa 0.42). Compared to runoff CTA, mean HU values were higher ($p < 0.001$) with DCTA in all arteries: ATA (+48%), APer (+53%), ATP (+42%). The additional dose of the DCTA (0.2mSv) was 3.9% of the CTA (5.1mSv).
Conclusion: The addition of dynamic CT angiography could improve diagnostic confidence in the evaluation of patients with PAD.

B-1045 10:54

Establishing a new protocol for aortofemoral CT angiography using the lowest possible contrast media with the advent of faster scanners

A. Hatem[1], B.K. Hazaimeh[1], I. Alhyari[1], A. Jalaileh[1], S. Salman[2], A. Al-Omari[1];
[1]*Amman/JO*, [2]*Beirut/LB (bhazaimeh@gmail.com)*

Purpose: To establish low-contrast-dose protocol for imaging of lower extremity arteries adjusting scan parameters without affecting image quality. This is particularly important in diabetics, elderlies and patients with renal impairment.
Methods and Materials: 81 patients have been examined in this study on 64 slice CT scanners or higher from different vendors. Double test bolus technique was used to calculate time to peak (TTP) in descending aorta and in popliteal artery using 5 and 8mL of contrast for each patient consequently. Scan time was calculated subtracting TTP1 from TTP2. Total scan time and delay values were adjusted according to a formula related to scan length and TTP-interval. Machine parameters were adjusted to fit with the scan length and time needed. CT density was measured in 4 consecutive levels to ensure satisfactory enhancement within the aorta, iliac, popliteal and distal posterior tibial (PTA) arteries.
Results: Contrast volume used was 40ml for 72% of case and 50ml for 24% of the cases. In two cases, 60mL of contrast was used due to prolonged TTP2/TTP1 interval. Average CT densities were 529, 430, 379 and 224HU at aorta, iliac, popliteal and PTA levels respectively. 92.5% of cases had density values more than 200HU at popliteal level and 97.5% were more than 115HU at level of PTA. All studies revealed satisfactory enhancement at all scan levels.
Conclusion: Volume of contrast media needed to do angiography studies can be lowered with the advent of faster CT machines.

B-1046 11:02

Combined assessment of peripheral artery disease by MRI-based vascular calcification visualisation and quiescent interval single-shot (QISS) MRA

A. Varga-Szemes[1], T. Duguay[1], T. Todoran[1], S. Fuller[1], C.N. De Cecco[1], P. Suranyi[1], R.R. Edelman[2], I. Koktzoglou[2], U.J. Schoepf[1];
[1]*Charleston, SC/US*, [2]*Evanston, IL/US (vargaasz@musc.edu)*

Purpose: To investigate the added value of calcification visualisation on the diagnostic confidence and accuracy of detecting peripheral artery disease (PAD) and to compare the accuracy of calcium quantification between prototype proton density weighted, in-phase 3D stack-of-stars gradient-echo (PDIP-GRE) MRI in patients undergoing quiescent interval single shot (QISS)-MRA and CTA.
Methods and Materials: Fourteen patients (68±9 years) referred for lower extremity CTA prior to digital subtraction angiography (DSA) were prospectively enrolled for a same-day 1.5T MRI. PDIP-GRE MRI and QISS-MRA were acquired covering the iliofemoral region. Two readers rated diagnostic confidence (3-point scale) and graded stenosis (< or >50%) on QISS-MRA without and with the visualisation of calcification. Sensitivity and specificity were calculated using DSA as reference. Intra-arterial calcium was quantified using ImageJ (NIH) and compared between MRA and CTA using paired t test and Bland-Altman analysis.
Results: Of the 84 segments available for calcification assessment, >50% stenosis was detected in 37 (44%), while calcium was present in 58 (69%). The diagnostic confidence (2.1 [1.9-2.3] vs 2.3 [2.1-2.5]; $P<0.0001$) and the sensitivity and specificity of QISS-MRA in the detection of >50% stenosis (83.2% and 97.6% vs 86.4% and 98.0%, respectively) were improved when calcification data were available. Calcium quantification showed no statistical difference between MRI and CTA (121±77mm^3 vs 127±84mm^3; $P=0.0249$). Bland-Altman analysis revealed excellent agreement with a mean of difference at -5.8mm^3.
Conclusion: Based on our initial results, QISS-MRA combined with PDIP-GRE MRI seems to be promising for the complex assessment of vascular anatomy in PAD, which could be beneficial in interventional procedure planning.

B-1047 11:10

Quiescent-interval single-shot (QISS) MRA for interventional procedure planning: a feasibility study in patients with peripheral artery disease

A. Varga-Szemes[1], T. Duguay[1], T. Todoran[1], M. Penmetsa[1], S. Fuller[1], P. Suranyi[1], C.N. De Cecco[1], D. Mastrodicasa[2], U.J. Schoepf[1];
[1]*Charleston, SC/US*, [2]*Chieti/IT (vargaasz@musc.edu)*

Purpose: To investigate the feasibility of interventional procedure planning using quiescent-interval single-shot (QISS) MRA in patients with peripheral artery disease (PAD).
Methods and Materials: Twenty-one PAD patients (67±8 years) underwent lower extremity CTA and QISS-MRA at 1.5T (prototype QISS sequence) prior to digital subtraction angiography (DSA). Segmental vascular diameter was compared among QISS-MRA, CTA, and DSA using the Friedman test. For each significant stenosis observed on QISS-MRA, intravascular stent length and diameter needed to reinstate flow in the vessel was estimated. The estimated stent size was compared to the stent implanted using the Wilcoxon test and Bland-Altman analysis.
Results: Of the 346 segments analysed with QISS-MRA, significant stenosis was detected in 82 (23.6%). Vascular diameters showed good agreement among QISS-MRA, CTA, and DSA (overall $P>0.05$). Based on DSA evaluation, 25 stents were implanted involving 31 segments. Average estimated stent diameter was in good agreement with the average actual diameter (8.4±2.8mm vs 8.1±3.7mm, respectively; $P=0.0934$; Bland-Altman mean of differences 0.3mm). However, QISS-MRA-based stenosis length measurement underestimated the length of the stent necessary to bridge the stenosis (35.5±11.9mm vs 40.1±13.9mm, $P=0.0215$, respectively; Bland-Altman mean of differences -4.6mm).
Conclusion: The prediction of stent diameter required to treat stenosis in patients with PAD was feasible using QISS-MRA. QISS-MRA slightly underestimated the actual stent length, which is most likely attributed to the fact that implanted stents usually extend beyond the proximal and distal ends of a stenosis. Based on these preliminary results, QISS-MRA seems promising for the non-contrast evaluation of vascular anatomy in PAD patients prior to intervention.

Accuracy of diameter measurement of vascular model: comparison of virtual monochromatic imaging in dual-energy CT with conventional 120-kVp scan

H. Sugawara, S. Suzuki, Y. Katada, T. Ishikawa, R. Fukui, Y. Yamamoto;
Tokyo/JP (capy.sugawara@gmail.com)

Purpose: To compare the performance of virtual monochromatic imaging (VMI) in dual-energy CT and conventional 120-kVp scan in measurement of the inner diameter of vascular models.
Methods and Materials: We compared 50-keV VMI, 70-keV VMI, and conventional 120-kVp scan using images of an acrylic phantom for MTF calculation and another vascular phantom. The vascular phantom contains 12 vascular models with 4 diameter (1.5, 2.0, 2.5, 3.0 mm) and filled with 3 densities of contrast material (high, 20-fold dilution; middle, 40-fold dilution; low, 60-fold dilution). We evaluated intraluminal peak CT value and full width at half maximum (FWHM) for each 3.0-mm vascular model on CT attenuation profile. The diameters of all 12 vascular models were measured by software automation. Analysis of variance with repeated measures was used for statistics.
Results: Calculated MTF indicated 120-kVp scan has better spatial resolution than VMI. Intraluminal peak CT value and FWHM were 50-keV VMI > 120-kVp scan > 70-keV VMI. Measurement errors of 70-keV VMI were significantly larger or comparable than that of 120-kVp scan in all 12 vascular models. Measurement errors of 50-keV VMI were significantly smaller than that of 120-kVp scan in low-density vascular models, but larger in most of high/middle density vascular models.
Conclusion: In comparison with conventional 120-kVp scan, VMI at low keV can improve the accuracy of diameter measurement of poorly enhanced vessels. However, in other conditions, VMI can increase the measurement errors with decreased spatial resolution, and should be applied carefully in evaluating vessel diameter.

B-1049 11:26

Modified calcium subtraction in dual-energy CT angiography of the lower extremity runoff: impact on diagnostic accuracy for stenosis detection

D. De Santis[1], C.N. De Cecco[1], M.H. Albrecht[2], B.A. Thomas[1], B.E. Jacobs[1], U.J. Schoepf[1], K. Otani[3], K. Grant[4], A. Laghi[5]; [1]*Charleston, SC/US*, [2]*Frankfurt a. Main/DE*, [3]*Tokyo/JP*, [4]*Rochester, MN/US*, [5]*Latina/IT (domenico.desantis@hotmail.it)*

Purpose: To investigate the diagnostic accuracy of a modified three-material decomposition calcium subtraction (CS) algorithm for arterial stenosis detection in dual-energy (DE) computed tomography angiography (CTA) of the lower extremity runoff compared to standard images using digital subtraction angiography (DSA) as the reference standard.
Methods and Materials: Eighty-eight patients (53 males; mean age, 65.9±11 years) with peripheral artery disease (PAD) who had undergone DE-CTA of the lower extremity runoff were included in this IRB-approved, HIPAA-compliant retrospective study. Linearly blended (M_0.5) and CS datasets were reconstructed. Contrast-to-noise ratios (CNR) for both datasets were quantified. Two independent readers assessed subjective image quality using 5-point Likert scales. A subgroup of 45 patients with DSA was used to assess the diagnostic accuracy of the two datasets for ≥50% stenosis detection. Diagnostic performance parameters were estimated using random-effects logistic regression analysis and compared using generalized estimating equations.
Results: The overall diagnostic accuracy (sensitivity, specificity, positive and negative predictive values) for CS reconstructions was 96.5% (97.5%, 95.6%, 90.9%, and 98.1%) and for M_0.5 images 93.1% (98.8% 90.4%, 82.3%, and 99.1%). CS datasets showed higher CNR (15.3±7.3) compared to M_0.5 images (13.5±6.5, *P*<0.001). Both reconstruction series showed comparable subjective image quality scores (CS, 4.64; M_0.5, 4.57; *P*=0.220).
Conclusion: The modified three-material decomposition CS algorithm provides greater diagnostic accuracy for stenosis detection of the lower extremity runoff compared with standard linearly-blended images.

B-1050 11:34

Quantification of blood velocity from time-resolved CT angiography on a 256-slice CT

P.T. Boonen[1], N. Buls[1], J. Vandemeulebroucke[2], G. Van Gompel[1], Y. De Brucker[1], D. Aerden[1], J. De Mey[1]; [1]*Jette/BE*, [2]*Etterbeek/BE (pieter.thomas.boonen@vub.be)*

Purpose: To quantify the blood velocity in the arteries of the lower extremities and to investigate the correlation with peripheral arterial disease (PAD).
Methods and Materials: 7 Patients with suspicion of PAD underwent time-resolved Computed Tomography Angiography (CTA) in addition to their standard run-off CTA, consisting of 18 repeated axial acquisitions at 2s interphase delay at the level of the calves with 16cm collimation (Revolution CT, GE Healthcare). Image data was processed using in-house developed processing tools. Motion during the acquisitions was compensated by applying registration, after which the anterior tibial artery, posterior tibial artery and peroneal artery were automatically segmented by identifying large intensity changes over time. Subsequently, blood velocity was quantified in the arteries by creating time attenuation curves (TAC) of the arterial cross-sections in every slice and determining the time to peak (TTP).
Results: The described method led to plausible velocity estimations in all arteries (n=18) for patients that were considered healthy (n=3). For pathological patients (n=4), only 12 out of 22 arteries could be quantified due to suboptimal bolus arrival, severe calcification or occlusions. For arteries of healthy patients, blood velocity was normally distributed (p=0.282) with a median value of 82.3 mm/s (95% CI= 55.5- 89.9 mm/s). Blood velocity in arteries of pathological patients was observed to be significantly lower, 30.7 mm/s (95% CI= 27.4-45.7 mm/s), p<0.01.
Conclusion: Time-resolved CT data allows to quantify blood velocity in the arteries of the lower extremities. In heavily occluded arteries, the contrast was insufficient in order to quantify velocity.

B-1051 11:42

Resveratrol treatment does not reduce vascular inflammation in male subjects at risk of developing type 2 diabetes: an ^{18}F-FDG PET/CT study

E. Boswijk, M. de Ligt, M.-F. Habets, W. van Marken Lichtenbelt, J.E. Wildberger, F. Mottaghy, P. Schrauwen, J. Bucerius; *Maastricht/NL (eboswijk@gmail.com)*

Purpose: Resveratrol has shown anti-inflammatory effects in in vitro and animal studies. We investigated the effect of resveratrol on vascular inflammation and systemic inflammatory activation in the spleen and bone marrow in humans.
Methods and Materials: This was a sub-study of a double-blind randomized crossover trial and included eight men with decreased insulin sensitivity undergoing an ^{18}F-FDG PET/CT after, respectively, 34 days of placebo and resveratrol treatment (150 mg/day) to evaluate its effect on brown adipose tissue activity. ^{18}F-FDG uptake was analysed in the carotids, ascending aorta, aortic arch, descending and abdominal aorta, as well as in adipose tissue regions, spleen and bone marrow to investigate resveratrol's effect on these structures. Mean and maximum target-to-background ratios (TBRs; TBR_{mean} and TBR_{max}) were compared between periods (paired *T* test or Wilcoxon signed-rank test).
Results: In all arterial territories, TBR_{mean} and TBR_{max} were slightly higher after resveratrol treatment compared to placebo treatment (n.s.). The TBR_{max} of the most diseased segment and the percentage of active segments (TBR_{max}≥1.6) were also higher after resveratrol treatment (n.s.). A similar trend was seen for the spleen (n.s.), bone marrow (n.s.) and visceral adipose tissue (TBR_{max} 0.3±0.1 vs. 0.5±0.2, p=0.011), but not for subcutaneous adipose tissue (n.s.).
Conclusion: Arterial inflammation was not reduced by resveratrol in subjects at risk of developing type 2 diabetes as assessed with ^{18}F-FDG PET/CT. In addition, systemic inflammatory activation in the spleen, bone marrow and adipose tissue was not attenuated by resveratrol. Our results could underline findings of recent studies questioning the effects of resveratrol in humans.

B-1052 11:50

Automated tube potential selection of the lower extremity runoff: comparison to fixed kV with mAs modulation

M. Beeres, K. Juhee, A.M. Bucher, C. Frellesen, M.H. Albrecht, J.L. Wichmann, J.-E. Scholtz, T.J. Vogl, T. Gruber-Rouh; *Frankfurt a. Main/DE (beeres@gmx.net)*

Purpose: To evaluate the impact of automated attenuation-based tube potential selection (ATPS) on image quality and radiation dose exposure parameters by a computed tomography angiography (CTA) lower extremity runoff.
Methods and Materials: Two hundred and forty patients (156 men, 84 women) underwent CTA examinations of the lower extremity runoff on a second-generation dual-source CT system: 120 patients at a fixed tube potential of 120 kV and a tube current of 180 reference mAs, another 120 patients using automated attenuation-based tube potential selection (ATPS). Volume CT dose index (CTDIvol), dose-length-product (DLP), body diameters, noise, signal-to-noise ratio (SNR) and subjective image quality were compared.
Results: In the ATPS group, 80 kV was automatically selected in 102 patients, 100 kV in 15 patients and 120 kV in 3 patients. 140 kV was not chosen in any of the cases. The median CTDIvol 4.81 (2.2-10.6) mGy and DLP 568 (203 - 1324) mGy·cm in the ATPS group were significantly lower compared to the fixed 120 kV group with CTDIvol 8.1 (4.4-14.4) mGy and DLP 1027.5 (509 - 1806) mGy·cm; p < 0.01. Image quality was comparable (p>0.05).
Conclusion: Automated attenuation-based tube potential selection allows for significant dose savings in lower extremity runoff CTA while image quality remains constant at a high level.

Treatment of non resectable HCC: SIRT vs TACE liver toxicity comparison with MELD score

J. Delicque, C. Allimant, C. Cassinotto, L. Piron, L. Escal, A.-D. Ilonca, E. Assenat, B. Guiu; *Montpellier/FR (j-delicque@chu-montpellier.fr)*

Purpose: To evaluate and compare liver toxicity of trans-arterial chemo-embolization (TACE) and selective internal radiation therapy (SIRT) in non resectable hepatocellular carcinoma (HCC).
Methods and Materials: 158 TACE treatments (80 patients) and 37 SIRT treatments (31 patients) performed from August 2012 to July 2015 were included and analysed. Pre and post treatment (1month) MELD score were calculated and compared. Datas about technical points of TACE and SIRT, liver disease and HCC were noted. Post treatment evaluation was about MELD score variation (Delta MELD) and post treatment score >15, with calculation models that integrated possibility of multiple treatments (Generalized Estimating Equations).

Results: SIRT patients had higher tumor burden (AFP score > 2) and portal vein thrombosis (PVT) rate than TACE patients (p< 0.005). In univariate analysis, there were a trend (p=0.11) to a higher MELD variation with TACE than with SIRT and a statistical association with a post treatment MELD >15 with TACE than with SIRT. In multivariate analysis, factors associated with Delta MELD and MELD > 15 were all related to liver disease.
Conclusion: There is a trend to a lower degradation in liver function with SIRT compared with TACE in the treatment of non-resectable HCC, taking into account the possibility of multiple treatments. Further investigations should be performed due to a higher tumor burden and PVT in our SIRT population.

B-1054 10:38

TACE of HCC using mitomycin and lipiodol with or without DSM for HCC: comparative study

T. Gruber-Rouh, K. Eichler, N.N.N. Naguib, M.C. Langenbach, B. Kaltenbach, T.J. Vogl; *Frankfurt a. Main/DE*

Purpose: Evaluation of survival data and local tumour control after TACE in two groups with different embolisation protocols in the treatment of HCC patients.
Methods and Materials: 99 patients (mean age: 63.6 years), 78 male (78.8%) and 21 female (21.2%) with HCC were repeatedly treated with chemoembolisation in 4-week intervals. Eighty-eight patients had BCLC-stage-B, in 11 patients chemoembolisation was performed for bridging (BCLC-Stage-A). In total, 667 chemoembolisation treatments were performed (mean 6.7 treatments/patient). The administered chemotherapeutic agent included mitomycin. For embolisation, lipiodol only (n=51; 51.5%) or lipiodol plus degradable starch microspheres (DSM) (n=48; 48.5%) was used. The local response of the tumours was assessed by MRI using response evaluation criteria in solid tumours 1.1 (RECIST 1.1) Patient survival times were evaluated using Kaplan-Meier curves and log-rank tests.
Results: The local tumour control in the lipiodol group was: PR (partial response) in 11 (21.6%), SD (stable disease) in 32 (62.7%) and PD (progressive disease) in 8 cases (15.7%). In the lipiodol DSM group, the PR was encountered in 14 cases (29.2%), SD in 22 (45.8%) and PD in 12 (25.0%) (p=0.211). The median survival of patients after chemoembolisation with lipiodol was 25 months and in the lipiodol DSM group 28 months (p=0.845).
Conclusion: There was no statistical significant benefit reported of using lipiodol and DSM in comparison of using lipiodol-only for chemoembolisation of HCC in achieving local control and survival data. Only a slight trend for benefit of using lipiodol and DSM was shown.

B-1055 10:46

Safety and efficacy of transarterial chemoembolization using very small drug-eluting beads for advanced stage hepatocellular carcinoma

A.M.K. Abdel Aal[1,2], S. Tatum[1], K. Mahmoud[1], S. Moawad[1], N. Ertel[1], R. Oser[1], S. Saddekni[1], N. A. Aboueldahab[1], A. Gunn[1]; [1]*Birmingham, AL/US*, [2]*Cairo/EG (akamel@uabmc.edu)*

Purpose: To evaluate the safety and efficacy of transarterial chemoembolization (TACE) in the treatment of advanced stage hepatocellular carcinoma (HCC) using very small drug-eluting beads (DEB).
Methods and Materials: We retrospectively reviewed the medical records of 47 patients with advanced-stage HCC (BCLC-C) who underwent TACE using 75um DEB as their first therapy for HCC between November 2013 and March 2016. Patients were evaluated for median hospital stay, 30-day adverse events, 30-day mortality, toxicity profile, radiologic response, progression-free survival (PFS) and overall survival (OS).
Results: The study included 36 (78.2%) males with a mean age of 65.5 (SD=9.4) years. HCV and alcoholic cirrhosis were present in 56.5% and 30.4% of the patients, respectively. Child-Pugh A, ECOG 1 and portal vein invasion were seen in 71.7%, 69.7% and 19.6% of the patients, respectively. Segmental TACE was performed in 91.3% of the patients. The median hospital stay was 1 day (range: 1-4). There were no 30-day mortality. There was a single occurrence of hepatic abscess. Grades 1 and 2 toxicities were seen in 21.7% of the patients. There was no grade 3, 4 or 5 toxicity recorded. Complete response, objective response and disease control were 21%, 61% and 79%, respectively. The PFS and OS were 7.2 and 14.3 months, respectively. The 6, 12 and 24 months survival were 93%, 89% and 71%, respectively.
Conclusion: TACE using very small (75um) DEB is safe and effective in the treatment of patients with advanced stage HCC, with OS of 14.3 months and very low toxicity.

B-1056 10:54

Comparing HCC tumour vascularisation on baseline imaging and after Lipiodol cTACE: how do estimations of enhancing tumour volumes differ on contrast-enhanced MR and CT?

W. Lüdemann[1], F. Collettini[1], D. Geisel[1], D. Schnapauff[1], G. Wieners[1], B. Gebauer[1], J. Chapiro[2], J. Kahn[1]; [1]*Berlin/DE*, [2]*New Haven, CT/US (willie-magnus.luedemann@charite.de)*

Purpose: Arterial tumour vascularisation and Lipiodol deposition after cTACE of HCC are known to be associated. Nature and strength of the correlation between enhancing tumour volume on baseline imaging and Lipiodol deposition after cTACE were analyzed. Estimations of enhancing tumour volumes on contrast enhanced (CE)-CT or MRI were compared using Lipiodol deposition as a benchmark for arterial tumour vascularisation.
Methods and Materials: 78 HCC patients who underwent their first cTACE procedure were retrospectively enrolled. A segmentation-based quantification of overall and enhancing target lesion volumes (qEASL) was performed on baseline arterial phase CE-CT (55 patients) or MR (23 patients), post treatment Lipiodol deposition was quantified on native CT imaging. Correlations were analyzed using scatter plots, the Pearson correlation coefficient (PCC) and linear regression analysis. Subgroup analysis was performed according to lobar, segmental and subsegmental execution of cTACE.
Results: The PCC for each of the baseline imaging modalities and Lipiodol deposition as dependent variable was 0.91, after stratification according to selectivity of cTACE the PCCs ranged between 0.91 and 0.98. The linear regression equations for the non-stratified data sets were $y=1.39x+15.44$, $R^2=0.83$ for CT and $y=0.33x+12.58$, $R^2=0.82$ for MR imaging, hence, the regression coefficient for CT as baseline modality was 4.21 times greater.
Conclusion: There is a highly linear correlation for both MR and CT baseline enhancing tumour volume and Lipiodol deposition after TACE. Using Lipiodol deposition as a benchmark, it could be objectified that MR imaging is more sensitive for the detection and estimation of arterial tumour vascularisation than CT imaging.

B-1057 11:02

Tumour targeting and 3D voxel-based dosimetry to predict tumour response, toxicity and survival after Y-90 resin microsphere radioembolisation in HCC

C. Allimant, M. Kafrouni, J. Delicque, A.-D. Ilonca, M. Fourcade, D. Mariano-Goulard, C. Cassinotto, L. Piron, B. Guiu; *Montpellier/FR (carole.allimant@gmail.com)*

Purpose: To evaluate the impact of complete targeting and 3D-voxel-based dosimetry on post-treatment Y90-PET/CT to predict tumour response, survival and toxicity in patients with advanced HCC treated with Y90-resin microspheres.
Methods and Materials: 42 Sir-sphere® treatments administered in our centre from February 2012 to December 2015 were retrospectively analysed. 3D-dosimetry was calculated using a treatment planning system to obtain dose-volume histogram and the area under the DVH (AUDVH, in Gy) to measure Y90 dose deposition in different liver volume (tumour, non-tumoural). Tumour control was defined upon mRECIST criteria at 6 months. We documented toxicity by radioembolization-induced liver disease (REILD) occurrences. Uni- and multivariate logistic regressions were used to compute corresponding odds ratios [95%CI] according to tumour complete targeting and $AUDVH_{Tumour}$. Second endpoints were survival analysis using the Kaplan-Meier method and compared using log-rank tests and toxicity analysis comparing mean dose deposition in non-tumoural irradiated liver in REILD versus non-REILD patients using Mann-Whitney test.
Results: The 6-month tumour control rate was 40.5%. Complete targeting was observed in 60% of cases. By univariate logistic regression, tumour targeting and $AUDVH_{Tumour}$ were significantly associated with tumour control ($p<0.001$ and $p=0.008$ resp.). By multivariate analysis, both factors independently predicted tumour control (OR=36.97[1.83-747] $p<0.001$ and OR=1.027 [1.002-1.071], $p=0.0325$ resp.). Overall survival was significantly higher for both factors ($p<0.002$). We observed 4 REILD (9.5%) with significantly higher dose to the normal irradiated liver ($p=0.004$).
Conclusion: Complete targeting and Y90-dose to the tumour, for the first time represented by $AUDVH_{Tumour}$ are independent factors associated with tumour control.

B-1058 11:10

Transarterial Radio-embolisation with 131I-Lipiodol for Hepatic metastases: experience intertiary care oncology centre in India

V. Bhargavi, I. Subbanna, S.S. Swamy; *Bangalore/IN*
(bhargavi_vidya@yahoo.in)

Purpose: Surgical resection is often not feasible in metastatic hepatic disease To analyse the response and survival benefits of Transarterial Radioembolization (TARE) with Iodine-131(I131) Lipiodol for hepatic metastases.
Methods and Materials: Prospective study of 65 patients (between May 2011 to December 2016) with pathologically proven hepatic metastases from varying groups of primary carcinomas having poor response to other treatments. All patients fulfilling the inclusion/exclusion criteria underwent transarterial radioembolization (TARE) with I131 Lipiodol. All patients were isolated for at least 5 days for radiation safety purpose. Post procedure the patients were reviewed after one month with a follow up PET CT and tumour marker levels to evaluate response of treatment. Overall survival for each patient was calculated .
Results: At the end of follow up period, 17 of 65 patients died with 48 alive.Mean overall survival was 34.415 ± 3.0 months. Mean survival duration was 38.88 ± 5 months in NET, 35.118± 3.95 in GI , 27.21 ± 8.3 with pancreatico-biliary and 20.685 ± 5.2 with other malignancies(p=0.17).Overall survival after 45 months was 70%. 45 months survival in NET was 76% , 75 % in GI , 57% in pancreatico-biliary and 50% in other malignancies . Response evaluation int 22 patients, 7 (32%) showed partial response , 3 (14%) showed stable disease and 12 (54%) showed progressive diseases. All patients showed reduction in serum tumour marker levels..
Conclusion: TARE with 131I-Lipiodol is highly effective with significant survival benefit in patients with hepatic metastases , refractory to other treatments.

B-1059 11:18

Prospective randomised trial: tumour response of colorectal liver metastasis after transarterial chemoembolisation with two different protocols using MRI

T.J. Vogl, M.C. Langenbach, R. Hammerstingl, J. Scholz, T. Gruber-Rouh;
Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)

Purpose: To prospectively evaluate therapy response of third-line transarterial chemoembolisation (TACE) for colorectal liver metastases with either degradable starch microspheres (DSM) or lipiodol using regular and diffusion MRI.
Methods and Materials: In total, 50 patients (35 males, 15 females, mean 62 years, range 40-79) underwent TACE. They were randomly assigned into two groups: group A receiving DSM and group B receiving lipiodol as embolisation agents. Chemotherapy consisted of a combination of cisplatin, irinotecan and mitomycin. Therapy response was evaluated using MRI with diffusion imaging and unenhanced MRI sequences, which were performed before each of the three TACE cycles to obtain tumour volume and apparent effusion coefficient (ADC). Moreover, contrast-enhanced MRI sequences were performed before the first and after the last TACE cycle. Tumour response was evaluated using the RECIST criteria. Differences in tumour volume response between the lipiodol and DSM group were calculated with BIAS using the Friedman test and the Mann-Whitney U test.
Results: The DSM group showed statistically significant reduction in the average tumour volume compared with lipiodol during the course of the therapy (mean -59%, p=0.006). Additionally the dynamics of ADC values during the therapy correlated significantly with therapy response, stating partial response as responders and stable disease with progressive disease as nonresponders (p=0.046). No statistically significant difference in tumour response was found comparing the lipiodol and DSM group.
Conclusion: A statistically significant reduction in tumour volume was found in the DSM group. No significant difference in tumour response was found comparing the Lipiodol and DSM group.

B-1060 11:26

Idarubicin-loaded beads for chemoembolisation of HCC: interim analysis of IDASPHERE II (FFCD 1307) multicentre single-arm phase II trial

B. Guiu[1], P. Chevallier[2], A. Rode[3], A. Bouvier[4], P.-J. Valette[3], C. Cassinotto[1], L. Piron[1], M. Boulin[5]; [1]*Montpellier/FR*, [2]*Nice/FR*, [3]*Lyon/FR*, [4]*Angers/FR*, [5]*Dijon/FR (b-guiu@chu-montpellier.fr)*

Purpose: The primary end point was to assess the objective response (OR) rate at six months after trans-arterial chemoembolisation (TACE) for HCC using idarubicin-loaded beads.
Methods and Materials: TACE sessions (1-4) were performed using 10 mg of idarubicin loaded in 100-300 micron DC Bead. Toxicity was assessed according to NCI-CTCTAE v4.0. The objective response (primary end point) was evaluated (mRECIST) using MRI (centralized review). The study was a 2-step Fleming design (H0: 25% of OR at 6 months vs H1: 40%, power=90%, one sided: α=5%). 46 patients were included for the interim analysis.
Results: 46 patients (median age: 71y; range: 44-89y) were enrolled in seven centres at interim analysis. Performance status was 0 in 83%, 1 in 15% and 3 in 2%. BCLC status was A in 10.9%, B in 76.1% and C in 13%. Bilobar disease was reported in 51% with >3 HCC nodules in 53.5% patients. Complete response, partial response and stable disease were observed in 6 (13.6%), 16 (36.4%) and 4 (9.1%) patients, respectively. OR rate at 6 months was 50% (90%CI: 36.8-63.2%). The trial was stopped at interim analysis because of its efficacy.
Conclusion: TACE of HCC using idarubicin-loaded beads is well tolerated and provides a 50% objective response rate at 6 months. A randomised phase 3 trial is warranted.

B-1061 11:34

Transradial versus transfemoral access for hepatic chemo-embolisation: intrapatient prospective single-center study

A. Posa, R. Iezzi, F. Carchesio, C.A. Barone, A. Gasbarrini, R. Manfredi;
Rome/IT (alessandro.posa@gmail.com)

Purpose: To compare transfemoral approach (TFA) and transradial approach (TRA) in patients undergoing hepatic chemoembolization in terms of safety, feasibility, and procedural variables, including fluoroscopy time, radiation dose (reference air kerma [RAK]), and patient preference.
Methods and Materials: A single-center prospective intrapatient comparative study was conducted with 42 consecutive patients with hepatic malignancies who received 2 consecutive treatment sessions of unilobar hepatic chemoembolization within a 4-week interval over a 6-month period with both TRA and TFA. All procedures were performed by 1 interventional radiologist who assessed the eligibility of patients for inclusion in the study. The primary endpoint was intraprocedural conversion rate. Secondary endpoints were access site complications, angiographic and procedural variables, and evaluation of patient discomfort and preferences.
Results: A 100% technical success rate and a crossover rate of 0% were recorded. There were no major vascular complications and similar rates of minor complications (4.8% for TRA, 7.1% for TFA; P=.095), which were self-limited and without any clinical sequelae. TRA treatments required a significantly longer preparation time for the procedure (P=.008) with no significant differences for other procedural variables. Greater discomfort at the access route and patient inability to perform basic activities after the procedure were recorded for TFA (P<.001). TRA was preferred by 35 patients (35/42) for potential future transarterial procedures.
Conclusion: TRA is safe and feasible for transarterial hepatic chemoembolization, with high technical success, low overall complications, and improved patient comfort.

B-1062 11:42

A comparative study of a new generation robotic angiography system based on patient dose and image quality during transarterial chemoembolisation

T.J. Vogl, L. Alizadeh, M.H. Albrecht, P. Tischendorf; *Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: Comparison of patient dose and diagnostic image quality between two generations of robotic angiographic systems for transarterial chemoembolization (TACE) therapy of malignant liver tumours.
Methods and Materials: 159 patients undergoing TACE treatment were divided randomly into three groups: generation one, generation two before and generation two after the protocol update. Patient imaging was performed with fluoroscopy and digital subtraction angiography (DSA) acquisition protocols. Radiation dose was measured using an ionization chamber, measuring dose-area-product (DAP) in Gy·cm2 and reference-point-air-kerma (RP) in mGy. Image quality was analysed by three radiologists through a blinded evaluation, considering clinically relevant image parameters.
Results: The second-generation system provided significantly ($p < 0.05$) better clinical image quality (IQ) of 30% in DSA and 81% before and 76% after digital fluoroscopy protocols vs the older generation system. The new generation system also showed a lower radiation exposure, by RP -48% and -40% DAP in DSA acquisition. In fluoroscopy protocols a decrease of RP -3% and -5% DAP before, and RP -50% and -49% DAP after update was found for second-generation systems, compared to first-generation systems.
Conclusion: Recent generation angiography systems allow significant dose reductions, while improving image quality in fluoroscopy and DSA during TACE treatment.

B-1063 11:50

Generation I vs new-generation cone-beam CT, digital subtraction angiography and digital fluoroscopy in patients undergoing TACE: comparison of radiation dose and image quality

T.J. Vogl, L. Alizadeh, K. Graef, N.-E.A. Nour-Eldin; *Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: To compare radiation dose, clinical image quality (IQ) and aspects of workflow and usability in a clinical environment for patients and radiologists during transarterial chemoembolization (TACE) of hepatic malignancies using generation I (A.Zeego) C-arm cone-beam CT (CBCT) or the new generation II (A.Pheno) CBCT.
Methods and Materials: 153 patients with liver malignancies underwent preprocedural MRI and TACE in a 4- to 6-week interval. During TACE generation I and generation II CBCT were both operated by the same experienced radiologists and patients were randomized. From 02/17 onwards a software patch was applied on the generation II system for reducing the radiation dose in fluoroscopy. Radiation dose and image data were collected as DICOM (SR,XA) system data from each CBCT. Radiation doses were measured with the built-in standardized measuring units of the CBCTs (Siemens-Healthineers/Forchheim) measuring DAP and SED. Afterwards qualitative image quality was compared in a blinded trial of three individual experienced readers through a scale-based evaluation.
Results: Generation II system provided a significantly better IQ of $\bar{x}$=30% before and $\bar{x}$=25% after patch in digital subtraction angiography (DSA) and of $\bar{x}$=81% before and $\bar{x}$=76% after patch in digital fluoroscopy protocols vs the older generation. Moreover, detectability of guidewire and microcatheters in fluoroscopy protocols was improved. It also showed a lower radiation exposure after patch fluoroscopy and in DSA acquisitions vs generation I system.
Conclusion: Generation II vs generation I system provides better IQ and workflow with lower radiation dose. Further, it facilitates very low-dose radiation spectrum for clinical use.

To evaluate the role of 68Ga-PSMA PET-CT in patients with newly diagnosed high-risk prostate cancer

S.M. Shaikh; *Hyderabad/IN (drsikandar_s@yahoo.co.in)*

Purpose: The aim of the current study was to assess the use of 68Ga-PSMA (prostate-specific membrane antigen) in patients with prostatic cancer.
Methods and Materials: 68Ga-PSMA PET-CT was performed after injection of radiotracer and scan done after one hour. 27 patients with diagnosed prostate cancer, Gleason score of 7or higher were included in inclusion criteria. The study is retrospective.
Results: All 27 patients had increased 68Ga-PSMA uptake in the prostate. In 8 patients (32%) uptake was localized. In 6 patients PET-CT findings suggested capsular involvement, in 3, seminal vesicles involvement and in 2, uptake was not separated from the rectum or urinary bladder wall which was suggestive of infiltration. Nineteen patients (72%) had increased lymph node uptake. In 14 patients nodal uptake was detected only in the pelvis (3 perirectal, 10 iliac, 1 superior rectal), in 3 also in retroperitoneal nodes and in 2 in mesenteric nodes. In 6 patients (23%) skeletal increased uptake intramedullary=1, cortical and intramedullary=2, and cortical =9. In 2 of the 6 patients the bone was the only site of uptake other than the primary tumour site. There was a single patient with lung nodules suggestive of metastasis. Of the 23, 6 had surgery (26%); 5 patients (in 2 with combination of radiation (R) and hormonal therapy (H)) and 1 with uptake also in pelvic lymph node dissected at surgery. 12 patients (54%) received hormonal therapy and one patient received chemotherapy.
Conclusion: 68Ga-PSMA PET-CT has a potential impact on treatment approach.

B-1064 10:38

Prediction of minimal extraprostatic extension with MRI: correlation with whole-mount histological sections

S. Pedalino, E. Appendino, E. Tabone, S. Mazzetti, D. Regge, F. Russo; *Candiolo/IT (salvatore.pedalino@ircc.it)*

Purpose: To differentiate with MRI organ-confined prostate cancers (PCas) that infiltrate the fibrous capsule from PCas with minimal extracapsular extension (mECE).
Methods and Materials: 70 prostatectomized patients with a total of 73 lesions were enrolled in this study. Of the 73 lesions, 57 were organ confined but with infiltration of the fibrous capsule (T2f); 16 had mECE (i.e. ≤0.7 mm in radial extension; T3m). An experienced uroradiologist retrospectively reviewed T2w images (axial, coronal, sagittal) of all 73 lesions to assess the presence/absence of mECE. For each tumour the contact length with the fibrous capsule in mm, the presence/absence of bulging, the presence/absence of plaque-like morphology without bulging were recorded. Receiver operating characteristic (ROC) curves were used to determine the contact length cut-off to differentiate T2f from T3m.
Results: Presence of bulging was found in 12% (7/57) and 44% (7/16) of T2f and T3m, respectively ($p<0.01$). Plaque-like morphology was present in 14% (8/57) T2f and in 19% (3/16) T3m tumours ($p=0.70$). Both plaque-like morphology and bulging were absent in 74% (42/57) of T2f and 37% (6/17) of T3m tumours ($p=0.02$). The median contact between lesion and prostatic capsule was 11mm (IQR 7-15) and 14mm (IQR 13-16) for T2f and T3m tumours, respectively ($p=0.02$). With ROC analysis a sensitivity of 75% and a specificity of 65% were obtained in the prediction of the T3f at the best cut-off value (12mm).
Conclusion: Presence of bulging and a of broad contact (>12 mm) of the tumour with the fibrous capsule are predictive of mECE.

B-1065 10:46

Added value of MRI tractography of periprostatic nerve plexus to conventional T2-WI in detection of extra-capsular extension of prostatic cancer

A. Cybulski, M. Catania, R. Negrelli, E. Boninsegna, S. Brancato, A. Tafuri, G. Zamboni, S. Siracusano, R. Pozzi Mucelli; *Verona/IT (matteocatania89@gmail.com)*

Purpose: To evaluate the role of MRI in detection the extra-capsular extension (ECE) of prostatic tumor through T2-WI, tractography of periprostatic nerve plexus and a combination of both.
Methods and Materials: 36 patients with diagnosis of prostatic neoplasia performed MRI and underwent radical prostatectomy. Histopathological analysis showed ECE in 15/36 and capsule sparing in 21/36. By means of T2-WI, ECE was evaluated in a qualitative manner: a score (1 to 4) was assigned to each lesion; sensitivity and specificity were calculated for each score group. We performed a quantitative analysis on 2 tractographic parameters, fractional anisotropy (FA) and apparent diffusion coefficient (ADC), and computed the ratio between the lesion quadrant and its controlateral (L/H ratio). We compared L/H ratios of patients with and without ECE; ROC analyses were performed to determinate ECE cut-off values of tractographic parameters. These cut-off values were used in association with T2-WI to reassess patients and to evaluate if specificity and sensitivity of ECE detection change.
Results: T2-WI showed a sensitivity of 80% and a specificity of 71% in detection of ECE. Tractography displayed a significant difference in L/H ratio for FA and ADC between patients with and without ECE. The simultaneous use of T2-WI and tractography revealed high sensitivity (100%) on patients with low suspect of ECE (score:1-2) and high specificity (80-100%) on patients with medium-high suspect of ECE (score:3-4).
Conclusion: MRI tractography combined with T2-WI is able to identify tumor ECE with higher sensitivity and specificity than conventional T2-WI alone.

B-1066 10:54

How to predict anterolateral extracapsular tumour extension in patients with prostate cancer

H. Ahn, S.I. Hwang, H.J. Lee; *Seongnam/KR (ahnhyungwoo@naver.com)*

Purpose: To investigate imaging markers indicating anterolateral extracapsular extension (ECE) of anteriorly located prostate cancer.
Methods and Materials: Among 505 anteriorly located prostate cancers on histopathological mapping between 2011 and 2016, 221 lesions of category 4 and 5 in prostate imaging reporting and data system on multiparametric MRI were enrolled. Two radiologists independently measured the largest tumour dimension, the length of the border where the tumour contacts the anterolateral prostate capsule if present and apparent diffusion coefficient value, and assessed the capsular morphology in five categories (intact, focal thinning, bulging, disrupted, or measurable extracapsular disease). Intraclass correlation coefficient (ICC) and Cohen's κ statistics were used to assess inter-reader agreement. Logistic regression analysis was done to assess the meaningful

indicator of ECE, along with Gleason score and prostate-specific antigen level with each measurement. The cutoff value of measurement in the prediction of ECE was obtained using Youden Index.
Results: Inter-reader agreement was excellent for the largest tumour dimension (ICC 0.81, 95% CI 0.76-0.85) and capsulotumoural border length (ICC 0.80, 95% CI 0.75-0.85), and was good in the categorisation of capsular morphology (κ 0.64, 95% CI 0.55-0.74). The capsulotumoural border length (odds ratio [OR], 1.1) and the preservation of capsular contour (OR 0.3) were found to be statistically significant in the prediction of ECE. A capsulotumoural border of 1.0 cm demonstrated a sensitivity and specificity of 82.6% (57/69) and 71.1% (108/152), respectively.
Conclusion: Anterolateral ECE should be suspected when the tumour is in contact with the anterolateral capsule with its border measuring 1.0 cm or longer, or when the capsular contour is disrupted.

B-1067 11:02

T-staging of prostate cancer: prevalence and predictive value of frequently used signs of extracapsular extension on prostate MRI
F. Pesapane, C. Standaert, P. De Visschere, G. Villeirs; *Ghent/BE (filippopesapane@gmail.com)*

Purpose: To evaluate the staging performance of frequently used signs of extracapsular extension (ECE) on prostate magnetic resonance imaging.
Methods and Materials: The presence of ECE in index lesions visible on prebiopsy mpMRI (consisting of T2w images, DWI and DCE on a 3 Tesla system) of 46 patients (mean age 63 years, mean PSA 17.2 ng/mL) with biopsy-proven prostate cancer, who underwent subsequent radical prostatectomy between 11/2011 and 12/2014, was retrospectively assessed by two radiologists (15 and 8 years of experience) on the basis of 8 criteria selected from literature. For each sign, the prevalence and positive predictive value (PPV) for histopathologically proven ECE was calculated as the average of both readers.
Results: Tumour-capsule contact was the most prevalent sign (56.9%), but with the lowest PPV (51.9%), although increasing with broader capsular contact (57.9% if ≥ 10 mm and 81.3% if ≥ 20 mm). Prevalence and PPV were 18.6% and 69.0% for capsular signal-intensity disruption, 14.7% and 75% for contour bulging, 11.8% and 75.0% for unsharp margin, 8.8% and 85.7% for irregular contour, 6.9% and 87.5% for periprostatic fat infiltration, and 2.9% and 100% for both rectoprostatic angle obliteration and periprostatic mass, respectively.
Conclusion: Broad tumor-capsular contact length, irregular contour, periprostatic fat infiltration, rectoprostatic angle obliteration and periprostatic mass are associated with the highest chance of ECE of the index lesion. All other signs are more prevalent, but less predictive of ECE. Reporting the chance of ECE can add important information to the treatment decision-making.

B-1068 11:10

Development of an extraprostatic extension imaging score based on multiparametric MRI and histopathology correlations
R. Campa, V. Salvo, M. Pecoraro, M. Del Monte, V. Panebianco, C. Catalano; *Rome/IT (riccardocampa23@gmail.com)*

Purpose: To develop an extraprostatic extension imaging score (EPEIS) based on multiparametric magnetic resonance (mpMRI) of prostate cancer (PCa). It may give the urologist an easily comprehensible information, either alone or embedded into a nomogram, that can be helpful for local staging and proper therapeutic planning.
Methods and Materials: A cohort of 32 consecutive patients with clinically localised PCa who underwent preoperative mpMRI and then radical prostatectomy (RP) were enrolled in the study from January 2015 to August 2017. Patients underwent staging 3T MpMRI (T2WI on axial and coronal planes, DWI with b values up to 2000 s/mm^2, DCE images). Two expert radiologists retrospectively evaluated the exams assigning a T-stage, according to ESUR MR prostate guidelines, and the EPEIS, ranging from 0 to 5, based on PIRADSv2 staging criteria. Histopathological prostatectomy data were used as standard reference.
Results: Extraprostatic extension (EPE) was present in 13/32 (41%) patients. ROC curves analysis shows How EPEIS proved to be a good indicator in the staging (AUC=0.76 [0.65-0.85]); better than the assignment of a T-stage (AUC=0.71 [0.60-0.82]). Youden's J statistic was made to select the best EPEIS cut-off. EPEIS proved good sensitivity (0.65-0.87) and specificity (0.73-0.95), especially if compared to the T-stage assignment sensitivity (0.58-0.80) and specificity (0.67-0.89).
Conclusion: EPEIS proved to be a promising mpMRI indicator of PCa micro- and macroscopic extracapsular extension. Its usefulness could be increased if included within appropriate nomograms.

B-1069 11:18

Whole-body MRI for bone metastasis detection in prostate cancer: the roles of static field intensity and contrast media in focus
D. Kovacevic, I. Papageorgiou, R.L. Chelaru, S. Winzler, A. Malich; *Nordhausen/DE (ismini.e.papageorgiou@gmail.com)*

Purpose: The purpose of this study is to define whether the static field intensity (1.5T vs 3T) and the use of gadolinium enhancer influence the diagnostic accuracy of whole-body magnetic resonance imaging (WB-MRI) for osseous metastasis in prostate cancer.
Methods and Materials: The study was retrospective for 96 patients scanned between 05/2007 and 08/2017. 49 patients were imaged at 1.5T and 47 at 3T with a T1-w FFE and a STIR or a Dixon at the coronal level. The slice thickness was 6 mm at 1.5T and 3 mm at 3T. In 24 (25%) patients, the scan was enhanced with gadoteridol (ProHance) 0.2 mmol/kg. Clinical or bioptic confirmation served as the gold standard.
Results: The sensitivity (Se) and specificity (Spe) for 1.5T was 88%/100%, and the positive predictive value (PPV)/negative predictive value (NPV) was 100%/88%. The static field strength of 3T showed Se/Spe 96.15%/90.48% and a PPV/NPV of 92.59%/95%. Binary logistic regression with Fisher´s exact test revealed no significant difference between 1.5T and 3T WB-MRI (*P* 1.0). The Se/Spe of WM-MRI (merged 1.5T and 3T) without enhancement was 92.5%/96.87%, with PPV/NPV 97.37%/91.18%. With administration of gadoteridol, the Se/Spe was 92.31%/90.91% and the PPV/NPV was 92.31%/90.91%. Binary logistic regression with Fisher´s exact test returned no significant effect for gadoteridol (*P* 1.0, odds ratio 1.545).
Conclusion: The diagnostic accuracy of WB-MRI for osseous metastatic disease in prostate cancer is equal for the most commonly used static field strengths, 1.5T and 3T, and independent of gadolinium enhancer administration.

B-1071 11:26

Multiparametric magnetic-resonance to confirm eligibility to an active surveillance programme for low-risk prostate cancer: intermediate time results of a high-volume centre protocol
S. Luzzago, M. Catellani, A. Russo, E. Di Trapani, F. Mistretta, G. Musi, P. Pricolo, G. Petralia, O. De Cobelli; *Milan/IT (stefanoluzzago@gmail.com)*

Purpose: To evaluate confirmatory multiparametric magnetic resonance imaging (mpMRI) of the prostate at the time of active surveillance (AS) enrollment to reduce disease misclassification.
Methods and Materials: From 2012 to 2016, 383 patients with low-risk disease respecting PRIAS criteria underwent confirmatory 1.5-T mpMRI. AS was proposed to patients with PI-RADS score≤3 and no extraprostatic extension (EPE) at mpMRI, whereas patients with PI-RADS score≥4 and/or EPE were treated actively. Kaplan-Meier analyses quantified progression-free survival (PFS) in patients enrolled in AS program. Logistic regression analyses tested the association between confirmatory mpMRI and clinically-significant-prostate-cancer (csPCa) at radical prostatectomy (RP). Diagnostic performance of mpMRI was calculated in patients submitted to immediate RP.
Results: Median time of persistence in AS protocol was 24 months (IQR 13-38). Progression-free-survival rate was 99%, 90%, and 86% at 1, 2 and 3 years, respectively. At multivariable analysis, PI-RADS 3, PI-RADS 4, PI-RADS 5 and EPE increased the probability of having csPCa at immediate RP (PI-RADS 3 [OR]: 1.2, p=0.26; PI-RADS 4 [OR]: 5.1, p=0.02; PI-RADS 5 [OR]: 6.7; p=0.009; EPE [OR]: 11.8, p<0.001). Confirmatory positive mpMRI showed sensibility, specificity, PPV and NPV of 85%, 55%, 68% and 76%, respectively.
Conclusion: Confirmatory mpMRI at the time of AS enrollment reduces misclassification rate of csPCa. We suggest to perform target biopsies in patients with PI-RADS score 3 and 4 lesions.

B-1072 11:34

Evaluation of MRI parameters for prediction of prostate cancer upgrading in active surveillance
D. Portalez, M. Jaffro; *Toulouse/FR (jaffro.m@chu-toulouse.fr)*

Purpose: To evaluate MRI parameters for Gleason score progression in patients with low-risk prostate cancer managed with active surveillance.
Methods and Materials: 125 patients enrolled in AS for prostate cancer with a PI-RADSv2 score 3 or higher underwent systematic biopsies (SB) and MRI-TRUS targeted-fusion biopsies (TB). MRI findings (PI-RADS v2 scoring, ADC value measurements, quantitative DCE parameters, tumour's volume, tumour's visibility on the high b value images) were correlated to pathological results for each lesion. The final study population included 111 patients with Gleason 3+3 on initial biopsies and MRI's target in the peripheral zone (PZ). Statistics consisted in Chi-squared or Fisher's exact test for categorical variables and Mann-Whitney test for continuous variables with a multivariate logistic regression between Gleason 7 and MRI parameters.
Results: Overall upgrade concerned 50/125 patients with 45/111 in the PZ and 1/14 in the transitional zone. Disease was upgraded in 23/125 patients on SB

and in 50/125 patients on TB. Sensitivity, specificity, positive and negative predictive values of ADC value for confirmatory biopsy upgrade in the PZ of 111 patients were 82.2%, 81.8%, 75.5% and 87.1% respectively. A higher performance of ADC value in the prediction of Gleason score upgrading was found compared to other MRI parameters. This upgrading was clearly associated with a lower tumour's ADC value and tumour visibility on the high b value Images.
Conclusion: ADC value tumour's measurement and tumour visibility on the high b value images provided greater accuracy in predicting upgrading on confirmatory biopsies than other MRI parameters.

B-1073 11:42

Added value of multiparametric magnetic resonance (mpMR) and transrectal ultrasound-MR fusion biopsy in active surveillance for prostate cancer

F. Ciccarese, B. Corcioni, C. Gaudiano, M. Garattoni, F. Busato, R. Golfieri; *Bologna/IT (ciccarese.f@gmail.com)*

Purpose: Active surveillance is currently reserved for selected low-risk patients affected by prostate cancer with a Gleason Score =6; at initial diagnosis, mpMR is considered for the high negative predictive value and to reduce misclassification. The aim of this study was to evaluate mpMR findings in patients in active surveillance, with focus on suspected lesions submitted to transrectal ultrasound-MR fusion biopsy.
Methods and Materials: We retrospectively reviewed mpMR scans performed from January 2016-June 2017; on a total of 744 exams, we selected 88 patients submitted to MR for a previous diagnosis of prostate cancer Gleason Score 3+3 suitable for active surveillance. MR data were expressed by using PIRADS classification. In case of PIRADS ≥3, we considered patients that underwent adjunctive transrectal ultrasound-MR fusion biopsy and we analyzed histological results.
Results: mpMR documented benign findings (i.e. PIRADS 1-2) in 39/88 patients (44.3%), while in the others 49/88 (55.7%) the presence of a clinically significant cancer was considered to be equivocal (PIRADS 3 in 35/88-39,8%) or probable (PIRADS 4-5 in 14/88-15.9%). 20/49 patients were submitted to fusion biopsy in our Institute; in 12/20-60.0% a higher Gleason score was detected (7-9)
Conclusion: Almost 50% of patients in active surveillance shows MR abnormalities. Prostate mpMR combined with target fusion biopsies reduce downstaging and help in correct management.

B-1074 11:50

Impact of upfront risk stratification on the negative predictive value of multiparametric MRI in patients under active surveillance

M. Abihanna[1], C. Melodelima[2], P.-C. Moldovan[1], R. Souchon[1], A. Ruffion[1], M. Colombel[1], S. Crouzet[1], O. Rouviere[1]; [1]*Lyon/FR*, [2]*Grenoble/FR (m_abihanna@hotmail.fr)*

Purpose: To assess the impact of upfront risk stratification on the negative predictive value (NPV) of multiparametric MRI in patients under active surveillance (AS).
Methods and Materials: We retrospectively analysed a prospective database of 326 patients under AS who underwent multiparametric MRI before biopsy. The prediction of clinically significant prostate cancer (csPCa) at biopsy by clinical (age, digital rectal examination, PSA density [PSAd], history of prior negative biopsy) and imaging (Likert score, extracapsular extension [ECE], magnetic field strength, experience of radiologist and presence of a concordant hypoechoic lesion [Concord-Echo]) variables was assessed by multivariate analysis. Significant clinical variables were included in a 'clinical model'. Three definitions for csPCa were used (csPCa1: grade group ≥3; csPCa2: grade group ≥2; csPCa3: csPCa2 and grade group 1 with cancer invasion length ≥5mm).
Results: Age, PSAd and Likert score significantly predicted the presence of csPCa1-3. In addition, ECE significantly predicted the presence of csPCa1-2. Adding the Likert score to the clinical models significantly increased the model's performance for csPCa1-3. Omitting biopsy in patients with negative mpMRI would have avoided 37.4% (Likert ≤3/5) or 53.1% (Likert ≤4/5) of biopsies while missing csPCa in 7.1% (csPCa1), 20.2-33.7% (csPCa2) and 35.8-48.9% (csPCa3) patients. mpMRI NPV decreased when the probability of csPCa given by the clinical models increased. Therefore, considering clinical models' output allowed defining scenarios missing <5% of csPCa and omitting biopsies in 33.4-45.4% (csPCa1), 13.5-16.6% (csPCa2), and 7.1-8.9% (csPCa3) patients.
Conclusion: Upfront risk stratification of patients can allow rational use of mpMRI NPV.

Combined diffusion-weighted MRI with conventional T2 and T1 in-phase/out-of-phase sequences: a short screening protocol for liver metastases

S. De Vuysere[1,2], V. Vandecaveye[1], R. Dresen[1]; [1]*Leuven/BE*, [2]*Bonheiden/BE (sofie.devuysere@gmail.com)*

Purpose: To evaluate whether a short magnetic resonance imaging (MRI) protocol consisting of diffusion-weighted imaging (DWI), T1 in-phase/out-of-phase and T2-weighted sequences can accurately detect liver metastases without the need of post-contrast imaging.
Methods and Materials: Liver MRI was performed in 124 consecutive patients with various primary cancers. Three independent readers with different experience level (1 year, 10 years and 15 years respectively) retrospectively reviewed the DWI, T2 and T1 in-phase/out-of-phase sequences. All observers used confidence levels for the prediction of metastases (1 = definitely no metastases, 2 = probably no metastases, 3 = inconclusive, 4 = probably metastases, and 5 = definitely metastases). Sensitivity, specificity, positive predictive value, and negative predictive value were calculated with the cut-off level between 2 and 3 (rating 1) and 3 and 4 (rating 2). Histopathology or 2-years imaging follow-up were the reference standard.

Results: Reader 1 had a sensitivity and NPV of 100% in both ratings. Specificity was respectively 72% versus 96%, PPV of 61% versus 92%.
Reader 2 had a sensitivity of 100%, specificity 98%, PPV 97%; NPV 100% in rating 1 ; sensitivity 94%, specificity 100%, PPV 100%, NPV 97% in rating 2.Reader 3 had no inconclusive results. In both ratings sensitivity was 100%, specificity 97%, PPV 97%, NPV 100%.
Conclusion: DWI, T2 and T1 in-phase/out-of-phase sequences allowed accurate detection of liver metastases in an experienced reader. In future, this time-efficient protocol could be used for screening of liver metastases, without the need for post-contrast imaging.

B-1076 10:38

CT attenuation of liver metastases of colorectal cancer is a prognostic factor of overall survival

M.F. Froelich, V. Heinemann, W.H. Sommer, J. Holch, J. Ricke, D. Modest, F.O. Hofmann; *Munich/DE*

Purpose: To investigate the prognostic value of mean CT-attenuation of liver metastases for overall survival (OS) in metastatic colorectal cancer (mCRC).
Methods and Materials: Patients with histologically confirmed mCRC from a clinical phase III trial who received 5-FU, leucovorin and irinotecan with cetuximab or bevacizumab were included into the analysis. In a baseline CT in portal venous phase the mean attenuation of liver metastases was assessed using semi-automated volumetry. ROC analysis was used to determine an optimal threshold identifying long-term survivors. Its influence on OS was investigated in Kaplan-Meier and Cox proportional hazard regression.
Results: Of a total of 592 patients, 347 were eligible for volumetric segmentation of liver metastases. Mean attenuation was 60.09HU. A higher attenuation was associated with longer OS (per 10HU: HR 0.85 (0.75; 0.93), p<0.001). 61.62HU was found as optimal threshold to predict longer OS (median 21.3 vs 30.6 month; HR 0.61 (0.47; 0.80), p<0.001) and was confirmed in multivariate regression (HR 0.61 (0.46; 0.82), p<0.001).
Conclusion: Increased mean baseline CT attenuation of liver metastases may be utilised to identify mCRC patients with longer OS.

Predicting the response of colorectal cancer liver metastases (CRCLM) to preoperative chemotherapy using gadoxetic acid-enhanced MRI

N.V.V.P. Costa[1], N. Bastati[2], S. Pötter-Lang[2], Z. Guengoern[2], Y. Bican[2], A. Ba-Ssalamah[2]; [1]*Lisbon/PT*, [2]*Vienna/AT (nunovpc@gmail.com)*

Purpose: The aim of the study was to create a scoring system based upon gadoxetic acid-enhanced magnetic resonance imaging (^{ga}MRI) features to predict the treatment response (TR) to chemotherapy.
Methods and Materials: This was a retrospective study of 30 consecutive patients (65.2±11.2years) with CRCLM, who underwent ^{ga}MRI after chemotherapy and before hepatic resection. Metastases were classified according to a suggested scoring system (0-6 points) in three groups of response: optimal (≤2 points); partial (2-4 points); and no-response (≥4 points). The scoring system comprised three features: overall homogeneity (homogeneous=0, mixed=1, heterogeneous=2); tumour-liver interface (sharp=0, mixed=1, ill defined=2); and peripheral rim enhancement (≤2 mm=0, 2-4 mm=1, ≥4 mm=2). Apparent diffusion coefficient (ADC) values were measured.The primary outcome was residual vital tumour (RVT). The scoring system, response groups, and ADC values were calculated and compared with the RVT percentage. Demographic, laboratory, and imaging findings were included in a multivariate statistical analysis. The three groups of response were correlated with patient survival and the log-rank test was used to compare two survival distributions (optimal/partial response vs no-response groups).
Results: Forty-one CRCLM showed good inter-observer agreement (κ=0.86). Multiple regression demonstrated an association between RVT (32.9±11.2) and the scoring system (p<0.001), the response group (p<0.001), and the ADC values (p<0.021). The survival distributions between optimal/partial response and no-response showed a trend to be different (p=0.066).
Conclusion: ^{ga}MRI correlated well with our scoring system, different response groups, and ADC values in patients with CRCLM treated with chemotherapy, and may be used to assess the RVT percentage.

MRI-based treatment response assessment for liver metastasis stereotactic radiotherapy

D.I. Kuplevatskaya, A. Babiy, N. Vorobyov, V.I. Kuplevatsky, N. Berezina, M. Cherkashin; *St. Petersburg/RU (dkupl@ldc.ru)*

Purpose: To develop MRI criteria for stereotactic body radiation therapy (SBRT) treatment response assessment in patients with liver metastases.
Methods and Materials: In our study 39 patients with liver metastasis, treated by SBRT were included. Abdominal MRI (1.5T scanner) was performed before radiation and after 1, 4, 6, 12 months. The protocols include: T2 Cor, T2 CorFS, T2 Sag, T2 tra, T1 tra in a phase-antiphase, DWI (b 50, 400, 1000), T2 Ax TSE BLADE FS 3 mm on the liver area, dynamic contrast T1tra VIBE FS 1.5 mm. Analysis included target measurement by RECIST 1.1 criteria, necrotic area volume measurement by "Segmentation volume" (OleaSphere V2.3 SP1), DWI, dynamic contrast enhancement and parenchymal postradiation change assessment.
Results: Tumour response after SBRT was revealed in 62% in month 1 and in 49% in month 4. Size decreasing by 30% or more was maximal in 76.9% patients (month 1) and maximal tumour necrosis (25 to 50% lesions) was detected in month 4. In 6 and 12 months after radiation, stabilization was observed in 64% and 71% of cases. Necrotic changes (more than 50% of target volume) were revealed in 61.2% of patients. Complete tumour response after 12 months of SBRT was detected in 13% of patients.
Conclusion: Multiparametric MRI allows to assess morphological characteristics and functional status of radiated metastases and liver parenchyma after SBRT. Complex imaging support radiation oncologist with clear treatment response assessment and is a helpful tool for timely treatment strategy changing.

Multi-parametric MRI assessment of acute response to stereotactic body radiation therapy in patients with hepatocellular carcinoma or non-small cell lung cancer

X. Yang, E. Miller, P. Subramanian, T.M. Williams, M.V. Knopp; *Columbus, OH/US*

Purpose: To study tumour's acute response to stereotactic body radiation therapy (SBRT) with multi-parametric functional MRI.
Methods and Materials: Patients with unresectable hepatocellular carcinoma (HCC) or non-small cell lung cancer (NSCLC) received multi-parametric MRI prior to and within 24 hours after a single fraction of SBRT. BOLD, DWI (NSCLC: b=0/600; HCC: b=0/50/600), and DCE-MRI (Gadobenate, 0.5mL/s infusion) sequences were acquired on a 3T scanner. BOLD response to an oxygen challenge (15L/min) was measured with the R2* difference between air-breathing and oxygen-breathing cycles. Apparent Diffusion Coefficient (ADC) was calculated from the DWI data. DCE-MRI was analyzed with the modified Brix's pharmacokinetic model. Linear mixed effects model was used for statistical analysis.
Results: Sixteen lesions (9 HCC/7 NSCLC) were identified for analysis. BOLD/DWI/DCE data were available for 16/15/11 lesions. Statistically significant BOLD response to the oxygen challenge was observed in 5 HCCs but in only 1 NSCLC. SBRT induced significant decreases in air-breathing R2* in both HCC (2.1 s^{-1}, P<0.001) and NSCLC (3.4 s^{-1}, P=0.006). This decrease in R2* was positively correlated with an increase in DCE parameter k_{ep} (r=0.74/0.70 for HCC/NSCLC). The correlation between R2* decrease and ADC increase was negative for NSCLC (r=-0.68), and close to zero for HCC (r=0.1).
Conclusion: SBRT induces an acute decrease in R2* within 24 hours post-treatment in different types of lesions regardless of their BOLD responses. This change cannot be explained by radiation-induced vasogenic edema. It is more likely to be an indicator of improved tumour oxygenation due to a temporary increase in perfusion.

B-1080 11:10

Impact of the MRI sequence and observer on the gross tumour volume (GTV) in patients with oesophageal and gastro-oesophageal junction (GOJ) cancer

K. Owczarczyk, C. Kelly-Morland, S. Mcelroy, J. Winfield, M.M. Siddique, A. Qureshi, G. Cook, V.J. Goh; *London/UK (christian.kelly-morland@kcl.ac.uk)*

Purpose: Target volume definition for oesophageal/GOJ cancer is challenging and guided by a combination of diagnostic modalities. The high contrast-to-noise of MRI may be of value for radiotherapy treatment planning (RTP). Our aim was to compare the gross tumour volume (GTV) using T2-weighted (T2w) and diffusion weighted (DWI) MRI and to evaluate the agreement between a radiation oncologist and radiologist.
Methods and Materials: Following ethics approval and consent, 26 oesophageal/GOJ cancer patients underwent prospective 1.5T MRI. The GTV was delineated on both T2-w and high b-value (b-900s/mm^2) DWI images by a radiation oncologist and subspeciality radiologist independently. GTV was compared for each reader and sequence using the paired t-test (comparing means); and Dice Coefficient (DC), and Jaccard Similarity Index (JSI; assessing volume congruity). Inter-observer agreement was assessed using Bland-Altman statistics.
Results: DWI GTV was larger by a mean of 14.8% (95% CI -6.7%-36.6%) when delineated by the radiation oncologist while T2w GTV was larger by 18.2% (95%CI -48.2%-4.8%) when delineated by the radiologist, p>0.05. DC and JSI were higher for the T2w than DWI GTV (DC: 0.46±0.19 vs. 0.56±0.16; JSI: 0.41±0.15 vs 0.31±0.16). Bland-Altman limits of agreement were similar (DWI: -137.7to -130.5%; T2-w: -146 to -149.5% respectively).
Conclusion: Sequence selection and reader affects GTV measurements. These results emphasize the importance of sub-speciality radiologist input in RTP of oesophageal cancer as well as combining the information from multiple sequences at the time of target volume delineation.

B-1081 11:18

Comparison of 4'-[methyl-^{11}C] thiothymidine (4DST) PET/CT and FDG PET/CT for predicting response to neoadjuvant therapy in patients with oesophageal cancer

M. Hotta[1], R. Minamimoto[1], K. Yamada[1], K. Yokoyama[1], J. Toyohara[2]; [1]*Shinjyuku-ku, Tokyo/JP*, [2]*Itabashi-ku, Tokyo/JP (masatoshihotta@yahoo.co.jp)*

Purpose: Imaging of DNA synthesis can be achieved using 4'-[methyl-^{11}C] thiothymidine (4DST) PET/CT, which shows a high correlation with cell proliferation. The aim of this study was to evaluate the diagnostic value of 4DST PET/CT for predicting response to neoadjuvant therapy in patients with oesophageal cancer, compared with FDG PET/CT.
Methods and Materials: Twenty-five patients (23 males, 2 females; mean age, 64.8±9.2 years) with histologically diagnosed oesophageal cancer underwent 4DST and FDG PET/CT after completion of neoadjuvant chemotherapy or chemoradiation therapy. All patients subsequently underwent oesophagogastrectomy after neoadjuvant therapy. Based on pathological findings, patients were divided into responder and non-responder groups. The maximum standardized uptake value (SUVmax) of the primary lesion was measured for 4DST and FDG, and compared between responder and non-responder groups. Receiver operating characteristics (ROC) analysis was used to evaluate the diagnostic performance of 4DST and FDG SUVmax for predicting response.
Results: The pathological diagnosis revealed 13 responders and 12 non-responders. The responder group showed lower 4DST and FDG SUVmax than the non-responder group, which was statistically significant for 4DST (4.0±1.6 vs 6.8±3.1 for 4DST, p=0.01; 4.3±1.2 vs 7.3±4.3 for FDG, p=0.07). Area under

the curve (AUC) was higher for 4DST SUVmax (0.82; CI, 0.66-0.98) than for FDG SUVmax (0.72; CI, 0.50-0.93).
Conclusion: 4DST PET/CT has a potential for predicting response to neoadjuvant therapy in patients with oesophageal cancer compared with FDG PET/CT. Higher uptake of 4DST after neoadjuvant therapy may indicate inadequate response to neoadjuvant therapy.

Efficiency of perfusion CT in pancreatic mass characterisation
S. Aslan, M. Nural, I. Camlidag, M. Danaci; *Samsun/TR (serdaraslan28@hotmail.com)*

Purpose: To evaluate the efficacy of perfusion CT (PCT) in pancreatic lesion detection and characterisation.
Methods and Materials: 56 patients with tumour or tumour suspicion on dynamic MDCT underwent PCT. Perfusion parameters (BV, BF, MTT, PS) of the tumour and normal parenchyma was calculated separately by two different readers. Lesions were grouped as adenocarcinoma, neuroendocrine tumour (NET) and mass-forming chronic pancreatitis (MFCP) according to histopathological diagnoses. Isoattenuating lesions were evaluated as a subgroup.
Results: All perfusion parameters in 42 adenocarcinoma cases were significantly different from normal pancreatic parenchyma and MFCP cases ($p < 0.001$ and $p < 0.001$, respectively). 5 MFCP cases had significantly prolonged MTT and lower BV, BF, and PS ($p < 0.05$) whereas 5 NET cases had higher BV, BF, and PS compared with normal parenchyma ($p < 0.05$). When BV, BF, PS, and MTT were chosen as 6.84 ml, 64.43 ml, 28.08 ml/100 ml/min and 7.47 sec, respectively, differentiation between adenocarcinoma and MFCP were made with high sensitivity (%100, %100, %97.8 and %100, respectively) and specificity (%92.3, %100, %80 and %100, respectively). 11 isoattenuating lesions also had prolonged MTT and lower BV, BF, and PS compared with normal parenchyma ($p < 0.05$). Of isoattenuating lesions, 6 adenocarcinomas had significantly lower BV, BF, PS and prolonged MTT compared with 5 MFCP cases ($p < 0.001$). Interreader agreement was high-very high (ICC = 0.76 - 0.99).
Conclusion: PCT is a reliable method for diagnosis and characterisation of pancreatic masses and in cases of the diagnostic dilemma.

B-1083 11:34

Pancreatic ductal adenocarcinoma: association of RECIST1.1 and Choi criteria with survival data and clinical outcome
E. Raimondi[1,2], K. Young[2], K. Kouvelakis[2], D.-M. Koh[2], V. Calamai[2], N. Starling[2], M.A. Bali[2]; [1]*Ferrara/IT*, [2]*London/UK (edoardo.raimondi@unife.it)*

Purpose: To compare overall survival (OS) and progression-free survival (PFS) of pancreatic ductal adenocarcinoma (PDA) patients treated with FOLFIRINOX chemotherapy with RECIST1.1 and Choi criteria response categorisation.
Methods and Materials: After IRB approval, 32 patients with locally advanced (LAPDA) and 35 patients with metastatic (MPDA) PDA treated with FOLFIRINOX were retrospectively included. Pre and post-treatment CT studies were analysed using Mint Lesion™. Within each group, patients were categorised as responder (R) and non-responder (NR) according to RECIST1.1 and Choi criteria. Kaplan-Meier analysis was performed for R and NR categories for each radiological criteria for OS and PFS.
Results: Significant differences between R and NR for OS and PFS were observed in both groups for both radiological response criteria (Log-rank test: $p<0.05$). For LAPDA median OS was 34.57 vs 13.82 months by RECIST1.1 (HRs: 2.62-32.59) and 21.12 vs 12.34 months by Choi (HRs: 1.44-12.12). Median PFS was 27.07 vs 11.74 months for RECIST1.1 (HRs: 1.89-13.79) and 15.10 vs 10.59 by Choi (HRs: 1.16-8.98). For MPDA, median OS was 20.89 vs 8.88 months by RECIST1.1 (HRs: 1.34-6.66) and 18.49 vs 8.22 months by Choi (HRs: 2.47-15.26). Median PFS was 13.82 vs 5.56 months by RECIST1.1 (HRs: 1.59-7.95) and 13.39 vs 2.76 months by Choi (HRs: 4.95-55.56).
Conclusion: Response categorisation by RECIST1.1 was superior to Choi criteria in LAPDA in stratifying patient outcomes, but Choi criteria better associated with OS and PFS in MPDA. These observations may suggest differences in the disease imaging phenotypes.

B-1084 11:42

Virtual touch quantification technology in differentiation between benign and malignant solid small pancreatic tumors: initial results
Y. Dong, F. Mao, J. Cao, P. Fan, W. Wang; *Shanghai/CN (dr_mimi@163.com)*

Purpose: To evaluate the feasibility of differentiating between pancreatic ductal adenocarcinomas (PDA) and other solid benign pancreatic tumors with virtual touch quantification (VTQ) shear wave technology.
Methods and Materials: Over the periods of January 2016 to October 2017, a total of 78 patients with unclassified solid small pancreatic lesion ≤ 20 mm were prospectively evaluated. ACUSON AXONA US system (Siemens Medical Solutions, Mountain View, CA, USA), equipped with a C6-1 transducer was used. VTQ were performed, shear wave velocity (SWV) and the differences in SWV ratio of solid pancreatic lesion to surrounding parenchyma were evaluated. In all patients VTQ elastography results were compared with cytology or histology findings as the gold standard.
Results: A total of 78 pancreatic lesions including 58 (74.3 %) PDA, 13 (16.7 %) solid pseudopapillary tumors (SPT) and 7 (8.9 %) pancreatic neuroendocrine tumors (NET) were analysed. The mean SWV values obtained were (3.59 ± 0.32) m/s for PDA, (2.61 ± 0.11) m/s for SPT and (2.47 ± 0.54) m/s for NET ($P < 0.05$). The SWV ratios were 2.43 ± 0.22 for PDA and 1.19 ± 0.21 for benign lesions ($P < 0.05$). For the diagnosis of PDA, while using the cut off value 3.67 m/s for SWV and 2.51 for SWV ratio, good sensitivity (81.3%) and specificity (77.5%) were obtained for the characterization of PDA.
Conclusion: VTQ is a new elastography method that shows promising clinical application for the quantification of PDA elasticity. Increasing tissue stiffness of PDA is represented by greater SWV values.

B-1085 11:50

Dedicated DW-MR imaging as an accurate selection tool for hyperthermic intraperitoneal chemotherapy (HIPEC) in patients with peritoneal carcinomatosis (PC) from colorectal origin
I. van't Sant-Jansen, M. Engbersen, S. Chandrasegaram-Shanmuganathan, D.M. Lambregts, N.F. Kok, G.L. Beets, R.G.H. Beets-Tan, A.G. Aalbers, M.J. Lahaye; *Amsterdam/NL (M.Lahaye@nki.nl)*

Purpose: The peritoneal cancer index (PCI) is a surgical scoring system to quantify the extent of PC. It is used to select patients who might benefit form cytoreductive surgery (CRS)/HIPEC. To prevent unnecessary surgery in patients whose peritoneal tumour burden is too extensive, patient selection based on preoperative imaging is highly desirable. Computed tomography is inaccurate in predicting PCI. In order to assess whether DW-MRI can select potentially operable patients we compared PCI estimated preoperatively by DW-MRI with PCI found at surgery.
Methods and Materials: Forty-seven consecutive patients (M/F=21/26) with histologically proven colorectal cancer and suspected or confirmed PC were included. All patients underwent preoperative dedicated whole-body DW-MRI (scantime=35min) before exploratory laparoscopy or CRS/HIPEC. PCI was prospectively assessed by two independent radiologists on MR-imaging and was compared to PCI at surgery (=reference standard). Based on PCI patients were categorised as operable (PCI 0-20) or inoperable (PCI 21-39).
Results: Mean PCI at surgery was 11.6(range 0-31). Mean radiological PCI for reader 1 was 10.8 (range 2-33) and 9.2(range 0-31) for reader 2. Radiologist 1 and 2 staged respectively 44/47 and 41/47 patients correctly (accuracy 94%/87%). Both radiologists detected all operable patients with a PCI<21 at surgery (sens=100%). Respectively, 3 and 6 patients were understaged by DW-MRI. There were no false negatives results. The intraclass correlation between the two radiologists was excellent (ICC=0.91, 95%CI:0.765-0.956).
Conclusion: DW-MRI is an accurate and reproducible selection tool to non-invasively select patients who could potentially benefit from CRS/HIPEC. DW-MRI may replace surgical PCI staging in selected patients.

Role of one-pass breast lesion excision system in complete excision of high-risk breast lesions expressed as clusters of microcalcifications

A. Christou[1], V. Koutoulidis[2], D. Koulocheri[2], K. Zografos[2], G. Zografos[2]; [1]*Doncaster/UK*, [2]*Athens/GR (alexandrachristou@gmail.com)*

Purpose: To assess the role of the breast lesion excision system (BLES) in complete removal of clusters of microcalcifications found on mammogram proved histologically to be high-risk lesions.
Methods and Materials: 394 consecutive women with 400 cases of suspicious clusters of microcalcifications underwent stereotactic biopsy using the intact BLES device between January 2014 and January 2016. 38/400(9.5%) cases proved histologically to be high-risk lesions and were subsequently assessed for underestimation and complete removal.
Results: Mean size was 9.75mm (1.5mm-18mm) which was within the size that BLES needle can excise (20 mm). 4 papillomas with atypia (10.5%), 14 cases with flat epithelial atypia (FEA) (36.8%), 10 cases with lobular neoplasia (LN-atypical lobular neoplasia [ALN], lobular carcinoma in situ [LCIS]) (26.3%), 8 with atypical ductal hyperplasia (ADH) (21.2 %) and 2 cases with mucocele-like lesions (MLL) with atypia (5.3%) were found. 29/ 38 lesions had subsequent surgery and all 38 had a 2-year follow up. Complete excision was achieved in 23/29 lesions (79.3%). No underestimation was found. 2-years mammographic stability was found in all lesions. Mann Whitney test showed that clear BLES specimen margins over 1mm was statistically significant predictive factor for complete removal (p=0,041).
Conclusion: One-pass BLES intact stereotactic technique is a safe and accurate biopsy method with high rates of complete removal of small high-risk lesions which could be potentially used as an alternative excision method to diagnostic surgery and avoid subsequent surgical excision.

B-1087 10:38

Prognostic characteristics of B3 lesions detected by mammographic screening programmes in the Veneto region

I. Brilli[1], E. Tosi[1], M. Zorzi[1], A. Rizzo[2], C. Fedato[3], E. Orvieto[1], M. Lo Mele[1], M. Baracco[1], A. Fiore[1]; [1]*Padua/IT*, [2]*Treviso/IT*, [3]*Dorsoduro/IT (isa.brilli@libero.it)*

Purpose: Breast lesions with uncertain malignant potential (B3) are extremely heterogeneous and have a mean predictive value (PPV) for cancer of 31.7%. We retrospectively analysed a case series of B3 detected by screening programmes of Veneto region to identify selection criteria for surgery.
Methods and Materials: Among the 2.239.137 women screened from 2003 to 2015, 7.179 performed a biopsy (VAB or CNB) and 757 had a B3 outcome, 542 of which confirmed at histological revision. We evaluated the PPV for cancer of age, mammographic and/or ultrasound findings, radiological suspicion (R), biopsy diagnosis, presence of atypia.
Results: B3 cases referred to surgery were 447/542 (82%). Out of the 419 with available outcome, 133 (31.7%) were positive for carcinoma (43 invasive - PPV 10.3%, and 90 in situ - PPV 21.5%). At preoperative mammography, 57% of B3 lesions showed cluster of microcalcifications, 30% opacity and 13% distortions. PPV for invasive lesions was higher for distortions (RR 3.63; 95% CI 1.39-9.14) and for R4 radiological classification (RR 2.15; 95% CI 1.06-4.43). PPV was reduced in the absence of atypia (RR 0.49; 95% CI 0.23-0.99) and for the B3 class of papillary lesion (RR 0.12; 95% CI 0.003-0.81). Age was not significantly associated with PPV.
Conclusion: Radiological distortion, R4 classification and the presence of epithelial atypia could be considered as valid selection criteria for surgical excision. The low risk for malignant neoplasm suggests to select the B3 cases to refer for surgery through discussion in multidisciplinar team to limit overtreatment.

B-1088 10:46

A prospective study on uncertain biological potential lesion (B3) overtreatment in tomosynthesis breast screening: role of tomosynthesis-guided biopsy (DBT-VAB)

G. Romanucci[1], S. Brunelli[1], A. Caneva[2], S.A. Montemezzi[1], F. Caumo[3]; [1]*Verona/IT*, [2]*San Bonifacio/IT*, [3]*Padua/IT (giovi.romanucci@libero.it)*

Purpose: DBT in screening practice improves the detection of architectural distortions, often associated with B3 lesions. B3 category represents a clinical dilemma due to the significant risk of associated malignancy with often subsequent surgical excision to histologically examine the entire lesion. Aim of this study is to assess the accuracy of DBT-VAB in reducing overtreatment of B3 lesions , detected with tomosynthesis as architectural distortions.
Methods and Materials: 265 DBT-VAB were performed from 1st April 2015 to 31th March 2017, 97 of them on architectural distortions. At least 24 biopsy specimens were obtained in each procedure. Radial scars and papillary lesions, usually considered B3 lesions, if <20 mm and completely removed after DBT-VAB, were downgraded to B2 and sent to yearly follow-up.
Results: Microhistological result of architectural distortions was malignant in 22/98 cases (22.4%). According to the new proposed categorization, B3 lesions lowered from 61/98 (62.2%) to 21/98 (21.4%) with the subsequent management: 9 were sent to yearly follow up; the remaining 12 lesions underwent surgical excision which revealed 3 malignancies, both seen only on DBT. Similarly, B2 lesions raised from 15.3% (15/98) to 56.1% (55/98), all sent to yearly follow-up.
Conclusion: DBT-VAB ensures the patient the most precise diagnostic and therapeutic workup for architectural distortion. It accurately characterizes architectural distortions and allows a B3 risk stratification to reduce overtreatment.

B-1089 10:54

Radial scars detected at screening mammography: is surgical excision always indicated?

T. Tarmey, P. McGreal, A. McDermott, M. Sheehan, A. OConnell; *Galway/IE (tarattarmey@gmail.com)*

Purpose: Radial scars (RS) diagnosed at percutaneous biopsy can be associated with ductal carcinoma in situ (DCIS) and invasive carcinoma and current management involves surgical excision. The occurrence of DCIS and invasion is increased when there is associated atypia at biopsy. We assessed any histological features at biopsy that may warrant more conservative management.
Methods and Materials: We retrospectively reviewed all cases from a National Breast Cancer Screening Program centre over a ten-year period (2007-2016) to identify all patients with a histological diagnosis of a RS made by percutaneous biopsy. All women underwent excision. For all cases, the core biopsy reports were analysed for the presence of atypia, carcinoma in situ or invasive carcinoma. Any progression in histological grade from a lesion on initial biopsy to the surgically excised specimen was considered an upgrade. Data were statistically analysed with SPSS V.23.
Results: 185,766 women were screened and 91 pure RS were identified at percutaneous biopsy giving an incidence of 0.05%. 9 (10%) cases were upgraded to atypia, 8 (9%) cases were upgraded to DCIS and 7 (8%) cases were upgraded to invasive carcinoma giving an overall upgrade rate of 26%. Therefore, initial core biopsy has a sensitivity of 37% and specificity of 92%.
Conclusion: In patients with RS, the overall histological upgrade rate of 26% from percutaneous biopsy to surgical excision suggests that lack of invasion, DCIS or even atypia at biopsy does not help differentiate between RS that warrant excision versus those that may be managed more conservatively.

B-1090 11:02

Atypical ductal hyperplasia: our experience in the management and long-term clinical follow-up in 71 patients

L. Nicosia[1], A. Latronico[1], A. Faggian[2], C. Cannataci[3], S. Penco[1], E. Cassano[1]; [1]*Milan/IT*, [2]*Acerra/IT*, [3]*Msida/MT (lucanicosia88@gmail.com)*

Purpose: Atypical ductal hyperplasia (ADH) is a high-risk benign lesion found in approximately 1-10% of breast biopsies and associated with a variable incidence of carcinoma after surgical excision.The main goal of our study is to present our experience in the management and long-term follow-up of 71 patients with ADH diagnosed on breast biopsy.
Methods and Materials: Results of 3808 breast biopsy specimens from 1 January 2000 to 31 December 2005 were analysed to identify all biopsies which resulted in a diagnosis of ADH. The histopathological results of the 45 patients who underwent surgery were analysed. Long-term follow-up for the remaining patients was carried out.
Results: 45 of 71 (63.4%) patients with histological diagnosis of ADH on breast biopsy underwent surgery. Definitive histological results revealed invasive carcinoma in 7 ftucases (15.6%), high-grade ductal carcinoma in situ (DCIS) in 10 (22.2%) patients, lobular carcinoma in situ (LCIS) in 4 cases

(8.9%) and benign findings in 24 cases (53.3%). 12 of 71 (16.9%) patients underwent only long-term follow-up; one (8,3%) of these developed invasive breast carcinoma after 6 years.
Conclusion: Atypical ductal hyperplasia diagnosed on breast biopsy is associated with a relatively high incidence of invasive carcinoma and high-grade ductal carcinoma in situ at the time of surgical excision. Certain radiological and cytological criteria can be used to help determine which patients should forgo surgery and be followed up with good results. Long-term follow-up is always crucial for patients who have not undergone surgery.

B-1091 11:10

Intraductal papilloma without atypia in breast biopsies: rate of upgrades to carcinoma at excision and radiological features predictive of an upgrade

D. Leithner[1,2], B. Kaltenbach[1], C. Park[1], K. Pinker[2,3], P. Hoedl[1], F. Stephan[1], V. Moebus[1], T.J. Vogl[1], M.P. Müller-Schimpfle[1]; [1]*Frankfurt a. Main/DE*, [2]*New York, NY/US*, [3]*Vienna/AT (doris.leithner@googlemail.com)*

Purpose: While excision of atypical papilloma of the breast is mandatory, the management of intraductal papilloma without atypia (IDP) diagnosed with biopsy remains controversial. This study sought to investigate the rate of upgrade to carcinoma at surgical excision of IDPs, and identify clinical and radiological features predictive of an upgrade.
Methods and Materials: Patients with a core-needle or vacuum-assisted biopsy diagnosis of papilloma without atypia and surgical excision of this lesion at a breast centre between 2007 and 2017 were enrolled in the study. Cases with radiologic-pathologic discordance and history of breast carcinoma were excluded. Appropriate statistical tests were performed to correlate clinical characteristics and radiologic features with an upgrade to malignancy at excision.
Results: For 60 women with 62 surgically removed IDPs, the upgrade rate to malignancy was 16.1% (10 upgrades; 4 IDC, 6 DCIS). Vacuum-assisted biopsy was used for 14 IDPs, while 46 were sampled by core-needle biopsy. IDP with upgrade to carcinoma showed a significantly greater distance to the nipple than benign papilloma after excision (63.5 vs. 36.8, P=0.013). No significant associations were found between upgrade to carcinoma and age, menopausal status, lesion size, presence of microcalcifications, BI-RADS descriptors, initial BI-RADS category, and biopsy modality.
Conclusion: The upgrade rate at surgical excision for IDPs diagnosed with biopsy was 16.1%, suggesting that observation only might not be appropriate for all patients with a biopsy diagnosis of IDP. For patients with peripheral IDP, excision of the lesion should be considered.

B-1092 11:18

Imaging findings of papillary lesions of the breast with histopathologic correlation: a five-year study from Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán"

D. Lara Nuñez, P. Gonzalez Balboa, M. Chapa Ibargüengoitia, R.E. Fuentes Corona, F. Candanedo González, M. Licano Zubiate, K.P. Castro German; *Mexico/MX (dennylaran5@gmail.com)*

Purpose: To establish the radiologic characteristics of benign and malignant papillary lesions of the breast.
Methods and Materials: A descriptive, cross-sectional study was used to examine all patients who underwent percutaneous or excisional breast biopsy between July 2012 and July 2017 at Instituto Nacional de Ciencias Médicas y Nutrición “Salvador Zubirán. All radiologic and histopathological images where rechecked for the study.
Results: Of the 94 papillary lesions, 47.3% were intraductal papilloma, 33.3% intraductal papillomatosis, 11.8% micropapillary ductal carcinoma in situ and 7.5% papillary carcinoma. 24.7% corresponded to BIRADS 4A, 41.5% to BIRADS 4B, 16.8% to BIRADS 4C, 9% to BIRADS 5, and 7.8% to BIRADS 6. Of these lesions, only 17% were located in a retroareolar region. 66% of the lesions corresponded to nodules with an average size of 13 mm(± 7.8 SD) and 24.5% contained calcifications.
Conclusion: It is difficult to differentiate between benign and malignant papillary lesions by their appearance, this is why the final diagnosis is done with radiologic-pathologic correlation.

B-1093 11:26

Probably benign findings (BI-RADS 3) at breast MRI: frequency and malignancy rate

M. Iodice[1], V. Pittari[1], R.M. Trimboli[2], N. Berger[3], L.A. Carbonaro[2], F. Sardanelli[1]; [1]*Milan/IT*, [2]*San Donato Milanese/IT*, [3]*Zurich/CH (maiodice@gmail.com)*

Purpose: Retrospectively evaluate the frequency of BI-RADS3 lesions on breast MRI and determine the rate of malignancy in women at average, intermediate and high risk of breast cancer.
Methods and Materials: Consecutive breast MRI examinations performed from July 2010 to February 2017 were retrospectively reviewed to identify lesions prospectively assigned with BI-RADS3 category. Women with histopathology or a minimum 2-year imaging follow-up entered the analysis. Findings reported as BI-RADS3 were reviewed. The frequency of BI-RADS3 assessment, the rate of cancer and negative predictive value (NPV) were calculated. 95% confidence interval (CI) were calculated using the binomial distribution.
Results: A total of 682 women underwent breast MRI in the study period. 444 women who underwent MRI before March 2015 were considered for this study. 47 lesions in 38 women were assigned with BI-RADS3 category (38/444, 8.5%, 95% CI 0.1%-2.0%). Outcomes were available for 44 lesions in 36 women:19/44 (43%, 95%, CI 28.3%-59.0%) were biopsied, 8/44 (18%, 95%, CI 8.2%-32.7%) were operated, 17/44 (38.6%, 95%, CI 24.4%-54.5%) did not have evidence of malignancy at 22-81 months. Malignancy was found in 3/44 lesions (6.8%, 95% CI 1.4%-18.7%), in 2/36 women (5.5%, 95% CI 0.7%-18.7%). NPV was 93.2% (41/44 lesions%, 95% CI 81.3%-98.6%) and 94.4% (34/36 women, 95%, CI 81.3%-99.3%). There were one invasive ductal carcinoma (IDC) and 2 IDC with in situ component; they appeared on MRI as masses (n=2) and focus (n=1).
Conclusion: The rate of women who received a BI-RADS3 assessment at breast MRI was 8.5% with a cancer rate higher of 5.5%. Careful adherence to lesion criteria is necessary to maintain a low malignancy rate for BI-RADS category 3 lesions. The presence of a unique suspicious feature deserves an up-graded rating.

B-1094 11:34

Optoacoustic imaging increases the sensitivity of mammography and specificity of US: implications for practice

O. Abeyakoon[1], R.A. Woitek[2], M. Wallis[1], P.L. Moyle[1], S. Morscher[3], N. Malchus[3], R. Manavaki[1], I.A. Mendichovszky[1], J. Joseph[1], I. Quiros-Gonzales[1], S. Bohndiek[1], F.J. Gilbert[1]; [1]*Cambridge/UK*, [2]*Vienna/AT*, [3]*Munich/DE (oshi.creativity@googlemail.com)*

Purpose: Optoacoustic (OA) imaging fused with ultrasound (OPUS) can provide novel functional and anatomical information on breast tissue microenvironment. The aim of our study was to develop a clinically useful OA feature set to differentiate benign and malignant breast lesions and investigate its usefulness in image interpretation.
Methods and Materials: Female patients with benign, indeterminate or suspicious lesions were recruited from our institution’s symptomatic and breast screening clinics and imaged at 800nm (total haemoglobin wavelength) mapping vascularity. An OA imaging feature set was developed using the first 38 lesions. Features for malignancy were (1) irregular high signal lesion cap, (2) feeding vessel, (3) high signal rim and (4) claw sign; for benignity (1) splayed/displaced vessels sign and (2) absence of OA signal were used, in combination with the ultrasound BIRADS lexicon. Two radiologists (5 and 25 years breast-imaging experience) trained initially on feature set examples. They then independently, blindly and randomly scored the mammography, ultrasound and OA images of the remaining 44 lesions.
Results: Of 92 lesions, 10 were excluded due to technical errors. The feature set had 12 malignant and 26 benign lesions; the test set included 31 malignant and 13 benign lesions. Sensitivity pairs for readers 1 and 2 for mammography, US and OPUS were (90.3%, 90.3%), (96.5%, 96.5%) and (96.5%, 96.5%), respectively, with specificities of (71.4%, 71.4%), (53.8%, 46.1%) and (84.6%, 84.6%). The weighted Kappa inter-reader agreement was 0.91, 0.79 and 0.997 for mammography, US and OPUS.
Conclusion: Combining OA with US information has the potential to improve reader specificity and decrease biopsy rates.

B-1095 11:42

Phyllodes tumours of breast: histogram analysis of the apparent diffusion coefficient for assessment of tumour grade

W. Tang, Y. Zhang, J. Cheng; *Zhengzhou/CN (597744255@qq.com)*

Purpose: Investigating the value of histogram analyses of apparent diffusion coefficient (ADC) values for determining phyllodes tumour grades.
Methods and Materials: In all, 48 patients with phyllodes tumours (PTs) of breast included low-grade (Group 1; n = 30), intermediate-grade (Group 2; n = 12), and high-grade (Group 2; n = 6) tumours. Diffusion-weighted imaging (DWI) was performed in the axial plane. The ADC maps were generated, regions of interest were drawn on the middle section of lesion. Calculated histographic parameters included mean, 0.1th, 10th, 50th, 90th, and 99th percentiles of ADC, skewness, and kurtosis. Histogram parameters were correlated with tumour grade. We divided intermediate-grade and high-grade tumours into Group 2, low-grade tumours into Group 1. The parameters of two groups were calculated and the diagnostic performance for distinguishing different pathologic features was assessed.
Results: The ADC mean, 50th, 90th, and 99th percentiles of ADC, skewness showed significant differences among the two groups. The ROC analysis between low-grade, intermediate-grade and high-grade tumours showed that the 90th percentile ADC achieved the highest area under curve (AUC) at 0.806.

Conclusion: ADC histogram analyses are able to differentiate histologic grades of PTs.

B-1096 11:50

Variations in BI-RADS mammographic density classification between radiologists at three breast centres

T. Hovda[1], Å.S. Holen[2], H. Bjørndal[1], S. Sebuødegård[2], S. Hofvind[2]; [1]*Drammen/NO*, [2]*Oslo/NO (tone.hovda@vestreviken.no)*

Purpose: Mammographic density is a risk factor for breast cancer and may serve as a basis for implementation of stratified screening. We explored variations in mammographic density classification performed by radiologists at three breast centres in BreastScreen Norway.
Methods and Materials: The initial classification of mammographic density according to BI-RADS 5th edition (a-d) for a total of 1617 screening examinations was performed in consensus at three different breast centres by local radiologists. Subsequently, the same examinations were re-viewed and re-classified by a consensus panel of two radiologists from each centre. We used descriptive statistics to compare the initial and subsequent classifications of mammographic density.
Results: The initial density classification yielded the following distribution: a: 13%; b: 43%; c: 35%; and d: 9%, while subsequent classification resulted in the distribution a:12%; b: 45%; c: 32%; and d:12%. For classification a), the percentage of examinations classified in the same density category initially and subsequently was 64% (n=132), ranging from 39 to 92% among the three centres; for b): 76% (n=523, range 58-82%); for c) 52% (n=359, range 55-64%); and for d): 67% (n=98, range 59-89%). When grouping the density categories a+b and c+d, 88% (range 74-96%) initially classified as category a or b remained in category a or b, while 82% (range 80-92%) initially classified as c or d remained in category c or d.
Conclusion: Mammographic density classification is subject to great variability among radiologists. This makes comparisons demanding and may complicate the use of density as a factor for stratification of mammographic screening.

Preliminary clinical application of high-resolution MRI of the optic nerve using a small loop coil combined with head coil

Q. Dai[1,2], Z. Yang[2], G. Hong[2], L. Rao[2], M. He[2], P. Geng[2]; [1]*Shenzhen/CN*, [2]*Guangzhou/CN (dqunyaod@163.com)*

Purpose: To preliminary explore the clinical application of high resolution MRI of the optic nerve using a small loop coil combined with head coil.
Methods and Materials: 102 optic nerves from optic neuritis and optic nerve radiation injury patients from October 2015 to February 2017 were prospectively collected. Transverse, coronal and sagittal images of optic nerves were obtained using a loop coil combined with head coil (group A) and single head coil (Group B), respectively. Whole brain 3D enhanced scan and optic nerve reconstruction were also performed. Image quality was scored and images were analysed by two neuroradiologists. The non-parametric Wilcoxon-signed rank test was used to compare the difference of quality scores between group A and B, and $P<0.05$ was statistically significant. Compared with the gold standard, sensitivity and specificity of displaying optic nerve lesions using different coils were calculated.
Results: The difference of FS-T2W image quality scores between two groups was statistically significant ($P<0.05$) in three planes, and group A was better than group B. Sensitivity of displaying optic nerve lesions of group A was 86%, and specificity was 100%; while sensitivity of group B was 38.7%, and specificity was 88.9%.
Conclusion: High resolution MRI of the optic nerve using a small loop coil combined with head coil is suitable for clinical application and has certain clinical application value, with better image quality and higher sensitivity and specificity in displaying optic neuritis and optic nerve radiation injury, compared with conventional MRI using single head coil.

B-1098 10:38

Selection of coil for high-resolution MRI of the optic nerve

Q. Dai[1,2], Z. Yang[2], G. Hong[2], L. Rao[2], P. Geng[2]; [1]*Shenzhen/CN*, [2]*Guangzhou/CN (dqunyaod@163.com)*

Purpose: To compare MR image quality of the optic nerve using a small loop coil combined with head coil, single head coil, and single small loop coil to choose the best coil for high-resolution MRI of the optic nerve.
Methods and Materials: Imaging was performed on 12 healthy volunteers with a 3.0T MR scanner using single 7-cm-diameter loop coil (group A), single head coil (group B) and a combination of these 2 coils (group C). Transverse, coronal and sagittal images of optic nerves were obtained. 3 groups of images were independently reviewed and scored according to an image quality scoring criterion by 2 neuroradiologists. The Kappa test, paired $\chi 2$ test and nonparametric Wilcoxon signed rank test were used. $P<0.05$ was statistically significant.
Results: 24 optic nerves were included. Group A can only display part of the intraorbital optic nerve and no quality scoring was performed. The Kappa values of scores of group B and C between the 2 radiologists were 0.880, 0.778, 0.600; 1.000, 0.882, 0.619, respectively. There was no significant difference between the scores by the 2 radiologists ($P>0.05$). Scores of transverse, coronal and sagittal FS- T2WI of group B and C were 2.250±0.909, 1.250±0.417, 2.521±0.499; 3.750±0.442, 3.771±0.417, 3.875±0.304. The difference between the two groups was statistically significant ($P<0.05$), with group C better than B.
Conclusion: Optic nerve MRI using a small loop coil combined with head coil is better than using single head coil or single small loop coil and can display the whole optic nerve with high resolution.

B-1099 10:46

The impact of trigeminal nerve atrophy and vascular compression on outcomes of trigeminal neuralgia after stereotactic radiosurgery

Y.-S. Hu, C.-C. Lee, W.-Y. Guo, C.-J. Lin, H.-C. Yang, H.-M. Wu, K.-D. Liu, W.-Y. Chung; *Taipei/TW (sam6526@hotmail.com)*

Purpose: Trigeminal nerve atrophy and neurovascular compression (NVC) are frequently observed in symptomatic nerves of classical trigeminal neuralgia (TN). The purpose of this study was to determine whether these nerve characteristics on MRI contribute to gamma knife surgery (GKS) outcomes in classical TN.
Methods and Materials: From 2006 to 2012, 67 patients of unilateral classical TN without previous surgery received GKS with a maximal dose of 90 Gy delivering to the trigeminal nerve proximal to the brainstem. Two evaluators, blinded to the side of pain, analysed the MRI before GKS to obtain the parameters, including proximal nerve cross-sectional area (CSA), vessel type of NVC, and site of NVC along the nerve. Correlations of the parameters with pain relief (Barrow Neurologic Institute [BNI] Grades I-IIIb) and pain recurrence (BNI Grades VI-V) after GKS were made using Cox regression and Kaplan-Meier analyses.
Results: The median CSA of the symptomatic nerves was significantly smaller than that of asymptomatic nerves (4.95 mm^2 vs 5.9 mm^2, $p<0.001$). After adjustment for age and sex, only the nerve CSA was predictive of initial pain relief (hazard ratio 0.81, $p=0.032$) and pain recurrence (hazard ratio 0.58, $p=0.028$) after GKS. Patients with nerve atrophy (defined as CSA≤4.4 mm^2) had a lower 5-year probability of maintaining pain relief than those without nerve atrophy (65% vs 86%, $p=0.044$).
Conclusion: Trigeminal nerve atrophy may predict pain recurrence in classical TN after GKS. Future studies are required to determine optimal treatment for long-term pain relief in classical TN with nerve atrophy.

B-1100 10:54

Measurement of normal optic nerve sheath diameter and nerve diameter on high resolution MRI

Q. Dai[1,2], Z. Yang[2]; [1]*Shenzhen/CN*, [2]*Guangzhou/CN (dqunyaod@163.com)*

Purpose: To measure normal optic nerve sheath diameter (ONSD) and nerve diameter (OND) on high resolution MR images using a small loop coil combined with head coil.
Methods and Materials: 33 normal optic nerves underwent MR scanning using a small loop coil combined with head coil. ONSD and OND (transverse and superior inferior) at levels 3, 6, 9, 12, 15, 18, 21mm after the eyeball were measured on coronal FS-T2W images. Nonparametric Wilcoxon signed rank test was used to compare transverse and superior inferior diameters on the same level, and Friedman test was used to compare diameters among different levels.
Results: (1)Transverse and superior inferior ONSD and OND on coronal images was statistically different ($P<0.05$) on levels 3, 6, 9mm after the eyeball. There was no statistical significance in difference between transverse and superior inferior ONSD and OND on levels 12, 15, 18, 21mm ($P>0.05$). (2) Difference of ONSD among levels 3, 6, 9mm was statistically significant

(P<0.001, both transverse and superior inferior). There was no statistical significance in difference of OND among levels 3, 6, 9mm (*P*>0.05), while OND among levels 3, 6, 9, 12mm was statistically different (*P*<0.05). No significant difference was in ONSD among levels 12, 15, 18, 21mm (*P>0.05*), similarly in OND (*P*>0.05).
Conclusion: Normal optic nerve shows oval on levels 3-9mm after the eyeball and nearly circular on levels 12-21mm on coronal plane. Subarachnoid space on levels 3-9mm decreases gradually. Consistent results of ONSD and OND among different levels can be obtained on levels 12-21mm.

B-1101 11:02

Diagnostic efficiency of ultrasonography in case of peripheral nerve traumatic injuries

E. Zhurbin, A. Gayvoronskiy, I. Zheleznyak, V. Dekan; *St. Petersburg/RU (Zhurbin-90@mail.ru)*

Purpose: To estimate the use and diagnostic efficiency of ultrasonography in case of peripheral nerve traumatic injuries.
Methods and Materials: The research includes 154 patients with post-traumatic peripheral nerve neuropathy. All patients underwent ultrasonography on the expert class machine with the linear transducer with frequency range of 5 to 15 MHz. For ultrasonography efficiency evaluation, a statistical analysis of sensibility, specificity and accuracy was used, by the procedure of a referential (surgical interference or positive conservative treatment) and studied method (ultrasonography) qualified assessment.
Results: It was discovered that ultrasonography is an efficient diagnostic method for peripheral nerve traumatic injuries. It allows assessesing injury localisation and the type to the full extent and to decide on further treatment tactics. According to ultrasonography results, 122 patients were operated and 32 patients treated conservatively. After comparative analysis of pre-operative ultrasonography data with the changes detected during the surgical interference and the results of conservative treatment, the diagnostic efficiency of ultrasonography in case of limb peripheral nerve traumatic injuries was estimated.
Conclusion: Ultrasonography is an efficient diagnostic method for limb peripheral nerve traumatic injuries . Ultrasonography with a sensitivity of 93,6% and specificity of 68,2% allows to detect injuries which always demand surgical interference, or prove the nerve trunk anatomical integrity, which does not demand a surgery as the injury appears to be reversible. The accuracy of ultrasonography is 86,4%, which makes it one of the leading methods of the given pathology diagnostics.

B-1102 11:10

Opportunities for the combined use of ultrasonography and neuromonitoring during the intra-operative phase of ultrasound guidance for the surgical treatment of radial nerve injury

V. Dekan, E. Zhurbin, A. Grishchenkov; *St. Petersburg/RU (dekanvs@mail.ru)*

Purpose: To assess the opportunities for the use of ultrasonography and neuromonitoring for ultrasound guidance during radial nerve surgical treatment.
Methods and Materials: A combination of ultrasound and neuromonitoring was applied to 37 patients during surgical treatment of radial nerve injuries. The research included patients with post-traumatic neuropathy of varying severity levels and duration.
Results: Intra-operative ultrasonography reduces operational trauma by 25% on average in each case, due to application of neurolysis from the nerve trunk injury in the direction of native anatomical structures and ending within the cicatricial adhesion. In five cases of radial nerve neurotmesis, proved visually afterwards, applying neuromonitoring in the nerve proximity test mode led to exposure of the safe muscular branches of the brachioradialis muscle, which were situated in the cicatricial conglomerate of the modified tissue and did not come in sight of the ultrasound detector. In the closing stage of neurolysis, due to the use of ultrasonography combined with neuromonitoring, in four cases an intrastem neuroma, undiscovered during the pre-operative percutaneous diagnostics, was detected.
Conclusion: The use of ultrasonography and neuromonitoring represents the opportunity of nerve trunk direct visualization and simultaneous nerve conduction assessment, which leads to a reduction in operational trauma and the number of early post-operative complications. It helps to increase the patient rehabilitation tempo. Intra-operative ultrasonography and neuromonitoring measurements are able to give a qualified failure mode assessment of all the nerve trunk structures and allows choosing more efficient and less traumatic surgical treatment tactics.

B-1103 11:18

Preliminary application study of optic nerve DTI in non-neoplastic lesions

Q. Dai[1,2], Z. Yang[2], G. Hong[2], L. Rao[2]; [1]*Shenzhen/CN*, [2]*Guangzhou/CN (dqunyaod@163.com)*

Purpose: To analyze DTI findings of normal optic nerve and measure normal ADC and FA values to offer reference for clinical application, and to explore clinical application value of DTI in non-neoplastic lesions of the optic nerve.
Methods and Materials: DTI was prospectively performed on 24 normal optic nerves and 73 optic nerves with non-neoplastic lesions from October 2015 to February 2017 using 3.0T MR scanner. Signal characteristics were observed and ADC, FA values were measured respectively. The difference of values between normal and lesion group was compared using independent sample t test. Ability of ADC and FA value in displaying non-neoplastic lesions was analyzed with ROC curve.
Results: Normal optic nerves showed slightly low signal on ADC maps and high signal on FA maps. Normal ADC value ($\times 10^{-3}mm^2/s$) was 1.102±0.202, and FA value was 0.540±0.073. Signal of lesions slightly increased on ADC maps and decreased on FA maps. ADC value of lesion group significantly increased (*P*=0.03), and FA value significantly decreased (*P*<0.001). Area under the ROC curve of ADC was 0.642, and that of FA was 0.768. When the cut-off point of FA value was ≤0.4827, Youden index being the biggest, sensitivity was 64.4% and specificity was 87.5%.
Conclusion: Normal optic nerve shows slightly low signal on ADC maps and high signal on FA maps. Signal of non-neoplastic lesions slightly increases on ADC maps and decreases on FA maps, with ADC value increasing and FA value decreasing. In displaying non-neoplastic lesions of the optic nerve, FA value is better.

B-1104 11:26

High-resolution MRI findings of the normal optic nerve using a small loop coil combined with head coil

Q. Dai[1,2], Z. Yang[2], L. Rao[2], G. Hong[2], P. Geng[2]; [1]*Shenzhen/CN*, [2]*Guangzhou/CN (dqunyaod@163.com)*

Purpose: To observe the morphology and signal characteristics of normal optic nerve on high-resolution MR images and analyse the anatomical and histological basis.
Methods and Materials: 33 normal and 2 cadaveric optic nerves underwent MR scanning using a small loop coil combined with head coil. The cadaveric optic nerves were separated and pathologically examined. The morphology and signal characteristics of the optic nerves were analysed by two neuroradiologists, and those of the cadaveric optic nerves were observed and compared with the histological findings.
Results: 31 normal optic nerves (2 were abandoned because of obvious artefact) and 2 cadaveric optic nerves were included. The normal optic nerve was round and showed mixed isointensity and hypointensity surrounded by hyperintense subarachnoid space on coronal FS-T2WI and elongated isointensity on transverse and sagittal FS-T2WI, and the optic nerve sheath showed hypointensity. MRI findings of the cadaveric optic nerves were similar, and histology showed that the optic nerve fibers were separated into bundles by connective tissue including vessels. Compared with MRI, the optic nerve fibers showed isointensity and septae showed hypointensity.
Conclusion: High-resolution MRI of the optic nerve using a small loop coil combined with head coil can show the anatomical details and signal characteristics on coronal images. The normal optic nerve is round and shows mixed isointensity and hypointensity similar to a chessboard on high-resolution coronal T2WI, which is consistent with cadaveric optic nerve MR findings and relative to nerve bundles and connective tissue septae in histology.

B-1105 11:34

Automated three-dimensional detection of dural ectasia in Marfan syndrome by means of isotropic MRI and shape-based machine learning

F. Rengier[1], O. Naas[1], T. Norajitra[1], M. Messerli[2], K. Kallenbach[1], M. Karck[1], K. Maier-Hein[1], H.-U. Kauczor[1]; [1]*Heidelberg/DE*, [2]*Zurich/CH (fabian.rengier@web.de)*

Purpose: To investigate automated three-dimensional detection of dural ectasia in Marfan syndrome using isotropic MRI and shape-based machine learning.
Methods and Materials: 211 patients being evaluated for Marfan syndrome during 2012-2016 underwent MRI including single slab 3D T2-weighted TSE sequence of the lumbosacral spine with a spatial resolution of 1x1x1mm in 5:06 min. A random sample of 40 patients (32.5±11.2 years, 22 female) was included, thereof 21 patients diagnosed with Marfan syndrome according to the 2010 Revised Ghent Nosology. A shape-based machine learning algorithm was developed for 3D segmentation of dural sac and vertebral bodies L4, L5 and S1. For comparison with current clinical standard, anteroposterior diameters of vertebral bodies and dural sac were assessed at mid-level

between the superior and inferior endplates and dural sac diameter ratios were calculated.
Results: Dural sac volumes for Marfan patients/controls were in ml: at L4 10.8±2.9/7.5±1.1 (p=0.013), L5 9.2±3.5/5.7±1.2 (p<0.001), and S1 10.2±8.4/3.3±1.3 (p<0.001). Sensitivity, specificity, positive predictive value and negative predictive value for diagnosis of Marfan syndrome were: for 3D segmentation using L4 >9.1ml or S1 >5.6ml as cut-off 81%/94%/94%/80%, for criteria of Habermann et al. 71%/65%/71%/65%, for criteria of Oosterhof et al. 57%/88%/86%/63%, and for dural sac diameter ratios with highest AUC 67%/94%/93%/70%. The false-positive rate was reduced to 6% using 3D segmentation compared to 35%/12% using criteria of Habermann/Oosterhof et al., respectively.
Conclusion: Automated three-dimensional detection of dural ectasia using isotropic MRI and shape-based machine learning is feasible and potentially superior to the current clinical standard of dural sac diameter ratios.

B-1106 11:42

The role of diffusion tensor imaging parameters in characterisation and differentiation of the spinal cord tumours
B. Szemplinska[1], E. Maj[2], W. Szeszkowski[2], M. Prokopienko[1], A. Cieszanowski[2], A. Marchel[2], O. Rowinski[2]; [1]*Warszawa/PL*, [2]*Warsaw/PL* *(bszemplinska@yahoo.com)*

Purpose: The aim of this study was to differentiate between infiltrating and and non-infiltrating nature of the intramedullary spinal tumours using diffusion tensor imaging (DTI) derived metrics from the enhancing parts of tumour and peri-tumoural regions.
Methods and Materials: 18 patients were included in the study: 6 with infiltrating (3 Astrocytomas, 2 Glioblastomas, 1 PNET) and 12 with non-infiltrating (Ependymomas) spinal cord tumours. Conventional MRI before and after IV Gadolinium administration was done followed by DTI. Fractional anisotropy (FA), diffusivity (TRACE) and apparent diffusion coefficient (ADC) were measured in the enhancing tumour parts, peritumoural margin (oedema most adjacent to the tumour), peritumoural oedema and normal-appearing spinal cord (24 DTI values per patient). ROI of a fixed size of 0.15 cm2 was used in all measurements. The results were compared between the two groups of tumours.
Results: FA values measured in the peritumoural margin were significantly higher in the non-infiltrating compared to the infiltrating tumours (p<0,007), whereas TRACE values were significantly lower (p<0,009). The differences were smaller in peritumoural oedema (p<0,03 and p<0,04 respectively). FA values measured in the enhancing tumour parts and in normal-appearing spinal cord showed no significant differences between the two groups of tumours.
Conclusion: The information provided by DTI may be used to help differentiate between infiltrating and non-infiltrating intramedullary spinal tumours by characterisation of surrounding spinal cord tissue. Our preliminary results showed that this technique, applied previously for the imaging of brain tumours, could also improve the preoperative assessment of spinal cord lesions.

B-1107 11:50

Three years of experience with magnetic resonance spectroscopy in spinal cord
P. Wawrzyniak, A. Hebda, B. Bobek-Billewicz; *Gliwice/PL* *(pawel.wawrzyniak@io.gliwice.pl)*

Purpose: Usefulness of MRS of spinal cord-own experience.
Methods and Materials: 1H MRS of spinal cord was performed in 44 patients with spinal cord lesion between 09.2014 and 09.2017 (total of 55 studies). Spinal cord lesions were localized: 42/55 in C spine, 3/55 in C-Th ,10/55 in Th. Mean lesion volume was 1.75 cm3. 8 patients had resection done with 5 cases of ependymoma 2 cases of pilocytic astrocytoma and one case of hemangioblastoma. Patients were divided into groups: presumed neoplastic lesion (n=28, 36 studies), proven tumours (n=8, 11 studies) and presumed non-neoplastic lesion (n=8, 8 studies). All spectra were analyzed in LCModel (version 6.1-4F) software. Spectra was deemed good quality when LCModel calculated SNR was above 1. Metabolite ratios were calculated as follows: Cho/Cr, NAA/Cr, Cho/NAA for long echo time and ml/Cr for short echo. 1H MRS study of spinal cord was performed on Siemens 3T MAGNETOM Prisma as a part of standard spinal cord imaging protocol. Sequence parameters: SVS PRESS; TE 30 and 135 ms; NEX, respectively, 256 and 320, FA 90°; water signal saturation; TR 1700 ms ;total acquisition window: 2000 ms.
Results: There was no statistically significant difference between these groups. From total of 110 spectra 57 were of good quality.
Conclusion: Spinal cord spectroscopy is very demanding technique for both patient and operator. No reference spectra was taken into account in this study which might help with proper evaluation, however, it is too time consuming for standard protocol

Apparent diffusion coefficient at 3T MRI in differentiating benign and malignant breast lesions: a quantitative analysis
P. Gupta, M. Popli, K. Diwan; *New Delhi/IN (dr.pranavg@gmail.com)*

Purpose: The purpose of this research work was to establish role of quantitative assessment of apparent diffusion coefficient (ADC) in distinguishing benign breast lesions (BBL) from malignant breast lesions (MBL).
Methods and Materials: In a cross sectional study from September 2013 to August 2016, 200 patients with palpable or mammographically detected breast lesions underwent 3T MRI. Of these, 120 patients with 126 lesions underwent specimen histologic examination and were included in the study for retrospective analysis. ADC values were calculated at b values of 0, 400 and 800 s/mm² after identification of maximally enhancing component on dynamic contrast enhanced images. ADC value and histopathology correlation was then done using appropriate statistical tools.
Results: Of the 126 lesions, 84 lesions were malignant and 42 were benign on histopathology. The mean ADC value varied significantly (p value < 0.01) between BBL ($1.52 \pm 0.45 \times 10^{-3}$ mm^2/s) and MBL ($0.98 \pm 0.21 \times 10^{-3}$ mm^2/s). An ADC cut-off value of 1.2×10^{-3} mm^2/s for MBL was calculated by drawing ROC curve and it achieved a sensitivity of 92.9% and specificity of 81%. The study showed a sensitivity of 94%, specificity of 83.3%, positive predictive value (PPV) of 91.8% and negative predictive value (NPV) of 87.5% upon using ADC cut off value 1.2×10^{-3} mm^2/s.
Conclusion: Diffusion weighted imaging (DWI) along with quantitative ADC value proves to be an effective complimentary parameter in differentiating MBL from BBL and needs to be integrated into the diagnostic algorithm of breast lesions.

B-1109 10:38

High reproducibility of breast lesion ADC values based on fixed size and shape region of interest in diffusion-weighted imaging
M. Wielema, M. Dorrius, H. Dijkstra, E. Langius, G. De Bock, M. Oudkerk, P. Sijens; *Groningen/NL (m.wielema@umcg.nl)*

Purpose: To evaluate three fixed-size region of interest (ROI) methods and the largest oval ROI positioned within breast lesions, in apparent diffusion coefficient (ADC) analysis of diffusion-weighted imaging (DWI) data.
Methods and Materials: Included were 98 consecutive women with 110 lesions (95 malignant) undergoing breast DWI between 11/2008 and 06/2014. Reproducibility of three smaller fixed-size circular ROIs in the middle of each lesion (ROI_2, 0.3 cm^2) and at lowest ADC (ROI_3, 0.3 cm^2; ROI_4, 0.6 cm^2) was compared with maximum oval ROI positioned within the lesion contours (ROI_1). ROIs were positioned by three independent observers at the largest cross section on the T1-weighted image and copied to the DW images, using b values 0 and 1000 s/mm^2 to obtain ADC maps. Intraclass-correlation coefficients (ICCs) were calculated to evaluate intra-and inter-observer agreement for each ROI method. ROC analysis was performed.
Results: Inter- and intra-observer ICCs were strong (0.80-0.94) in ROIs 2-4, and similar to ROI_1 (0.82-0.90). Highest agreement between observers (0.84-0.94) and highest accuracy (0.80) was reported for ROI_4.
Conclusion: Breast lesion ADCs derived from fixed-size subregion ROIs are highly reproducible. The proposed user-friendly methodology is equal or better in clinical performance as compared with whole lesion assessment, as assessed by ROC analysis and false-positive outcomes.

B-1110 10:46

A comparative study of the DKI model and the traditional DWI model in the diagnosis of breast cancer
T. Li, K. Li, Y. Xiong; *Shanghai/CN (kanganli@sina.com)*

Purpose: To compare the value of the diffusion kurtosis imaging model with the traditional single-index diffusion-weighted imaging model parameters in the differential diagnosis of breast lesions.
Methods and Materials: 64 cases of breast lesions were examined by DKI (b = 0,500, 1000, 1500, 2000, 2500, 3000 s/mm^2) and traditional DWI (b = 0, 1000 s/mm^2). The diagnostic efficacy of the DKI parameters (MK and MD) and the traditional DWI parameters (ADC) in benign and malignant breast lesions

was compared, and the correlation between MK, MD and ADC values and the prognostic factors of breast cancer was analysed.
Results: The difference of MK, MD and ADC between the benign and malignant groups was statistically significant (P <0.05).The area under the ROC curve of MK, MD and ADC was 0.897, 0.827 and 0.776, respectively. According to the Youden index, the sensitivity, specificity and accuracy of the MK were 83.3%, 85.3% and 84.4%, respectively. The combination of the three parameters could increase the AUC to 0.935. The MK of ER-positive lesions was higher than negative (P = 0.024). The correlation analysis showed that ER was low positively correlated with MK (r = 0.417, P = 0.022), and there was no significant correlation between the other prognostic factors and the parameters (P> 0.05).
Conclusion: The parameters of the DKI model and the traditional DWI model can be used to differentiate benign from malignant breast lesions. The diagnostic value of MK in the DKI model is the largest. There is a certain correlation between the DKI model parameters and the prognostic factors.

B-1111 10:54

Preoperative diagnostic value of DKI combined with quantitative dynamic contrast-enhanced MRI in breast lesions
T. Li, Y. Xiong, K. Li; *Shanghai/CN (kanganli@sina.com)*

Purpose: To evaluate the diagnostic efficacy of MRI diffusion kurtosis imaging and quantitative dynamic contrast enhancement in benign and malignant breast lesions.
Methods and Materials: Sixty-four females were enrolled in the study of MRI diffusion kurtosis imaging and quantitative dynamic contrast enhancement between November 20 and 2017 in May, respectively. All of them were confirmed benign and malignant after surgical resection or puncture. The MK and MD values were calculated by the DKI model, and the hemodynamic parameters were obtained by quantitative dynamic contrast enhancement, including Ktrans, Kep, Ve and Vp.
Results: The MK and MD values of breast cancer were 0.879±0.176 and 1.248±0.380*$10^{-3}$$mm^2$/s respectively in the DKI model. The MK and MD values of benign lesions were 0.577±0.142 and 1.792±0.505*$10^{-3}$$mm^2$/s , the difference was statistically significant (P <0.05). In the DCE model, the Ktrans and Kep mean values of breast cancer were 0.101 ± 0.039min^{-1} and 0.398 ± 0.194 min^{-1}, respectively. The mean values of Ktrans and Kep of benign lesions were 0.062 ± 0.067 min^{-1} and 0.210 ± 0.121 min^{-1}, respectively. The difference was statistically significant (p <0.05), and the other DCE parameters were not statistically significant. The highest sensitivity, specificity and accuracy of MK in all parameters were 91.3%, 80.5% and 84.4% respectively.
Conclusion: MRI diffusion kurtosis imaging and dynamic contrast-enhanced quantitative hemodynamic parameters are of great value in the differential diagnosis of benign and malignant breast lesions. The combination of both can significantly improve the diagnostic efficiency.

B-1112 11:02

Non-mass-like enhancement in MR imaging of the breast: lesion characterisation with morphologic criteria and diffusion-weighted imaging
W. Buchberger, K. Gautsch, W. Oberaigner; *Innsbruck/AT (wolfgang.buchberger@tirol-kliniken.at)*

Purpose: The purpose of this study was to assess the accuracy of contrast-enhanced magnetic resonance imaging and diffusion weigthed imaging in distinguishing benign from malignant non-mass-like breast lesions.
Methods and Materials: 76 lesions showing non-mass-like enhancement in 74 consecutive patients were analyzed. Distribution, internal enhancement patterns, and contrast kinetic curve patterns were classified according to the BI-RADS lexicon. Apparent diffusion coefficient (ADC) values were obtained from manually placed ROIs on diffusion weighted images. Univariate and multivariate analysis was performed to find indicators for malignancy. The probabibiliy of malignancy was calculated for various combinations of findings. Histological diagnosis obtained by means of vacuum-assisted core biopsy was used as gold standard.
Results: Clumped enhancement (p= < 0.001), heterogeneous or clustered ring enhancement (p=0.031), and ADC less than 1.3 x $10^{-3}$$mm^2$/s (p=0.028) were the strongest indicators of malignancy. Non-mass lesions with homogeneous internal enhancement and ADC values more than 1.3 x $10^{-3}$$mm^2$/s had a probability of malignancy of 5%, while all other combinations of findings had a probability of malignancy of 31- 85%.
Conclusion: The combination of internal enhancement characteristics and ADC showed a high accuracy in the characterization of non-mass-like lesions in contrast-enhanced breast MR imaging.

B-1113 11:10

DTI of the breast: is it worth the hassle?
W.R.A. Abdel Hamid; *Cairo/EG (w.gforever@yahoo.com)*

Purpose: The aim of this study is to assess the role of diffusion tensor imaging in characterization of equivocal breast lesions.
Methods and Materials: 30 female patients with 36 equivocal breast lesions were subjected to an MR study including T2W, STIR, DTI and dynamic post contrast study. DTI maps including direction, ADC and FA maps were assessed both qualitatively and quantitatively. All lesions were biopsied and verified histopathologically.
Results: The mean acquisition time of DTI was 14 min and its mean post processing time was 22 minutes. Based on histopathology the 36 lesions were 21 benign and 15 malignant. Based on time/intensity curves, 20 were considered suspicious with types IIb and III curves, while 16 were considered benign with types I and IIa curves with 7 false positive lesions and 2 false negative. Addition of DTI significantly improved the accuracy of characterization with only 2 false positive lesions and only 1 false negative with a sensitivity of 94.12% and specificity of 89.47%. Direction map proved beneficial in overcoming the pitfalls of ADC and FA value overlaps between benign and malignant entities.
Conclusion: Although DTI requires long acquisition and post processing times, yet our initial results are promising warranting further research over a larger scale of patients to confidently establish it as a diagnostic tool that can replace contrast and reduce the need for unwanted biopsies.

B-1114 11:18

Comparison of FOCUS (field-of-view optimised and constrained undistorted single-shot)-DWI with standard DWI-MRI and DCE-MRI in the qualitative assessment of breast lesions
L. Vassallo, V. Doronzio, G. Cappello, E. Tabone, D. Regge, L. Martincich; *Candiolo/IT (lorenzo.vassallo1987@libero.it)*

Purpose: To compare the performance of FOCUS-DWI with standard DWI-MRI and DCE-MRI in detecting breast lesions.
Methods and Materials: 50 consecutive women undergoing pre-surgical breast MRI from January to December 2016 were enrolled in the study. Exams were carried out with 1.5T magnet and dedicated 8-channel coil following the recommended technical requirements. FOCUS-DWI was performed on the axial plane with limited shimming to the rectangular area target. DCE-MRI was considered as the standard reference. The type (mass and non-mass) of each suspicious lesion detected at DCE-MRI was evaluated and then compared to similar findings identified at both standard DWI-MRI and FOCUS-DWI. The diagnostic confidence of FOCUS-DWI and DCE-MRI was compared by the following point scale: +1 (FOCUS-DWI > DCE-MRI), 0 (equal) and -1 (FOCUS-DWI < DCE-MRI). The same evaluation was performed between FOCUS DWI and standard DWI.
Results: DCE-MRI identified 59 malignant pathologically proven lesions, 48 mass and 11 non-mass (size range 6-90mm). All the lesions were correctly detected at standard DWI. 5 lesions (all mass; size range 7-15 mm) were not identified at FOCUS-DWI. In no case, diagnostic confidence with FOCUS-DWI was higher than that with DCE-MRI, while it was comparable in only 10/54 cases (18%). The diagnostic confidence between FOCUS-DWI and standard DWI was higher in 37% of cases (20/54), similar in 28% (15/54) and worse in 35% (19/54).
Conclusion: Our series shows that FOCUS-DWI has potential clinical utility since it can identify 85% of suspicious breast lesions. Because of better spatial resolution, FOCUS-DWI reached higher diagnostic confidence when compared with standard DWI-MRI.

B-1115 11:26

Breast MRI: circularity metrics in mass shape assessment of benign and malignant breast tumours
M. Nadrljanski, Z. Milosevic; *Belgrade/RS (dr.m.nadrljanski@gmail.com)*

Purpose: Mass shape metrics on breast MRI include parameters of tumour geometry reflecting the lesion growth pattern. Differences between benign and malignant breast masses in terms of circularity metrics (tumour ellipticity, linear eccentricity, tumour area surface, tumour volume, circulatory ratio, compactness, circularity, Cmax value) were tested in order to define the significance and potential use for better mass shape characterisation and differentiation between benign and malignant lesions.
Methods and Materials: Thirty histologically confirmed mass lesions were evaluated with MRI (1.5T) - benign tumours (n1=15) and carcinoma (n2=15) for the circularity parameters, which were computed and visualised in 3D, based on the mathematical expressions (volume, ellipticity, linear eccentricity, circulatory ratio, compactness, Cmax value) and (in)complete elliptic integrals (circumference assessment, surface area definition).
Results: Difference in linear eccentricity proved to be highly statistically significant between benign and malignant lesions (6.91+/-1.81 vs. 12.39+/-

3.75, p=0.0001). The same applied to tumour compactness (0.42+/-0.08 vs. 0.27+/-0.07, p=0.001) and Cmax value (0.96+/-0.02 vs. 0.82+/-0.12, p=0.001). Ellipticity was not considered highly significant in differentiation between benign and malignant mass lesions (0.65+/-0.09 vs. 0.56+/-0.18, p=0.04). Expectedly, linear eccentricity and compactness were considered correlated only in benign lesions (r=0.79, p=0.0004) and ellipticity and compactness only in malignant lesions (r=0.54, p=0.038).
Conclusion: Computed parameters of circularity metrics in mass shape assessment on breast MRI (tumour compactness, Cmax value and linear eccentricity), enabled binary classification: benign vs. malignant mass lesion. Possible compound mass-shape-score may be of help in better mass shape assessment, should the results of larger trials support these preliminary data.

B-1116 11:34

Background parenchymal enhancement at breast magnetic resonance imaging: association with tumour response to neoadjuvant chemotherapy

E. Horvath, E.H. Castillo Balladarez, C. Silva, C. Darrás, M. Uchida, M.A. Pinochet, A. Altamirano, E. Droguett, C. Galleguillos; *Santiago/CL (eliette88@hotmail.com)*

Purpose: Analyse neoadjuvant chemotherapy (NAC) effect on breast MRI background parenchymal enhancement (BPE). Determine association between BPE changes and tumour response.
Methods and Materials: IRB-approved, analytic retrospective study. All breast cancer patients who underwent NAC and had pre-treatment and follow-up 3T MRI studies between December 2013 and September 2017 were included. BPE was analysed on subtraction images and axial and sagittal MIP images, and categorised with BI-RADS lexicon. Tumours were classified according to histology as invasive ductal carcinoma (IDC) or invasive lobular carcinoma (ILC) and grouped by immunohistochemical (IHC) subtype: Luminal A, Luminal B, HER-Luminal (HL), HER2-enriched and Triple negative (TN). Imaging response was evaluated using *RECIST* 1.1 criteria.
Results: 40 patients were included, mean age of 47 ± 9.9 years, 67,5 % were premenopausal. Histopathological analysis revealed 37 cases of IDC, two ILC and one IDC+ILC. IHC assessment showed 12 TN, 10 Luminal A, 10 Luminal B and 8 (HL). There was a global reduction of BPE after NAC in all subgroups, larger in premenopausal women (Pv= 0.01). TN and HL had higher initial BPE, and postmenopausal patients had an OR of 6.4 for having a mild BPE prior to NAC. 32,5% of patients had complete imaging response. A prior absent-mild BPE, IDC tumour or Luminal A/B IHC subtype were associated with higher OR for partial tumour response (OR 1.8, 2 y 5.7, respectively), although only IHC subtype reached statistical significance.
Conclusion: Decrease in BPE signal after NAC may be used as a predictive factor of tumour response.

B-1117 11:42

Ultra-high field dynamic contrast-enhanced MRI (DCE-MRI) of the breast at 7T with pharmacokinetic (PK) modeling accurately differentiates between benign and malignant breast tumours

R.E. Ochoa Albíztegui[1], J.V. Horvat[1], S. Thakur[1], B. Bernard-Davila[1], S. Trattnig[2], T.H. Helbich[2], E.A. Morris[1], K. Pinker[1]; [1]*New York, NY/US*, [2]*Vienna/AT (eochoa.albiztegui@gmail.com)*

Purpose: To investigate whether ultra-high field dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) of the breast at 7T with pharmacokinetic (PK) modeling using the quantitative biomarkers can be used for differentiation of benign and malignant tumors.
Methods and Materials: Thirty-seven patients with 43 lesions with a suspicious imaging finding on mammography or sonography were included in this IRB-approved study and underwent DCE-MRI of the breast at 7T using a high spatial and temporal resolution sequence (spatial resolution of 0.7 mm3 voxel size, temporal resolution of 14 s). Quantitative PK imaging biomarkers (KTrans & kep) were assessed using the DCE-Tool OsiriX plugin (http://kyungs.bol.ucla.edu/software/DCE_tool/DCE_tool.html). A whole tumor 2D-ROI (wtROI) and a 10mm standardized 2D-ROI (sROI) were manually drawn by two readers independently in the slice with the maximum lesion diameter and the most enhancing part of the lesion. Appropriate statistics were used to assess inter-rater agreement.
Results: Mean (μ) and standard deviation ($\sigma_{\bar{x}}$) for KTrans of malignant lesions for wtROI and sROI were μ=0.322 ($\sigma_{\bar{x}}$=0.14), μ=0.379 ($\sigma_{\bar{x}}$=0.126) respectively. Kep of malignant wtROI and sROI was μ=0.553 ($\sigma_{\bar{x}}$=0.508), μ=0.613 ($\sigma_{\bar{x}}$=0.50) respectively. KTrans for malignant and benign lesions were significantly different in the wtROI (p=0.0070) and sROI (p=0.0023). Kep for malignant and benign lesions were also significantly different in the wtROI (p=0.0050) and sROI (p=0.0149). There was excellent inter-reader correlation between the 2 readers, with a (91%, 88%, 84%, 76%) p=<0.01.
Conclusion: DCE-MRI at 7T using PK modeling can differentiate between benign and malignant breast tumors using both wtROI or sROI.

Characterisation of breast lesions by whole lesion texture analysis of high b value diffusion-weighted imaging (DWI)

A. Christou[1], A. Ghiatas[2], K. Veliou[3], D. Priovolos[2], H. Bougias[3]; [1]*Doncaster/UK*, [2]*Athens/GR*, [3]*Ioannina/GR (alexandrachristou@gmail.com)*

Purpose: To retrospectively investigate texture parameters in distinguishing breast lesions using high b-value DWI.
Methods and Materials: 30 women with 34 breast lesions underwent breast MRI in 1.5T MRI unit. DWI was applied as part of the standard protocol. The b-value 800 images were analysed and classified by whole lesion texture analysis(TA). 21 features derived from the histogram, grey-level-co-occurrence matrix (GLCM) and grey-level-run-length-matrix (GLRLM) were analysed and compared between benign and malignant lesions with Mann-Whitney U test (p=0.05). ROC analysis was used to evaluate the most effective cut-off values.
Results: 19 cases were malignant and 15 benign. Statistically significant difference between malignant and benign lesions was found in contrast, correlation, dissimilarity and homogeneity regarding GLCM texture metrics. No significant difference found in entropy and energy metrics. Short-run low grey-level emphasis (SRLGE) regarding the GLRLM metrics showed significant difference. No statistical difference found in any feature from histogram metrics. Univariate logistic regression showed that contrast and dissimilarity yielded the highest area under curve (AUC) 0.836 and 0.845, respectively, whereas energy and entropy yielded the lowest AUC 0.576 and 0.561, respectively.
Conclusion: High b-value DWI whole lesion texture analysis is able to differentiate breast pathologies with contrast and dissimilarity from GLCM texture metrics being the most effective discriminators.

Reduction of metal artefacts in patients with spinal fusions: metal artefact reduction algorithms and virtual monoenergetic images from spectral detector computed tomography

N. Grosse Hokamp[1,2], N. Abdullayev[1], V. Neuhaus[1], A. Mpotsaris[1], D. Maintz[1], J. Borggrefe[1]; [1]*Cologne/DE*, [2]*Cleveland, OH/US (nils.grosse-hokamp@uk-koeln.de)*

Purpose: To compare the extent of metal artefact reduction by use of dedicated metal artefact reduction algorithms (MAR) and high keV virtual monoenergetic images (VMI) from spectral detector computed tomography (SDCT).
Methods and Materials: 25 patients with spinal fusion were included in this IRB-approved study. All examinations were performed using a SDCT (IQon, Philips Healthcare). Images were reconstructed as conventional images (CI), with a MAR algorithm and as VMI in range of 40-200keV (10keV increment). Quantitative image analysis was performed ROI-based by measurements of attenuation (HU) and standard deviation in most pronounced hypo- and hyperdense artefacts and posterior subcutaneous fat. Qualitatively, assessment of metal-bone interface, spinal canal and soft tissue were rated on 5-point Likert scales. Further, extent of artefact reduction was evaluated by two radiologists. Statistical analysis was performed using ANOVA and Wilcoxon test with correction for multiple comparisons.
Results: The hypo- and hyperattenuating artefacts showed a significant increase and decrease of HU values in both high keV VMI and MAR reconstructions (CI/MAR/$VMI_{200\ keV}$: -397/-115/-48 HU and 470/211/74 HU, respectively; p≤0.05). Artefacts in the subcutaneous fat, as depicted by image noise, did decrease in high keV VMI (p=0.09) and MAR (p≤0.05; CI/MAR/VMI_{200keV}: 27.0/20.2/17.6). Qualitatively, metal-bone interface was better assessable in high keV VMI (p≤0.05), while soft tissue was better assessable in MAR (p≤0.05). Artefacts were reduced in 24/28 examinations.

Conclusion: SDCT allows for metal artefact reduction through MAR algorithms and computation of virtual monoenergetic images in patients with spinal fusion. Thus, the combination of both techniques is promising to yield further artefact reduction.

B-1120 10:47

MR imaging with metal artefact reduction for the differentiation between patients with and without infected total hip arthroplasty

B.J. Schwaiger, A. Gersing, D. Münzel, J. Dangelmaier, P.M. Prodinger, C. Suren, E.J. Rummeny, K. Wörtler; *Munich/DE*

Purpose: To evaluate imaging parameters obtained from MRI with metal artefact reduction to differentiate between patients with and without infected total hip arthroplasty (THA).
Methods and Materials: In 46 patients (65±11 years; 25 women) with THA, 1.5T MRI was acquired with view angle tilting (VAT) and slice-encoding metal artefact correction (SEMAC). Parameters describing changes of metal/bone interface, surrounding bone and soft tissue including synovial response patterns were assessed independently by three radiologists. All patients underwent revision surgery, and signs of infection and loosening were assessed according to AAOS criteria. Chi-squared tests and sensitivity/specificity analyses were performed with intraoperative findings as standard of reference.
Results: At surgery, an infection was confirmed in 12 patients, 21 patients showed an implant loosening and 13 showed conditions not related to infection/loosening. Presence of the following findings was significantly more common in patients with infection compared to those without: T2-hyperintense lining at the metal/bone interface (p=0.037; sensitivity, 92%; specificity, 41%), periostitis (p=0.027; 58%; 77%), an oedema (p=0.001; 75%; 77%), contrast enhancement (p=0.030; 75%; 70%) or an abscess (p=0.026; 38%; 95%) in the surrounding soft tissue, enlarged lymph nodes (p=0.020; 25%; 97%) and lamellated synovial response (p=0.020; 25%; 97%).
Conclusion: The differentiation between patients with and without infected total hip arthroplasty may be possible using a set of parameters derived from MR with metal artefact reduction. The most sensitive parameter was a T2-hyperintense lining at the metal/bone interface, while the most specific findings were presence of an abscess, enlarged lymph nodes and lamellated synovial response.

B-1121 10:55

Comparison of metal artifact reduction by OMAR, MonoE or combined techniques derived from dual-layer spectral CT

J. Dangelmaier, B.J. Schwaiger, A.S. Gersing, A. Sauter, I. Riederer, D. Muenzel, A.A. Fingerle, E.J. Rummeny, P.B. Noel; *Munich/DE*

Purpose: To compare image quality using virtual monoenergetic images (MonoE), the orthopedic metal artifact reduction (OMAR) algorithm and a combination of both techniques in patients with arthroplasty or spondylodesis.
Methods and Materials: 30 patients (70±12 years; 19 women) with total hip/shoulder arthroplasty (n=20) or spondylodesis (n=10) were examined on a dual-layer spectral CT. Axial reconstructions (0.9 mm) of standard CT images, MonoE (160keV and 200keV), OMAR and combined techniques (MonoE+OMAR) were calculated in soft and hard convolution kernels. Image quality in all reconstructions was rated by four radiologists, blinded for the type of artifact reduction technique, using a 5-point Likert scale. Hounsfield units (HU) were measured within the most pronounced hypodense streak artifact as well as in the reference tissue. Friedman´s analyses and Wilcoxon-signed rank test were performed for each observer separately and the mean of all observers for each reconstruction. Inter-reader agreement was calculated with ICCs.
Results: Image quality was rated significantly higher in all artifact-reduced images, compared to standard CT (p<0.001; MonoE160 soft tissue kernel p=0.001). Images reconstructed with MonoE+OMAR were rated significantly better than MonoE or OMAR alone (p<0.001). HU measurements within artifacts were significantly closer to reference values in all artifact-reduced images, with a superior artifact reduction obtained with MonoE+OMAR (88 % vs. 80% for OMAR or 45% for MonoE). Inter-reader agreement was good to excellent (ICCs).
Conclusion: Both, the qualitative assessment and quantitative measurements, demonstrated superior artifact reduction using virtual monoenergetic images in combination with OMAR, suggesting a clinical advantage in patients with arthroplasty or spondylodesis.

B-1122 11:03

Bone marrow adiposity assessed by 3T MR-spectroscopy in the hip of women with anorexia nervosa

S. Badr[1], V.M. Pansini[1], I. Legroux-Gérot[1], J. Vignau[1], R. Stefan[2], D.C. Karampinos[2], C. Chauveau[3], B. Cortet[1], A. Cotten[1]; [1]*Lille/FR*, [2]*Munich/DE*, [3]*Boulogne-sur-Mer/FR (sammy@badr.fr)*

Purpose: Bone marrow adiposity (BMA) in women with anorexia nervosa is paradoxically increased, contrasting with a reduction of the subcutaneous and visceral fat compartment volumes. As BMA may contribute to bone fragility in anorexic patients, we studied its relationship with bone mineral density and body composition.
Methods and Materials: 82 anorexic patients were included between January 2014 and June 2017. BMA of the hip was quantified using 3 tesla MR spectroscopy, by calculating signal-weighted bone marrow fat fraction (BMFF) in 4 different locations: the acetabulum, greater trochanter, femoral neck and proximal femoral diaphysis. Bone mineral density of the hip and body composition (body mass index, percentage of lean body mass and body fat percentage) were determined using dual-energy x-ray absorptiometry.
Results: With the exception of the greater trochanter, correlations were significant between BMFF and bone mineral density in the different locations of the hip (Spearman's rank correlation coefficients: ρfemoral neck=-0.24, ρacetabulum=-0.28, ρdiaphysis=-0.28; p<0.05). Regarding body composition, BMFF was significantly correlated with the percentage of lean body mass and the body fat percentage only in the femoral neck (ρfat=0.29 and ρlean=-0.27; p<0.05). No significant correlation was found between body mass index and BMFF in the hip.
Conclusion: BMFF is negatively correlated with bone mineral density in the acetabulum, femoral neck and proximal femoral diaphysis of the hip of women with anorexia nervosa. However, correlations between BMFF and body composition were only found in the femoral neck, suggesting location-dependent relationships with the other fat compartments.

Augmented reality-guided lumbar facet joint injections

C.A. Agten, C. Dennler, A.B. Rosskopf, L. Jaberg, C.W. Pfirrmann, M. Farshad; *Zurich/CH (christoph.agten@balgrist.ch)*

Purpose: To assess accuracy of augmented reality-guided lumbar facet joint injections.
Methods and Materials: A spine phantom completely embedded in hardened opaque agar with three ring markers was built. A 3-D model of the phantom was uploaded to an augmented reality headset (Microsoft HoloLens). Two radiologists, independently performed twenty augmented reality-guided and 20 CT-guided facet joint injections each: for each augmented reality-guided injection, the hologram was manually aligned with the phantom container using the ring markers. The radiologists targeted the virtual facet joint and tried to place the needle tip in the holographic joint space. CT was performed after each needle placement to document final needle tip position. Time needed from grabbing the needle to final needle placement was measured for each simulated injection. An independent radiologist rated images of all needle placements in a randomized order blinded to modality (augmented reality vs CT) and performer as: perfect, acceptable, incorrect, unsafe. Accuracy and time to place needles were compared between augmented reality-guided and CT-guided facet joint injections.
Results: In total, 39/40 (97.5%) of augmented reality-guided needle placements were either perfect or acceptable compared to 40/40 (100%) CT-guided needle placements (*P*=.5). One augmented reality-guided injection missed the facet joint space by 2 mm. No unsafe needle placements occurred. Time to final needle placement was substantially faster with augmented reality guidance (mean 14 ± 6 s vs 39 ± 15 s, *P*<.001 for both readers).
Conclusion: Augmented reality-guided facet joint injections are safe and accurate in an experimental setting.

B-1124 11:19

3D MR-based simulation of hip impingement is as accurate as 3D CT-based impingement simulation

F. Schmaranzer, C. Degonda, T. Lerch, I. Todorski, K. Siebenrock, J.L. Cullmann, M. Tannast, G. Zheng; *Bern/CH*

Purpose: For complex cases of femoroacetabular impingement (FAI), CT-based 3D impingement simulation is the current gold standard for impingement detection. 3D MRI-based impingement simulation would offer a radiation-free alternative. We asked: (1) How many surface points of 3D models derived from 3D CT versus 3D MRI differ by <1mm? (2) Do impingement-free range of motion values correlate between 3D models derived from CT/MRI?
Methods and Materials: IRB-approved comparative, retrospective study of 20 symptomatic hips with FAI. 3D CT scans (isovoxel: 1mm^3) of the entire pelvis

and the distal femoral condyles were obtained. Preoperative MR arthrograms of the hip were obtained including 0.8mm^3 isovoxel T1 3D VIBE- and 1mm^3 isovoxel 3D T1 VIBE DIXON sequences of the entire pelvis and the distal femoral condyles. Threshold-based manual segmentation was performed using commercial software (AMIRA). Both 3D models were compared with in-house developed software to calculate (1) percentage of the surface points with < 1mm difference between the CT-/MR-based 3D models and to assess (2) the correlation in impingement-free range of motion (in: flexion; extension; internal rotation 90° of flexion; external rotation in 90° of flexion; abduction; adduction) and location of impingement on CT/MRI.
Results: (1) 83%/79% of the surface points of the proximal femur, respectively, of the acetabulum differed by <1mm between the CT-based and MRI-based 3D models. (2) Correlation for the range of motion values was excellent (Spearman rho=0.993, p<0.05) between CT/MRI.
Conclusion: MR-based 3D models of the hip joint can replace CT-based 3D models for impingement simulation in young FAI patients.

B-1125 11:27

Performance of an automated vs manual MR scanner workflow of whole-body MRI

D. Stocker[1], T. Finkenstaed[1], B. Kuehn[2], D. Nanz[1], M. Klarhöfer[1], B. Kiefer[2], C.S. Reiner[1]; [1]*Zurich/CH*, [2]*Erlangen/DE (daniel.stocker@usz.ch)*

Purpose: To evaluate the performance of an automated magnetic resonance imaging (MRI) scanner workflow reducing user interactions compared to the manual MRI workflow for whole-body (WB) MRI.
Methods and Materials: This prospective study was approved by the local ethics committee. 20 patients underwent WB-MRI for myopathy evaluation on a 3T MRI-scanner. 10 patients (7 females; age, 52±13ys; body mass index [BMI], 23.2±3.0) were examined with a prototypical automated scanner workflow (automated whole-body segmentation) and 10 patients (6 females; age, 35.9±12.4ys; BMI, 24.9±5.6) with a manual scan. For each sequence (coronal T2-weighted turbo inversion recovery magnitude [TIRM] and axial T1-weighted contrast-enhanced sequence with volume interpolated breath-hold examination [VIBE]) overall image quality (IQ; 5, excellent; 1, poor) and completeness of examination volume were assessed by two readers. Examination time, number of user interactions and the MR-technicians' planning effort (1, highest; 10, lowest) were compared.
Results: Overall IQ was similar between automated and manual MRI (TIRM: 4.00±.94 vs 3.45±1.19, p=.264; VIBE: 4.20±.88 vs 4.55±.55, p=.423). Total examination time was significantly shorter for automated MRI (30.0±4.2min vs 41.5±3.4min, p<.0001) with significantly shorter planning time (2.5±.79min vs 14.0±7.0min, p<.0001). Planning time was 8% vs 34% of total examination time for automated vs manual workflow (p<.0001). The number of user interactions and rated planning efforts with automated MRI were significantly lower compared to manual MRI (10.2±4.4 vs 48.2±17.2, p<.0001 and 2.20±.92 vs 4.80±2.39; p=.005, respectively).
Conclusion: The automated MRI workflow significantly reduced examination time and user interactions while producing comparable IQ in WB-MRI for evaluation of myopathies.

CAM type femoroacetabular impingement: correlations between alpha angle vs volumetric measurements and surgical findings

R.A.K. Dessouky[1,2], J. Wells[2], L. Zhang[3], A. Gleason[2], R. Chopra[2], Y. Chatzinoff[2], N.P. Fey[2], Y. Xi[2], A. Chhabra[2]; [1]*Zagazig/EG*, [2]*Dallas, TX/US*, [3]*Beijing/CN (rihamdessouky@gmail.com)*

Purpose: To determine the correlation of 3DCT measurements of CAM type femoro-acetabular impingement [FAI] with surgical findings of labral tear and cartilage loss.
Methods and Materials: Digital search of symptomatic FAI patients who underwent hip surgery for a CAM-type FAI from July 2013 to August 2016 yielded 43 patients. Demographic data, clinical and surgical findings were recorded. Two readers evaluated 3DCT images to calculate volumes of the femoral head and bump as well as alpha angles. Correlations between CT and surgical findings were obtained. Inter-reader reliability was determined using intraclass correlation [ICC].
Results: Thirteen men and fourteen women were included with a mean age of 37.3 ± 10.4 years. The most common clinical finding was positive FADIR [19/27, 70.4%]. Twenty-seven labral tears and twenty cartilage defects were found on surgery. Significant correlations between the femoral bump and head volumes with the extent of the labral tear [p values = 0.008 and 0.003, respectively] existed. No significant correlations were found between alpha angles at 1 and 2 O'clock and extent of the labral tear [p values >0.05] or any measurement with cartilage loss [p>0.05]. Inter-reader reliability was excellent to moderate [ICC= 0.85 and 0.52] for femoral head and bump volumes, and fair to poor [ICC = 0.40 and 0.05] for alpha angles at 1 and 2 o'clock, respectively.
Conclusion: Volumetric measurements of CAM type FAI significantly correlate with the extent of the labral tear with superior inter-reader reliability than alpha angle, rendering it a more clinically relevant method to quantify CAM morphology.

FDG-PET/CT for diagnosis of infection in post-traumatic non-unions

L. Antunovic, M. Catalano, L. Di Mento, E. Malagoli, L. Balzarini, A. Chiti, A. Kirienko, M. Berlusconi, N. Trenti; *Rozzano/IT (lidija.antunovic@humanitas.it)*

Purpose: To assess the diagnostic performance of FDG-PET/CT in the evaluation of infection causing post-traumatic bone non-unions.
Methods and Materials: 47 patients treated in our trauma center, who underwent pre-operative FDG-PET/CT for suspected infection, were retrospectively reviewed. Clinical history, diagnostic examinations, laboratory and microbiology results, patient outcome, were collected and analyzed. FDG PET/CT images were evaluated with the addition of semi-quantitative analysis using SUVmax. Imaging findings, as assessed by an experienced nuclear medicine physician and a musculoskeletal radiologist, were correlated with microbiological examination of the intraoperative specimens. Finally, diagnostic performance of FDG-PET/CT was assessed.
Results: 22 patients were not infected, while remaining 25 had positive intraoperative microbiological results. Infection was correctly detected on FDG-PET/CT images in 23 cases, while 2/25 infected patients had no significant FDG uptake and were considered as false negatives. In 6 cases FDG-PET/CT showed false positive results; 16/22 disease-free patients were correctly diagnosed. The diagnostic accuracy of FDG-PET/CT in the final diagnose of infection was 83% (39/47). Sensitivity, specificity, positive predictive value and negative predictive value of FDG-PET/CT were 92%, 73%, 79% and 88% respectively. Likelihood ratio for a positive test(LR+) 3.41. Likelihood ratio for a negative test resulted 0.11. Pre-test probability of disease was 53%. Post-test probability based on LR+ resulted 79%, while post-test probability based on LR- was 11%.
Conclusion: Our data indicate FDG-PET/CT is a valuable diagnostic tool in the evaluation of post-traumatic infection.

Iterative reconstruction algorithms in computed tomography: is it possible to go beyond Fourier metrics for image quality assessment?

N. Paruccini, R. Villa, S. Morzenti, C. Spadavecchia, M. Signoriello, D. Ippolito, A. Crespi; *Monza/IT (n.paruccini@asst-monza.it)*

Purpose: Iterative reconstruction algorithms (IR) have been introduced in clinical practice. In this condition, the Fourier analysis requirements are not completely satisfied because of the effects of non-linearity and non-stationarity produced by the iterative reconstruction process.Alternative metrics, not based on Fourier transform, have been used to evaluate image quality.
Methods and Materials: A cylindrical water filled phantom was equipped with central cylindrical inserts of various densities and then scanned changing CTDIvol, reconstruction algorithm, filter and slice thickness. Blur was investigated with a simple metric based on the comparison of the original images with the same images after a low pass filter application. A statistical method was employed to evaluate low contrast detectability (LCD) in a homogeneous region. Results were then used to characterise noise amount and texture. Furthermore, the relationship between Noise Power Spectrum (NPS) and LCD was investigated.
Results: The image quality improvement obtained with IR is underline with both metrics. Blur metric is able to detect the different sharpness degree. The relationship between noise and Blur underlines a different behaviour for IR; Blur increases with lower dose levels or with higher reconstruction thickness. LCD curves underline an averaged improvement of 35-45%. Through evaluation of the LCD curves, information regarding colour and texture of noise are obtained. Furthermore, the shapes of LCD and NPS curves are in accordance.

Conclusion: The metrics proposed can be applied to any kind of reconstruction algorithms and with few requirements. Results are in accordance with metrics based on Fourier analysis.

B-1130 10:38

Image quality of conventional images of dual-layer spectral CT: a phantom study

F. van Ommen[1], E. Bennink[1], A. Vlassenbroek[2], J.W. Dankbaar[1], A. Schilham[1], M.A. Viergever[1], H.W. De Jong[1]; [1]*Utrecht/NL*, [2]*Brussels/BE* *(f.vanommen@umcutrecht.nl)*

Purpose: As dual-layer spectral CT scanners are mainly used for routine non-spectral imaging, these images should not come with a dose or image quality penalty as compared to a conventional CT scanner. The influence of a dual-layer detector on the image quality of conventional CT images is evaluated by comparison with a conventional CT scanner.
Methods and Materials: A CATPHAN600 phantom was scanned on an IQon Spectral CT and a Brilliance iCT scanner (Philips Healthcare, Best, The Netherlands). Four protocols, and three tube voltages were used to assess image quality at equalized dose levels. Noise and spatial resolution were characterized. Furthermore, contrast-to-noise-ratio, image uniformity, CT number linearity, slice thickness, slice spacing, and spatial linearity were evaluated.
Results: Noise levels were equivalent for both scanners. Resolution levels showed small but significant differences up to 0.3 lp/cm in favour of the dual layer. Contrast-to-noise ratio was equivalent at 80 and 120 kVp, but at 140 kVp significant differences up to 0.4 in favour of the dual-layer detector were found. Both scanners showed perfect CT linearity for body scans, but both showed an underestimation of the CT numbers for high-opacity materials for head scans. Slice thickness was slightly overestimated, but slice spacing was reconstructed correctly. In addition, spatial linearity was excellent with a maximum error of 0.1 mm.
Conclusion: The performance of the IQon in routine non-spectral imaging is comparable to the performance of the iCT. The similar performance suggests that the introduction of a dual-layer detector does not compromise image quality of conventional CT images.

Evaluation of the effect of image noise on CT perfusion measurements using digital perfusion phantoms

S. Skornitzke, H.-U. Kauczor, W. Stiller; *Heidelberg/DE* *(Stephan.Skornitzke@med.uni-heidelberg.de)*

Purpose: Models used for computed tomography (CT) perfusion studies might react differently to image noise present in CT acquisitions. Different algorithms from one commercially available CT perfusion software were evaluated for susceptibility to image noise.
Methods and Materials: Digital perfusion phantoms were generated using a deconvolution model for simulating time-attenuation curves (TACs) for 16 different combinations of the perfusion parameter blood flow (BF: 30/60/90/120 ml/100 ml/min) and flow extraction product (FEP: 10/20/30/40 ml/100 ml/min) corresponding to values encountered in clinical studies. TACs were distorted with additive Gaussian noise at 50 different strengths to approximate various levels of image noise, performing 200 repetitions for each noise level. 160000 TACs were evaluated in total by measuring BF and FEP, and comparing results for the maximum-slope and Patlak model to those obtained with a deconvolution model (syngo.via Body Perfusion; Siemens Healthineers, Germany).
Results: All evaluated perfusion models show a dependence on image noise: means and standard deviations of BF and FEP over repetitions increase with increasing image noise. The increase in means is larger for low values of BF and FEP and nearly vanishes for high values. Deviations are below 50% under all conditions only for noise levels below 20 HU (BF) or 10 HU (FEP). BF measurements performed with the deconvolution model show a larger standard deviation than those performed with the maximum-slope model.
Conclusion: Measurements of perfusion parameters depend heavily on the magnitude of image noise, which has to be taken into account during the interpretation of results, e.g. as a quantitative imaging biomarker.

The optimal energy level of virtual monochromatic images from spectral CT for reducing beam-hardening artefacts due to contrast media in the thorax

D. Kim[1], C. Kim[2], K. Lee[1], E.-Y. Kang[3], Y.-W. Oh[3], H. Kim[1], J. Cha[1]; [1]*Ansan/KR*, [2]*Ulsan/KR*, [3]*Seoul/KR (dj8827@naver.com)*

Purpose: To determine the optimal energy level of virtual monoenergetic images (VME) from spectral CT compared to that of conventional polychromatic images (COV) for reducing beam-hardening artefacts caused by contrast media in the thorax.
Methods and Materials: A total of 101 consecutive patients who underwent chest CT were retrospectively included in this study. The same contrast media and injection protocols were applied to the whole study population. VME image data sets ranging from 70 to 200 keV and COV were obtained. Readers' subjective image quality scores were recorded in COV and VME at 70 keV (VME70), 100 keV (VME100), 130 keV (VME130), and 200 keV (VME200). Image noise, CT number difference, contrast-to-noise ratio (CNR), and signal-to-noise ratio (SNR) were also obtained in each algorithm. The Kruskal-Wallis test with Bonferroni correction was used compared to the differences in subjective image scores, CT numbers, image noise, SNR values, and CNR values between the reconstruction techniques.
Results: The best subjective image quality score and the lowest image noise were observed in VME130 compared to COV (all P&lt0.001). CT number differences were significantly lower in both VME100 and VME130 than in COV (all P&lt0.001). SNR was similar between VME130 and COV, although both SNR and CNR decreased as the energy level increased.
Conclusion: Optimal evaluation of chest CT was best achieved at 100-130 keV. VME130 offered the best image quality score and image noise. VME100 and VME130 showed significantly lower CT number differences than in COV.

B-1133 11:02

Sub-millisievertmultiphasic acquisitions for coronary CT angiography of congenital coronaryanomalies in paediatric patients

J. Le Roy, H. Vernhet Kovacsik, H. Zarqane, M. Vincenti, A. Lacampagne, P. Amedro; *Montpellier/FR (le.roy-julien@hotmail.com)*

Purpose: To assess feasibility and performance of selective multiphasic coronary CT angiography (CCTA) at very low dose for paediatric patients with coronary artery anomaly
Methods and Materials: 50 paediatric patients with coronary artery anomalies underwent a cardiac CT between December 2015 and October 2017. Several parameters were recorded, including age (6.1y± 4.9), BMI (15.8kg.m-2±2.5), heart rate (89bpm±26) and heart rate variability (14bpm±11). Depending on these parameter combinations, specific protocols were designed to target the best theoretical cardiac phase in every situation; giving best compromise between image quality and reduced radiation dose. Acquisitions were realized on last generation single-source CT (Revolution CT, GEHC). Image quality was assessed qualitatively on a four point scale by two radiologists.
Results: All acquisitions fully answered the diagnostic question (100% - 50/50). Image quality was considered as "good" or "excellent" in ninety percent of cases (90%-45/50). Ten percent (10%-5/50) were scored as "adequate" while no exam were "not assessable". Looking at these five patients, movement artefacts were principal causes of average -but still diagnostic- image quality. No significant visualisation differences were reported between the different coronary segments with a global score of 3.5±0.6 on a 4 point scale (200 segments analysed in total). No correlation between image quality and cardiac parameters were reported (r=-0.17 and r=-0.10 respectively for Heart rate and HR variability). Mean effective dose was 0.98 mSv.
Conclusion: Infra-milliSievert multiphasic CCTA acquisitions could be performed with diagnostic quality for a dose equivalent to only 20% of a paediatric chest CT dose.

B-1134 11:10

A preliminary study about the robustness of quantitative CT features of pancreatic NEN: inter-observer variability assessment in delineation of lesions contours on CT images

G. Benedetti[1], M. Panzeri[1], M. Mori[1], C. Sini[2], M. Barbera[1], S. Partelli[1], M. Falconi[1], C. Fiorino[1], F. De Cobelli[1]; [1]*Milan/IT*, [2]*Potenza/IT* *(benedetti.giulia@hsr.it)*

Purpose: Radiomic is a promising field to build predictive models relating imaging features to clinical outcomes, especially for neoplasms. Nevertheless, its robustness is still under investigation. Especially, a reliable delineation of the lesions is of fundamental importance for Radiomic Features(RF) extraction. Our aim was to assess interobserver variability in delineating pancreatic neuroendocrine neoplasms (NEN) on CT images, and its impact on RF.
Methods and Materials: 10 histologically confirmed pancreatic NEN were contoured on CT images by 3 blinded observers. Contours were delineated on arterial or venous phase, depending on where the tumour was best seen, and

then projected onto the pre-contrast acquisition and adjusted to correct small anatomical discrepancies. Interobserver contouring variability was assessed by DICE-index and volume distribution among contours; significance of differences between observers was tested with Wilcoxon. Paired analysis between observers was performed. 72 RF were extracted from each observer's contours; their robustness was investigated against contour variability with Spearman-R and Intra-Class Correlation (ICC).
Results: Volume mean and median were 7.6cc and 1.5cc. A satisfactory agreement was found, with mean DICE=0.77±0.075 and no significant differences between observers. 50/72 RF were very robust (ICC>0.9); 10/72 showed an ICC<0.8, mostly in the 'Neighbourhood intensity-difference' RF family. Average R-values were 0.89 for RF with ICC>0.9 and 0.84 for the others RF. Only 'sphericity' (i.e. external shape of the lesion) R-value was<0.6.
Conclusion: Results show a relatively small inter-observer variability in delineating pancreatic NEN with little impact on RF, suggesting the possibility of a robust CT-based RF extraction on larger population.

B-1135 11:18

Comparison of clinical and phantom image quality for low-contrast liver lesions in a prospective multicentre dose optimisation protocol

H. Brat[1], D. Racine[2], S. Montandon[3], S. Behzad Imsand[4], B. Rizk[5], D. Fournier[1]; [1]*Sion/CH*, [2]*Lausanne/CH*, [3]*Gland/CH*, [4]*Epalinges/CH*, [5]*Villars-sur-Glane/CH (hugobene@gmail.com)*

Purpose: To compare diagnostic performance for low-contrast liver lesions on patient and phantom images in a prospective multicentre CT scanner dose optimisation protocol.
Methods and Materials: A protocol optimisation based on clinical indication and BMI with stepwise dose reduction was implemented on 5 CT scanners (Philips™). 3035 abdomen CT examinations were prospectively assessed for diagnostic image quality (radiologist vote). 33 patients who underwent a CT examination for liver tumour or cancer staging before and after optimization were evaluated for image quality (European guidelines). In parallel, phantom (QRM™ 401 abdomen) acquisition with 2.5 (size M) and 5cm (size L) soft-tissue ring was performed before and after dose reduction using the liver tumour follow-up protocol. A channelized Hotelling (CHO) model observer was used to assess lesion detectability using the ROC paradigm with the area under the ROC curve (AUC) as figure of merit.
Results: Median patient $CTDI_{vol}$ value decreased from 6.8 to 5.2mGy (-24%) and from 10.8 to 8.5mGy (-22%), respectively, for BMI<25 and >25. For phantom images, mean $CTDI_{vol}$ value decreased from 8.8 to 6.3mGy (-28%) for M-sized and from 15.9 to 11.8mGy (-26%) for L-sized phantom. No negative vote was registered and no loss of image quality was observed in the 33 paired patients' subgroup. Phantom analysis showed constant low-contrast lesion detectability until 26% dose reduction. However, additional dose reduction impaired detectability of 5mm lesions.
Conclusion: Combining clinical and phantom diagnostic image quality enabled dose reduction according to the ALARA principle without impairing low-contrast liver lesion detectability.

B-1136 11:26

Endoleak detection with ultra-low radiation exposure CT based on sparse sampling and reduced tube current

F.K. Kopp[1], R.-D. Bippus[2], K. Mei[1], A. Sauter[1], B.J. Schwaiger[1], A. Gersing[1], J. Dangelmaier[1], E.J. Rummeny[1], P.B. Noel[1]; [1]*Munich/DE*, [2]*Hamburg/DE (felix.kopp@tum.de)*

Purpose: To assess the diagnostic performance of sparse sampling computed tomography with significantly reduced radiation dose regarding the detection of endoleaks after endovascular aortic repair (EVAR).
Methods and Materials: 11 patients (seven positive and four negative for the diagnosis of an endoleak after EVAR) were examined using a 256-slice CT scanner and were retrospectively included in this study. A reduced radiation exposure was simulated by combining tube current reduction and sparse sampling. Three datasets were calculated, hereby each dataset showed the same radiation dose (20% of clinical radiation dose): dataset A with continuous sampling, dataset B with 2-times sparse sampling (keeping every 2nd view) and dataset C with 4-times sparse sampling. Four blinded radiologists, evaluated each dataset for the presence of an endoleak, with at least seven days between the consecutive readings. Sensitivity, specificity, negative predictive value (NPV), positive predictive value (PPV) and the area under the ROC curve (AUC) were calculated with the clinical diagnosis as standard of reference.
Results: Sensitivity, specificity, NPV and PPV were 71%, 69%, 81% and 58% for dataset A; 75%, 81%, 88% and 65% for dataset B; and 82%, 75%, 87% and 75% for dataset C. AUC values, averaged over the four readers, were 0.80, 0.82 and 0.86 for dataset A, B and C, respectively.
Conclusion: Using sparse sampling, sensitivity, specificity, NPV, PPV and AUC is increased compared to continuous sampling at the investigated dose level (dose reduction of 80%), suggesting that sparse sampling may allow significant radiation dose reduction for follow-up examinations.

R. Bippus: Employee; Philips Research.

B-1137 11:34

Optimisation of abdominal CT examinations across different scanners in one hospital using a new liver phantom

S.F. Svensson[1], H. Heier-Baardson[2], B.E. Nielssen[2], E.B. Herud[2], L.O. Holmen[2], H.K. Andersen[1], A.C.T. Martinsen[1]; [1]*Oslo/NO*, [2]*Grålum/NO (sirifl@ous-hf.no)*

Purpose: To optimize a CT abdomen protocol using a newly developed liver phantom.
Methods and Materials: An anthropomorphic liver phantom with hyperdense lesions, designed for receiver operating characteristic (ROC) analysis, was scanned using three CT scanners, each with its own iterative reconstruction method: a Philips Ingenuity Elite with IMR, a Philips Brilliance with iDose[4] and a GE Revolution Evo with ASiR-V. The phantom was scanned at $CTDI_w$ 5, 10, 15 and 20 mGy, and the images were reconstructed using levels 3 and 5 of iDose[4], IMR 1 routine, IMR 2 routine and IMR 1 soft tissue, and ASiR-V 20%, 40%, 60% and 80%. Three radiologists interpreted the images independently, and a ROC analysis was performed.
Results: Generally, the area under curve (AUC) increased and the confidence interval (CI) narrowed with higher dose levels for all scanners. All reconstructions at 15 and 20 mGy had AUC values > 0.8. IMR scans at 10 mGy or higher had AUC > 0.9. At 10 mGy, IMR 2 routine had the highest score, 0.96 (CI 95%: 0.911-1.0). At 5 mGy, only IMR scored better than AUC 0.5. The interpreters are most familiar with Philips CT images, and preferences may have influenced image quality scoring.
Conclusion: In general, IMR had higher score than iDose[4] and ASiR-V for all dose levels. This was a phantom study, so a future clinical validation of the results is necessary.

B-1138 11:42

Feasibility of whole-body low-dose CT using spectral shaping for detection of osteolytic lesion in patients with multiple myeloma

S. Suntharalingam, C. Mikat, A. Wetter, N. Guberina, A. Salem, P. Heil, M. Forsting, K. Nassenstein; *Essen/DE (Saravanabavaan.Suntharalingam@uk-essen.de)*

Purpose: The aim of this study was to investigate radiation dose and image quality of a whole-body low-dose CT (WBLDCT) with tin filtration at 100 kV (Sn100 kV) for the assessment of osteolytic lesions in patients with multiple myeloma.
Methods and Materials: Thirty consecutive patients were retrospectively selected, who underwent a WBLDCT on a third generation DSCT (Sn100 kV, ref. mAs: 130). They were matched with patients, who were examined on a second generation DSCT with a standard low-dose protocol (100 kV, ref. mAs: 111). Objective and subjective image quality, radiation exposure as well as the frequency of osteolytic lesions were evaluated.
Results: All scans were of diagnostic image quality. Subjective overall image quality was significantly higher in the study group (p=0.0003). Objective image analysis revealed that signal intensities, signal-to-noise and contrast-to-noise of the bony structures were equal or significantly higher in the control group. There was no significant difference in the frequency of osteolytic lesions (p=0.259). The median effective dose of the study protocol was significantly lower (1.45 mSv vs. 5.65 mSv; p < 0.0001).
Conclusion: WBLDCT with Sn100 kV can obtain sufficient image quality for the depiction of osteolytic lesions while reducing radiation dose by approximately 74%.

B-1139 11:50

A procedure towards optimised prenatal CT scan protocols for low dose imaging of suspected skeletal dypsplasia

I. Indesteege, L. Cockmartin, J. Binst, W. Coudyzer, H. Bosmans, M. Aertsen; *Leuven/BE (ingeindesteege@gmail.com)*

Purpose: To work out a procedure for low dose computed tomography (CT) protocols allowing diagnosis and evaluation of prenatal skeletal dysplasia.
Methods and Materials: Three antropomorphic phantoms were constructed with a fresh-frozen female lumbar spine and pelvis, in combination with the (Leeds Test Objects) sedentexCT phantom at the theoretical position of the fetus, and water and fat slabs to simulate different sizes of mother and fetus. Scans were performed on a Somatom Force CT (Siemens) under tube current and kV modulation to verify with which patients the 3 phantoms would match (dose data collection with DOSE by Qaelum). The phantoms were also compared to patients in perimeter and size-specific dose estimate (SSDE). Scans were acquired for 5 kV settings at 5 dose levels each to find threshold detectability of hydroxyl-apathite inserts in the phantom and subsequently graded for several criteria by 2 readers.
Results: Perimeters, kV, CT Dose Index (CTDI) and SSDE confirmed that the phantoms covered the complete range of patients, with the perimeter being a

practical criterium for future patient categorisation. The following dose settings guaranteed proper quality (visual grading minimally 4 on a scale of 5) and lowest CTDI: perimeter 100.4 cm: 80 kVp, 18 mAs, CTDI 0.34mGy; perimeter 119.7 cm: 110kV, 34 mAs, CTDI 1.76 mGy, and perimeter 126.6 cm: 140 kVp, 18 mAs, CTDI 1.75mGy. The procedure worked out well in a first patient case.
Conclusion: A procedure for low dose prenatal CT scans with satisfactory image quality for skeletal evaluation was successfully established.

Development of a radiological anatomy free software as a teaching tool
M.V.L. Oliveira, P. Geambastiani, G.A. Lopez, M. Cambuí; *Salvador/BR (marcusradiology@gmail.com)*

Purpose: To develop a learning environment for radiologic anatomy education to assist radiographers/radiologic technologists students and professionals.
Methods and Materials: This study was divided into two phases: 1) image acquisition and 2) software development. The first step was to perform a tomographic scan and radiographic images from a tissue-equivalent phantom of the head and neck, containing the same density and atomic number as bone tissue. In addition, an anthropomorphic phantom of the chest was used for radiographic imaging. The radiographs were held using a computed radiography (CR) digitizer system. The second step consisted in the development of a macro using the imageJ free software. In this digital environment, radiologic anatomy reference points were inserted and multiple questions were applied.
Results: The software presented radiologic anatomy from 1) skull projections: Waters view, Caldwell view, Towne view, lateral, submentovertex, PA view, 2) thoracic spine projections: AP view and lateral view, and 3) chest (PA view, lateral and oblique). Tomographic imaging presented hundred anatomic points of the skull. Multiple choice questions and a report containing the number of correct answers, as well as the user ID and date of the test were presented. The tests were applied in three languages (Portuguese, Spanish, and English).
Conclusion: An user-friendly and inexpensive software was presented. Radiographers/radiologic technologists, students and professionals from several countries are able to practice, repeatedly, the identification of radiologic anatomic points. This method can be applied as a feasible technological tool for enhancing learning by interactive learning environment.

B-1141 10:38
Pregnancy and radiation: video as a tool for health professionals communicating knowledge and risks
A.F. Reitan[1], H.M. Olerud[2], A. Borthne[3]; [1]*Oslo/NO*, [2]*Kongsberg/NO*, [3]*Lørenskog/NO (anita.reitan@hioa.no)*

Purpose: To ensure that health care professional have the necessary basic knowledge of radiation protection recommendations by producing the information film “Pregnancy and radiation”. Pregnancy and radiation is a subject that can cause concern to both healthcare professionals and pregnant women. There is a lot of uncertainty about how much radiation a foetus is capable of taking and the risk of foetal damage after an x-ray examination.
Methods and Materials: Qualitative survey: semi-structured interviews of two general practitioners (GPs) to map which topics were relevant in an information film and how these should be conveyed in film. Video production: produce a short, research-based film with the aim of making existing knowledge more accessible and easier to understand.
Results: The information video is based on recommendations and available knowledge. The take-home message is delivered through dialogue, narration and text. The film consists of five cases that show examples of how x-ray examinations of pregnant women can be justified. Using focused, research-based knowledge, in a video as a tool, we can raise the knowledge of GPs on the subject of pregnancy and radiation.
Conclusion: Using focused, research-based knowledge, in a film as a tool, we are most likely to raise the knowledge of GPs on the subject of pregnancy and radiation. A quantitative survey showed that knowledge among GPs increased after them seeing the video.

B-1142 10:46
Application of the cognitive load theory in simulation experiences to stimulate critical thinking in 2nd year radiography students
A. Louw; *University of Johannesburg/ZA (amandal@uj.ac.za)*

Purpose: To explore the significance of the cognitive load theory as pedagogical strategy to enhance critical thinking in radiography students who participate in a high-fidelity simulation experience.
Methods and Materials: An inter-professional, high-fidelity simulation scenario was specifically designed to stimulate students’ higher cognitive skills such as critical thinking, multi-level communication, teamwork and prioritisation in a stress loaded scenario involving chest and elbow imaging. An authentic scenario setting, various role players, life-like sound effects and the demand of multiple cases realistically increased the cognitive load of students and exposed them to the pressures often encountered in casualty settings in South African hospitals. In line with the cognitive load theory, essential basic knowledge and skills were revised and layered well in advance of the simulation experience to be stored in students’ long-term memory for easy retrieval when immersed in a non-routine scenario.
Results: Students managed the demands of the scenario fairly well, performed up to the standard expected at their level of training and came to new insights not previously addressed in a classroom context. During the reflective debriefing session steered by student observers, four themes, namely prioritisation, communication, team roles and situational and mental preparedness emerged.
Conclusion: Students who were given explicit guidance regarding supportive knowledge and skills prior to being involved in a multi-case stress-loaded simulation experience achieved the targeted learning outcomes when allowed to reflect on their actions and decisions immediately after the simulation experience.

B-1143 10:54
Enhancing radiographer threshold CT competencies through simulation
M. Hardy[1], M.A. Harris[2]; [1]*Bradford/UK*, [2]*Wakefield/UK (M.L.Hardy1@bradford.ac.uk)*

Purpose: The last decade has seen extensive growth of computed tomography (CT) placing greater expectations on radiographers to participate in CT image acquisition early in their careers. Pre-qualification technical skills development is achieved through the integration of academic and clinical learning but pressures on service capacity limit opportunities for students to obtain practical experience. Practice simulation has been shown to be beneficial to learning but limited opportunities exist in relation to CT skills development. This proof of concept study explored whether a bespoke CT simulation web platform could increase student confidence and competence in non-contrast head acquisition.
Methods and Materials: Supported by funding from Health Education England, an integrated CT simulation programme distributed through the internet was developed. This programme reflected current clinical CT practice taking student from patient registration through to discharge and requiring decision-making on image acquisition and reconstruction processes. Both practice and assessment modes were incorporated for monitoring student CT skills development and errors in decision-making.
Results: The CT simulation programme enabled students to practice their clinical skills and see the consequence of errors in parameter choice on image quality. Students reported greater confidence in CT processes prior to clinical placement and ability to question clinical radiographers from a wider knowledge base.
Conclusion: CT simulation technologies that enable errors in judgement to be made, and consequences appreciated, increase fundamental knowledge and understanding of the technology. Expansion of the CT simulation programme to include chest imaging is being explored.

B-1144 11:02
A systematic methodology for the development and validation of inventories of biomedical imaging physics learning outcomes for radiography and radiology specialities
J. Castillo[1], C. Caruana[2], A. Mizzi[3], P.S. Morgan[4], C. Westbrook[5]; [1]*San Gwann/MT*, [2]*Msida/MT*, [3]*Attard/MT*, [4]*Nottingham/UK*, [5]*Cambridge/UK (josecast@melita.com)*

Purpose: To develop a research methodology for developing local CPD learning outcomes in imaging physics for radiographers and radiologists.
Methods and Materials: An extensive literature review on learning outcomes development and multi-stakeholder consensus validation approaches was carried out and best practices were identified. A methodology was developed and tested by application to the development of a physics learning outcomes (LO) for local MRI radiographers.
Results: The method follows: (a) a multi-stakeholder Delphi process was used to forecast the MRI service portfolio for the year 2020; (b) a multi-stakeholder

nominal group technique was used to optimise the MRI care pathway/service quality criteria; (c) a survey of MRI competence profiles (CP) from the major English-speaking countries was used to identify good practices in CP design; (d) an MRI CP was set up based on the results of steps (a)-(c) and validated with a multi-stakeholder group; (e) an inventory of biomedical imaging physics LO required to deliver the CP was developed via an analysis of textbooks and research literature and validated by a multi-stakeholder expert group. The multi-stakeholder group agreed that the current MRI service catalogue should be maintained, whilst proposing new specific services. The care pathway/associated quality criteria were optimised. CP from 6 countries were studied. A CP consisting of 43 competence statements was developed and validated. An inventory of physics LO closely integrated with the CP was developed and validated.
Conclusion: The process is sufficiently generic to be applicable to the development of physics learning outcomes for all radiography and radiology specialities.

B-1145 11:10

Periodic refresher course for the radiographers of multimodal radiology department: the role of IT technologies
A. Fedorov, M. Cherkashin; *St. Petersburg/RU (fedorov@ldc.ru)*

Purpose: To assess electronic-based educational programs' effectiveness in radiographers' professional development plan.
Methods and Materials: 18 MRI radiographers were included in study. We have used electronic testing system with ID binding, MR examination simulator. Electronic platform was created by IT specialist under MR technologist overview. On the first step, initial experience was evaluated by testing and interview and staff was divided in 3 groups (by knowledge level). Educational course was 2 days (12 hours in total) and includes lectures, MR simulator practice with case studies and final examination. After 6 months we have performed interim review (interview) and after 12 months final review with electronic testing and interview with feedback form.
Results: Based on 3 groups' scoring, radiographers were divided into qualification classes. 2 technicians were assigned to the highest qualification group. Moderate group was assigned to 11 employees. 5 radiographers were assigned to the lowest group of qualifications. All employees have passed re-certification in months 12 and the strong positive dynamic was revealed. 5 technicians from the lowest group increased their knowledge level and upgraded into group 2. 2 employees, received the highest qualification, were transferred to an expert multimodal centre for working with advanced technologies and to act as coaches. Personal satisfaction rate was revealed in 89%.
Conclusion: Electronic platform with face-to-face interviews, regular follow-ups and employees' motivation is the effective tool for staff development. For high-quality and full-fledged training of healthcare personnel it is obvious to use educational and development plans based on electronic technologies.

B-1146 11:18

Eyes on the future of mammography education and training: what needs to be focused to match the demands of the clinical practice?
A. Henner[1], E. Metsälä[2], N. Richli Meystre[3], C. Sá dos Reis[1], B. Strøm[4], J. Pires Jorge[3], T. Kukkes[5]; [1]*Oulu/FI*, [2]*Helsinki/FI*, [3]*Lausanne/CH*, [4]*Bergen/NO*, [5]*Tartu/EE (eija.metsala@metropolia.fi)*

Purpose: The purpose of this study was to identify areas that require update on specific knowledge to allow the progression of radiographers' practice in mammography.
Methods and Materials: This study was a cross sectional online survey based on online questionnaire addressed to clinical radiographers in five European countries about training including perceived challenges and continuous professional development (CPD). The questions were closed-ended with possibility to add comments. Answers were dichotomous, multiple choice or with a five point Likert Scale. The data collected (N= 140) was analysed and redundant data was disregarded. Statistical data analysis was performed using the software packages SPSS (version 21, IBM) by using descriptive methods, Chi square and independent samples t-test.
Results: Regardless of country, radiographers considered positioning (86%) and coping with pain (88%), anxiety (83%) and imaging breast implants (71%) as the most challenging tasks. Respondents participated on CPD training about mammography (88%). However, 62% had less than 10 hours CPD per year. Congresses (70%) and conferences (41%) were the most common sources to update knowledge.
Conclusion: The majority of the radiographers reported the need of more training in mammography. The lack of evidence-based knowledge especially related to clinical image quality appropriateness criteria and related to optimal breast compression suggest the importance of well-designed studies on these topics. Variability found could encourage radiographers and teachers to question their own practice and to revise the training programs.

B-1147 11:26

Comparison of curricula, clinical experiences and attributes of radiography programmes delivered by four European educational institutions
C.S. Reis[1], S. Mæhle[2], J.A. Pires Jorge[3], H. York[4], L. Flaction[3], S. Johansen[2]; [1]*Perth/AU*, [2]*Oslo/NO*, [3]*Lausanne/CH*, [4]*Herts/UK (Jose.JORGE@hesav.ch)*

Purpose: To compare the curricula, teaching/learning strategies, skills, clinical practice outcomes and research of radiography programmes delivered by four different European educational institutions.
Methods and Materials: This study was developed in two phases: one focused on curricula analysis using an observation grid and another involving a survey performed on students and teaching staff. Questionnaires were design to explore teaching and learning strategies, skills and outcomes of clinical practice.
Results: ECTS dedicated per core area (natural sciences, clinical practice, research, imaging technology, humanities) differed between institutions. Research practice was similar for three institutions out of four. Students classified technical, practical and communication skills as the most important, while teaching staff highlighted critical thinking. The majority of students defined as “very good” their experience in radiography (58.5%) and computed tomography (45%). Magnetic resonance imaging training was considered “average” by 53% of the UK students and “good” by the others (40%). Mammography, nuclear medicine and radiotherapy were not always available for some students. For 71% (55/78) of the students, the research work contributed to the development of critical/reflective thinking.
Conclusion: The four radiography programmes analysed in this study presented variations on curricula, contact hours and clinical experiences with impact on the outcomes. The critical thinking was emphasised as one of the most important skills that a radiographer should develop and, for that reason, research should be considered as a core unit in radiography/medical imaging education. Further work is needed to assess the real impact of different programmes on professional and academic mobility across Europe.

B-1148 11:34

The development of a CAD tool employing TELTA, designed to support the training of radiographers in chest pattern recognition
S. Mdletshe[1], A. Nel[1], L. Rainford[2], H.A. Lawrence[1]; [1]*Johannesburg/ZA*, [2]*Dublin/IE (sibusisom@uj.ac.za)*

Purpose: Radiography is a dynamic profession that has undergone rapid technological advancements in recent years. The use of technology-enhanced learning, teaching and assessment (TELTA) to support innovative training options for radiographers to enhance their radiographic image evaluation and pattern recognition skills is warranted. However, a gap in current practice exists in the availability of custom designed computer-aided detection (CAD) tools to augment TELTA use in radiography.
Methods and Materials: A CAD tool for teaching pattern recognition in chest imaging was designed as a collaborative project between the Mechanical Engineering Science and Medical Imaging and Radiation Sciences Departments, the University of Johannesburg. A Design Science Research (DSR) paradigm was used. An initial needs analysis was performed involving a focus group interview of eight practising radiography educators. The findings of a systematic literature review coupled with the needs analysis outcomes were used to compile a software requirements specification document to guide the CAD tool development process.
Results: A CAD prototype was designed to function as a live tool for LTA purposes. The CAD tool design facilitates the collection of data on student tool usage, performance in automated assessments and managed progress based on user-tracked data. Important to the tool was that the students should be able to apply standard pattern recognition tools to manipulate the image without altering the original.
Conclusion: Details of how the prototype was developed will be given; the development base provides an evidence based mechanism for further prototype innovations. Initial data from prototype testing will be provided.

B-1149 11:42

Internship supervisors' perception of the radiography students in clinical environment
A.F. Abrantes[1], V.L. Gaspar[1], L.P. Ribeiro[1], O. Lesyuk[2], A.M. Ribeiro[1], R.P. Almeida[1], C.A. da Silva[3]; [1]*Faro/PT*, [2]*São Brás de Alportel/PT*, [3]*Evora/PT (oksanalesyuk@gmail.com)*

Purpose: To identify and describe the perception of internship supervisors of the radiography students in clinical environment about their competencies, skills and characteristics.
Methods and Materials: A quantitative descriptive, correlational design was used. Data were collected through an adapted version of the Clinical Learning Assessment Inventory-Mentor (CLASI-M) questionnaire with a final sample of

34 radiographer supervisors of the last year undergraduated radiography students from a public university.
Results: The training and education provided to the undergraduated radiography students prior to their internship is sufficient to assure the gradual development of the competencies and characteristics of the future radiorgaphers. Additionally, the effective integration into the multidisciplinary team and a relationship of trust with the supervisor are also fundamental for the student's development. The majority of the supervisores are very satisfied with the students' availability (93,6%) and the levels of supervision (96,7%) throughout the radiography clinical internship.
Conclusion: The pedagogical atmosphere is considered pivotal, with reference to students' learning activities and competent development within the clinical setting. The most desired competencies in a student by supervisors are communication skills with both patients and other team members, a high level of theoretical knowledge and performance in practice, fast learning and the overall motivation exhibited throughout the internship. Furthermore, supervisores are satisfied with both their own and students' availability, showing great expectations for the future radiographers.

The use of moulage to prepare first year diagnostic radiography students for the sight of open wounds: initial findings of a doctoral pilot study
N. Shiner; *Derby/UK (N.shiner@derby.ac.uk)*

Purpose: Transitioning to clinical placement is challenging for first year diagnostic radiography students; specifically working with ill patients. Focus groups held with students following their first clinical placements indicated issues comprehending the sight of open wounds. Witnessing the result of trauma is linked with anxiety and psychological trauma. Simulated practice offers experiential learning to students in a safe environment. Active participation and the debrief stage offers opportunity for analysis, problem solving and reflection. The use of moulage (make-up) increases fidelity and immersion of participants in simulated practice. A gap in the literature was identified and led to this pilot study for a doctoral thesis; preparing students for open wounds prior to clinical placement.
Methods and Materials: Ethical approval was gained. A mixed method quasi-experimental study was designed. Twelve first year radiography students were randomly assigned to control and experimental groups. The experimental group attended a simulation of a patient suffering open wounds (moulage). Quantitative data was gathered from both groups at the same time points using visual analogue scales. Focus groups will be held post clinical placement to gather qualitative data.
Results: It is hypothesised that the experimental group will value the opportunity to explore and discuss experiencing patients with open wounds. The control group will have similar experiences to previous cohorts indicating difficulties in this area.
Conclusion: As work is in progress the findings of this study will be reported. This is an innovative use of moulage in this context, contributing to the evidence base supporting transitioning students.

Impact of local native T1 times on pixel-wise quantification of myocardial blood flow
C. Kräuter, U. Reiter, C. Reiter, A. Schmidt, M.H. Fuchsjäger, R. Stollberger, G. Reiter; *Graz/AT (corina.kraeuter@medunigraz.at)*

Purpose: To investigate the impact of local native T1 time variations on pixel-wise quantification of myocardial blood flow (MBF) from dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI).
Methods and Materials: 15 patients with coronary heart disease underwent 3T pre-contrast T1 mapping and cardiac DCE-MRI at rest using a saturation recovery fast low angle shot sequence. Gadolinium-based contrast agent was administered as bolus at a dose of 0.05 mmol/kg. After coil sensitivity and motion correction of DCE series, signal intensity was converted to contrast agent concentration employing a signal intensity model and incorporating measured native T1 times. MBF was calculated pixel-wise using Fermi modelling. Segmental mean MBF values calculated with global and local native myocardial T1 times, respectively, were compared using paired t-test. Myocardial segments exhibiting perfusion deficits were identified by visual analysis of DCE series.
Results: Segmental mean MBF values calculated with global and local native T1 times, respectively, did not yield a significant difference (MBF global T1, 0.61±0.16 ml/min/g; MBF local T1, 0.62±0.16 ml/min/g; p=0.4354). However, considering segments with and without perfusion deficits individually revealed a decrease in MBF for segments with perfusion deficits if local instead of global native T1 times were employed (MBF global T1, 0.47±0.17 ml/min/g; MBF local T1, 0.43±0.16 ml/min/g; p=0.0016); segments without perfusion deficits showed the opposite behavior (MBF global T1, 0.64±0.14 ml/min/g; MBF local T1, 0.65±0.14 ml/min/g; p=0.0083).
Conclusion: Local instead of global native T1 times should be used in pixel-wise MBF quantification to avoid overestimation of MBF in myocardial regions with perfusion deficits.

Cardiac magnetic resonance T1 reactivity in coronary artery disease
M. van Assen, R. van Dijk, D. Kuijpers, R. Vliegenthart, M. Oudkerk; *Groningen/NL (m.van.assen@umcg.nl)*

Purpose: To assess the potential of rest and stress T1-mapping for differentiating normal and diseased myocardium without Gadolinium in patients with suspected coronary artery disease (CAD).
Methods and Materials: Patients underwent 1.5T magnetic resonance imaging (MRI) as part of clinical work-up due to suspicion of CAD. To identify ischemic and infarcted myocardium adenosine stress perfusion and late gadolinium enhancement (LGE) MRI were performed. Patients were categorized into an ischemic, infarct, and control group based on perfusion and LGE images. Patients were excluded if they had both ischemic and infarcted myocardium. At rest and stress, a native Modified Look-Locker Inversion Recovery (MOLLI) T1-mapping acquisition was performed. Short-axis pixel-wise myocardial T1-maps were acquired with inline motion-correction. Regions of interest (ROI) were placed in the septal (normal myocardium), ischemic and infarcted areas.
Results: 64 patients were included: 10 with myocardial ischemia, 15 with myocardial infarction, and 39 controls. Rest and stress native T1-values were significantly higher in infarcted myocardium (median 1044ms [interquartile range (IQR) 985-1076] and 1053ms [IQR 989-1088]) compared to ischemic myocardium (median 961ms [IQR, 939-988] and 958ms [IQR, 945-988]). T1-reactivity was significantly lower in ischemic and infarcted myocardium (median 0.00% [IQR,-0.18-0.16] and 0.41% [IQR, 0.09-0.86]) compared to remote myocardium (median 3.54% [IQR, 1.48-5.78] and 3.21% [IQR, 1.95-4.79]).

Conclusion: T1-mapping in rest and stress is able to distinguish between normal, ischemic, infarcted and remote myocardium using native T1-values and T1-reactivity, and holds potential as an imaging biomarker for tissue characterization using MRI.

B-1153 10:55

Myocardial microvascular dysfunction in patients with end-stage renal disease: assessment with 3.0T cardiac magnetic resonance

R. Xu, H. Xu, Z. Yang, Y. Guo; *Chengdu/CN (Xrongdoctor@163.com)*

Purpose: To quantitatively evaluate the left ventricular regional myocardial microvascular function in patients with end-stage renal disease (ESRD), and to clarify the feasibility of first-pass perfusion imaging for detection myocardial microvascular dysfunction in patients with ERSD.
Methods and Materials: In total, 67 patients with ERSD and 19 healthy subjects were enrolled and the first-pass perfusion was analysed. The ERSD patients were divided into two groups including 16 patients with systolic dysfunction (EF<50%) and 51 patients with preserved systolic function (EF≥50%). The LV myocardial perfusion parameters included Upslope, time to maximum signal intensity (TTM) and max signal intensity (MaxSI) which were compared among the patient groups and controls. Continuous variables were compared using independent one-way analysis of variance (ANOVA).
Results: The ERSD patients with impaired LVEF had significantly lower SV than that of the normal subjects, and the LV mass was markedly increased (all $P < 0.001$). The patients with ERSD had significantly reduced first-pass perfusion MaxSI in the all segment compared with the normal subjects (all $P < 0.001$). For the Upslope and TTM, the patients with ERSD (impaired EF) had lower Upslope in the basal segment (2.53±1.21 vs 2.04±0.81, $P < 0.05$) than the patients with ERSD (preserved EF); all patients had lower Upslope in the mid-segment and shorter TTM in the apical segment than the controls ($P < 0.05$).
Conclusion: The first-pass perfusion CMR can discover and monitor the myocardial microvascular dysfunction in ERSD patients.

B-1154 11:03

Impaired segmental myocardial microvascular dysfunction in chronic kidney diseases patients: assessed by cardiac magnetic resonance first-pass perfusion imaging

H. Xu, Z. Yang, Y. Guo, W. Peng, W. Peng; *Chengdu/CN (xuhuayan89@sina.com)*

Purpose: This research is aimed to access the myocardial microvascular dysfunction in chronic kidney disease(CKD) patients by using cardiac magnetic resonance (CMR) first-pass perfusion imaging, and investigate its association with left ventricular (LV) dysfunction.
Methods and Materials: Seventy-five CKD patients and 29 normal controls were enrolled. All subjects were underwent 3.0T CMR examination. First-pass perfusion imaging in three standard short-axis slices (apical, middle, and basal) and one the 4-chamber view were obtained immediately after intravenous injecting gadobenate dimeglumine. All imaging were calculated on the offline dedicated software (cvi42).Perfusion slope, time to peak(TTP) and max signal intensity(mSI) were obtained. LV dysfunction were defined as LV ejection fraction(EF) <50%.
Results: The slope and mSI of basal, middle and apical segment in CKD patients with LV dysfunction was lower than those without LV dysfunction and normal controls; and those preceding slope of CKD patients without LV dysfunction were also reduced comparing with normal controls(all P≤0.05). For the TTP, only basal segment of patients with LV dysfunction were elongated comparing with those without LV dysfunction and normal controls(37.52±16.10s vs.26.92±14.02s and 28.30±8.29s). LVEF were positively correlated with basal and middle slope(r=0.293 and 0.129, P≤0.05).In addition, LVEF is significantly related to basal mSI(r=0.301, P≤0.05). Logistic regression analysis demonstrated that myocardial perfusion slope is the independent risk factor of LV dysfunction.
Conclusion: Segmental myocardial microvascular dysfunction was found in CKD patients without LV dysfunction. Segmental slope and basal mSI were significantly associated with LVEF. Perfusion slope was demonstrated the independent risk factor of LV dysfunction.

B-1155 11:11

Semi-quantitative and quantitative magnetic resonance perfusion analysis: a meta-analysis

R. van Dijk[1], M. van Assen[2], R. Vliegenthart[1], G. de Bock[1], P. van der Harst[1], M. Oudkerk[1]; [1]*Groningen/NL*, [2]*Charleston, SC/US (r.van.dijk02@umcg.nl)*

Purpose: To assess the diagnostic accuracy of semi-quantitative and quantitative magnetic resonance perfusion (MR) analysis.
Methods and Materials: Pubmed, WebOfScience, and Embase were systematically searched using the following eligibility criteria: study domain - patients with known or suspected CAD. Index test - quantitative or semi-quantitative MR perfusion. Reference standard - ICA+/-FFR or QCA. Outcome - diagnostic accuracy of index test compared to reference standard. Study design - observational. The summary measures used to assess diagnostic accuracy were sensitivity, specificity, and area under the receiver operating curve (AUC). Data were pooled according to analysis territory, reference standard and perfusion parameter. Significant heterogeneity was defined as Q-statistic <0.10 and/or I^2 of >50%.
Results: After removal of duplicates 1967 articles were screened based on title and abstract. 137 articles were selected for full text assessment and 22 studies were included in the final analysis. Pooled diagnostic accuracy for segment-, territory- and patient-based analyses showed good diagnostic performance with sensitivity of 0.88, 0.82, and 0.83, specificity of 0.72, 0.83, and 0.76 and AUC of 0.90, 0.84, and 0.87, respectively. Only per territory analysis pooled sensitivity, per territory anatomical reference standard sensitivity and per territory semi-quantitative specificity did not show significant heterogeneity.
Conclusion: Overall, the diagnostic performance of both semi-quantitative and quantitative MR perfusion analysis is quite good. However, the real clinical value of semi-quantitative and quantitative MR perfusion analysis remains uncertain due to extensive inter-study heterogeneity and large differences in MR perfusion acquisition protocols, reference standards, and methods of assessment of myocardial perfusion parameters.

B-1156 11:19

Compressed sensing real-time cine imaging in patients with cardiac arrhythmia: does it help to reduce mistriggering artefacts?

P.-E. Allard[1], A. Bridoux[1], B. Longere[1], V. Silvestri[1], M. Schmidt[2], C. Forman[2], F. Pontana[1]; [1]*Lille/FR*, [2]*Erlangen/DE (pauledouardallard@hotmail.fr)*

Purpose: To evaluate the impact of a compressed sensing (CS) real-time prototype cine sequence (sparse 2D cine, Siemens Healthineers) on mistriggering artefacts in patients with arrhythmia, in comparison with the reference cine-imaging technique.
Methods and Materials: 71 consecutive patients (41 males; mean age=59±20.6 years), referred for cardiac magnetic resonance (CMR) examination with concomitant irregular heart rate (defined by R-R interval variation >10%), were prospectively enrolled. For each patient, a standard segmented multi-breath-hold steady-state free precession (bSSFP) sequence (Group 1) and a real-time CS single-breath-hold prototype sequence (Group 2) were systematically acquired. Two radiologists independently assessed mistriggering artefacts, objective and subjective image quality for both acquisition techniques.
Results: The mean heart rate variation was 38% ±22.6 (range: 12-122). A total of 599 cine slices were evaluated in each Group (mean number of slices per patient=8.4 ±1.9). The number of slices with mistriggering artefacts per patient was higher in Group 1 than in Group 2 (7.2 ±2.4 vs 0.03 ±0.08, p<0.0001). The European CMR registry standardised artefact score was lower in Group 2 than in Group 1 (1.6 ±1.5 vs 2.9 ±0.5, respectively, p<0,0001). Subjective image quality score was improved in Group 2 compared to Group 1 (2.6 ±0.7 vs 1.9 ±0.8, respectively, p<0.0001).
Conclusion: Compressed sensing real-time cine imaging drastically reduces mistriggering artefacts and improves image quality of CMR cine acquisition in patients with arrhythmia.

Strain parameters for the right ventricle in cardiac MRI: the forgotten child?

S. Benz, M.C. Halfmann, J. Eichstädt, A. Lollert, C. Düber, K.-F. Kreitner, T. Emrich; *Mainz/DE (sbenz@students.uni-mainz.de)*

Purpose: Since the original work from Zerhouni et al. in 1988, strain analysis in cardiac magnetic resonance (CMR) imaging has been dwelling under the surface of clinical routine. Recently, through the development of post-processing approaches such as feature tracking, strain analysis is in the focus of interest. In a meta-analysis by Vo et al., only 9 out of the 17 publications included the right ventricle by just measuring global longitudinal strain (GLS_{RV}). The purpose of our study was to establish the reference values of the RV in healthy volunteers.
Methods and Materials: In this study, 62 healthy volunteers underwent CMR imaging at 3T (Magnetom Skyra®, Siemens Healthineers). We manually traced the endocardial and epicardial contours for both late systolic and diastolic phases in both ventricles on the short- and long-axis cine images. The software (CVI42 Circle®) then subsequently tracked the movement of these contours.
Results: We measured all three strains for both ventricles, leading to the following values for right ventricle: global radial strain (GRS_{RV}) 13.47% (± 6.46), global circumferential strain (GCS_{RV}) -7.61% (± 3.92) and median global longitudinal strain (GLS_{RV}) -24.35% (± 5.22). There was a significant difference

between GLS_{RV} in the present study from the pooled mean value of meta-analysis.
Conclusion: The amount of variance between our and the published data might be explained by the use of different tracking softwares and the absence of standardized protocols. However, there is a need for establishment of those as a basis for assessment of RV strains in cardiac diseases in future studies.

B-1158 11:35

Global and segmental cardiac magnetic resonance tissue tracking of hypertrophic cardiomyopathy: how do hypertrophy and fibrosis contribute to myocardial deformation?

R.-Y. Shi, R. Wu, D. An, B. Chen, L. WU, J.-R. Xu; *Shanghai/CN (ryshicn@hotmail.com)*

Purpose: In hypertrophic cardiomyopathy (HCM), both heterogeneous left ventricular hypertrophy and focal fibrosis influence regional deformation. The goal of this study was to assess global strain, native T1 and extracellular volume (ECV) changes to differentiate the extent of hypertrophy, and to measure the contribution of hypertrophy and fibrosis in segmental strain deformation.
Methods and Materials: Forty early-stage HCM patients were examined by a 3.0 Tesla magnetic resonance scanner. We analysed circumferential, longitudinal and radial strain, systolic and diastolic strain rates using 2D and 3D modes. Native T1, ECV values and focal fibrosis were assessed. The generalised equation estimating (GEE) module was applied to evaluate in segmental levels.
Results: At the global level, ECV significantly correlated with conventional LV function and strain parameters, but not native T1 values. Global strain parameters in 3 directions were found to correlate best with the extent of hypertrophy (LV mass/ BSA). At the segmental level, LGE presence significantly correlated with segmental hypertrophy ($P < 0.0001$). The GEE module suggested that LGE presence and segmental hypertrophy (thickness ≥ 15mm) were observed antagonistic in 2D radial strain (beta = 12.756, P = 0.006) and diastolic radial strain rate (beta = 1.314, P = 0.005).
Conclusion: Subtle LV deformations can be observed and measured by strain before the manifestation of LV functional changes. Our study demonstrated 2D CS is a stable global parameter correlated with LV functional and ECV changes. At the segmental level, hypertrophy and LGE presence are antagonistic in 2D RS and diastolic RSR.

B-1159 11:43

Taking CMR strain into the next dimension

S. Benz, M.C. Halfmann, J. Eichstädt, A. Lollert, C. Düber, K.-F. Kreitner, T. Emrich; *Mainz/DE (sbenz@students.uni-mainz.de)*

Purpose: Cardiac magnetic resonance (CMR) imaging and post-processed tissue tracking are evolving for characterisation of a wide variety of pathologies. Though the images are captured two-dimensionally, tissue tracking algorithms allow for accurately visualised and measured 3D movements. We therefore analysed similarities and differences between 2D and 3D strain analysis.
Methods and Materials: CMR was performed on 62 healthy volunteers at 3T (Magnetom Skyra®, Siemens Healthineers). Based on cine images, endocardial and epicardial contours were manually traced on late systolic and diastolic images in both ventricles. This comprised multiple slices in the short axis and four chamber views for both ventricles, respectively two chamber view for the left ventricle. The tissue tracking software (CVI42 Circle®) then subsequently tracked the movement of the drawn contours and calculated 2D and 3D strain parameters.
Results: We found significant differences between 2D and 3D in global values concerning radial and longitudinal strains ($p < .0001$, respectively), while the circumferential strain was not significantly different. After adjusting for gender and age we were not able to explain the differences.
Conclusion: Due to the complex myocardial architecture and the three-dimensional movements of the heart, it appears plausible that the 3D strain comes closer to measuring the physiological motion. Therefore we suggest adding it to standard protocol, especially as long as superiority of either 2D or 3D strains has not been proven. Furthermore, there is a need for general standardisation in CMR tissue tracking.

B-1160 11:51

Age and sex dependency of myocardial strain in CMR: an urgent need to standardise

M.C. Halfmann, S. Benz, J. Eichstädt, A. Lollert, C. Düber, K.-F. Kreitner, T. Emrich; *Mainz/DE (Moritz.Halfmann@gmx.de)*

Purpose: Data concerning feature tracking strain analyses are still rare. Therefore, it is difficult to perform reliable analyses of influencing factors. We aim at providing additional data to consolidate feature tracking cardiac magnetic resonance imaging (FT-CMR) as a method eligible for clinical use.
Methods and Materials: We performed 62 FT-CMR examinations for the left and right ventricles in healthy volunteers using semi-automatic tracking software (CVI42 Circle®). The calculated global strain values were subsequently tested for influencing factors like age, sex and their combination using an analysis of variance (ANOVA). Post-hoc testing using the Bonferroni correction was performed for the various subgroup analyses.
Results: The left ventricular global strains (radial, circumferential and longitudinal) both in 2D and 3D showed statistically significant differences with regard to sex but not with regard to age. The combination of both factors did not reveal a significant influence. Interestingly, in the right ventricle we found statistically significant differences of strain values between old and young individuals, while sex had a smaller impact. Again, the combination of the subgroups did not yield any significant results.
Conclusion: Our results contrast those of a recently published meta-analysis of *Vo et al.,* where sex or age did not have a significant influence. These differences might be explained by use of different software, number of slices used for tracking and measured strain parameters. This shows the urgent need of standardisation for feature tracking algorithms before we can effectively employ FT-CMR in clinical routine.

Establishing age-specific reference values of lung volume in preterm born infants using MR-based volumetry

G. Negrao de Figueiredo, F. Schöppe, A. Pomschar, K. Förster, A. Hilgendorff, S. Stöcklein, B. Ertl-Wagner; *Munich/DE (giofigueiredo@yahoo.de)*

Purpose: Although reference values of total lung volume (TLV) exist for foetal MRI, age-specific normal values of TLV in preterm infants based on MRI are not yet available. We aimed to evaluate the influence of gestational age (GA) at birth, and severity of bronchopulmonary (BPD) on TLV in preterm infants establishing age-specific values of TLV.
Methods and Materials: 38 preterm neonates with no (n=20) and mild (n=18) BPD (grades 0 and 1, respectively) were evaluated. GA at scan ranged between 34 and 38 gestational weeks (GW) and GA at birth from 24 to 31 weeks. The whole lung was segmented manually on axial T2w images. TLV across BPD grades was compared using the t-test. Multivariate linear regression was used to evaluate the influence of GW at birth, at scan and BPD grade on TLV.
Results: The median (IQR) TLV was 56.76cm^3 (47.07-68.12). There was no significant difference in TLV between BPD 0 vs. 1 (P=0.987). Neither GW at birth, nor BPD grade had a significant influence on TLV (P=0.637 and P=0.958). Only GW at scan was significantly associated with TLV (P=0.015). Therefore, reference values for GA at scan around term (36±2 weeks) were established. The TLV increased with GW at scan, with the median TLV ranging from 48.71cm^3 at 34 GW to 78.11cm^3 at 38 GW.
Conclusion: We demonstrated that manual MR-based volumetry of TLV in preterm neonates is a feasible approach. The established age-specific reference values of TLV may provide an important basis to detect alterations of TLV.

B-1162 10:47

Towards an elastographic atlas of the neonatal brain

E.F. Garces Iñigo, L. Marti-Bonmati, R. Llorens, M. Vento Torres; *Valencia/ES (engari@alumni.uv.es)*

Purpose: To define the normal elasticity values of the grey and white matter in the neonate.
Methods and Materials: Randomised healthy term new born neonates were recruited from our maternity ward between their 2nd and 3rd day of live. A total of 57 cerebral ultrasound elastography were archived. All examinations were performed using a Siemens Acuson S2000 ultrasound system with a multifrequency 4-9 MHz probe. In all cases, a quantitative shear wave imaging method (Virtual Touch ™ Imaging Quantification) was applied. Protocol included bilateral sagittal planes of the thalamus and of the corona radiata.

Elastograms with at least 5 non-overlapping quantitative measurements were obtained from each anatomic location.
Results: Statistical analysis was made from a total of 1.885 quantitative measurements of the shear wave velocity (493 from right thalamus, 513 from left thalamus, 434 from right corona radiata and 445 from left corona radiata). The estimated mean value of the velocity in the thalamus is 1,184 m/s with a IC95% [1,147 - 1,221] and that of the corona radiata is 1,608 m/s with a IC95% [1,573 - 1,642]. No significant association was found with laterality, gestational age, cephalic perimeter, sex, height, or type of delivery.
Conclusion: There is a clear difference in the elasticity of the grey and white matter in healthy term neonates. Knowledge of the normal values is essential since changes from normal elasticity are expected in pathological tissues.

B-1163 10:55

Respiratory distress syndrome in neonates-comparison between lung ultrasound and chest x-ray

I. Sefic-Pasic, A. Džananovic, M. Bukvic, S. Terzic, M. Agovic, S. Vegar-Zubovic; *Sarajevo/BA (irmina.sefic@gmail.com)*

Purpose: The aim of this paper is to introduce basic principles of lung ultrasonound, technique and ultrasound findings in neonatal respiratory distress syndrome and to compare it with chest X-ray.
Methods and Materials: Lung ultrasound examinations were performed prospectively in 49 neonates (25 boys, 24 girls) with positive clinical and laboratory signs of respiratory distress syndrome and ultrasound findings were compared with chest X-ray. All ultrasound examinations were performed with a high frequency linear-array probes of 7,5 and 10 MHz. Interpretation of findings have been done by two radiologists. Interpretation of chest x -ray was based on 4-grade scale and ultrasound findings were classified into 3-stage profiles. Results were compared with statistical analysis.
Results: In the cohort of 49 patients we calculated Pearson Correlation Coefficient and the value of R was -0.5161. This is a moderate negative correlation , but these results correlate with grading system of RDS (respiratory distress syndrome) - high x-ray score and low ultrasound score refers to most severe grade of RDS and vice versa. Sensitivity of ultrasound was 98,4% and PPV 93%. We have found pathological findings on ultrasound presented with confluent B-lines-white lungs, subpleural consolidation of lung parenchyma, pneumothorax, abnormalities of pleural line and A lines in resolution of disease.
Conclusion: Lung ultrasonound is a reliable tool for diagnosing and follow up of respiratory distress syndrome in neonates. Introducing lung ultrasound in diagnostic algorithm, number of x-ray examinations can be decreased and exposure of neonates to ionizing radiation.

B-1164 11:03

The role of lung ultrasound in the differential diagnosis of respiratory distress syndrome and transient tachypnoea in preterm and newborn infants

M. Mughetti[1], G. Gardelli[1], E. Giampalma[1], M. Zompatori[2]; [1]*Cesena/IT*, [2]*Bologna/IT (martinamughetti@gmail.com)*

Purpose: Respiratory distress syndrome (RDS) and transient tachypnoea (TTN) are the most common causes of respiratory distress in premature and newborn infants. The diagnosis of RDS and TTN is based on clinical diagnosis and chest x-ray, but sometimes these entities show overlapping radiographic patterns. For this reason, pulmonary ultrasound is emerging as a reliable diagnostic tool to integrate radiography. The aim of our study was to evaluate the role of pulmonary ultrasonography in the differential diagnosis of RDS and TTN in the newborn.
Methods and Materials: From September 2016 to June 2017, 62 preterm or newborn infants with respiratory distress admitted to the Neonatal Intensive Care Unit were studied with chest x-ray and lung ultrasound.
Results: The white lung was demonstrated exclusively in patients with RDS (p = 0,000) and the simultaneous presence of a white lung and pleural irregularities and absence of spared areas showed high specificity (100%) and discrete sensitivity (76%) in identifying RDS. The double lung point was detected in both lung fields in 16 out of 21 TTN patients and in no patients with RDS (p = 0,000), exhibiting 100% sensitivity, 76% sensitivity, 100% positive predictive value and 88% negative predictive value.
Conclusion: The results of this study show that pulmonary ultrasound is a reliable and accurate tool for the differential diagnosis of RDS and TTN. However, chest RX remains the first-level diagnostic tool and can be integrated by ultrasound examination, which also allows a radiation-free follow-up.

B-1165 11:11

Italian guidelines for diagnostic exposure in neonatal intensive care units

A. del Vecchio[1,1], S. Salerno[1,2], M. Barbagallo[3,1], M. Campoleoni[1,1], V. Cannatà[4,1], G. Chirico[1,5], C. Granata[1,6], A. Loria[1,1], A. Magistrelli[1,4]; [1]*Milan/IT*, [2]*Palermo/IT*, [3]*Catania/IT*, [4]*Rome/IT*, [5]*Brescia/IT*, [6]*Genoa/IT (loria.alessandro@hsr.it)*

Purpose: In the recent years, clinical progress and better medical assistance for pregnant women, together with the introduction of sophisticated technologies, have improved the survival of preterm infants. However, this result requires frequent radiological investigations mostly represented by thoracic and abdominal radiographs in incubators.The aim of this document is to help public and private health-care operators in taking choices involving radiation exposures of newborns.
Methods and Materials: The guideline has been written and shared by four scientific societies: AIFM (Italian Association of Physics in Medicine), SIN (Italian Neonatology Society), SIP (Italian Paediatric Society), and SIRM (Italian Medical Radiology Society) to guarantee good standard practices for every professional involved in neonatal intensive care units (NICUs). The report is divided into clinical and physical dosimetric sections as follows: clinical indications (thorax x-ray indications; abdominal x-ray indications); good practice in radiological exposures (devices; exposure parameters and modalities; x-ray field collimation; patient positioning and immobilisation; diagnostic reference levels); radiation protection (patient, operators and environmental protection; shieldings); incubators (commercial incubators and their characteristics; the results of attenuation measurements).
Results: Taking into account the experience and expertise of 10 Italian centres, the guideline set out the criteria to ensure a high standard of neonatal care in NICU about procedures, facilities, recommended equipment, quality assurance, radiation protection measures for children and staff members and communication on radiation risk.
Conclusion: This document will allow a standardisation of the approach to the exposures in NICU.

B-1166 11:19

Magnetic resonance imaging of congenital lung lesions

C. Amaxopoulou[1], J. Geiger[1], P. Grehten[1], R. Gnannt[2], P. Bode[1], U. Moehrlen[1]; [1]*Zurich/CH*, [2]*Zollikerberg/CH (camaxopulu@hotmail.com)*

Purpose: To evaluate the performance of magnetic resonance imaging (MRI) for assessment of congenital pulmonary malformations.
Methods and Materials: Retrospective review of consecutive lung MRI performed (2013-2017) in 29 children (median age 0.4y, range 2d-15y) for suspected congenital lung anomalies with detection of 31 lesions: congenital pulmonary airway malformation (n=15), sequestration (n=3), hybrid lesion (n=3), hypogenetic lung syndrome (n=3), congenital lobar hyperinflation (n=3), bronchogenic cyst (n=1), and bronchial atresia (n=3). Respiratory-gated fast-spin-echo and dynamic contrast-enhanced images obtained at 1.5 T (free-breathing) were assessed for parenchymal, vascular and perfusion abnormalities. MRI findings were compared to results obtained from computed tomography (CT) and pathology following surgery.
Results: Lung parenchyma was delineated as normal (n=5; 16%), solid (n=8; 26%), cystic (n=13; 42%), hyperinflated (n=6; 19%), or mixed (n=7; 23%). Mucus plugs were seen in 5 cases. Systemic arterial supply was evident in 10 cases, systemic or anomalous venous drainage in 7 cases. All parenchymal lesions showed altered perfusion, either defects (n=22;71%), delayed systemic perfusion (n=8;26%) or both (n=2;7%). Perfusion was helpful for lesion characterization in 18 cases (58%). Parenchymal findings were confirmed by CT in 11/11 cases. The type of congenital lesion was verified by pathological findings in 17/17 cases. No correlation is available in 13 patients managed conservatively and in 2 patients awaiting surgery.
Conclusion: A dedicated MRI lung protocol is able to reliably delineate not only vascular but also parenchymal abnormalities. As characterization of congenital lung lesions has become feasible, lung MRI should be considered as radiation-free alternative to CT for evaluation of these lesions.

B-1167 11:27

The meconium sign in foetal MRI performed for the diagnosis of diaphragmatic hernia

C. Sofia[1], M. Tropea[1], L. Di Grazia[1], P. Spillare[1], N. Boscolo Bariga[1], M. Marino[2], A. Tregnaghi[1]; [1]*Venice/IT*, [2]*Messina/IT (carm.sofia@tiscali.it)*

Purpose: To assess the presence of T1 hyperintensity due to meconium in the herniated bowel of foetuses with diaphragmatic hernia.*Background:* Meconium is the material retained in the intestine of foetus from the 13 weeks gestation. It is composed of paramagnetic substances as minerals (Fe, Mn and Mg) and of free fatty acids, carbohydrates and minerals that explain its hyperintense signal on T1 sequences. Meconium slowly migrates from the small bowel to the colon and rectum, increasing in T1 brightness and amount throughout the gestation.

Methods and Materials: 56 foetal MRI examinations were reviewed by two different readers, with different expertise in foetal MRI, in consensus. All the examinations were performed using both T1 and T2 weighted acquisitions. Among the studies 9 diaphragmatic hernias were found. Intestine filled with meconium was considered present in the thorax when a bowel-shaped T1 hyperintensity was seen. The final diagnosis was made by surgical or pathological follow-up. Sensitivity and specificity of the "meconium" sign as diagnostic feature for diaphragmatic hernia were calculated.
Results: 8 foetuses showed the meconium sign. In one case of diaphragmatic hernia no bowel-shaped T1 hyperintensity was seen in the thorax. The sensitivity and specificity of meconium sign alone in the diagnosis of diaphragmatic hernia were 88.89 and 100 %.
Conclusion: Meconium sign can reliably detect diaphragmatic hernia in foetal mri examinations. However, the evaluation of all the other MRI diagnostic criteria and features is mandatory.

B-1168 11:35

Fetal-MRI based segmentation of the diaphragm in fetuses with congenital diaphragmatic hernia: a retrospective pilot study
F. Prayer, W. Krois, M. Metzelder, G. Kasprian, P. Brugger, G.M. Gruber, M. Weber, D. Prayer, J.M. Patsch; *Vienna/AT (florian.prayer@gmail.com)*

Purpose: Characterization of congenital diaphragmatic hernia (CDH) type and extent during fetal development may provide an opportunity for personalised therapy planning. This pilot study investigates the feasibility of fetal MRI-based manual diaphragmatic segmentation in fetuses with CDH.
Methods and Materials: Routine fetal MRI data of 22 fetuses with CDH (GW 22-36), who later underwent diaphragmatic repair surgery, were utilised to perform manual segmentation of the diaphragm and diaphragmatic defect using ITK-SNAP. Three-dimensional visualisation and surface area measurements of the normal diaphragm and diaphragmatic defect were obtained. Ratios of diaphragmatic and diaphragmatic defect surface areas, as well as diaphragmatic defect surface area and lung volume were calculated. Three-dimensional visualistions and surface area measurements were used to determine type and size of the diaphragmatic defect, and findings were compared with information extracted from diaphragmatic repair surgery reports regarding diaphragmatic defect location, size, and possible use of a patch.
Results: Diaphragmatic segmentation, subsequent three-dimensional visualisation and diaphragmatic (defect) surface area measurements were feasible in 20 of 22 (90.91%) fetuses with CDH. In two cases diaphragmatic segmentation was not possible due to excessive fetal movement. Findings regarding diaphragmatic defect type and size showed good accordance with information extracted from diaphragmatic repair surgery reports.
Conclusion: Fetal MRI-based diaphragmatic segmentation is feasible in a majority of CDH cases. Three-dimensional visualisation and surface area measurements of the diaphragm and diaphragmatic defect may support therapeutic decision-making and promote a personalised approach in CDH.

B-1169 11:43

Post-mortem magnetic resonance imaging appearances of foeticide in perinatal deaths
S.C. Shelmerdine, M. Hickson, N.J. Sebire, O.J. Arthurs; *London/UK (susie_c_s@yahoo.co.uk)*

Purpose: Determine the imaging features of foeticide at post-mortem MRI findings to eliminate confusion at post-mortem where mode of death is unknown.
Methods and Materials: A retrospective review over a 5.5-year period was performed comparing two groups of post-mortem foetal cases, cases which underwent termination of pregnancy matched to a group of controls which had undergone spontaneous miscarriage or stillbirth. The groups were matched according to gestational ages, weight and time since death. Two readers blinded to the patient's antenatal history recorded the presence of gas, blood and fluid in different body compartments. Statistical analysis was conducted using a Fisher's exact test.
Results: 26 cases of foeticide (mean age 25wks (range: 20 - 36)) and 75 non-terminated foetuses (mean GA 26.7wks (19 - 36)) were compared. A higher proportion of foeticide cases had pneumothoraces (23.1% vs 1.3%, p= 0.001), haemothoraces (42.3% vs 4%, p = 0.001), pneumopericardium (30.8% vs 5.3%, p = 0.002) and haemopericardium (34.6% vs 0%, p = 0.0001) compared to controls. The presence of intracardiac gas and abdominal findings (ascites, haemoperitoneum and free gas) were higher in the foeticide group but did not reach statistical significance. Pericardial and pleural effusions and soft tissue oedematous changes were not statistically different and are likely to represent post-mortem change.
Conclusion: Characteristic imaging features of foeticide can help the reporting radiologist differentiate iatrogenic from physiological and pathological causes of body fluid and gas disturbance on post-mortem perinatal MRI.

B-1170 11:51

High-resolution isotropic diffusion-weighted imaging in neonatal death investigation
S.C. Shelmerdine, A. Mcdowell, D. Carmichael, O.J. Arthurs; *London/UK (susie_c_s@yahoo.co.uk)*

Purpose: To develop/assess a new multi-band diffusion imaging at 3T for perinatal post-mortem MRI (PMMR).
Methods and Materials: We acquired PMMR brain and body imaging in 7 neonates, mean gestational age 33 weeks (range 30-37 weeks) at 3T. Whole-body 3T quantitative DWI imaging scan parameters were TE 53.4ms; TR 5600ms; voxel size 1.8mm isotropic; multi-band factor 2. One unweighted image and four diffusion-weighted images at b=250, 750, 1250 and 1750smm^{-2} with gradients applied in 12 uniformly distributed directions, and a reversed phase encoding scan were acquired and corrected for distortion. Image quality was scored by one radiologist blinded to acquisition technique on a visual analogue scale (1 to 5, unacceptable to excellent, respectively) at individual b values and on combined b-score mean diffusivity (MD) map.
Results: There was good image quality for the multiband, multislice DWI PMMR, attributable to increased resolution and signal-to-noise ratio. The average mean quality score increased with increasing b values with score of 2.7 for b=250, 3.6 for b=750, 4.1 for b=1250, 4.7 for b=1750 and 4.9 for combined b-value map. This improved quality allowed separation between average MD and fractional anisotropy signal values in all major body organs at 3T.
Conclusion: Multi-slice multi-band quantitative DWI is feasible for whole-body perinatal post-mortem imaging. Our optimised sequence utilising higher field strength and gradient performance gave improved whole-body isotropic high-resolution imaging compared to the current clinical approach, reducing partial volume effects and allowing detailed future PMMR investigation.

Orthotopic lung cancer: molecular imaging-monitored intratumoural radiofrequency heat-enhanced HSV-TK gene therapy
Q. Weng[1,2], F. Zhang[1], F. Xiong[1], Y. Jin[1], J. Song[2], M. Chen[2], J. Hui[2], J. Ji[2], X. Yang[1]; [1]*Seattle, WA/US*, [2]*Lishui/CN (wengqy99@gmail.com)*

Purpose: To validate the feasibility and efficacy of intratumoural radiofrequency hyperthermia (RFH)-enhanced herpes simplex virus thymidine kinase (HSV-TK)/ganciclovir (GCV) gene therapy for non-small cell lung cancer (NSCLC).
Methods and Materials: Animal protocols were approved by the Institutional Animal Care and Use Committee. The study included: (1) in vitro experiments using human NSCLC cells to establish the "proof of principle" of the new RFH-enhanced HSV-TK/GCV gene therapy; (2) in vivo experiments using mouse models with NSCLC to further demonstrate the principle; and (3) in vivo experiments using rat models with orthotopic NSCLC to validate feasibility of the new technique. Cells and animals were divided into four groups (n=6/group): (i) combination therapy (HSV-TK/GCV gene therapy plus RFH); (ii) RFH alone; (iii) HSV-TK/GCV gene therapy; and (iv) PBS. Molecular imaging findings were confirmed by subsequent pathology.
Results: For the in vitro experiments, the confocal microscopy, MTS assay, and bioluminescent imaging demonstrated significantly diminished viable cells and cell proliferation with the combination therapy, compared to the other three treatments (P<0.05). For the in vivo experiments, the optical and/or ultrasound imaging demonstrated significantly decreased relative bioluminescence signals and sizes of tumours, respectively, with the combination therapy, compared to other treatments (P<0.05). These results were confirmed with pathology.
Conclusion: This study demonstrates the feasibility and efficacy of intratumoural RFH-enhanced HSV-TK/GCV gene therapy for NSCLC, as guided and monitored by molecular imaging. This technical development may introduce a new paradigm for effective management of unresectable lung cancer by integrating the advantages of interventional molecular imaging, RF technology, and direct intratumoural gene therapy.

B-1172 10:47

Radiofrequency hyperthermia-enhanced intratumoral herpes simplex virus-thymidine kinase (HSV-TK) gene therapy of ovarian cancer: monitored by ultrasound and optical imaging

Y. Li[1], F. Zhang[2], S. Zhao[2], G. Jin[3], L. Zhao[4], Y. Zhou[2], P. Li[2], X. Yang[2]; [1]*Guiyang/CN*, [2]*Seattle, WA/US*, [3]*Shanghai/CN*, [4]*Wenzhou/CN* *(Liyaying1120@163.com)*

Purpose: To investigate the feasibility of using imaging-guided RF hyperthermia (RFH) to enhance intratumoural HSV-TK/ganciclovir (GCV) suicide gene therapy of ovarian cancers, monitored by optical and ultrasound imaging.
Methods and Materials: Human ovarian cancer cells (SK-OV-3) labelled with luciferase/lentivirus and rats with luciferase-positive orthotopic ovarian cancers in four groups received different treatments: (i) combination treatment with HSV-TK/GCV-mediated gene therapy plus RFH; (ii) gene therapy; (iii)RFH and (iv) control. MTS assay and confocal microscopy were used to evaluate the cell viability. Bioluminescence optical and ultrasound imaging were used to monitor the changes of tumour size and bioluminescence signal intensities at different time points. The imaging findings were correlated with subsequent pathology confirmation.
Results: MTS assay demonstrated the lowest cell proliferation in the group with combination therapy, compared with three control treatments (41.0% vs 47.8% vs 97.3% vs 100%), as corresponded to the smallest number of survived cells by confocal microscopy and the lowest bioluminescence signal by optical imaging. Ultrasound imaging showed the smallest relative tumour volume with combination therapy, compared with the other three groups (0.23 vs 1.26 vs 5.43 vs 6.74). Bioluminescent optical imaging demonstrated a significantly decreased relative bioluminescence signal in combination therapy, compared with the other three treatments (0.35 vs 1.26 vs 3.43 vs 3.90). Both imaging findings were confirmed by pathology, demonstrated as the significantly increased apoptotic cells in the combination therapy group.
Conclusion: Image-guided intratumoural RFH could enhance HSV-TK/GCV gene therapy of rat ovarian cancers, which provides a new opportunity for effectively managing ovarian cancers.

In vivo tracking of the tropism of mesenchymal stem cells to malignant gliomas using reporter gene-based MR imaging

M. Cao; *Guangzhou/CN (caominghui1019@163.com)*

Purpose: Mesenchymal stem cells (MSCs) have emerged as a promising cellular vehicle for gene therapy of malignant gliomas due to their property of tumour tropism. However, MSCs may show bidirectional and divergent effects on tumour growth. Therefore, a robust surveillance system with a capacity for noninvasive monitoring of the homing, distribution and fate of stem cells in vivo is highly desired for developing stem cell-based gene therapies for tumours.
Methods and Materials: In this study, we used ferritin gene-based magnetic resonance imaging (MRI) to track the tumour tropism of MSCs in a rat orthotopic xenograft model of glioma. MSCs were transduced with lentiviral vectors expressing ferritin heavy chain (FTH) and enhanced green fluorescent protein (eGFP). Intra-arterial, intravenous and intertumoural injections of these FTH transgenic MSCs (FTH-MSCs) were performed in rats bearing intracranial C6 gliomas.
Results: The FTH-MSCs were detected as hypointense signals on T2- and T2*-weighted images on a 3.0 T clinical MRI. After intra-arterial injection, 17% of FTH-MSCs migrated toward the tumour and gradually diffused throughout the orthotopic glioma. This dynamic process could be tracked in vivo by MRI up to 10 days of follow-up, as confirmed by histology. Moreover, the tumour tropism of MSCs showed no appreciable impact on the progression of the tumour.
Conclusion: These results suggest that FTH gene-based MRI can be used to reliably track the tropism and fate of MSCs after their systemic transplantation in orthotopic gliomas. This in vivo tracking system will facilitate the development of stem cell-based therapies for malignant gliomas.

B-1174 11:03

Tumour microenvironment-responsive intelligent nanocomposites for efficient theranostics of glioma

H. Liu, W. Zhang; *Chongqing/CN (303609940@qq.com)*

Purpose: To evaluate the applicability of an intelligent nanocomposite for tumour microenvironment (TME)-responsive multi-modality imaging and enhanced photodynamic therapy of glioma in vivo.
Methods and Materials: Bovine serum albumin (BSA)-stabilized manganese dioxide (MnO_2) and gold nanoclusters (AuNCs) hybrid nanocomposites (BSA-MnO_2-AuNCs, BMANCs) were synthesized via a facile and environmentally friendly one-pot biomineralization approach. The response of BMANCs to acidic hydrogen peroxide (H_2O_2) was evaluated in vitro. The applicability of BMANCs for MRI/NIRF/CT multi-modality imaging was performed in glioma-bearing nude mice. The efficacy of BMANCs on TME regulation tumour and photodynamic therapy were also investigated.
Results: BMANCs with suitable size, desirable water dispersibility and excellent biocompatibility were prepared. The AuNCs exhibited an intense red fluorescence (Ex/Em=520/720 nm) and a satisfactory CT contrast ability. The high reactivity of MnO_2 towards endogenous H_2O_2 within the acidic TME could release Mn^{2+} ions and realize TME-responsive MR imaging. Owing to the efficient tumour accumulation of BMANCs and generated O_2 in situ resulting from the reaction between MnO_2 and H_2O_2, tumour hypoxia, acidification and tumour angiogenesis were effectively alleviated. Furthermore, the BMANCs exhibited remarkably enhanced photodynamic therapy than that of BSA-AuNCs, due to the improved oxygenation at the tumour site.
Conclusion: The as-prepared BMANCs hold great potential for comprehensive TME regulation and enhanced theranostics against hypoxic solid tumours.

B-1175 11:11

Fluorescence molecular imaging of infection and inflammation utilizing a novel probe specific for myeloperoxidase

B. Pulli, C. Wang, G.R. Wojtkiewicz, J. Chen; *Boston, MA/US* *(pulli.benjamin@mgh.harvard.edu)*

Purpose: Myeloperoxidase (MPO) is an important oxidative enzyme that is crucial for defence against pathogens, but also contributes to tissue damage in inflammation. We sought to develop a molecular imaging probe sensitive and specific to MPO that is suitable for fluorescence imaging applications.
Methods and Materials: Sixteen female C57BL/6J (wild-type) mice and 6 MPO-knockout mice were either injected subcutaneously with purified MPO, treated topically with PMA to induce irritant contact dermatitis, injected intracerebrally with *Salmonella* to induce brain abscess, or injected subcutaneously with *Streptococcus pneumoniae* to induce bacterial cellulitis. 6 hours after induction, mice were injected with the MPO sensor or a non-specific control analogue. Mice underwent fluorescence reflectance imaging. Brains were cut into sections on a cryotome, and immunohistochemistry for MPO was performed.
Results: A linear increase in signal is observed with increasing concentrations of purified MPO (R^2=0.991). In irritant contact dermatitis and bacterial cellulitis, increased fluorescence signal was detected in wild-type mice injected with MPO sensor (P<0.01). In MPO-knockout mice injected with MPO sensor and in wild-type mice injected with control analogue, no signal increase was detectable (P>0.05). In cerebral abscess, MPO activity (MPO sensor) was only observed within the abscess, whereas MPO protein (immunohistochemistry) was detected in adjacent brain areas as well.
Conclusion: The fluorescent MPO sensor can specifically detect MPO activity in vivo at relevant biological concentrations. This was validated in mouse models of infection and inflammation. Importantly, we found that MPO activity does not always colocalize with MPO protein, differentiating between active and latent inflammation.

B-1176 11:19

Integrin-targeted multispectral optoacoustic tomography with MRI correlation for monitoring a BRAF/MEK inhibitor combination therapy in a murine model of human melanoma

P.M. Kazmierczak, N.C. Burton, G. Keinrath, H. Hirner-Eppeneder, M. Schneider, R.S. Eschbach, M.F. Reiser, J. Ricke, C.C. Cyran; *Munich/DE* *(Philipp.Kazmierczak@med.uni-muenchen.de)*

Purpose: To investigate $\alpha_v\beta_3$-integrin-targeted multispectral optoacoustic tomography (MSOT) and MRI for monitoring a BRAF/MEK inhibitor combination therapy in a murine model of human melanoma.
Methods and Materials: Human BRAF V600E-positive melanoma xenograft (A375)-bearing Balb/c nude mice (n=10) were imaged before (day 0) and after (day 7) a BRAF/MEK inhibitor combination therapy (encorafenib, 1.3 mg/kg/d; binimetinib, 0.6 mg/kg/d, Array BioPharma Inc.; n=5) or placebo (n=5), respectively. MSOT was performed on a preclinical system (inVision 256-TF, iThera Medical GmbH) unenhanced and 5 h after i. v. injection of an $\alpha_v\beta_3$-integrin-targeted fluorescent probe (IntegriSense 750, Perkin Elmer; 4 nmol). The $\alpha_v\beta_3$-integrin-specific tumor signal was derived by spectral unmixing. T2w MRI data sets were acquired on a clinical 3 Tesla scanner (MAGNETOM Skyra, Siemens Healthineers). The imaging results were validated by multiparametric immunohistochemistry (β_3-integrin expression, CD31-microvascular density, Ki-67-proliferation).
Results: The $\alpha_v\beta_3$-integrin-specific tumour signal was significantly reduced under therapy showing a unidirectional decline in all animals (from 7.98±2.22 to 1.67±1.30; p=0.043). No significant signal change was observed in the control group (from 6.60±6.51 to 3.69±1.93; p=0.155). Immunohistochemistry revealed a significantly lower integrin expression (β_3: 0.20±0.02 vs. 0.39±0.05; p=0.008) and microvascular density (CD31; 119±15 vs. 292±49; p=0.008) in the therapy group. Tumour volumes increased with no significant intergroup difference (therapy: +107±42 mm^3; control +112±44mm^3, p=0.841). In vivo blocking

studies using the $\alpha_v\beta_3$-integrin antagonist cilengitide (Selleck Chemicals) confirmed the target specificity of the fluorescent probe.
Conclusion: $\alpha_v\beta_3$-integrin-targeted MSOT allowed for the early non-invasive monitoring of a BRAF/MEK inhibitor combination therapy in a murine model of human melanoma.

Molecular MR imaging of myeloperoxidase reveals a new myeloid cell treatment effect of interferon-beta in experimental multiple sclerosis
B. Pulli[1], R. Forghani[2], C. Wang[1], G.R. Wojtkiewicz[1], J. Chen[1];
[1]*Boston, MA/US*, [2]*Montreal, QC/CA (pulli.benjamin@mgh.harvard.edu)*

Purpose: Treatment effects of interferon-beta (IFN) and glatiramer acetate (GA), two first-line agents used in multiple sclerosis (MS), are similar as evaluated by conventional MRI. We investigated the effects of these two drugs on myeloid cells with MPO-Gd, an activable molecular MR probe specific to the pro-inflammatory enzyme myeloperoxidase (MPO).
Methods and Materials: Fifty female wild-type or MPO knockout mice were induced with EAE, a mouse model of MS, and treated with IFN (1 µg/day), GA (150 µg/day), MPO inhibitor ABAH (0.8 mg/day), or saline. The mice underwent MRI at 4.7T with MPO-Gd at disease peak (day 12). Lesion volume, number, contrast-to-noise ratio (CNR), and total MPO-Gd enhancement were quantified, and mechanistic in vitro experiments were performed.
Results: MPO-Gd CNR (representing MPO activity in vivo) decreased after ABAH and IFN administration, but not with GA. Lesion volume, lesion number, and total MPO-Gd enhancement decreased with all three agents. These findings suggest that IFN may have the imaging signature of an MPO inhibitor. However, direct enzymatic inhibition was only found with ABAH. When isolated myeloid cells were stimulated to secrete MPO, IFN decreased MPO activity, similar to ABAH. Inhibition of superoxide anion production resulted in the restoration of MPO activity from stimulated cells. Spectrophotometry revealed that IFN destroys the iron-containing prosthetic group of MPO and thus inactivates the enzyme.
Conclusion: Molecular imaging profiling revealed a novel myeloid cell-specific treatment effect of IFN, a first-line treatment of MS. IFN irreversibly inactivates MPO via a superoxide-dependent pathway, which improves clinical disease.

B-1179 11:35

$NaluF_4$ for spectral CT in the diagnosis of osteoscarcoma
Y. Jin, L. Gao, F. Han, Y. Lv, J. Zhang; *Shanghai/CN (yingyingjin@yahoo.com)*

Purpose: To investigate the potential of spectral computed tomography (CT), used in combination with a Lutecium-based upconversion nanoparticles (UCNPs), for characterization of osteosarcoma and bone.
Methods and Materials: Spectral CT which can enrich conventional CT images with the capability to image and quantify certain elements based on their distinctive Kedge energies was chosen as a powerful tool. Lutecium-based upconversion nanoparticle (UCNPs) had higher spectral CT performance compared with clinically used iohexol. Spectral CT performance was investigated by testing gradient concentration of these contrast agents (CAs) in vitro. Balb/c nude mice were used as model for imaging osteosarcoma in vivo. Cellular uptake of Lutecium-based UCNPs was further evaluated by using confocal microscopy. Toxicity tests were also carried out including cellular toxicity tests, blood routine examinations, hepatorenal function, body weight and some other indexes.
Results: Spectral CT enabled differentiation of Lutecium-based UCNPs, iohexol and bone. Different materials were presented as colorized voxels against the normal grayscale X-ray background, distinguishing the high attenuation of calcium from the osteosarcoma tumor tissues that contained the Lutecium-based CAs. The results of in vivo and in vitro experiments demonstrated that Lutecium-based CAs had higher spectral CT performance and could still be obviously observed at higher KeV (120-140 KeV) images while the signals of iohexol and bone were relatively weak. The toxicity was proven to be low which made it potential for clinical application in the future.
Conclusion: Spectral CT imaging, combined with Lutecium-based CAs, provided a promising opportunity for effectively distinguishing bone and osteosarcoma in vivo.

B-1180 11:43

Ultrasound molecular imaging of breast cancer in mcf-7 orthotopic mice model using a novel dual-targeted ultrasound contrast agent
L. Xu, F. Li, J. Du; *Shanghai/CN (ly230502@163.com)*

Purpose: To prospectively evaluate ultrasound molecular imaging with dual-targeted gold nanoshelled poly(lactide-co-glycolic acid) nanocapsules carrying p53 and vascular endothelial growth factor receptor type 2 (VEGFR2) antibodies (V&p53-PLGA@Au NCs) in MCF-7 orthotopic mice model.
Methods and Materials: V&p53-PLGA@Au NCs were fabricated with an inner PLGA and outer gold nanoshell spherical structure. Its targeting capabilities were evaluated in targeted cells (HUVEC, MCF-7 cells) and control cells (4T1, MDA-MB-231 cells). Contrast-enhanced ultrasound imaging with V&p53-PLGA@Au NCs was evaluated qualitatively and quantitatively in vitro and in MCF-7 orthotopic mice model by two different systems. The biodistribution of NCs in mouse was preliminarily investigated. Differences were calculated using analysis of variance. Expression of p53 and VEGFR2 in mice tumour tissues were tested with immunofluorescence.
Results: The V&p53-PLGA@Au NCs showed well-defined spherical shape with the average diameter of 276.90±110.50 nm. In cell culture, targeted cells showed higher fluorescence signals and targeting rate than control cells (79.01±5.63% vs 2.11±1.07%, P<0.01; 75.54±6.58% vs 5.21±3.12%, P<0.01). In vivo, contrast-enhanced ultrasound imaging showed significantly higher video intensity when using V&p53-PLGA@Au NCs compared with non-targeted NCs. There were more V&p53-PLGA@Au NCs in tumours in mice than non-targeted NCs (P<0.05).
Conclusion: V&p53-PLGA@Au NCs are demonstrated to be novel dual-targeted ultrasound molecular contrast agents and may have potential applications in early noninvasive visualization of breast cancer.

Evaluation of the differentiation in head and neck squamous cell carcinoma with PET/MR
H. Dang, Y. Chen, Z. Jin, H. Xue, B. Hou, F. Li; *Beijing/CN (shengdai23@126.com)*

Purpose: To preoperatively evaluate the performance of discrimination with integrated positron emission tomography/magnetic resonance imaging (PET/MR) in the tumour differentiation of head and neck squamous cell carcinoma(HNSCC).
Methods and Materials: 18F-FDG PET imaging was performed with ToF method. MR imaging included the anatomic and functional sequences of T1-weighted and T2-weighted imaging , diffusion-weighted imaging and dynamic contrast enhanced imaging. The values of standardise uptake value(SUV_{mean}) which was measured based on 42% contour lines, apparent diffusion coefficients(ADC_{mean}), and the volume transfer coefficient (K^{trans}) were used as the qualitative analysis measurements. Pearson correlation coefficients were calculated between each pair of the three parameters. One-way ANOVA was used to evaluate the discrimination of each parameter among different differentiation groups. The PET/MR multi parameters were combined with Logistic Regression. ROC was used to evaluate the diagnostic efficiency of tumour differentiation with individual parameters and the combination of PET/MR.
Results: Finally, a total of 23 subjects included in this study. The correlations between each of the three individual parameters are weak. The statistic differences are significant in different degrees of tumour differentiation for all three individual parameters, and the value of ADC_{mean} is the best one. The accuracy of SUV_{mean} , ADC_{mean} and K^{trans} are 74.3%, 77.1%, 57.1%. The combination of PET/MR demonstrated an improved diagnostic efficiency with an accuracy of 85.7%.
Conclusion: This preliminary integrated PET/MR study demonstrated that compared with the individual parameters of PET/MR, the combination of PET/MR can improve the diagnostic efficiency of tumour differentiation in HNSCC.

B-1182 10:34

Is it benign or malignant? Assessing isolated lymphadenopathy of the head and neck using textural analysis
S. Chin, A. Kamalasanan, S. Henderson, T.A. Sudarshan; *Dundee/UK (sookcheng@doctors.org.uk)*

Purpose: Isolated lymphadenopathy can be the only initial presentation of squamous cell cancer (SCC) of the head and neck. Accurate identification of benign lymphadenopathy from malignant nodal disease and lymphoma is difficult. Due to this, patients are subjected to invasive nodal biopsies, majority of which will be benign disease and a small proportion will be non-diagnostic. We aim to analyse if the use of textural analysis can help identify malignant disease and aid differentiation between lymphoma and metastatic disease.

Methods and Materials: Twenty patients each with normal lymph nodes, histology-proven lymphoma and SCC with nodal involvement were restrospectively selected. Lymph node textural analysis on computed tomography (CT) images was analysed using MaZda software (Technical University of Lodz, Poland). Statistical differences were assessed using the Mann-Whitney U test.
Results: From the eleven textural features analysed, there were significant differences in entropy, contrast, correlation, difference entropy and inverse difference moment between metastatic nodes, lymphoma nodes and normal nodes (all $p < 0.001$). Entropy has been shown to be a good differentiator between pathology; entropy of normal nodes was 1.448, metastatic nodes 2.163 and lymphoma nodes 0.143.
Conclusion: Significant differences in the various textural features between lymphoma, metastatic and normal lymph nodes exist. This suggests an avenue for the use of lymph node textural analysis to aid diagnosis and reduce the number of benign nodal biopsies.

Head and neck cancer heterogeneity assessed by CT texture analysis: can it predict the human papilloma virus status?
F. Mungai, M. Pietragalla, L. Bonasera, M. Bartolucci, V. Berti, V. Miele; *Florence/IT (f.mungai@gmail.com)*

Purpose: Human papillomavirus-positive (HPV+) head and neck (HN) squamous cell carcinoma represents a different molecular, clinical and prognostic entity from HPV-negative (HPV-) disease. The purpose of this study was to determine if analysis of texture features of primary lesion on contrast-enhanced CT (CECT) images can be useful in predicting the HPV status.
Methods and Materials: Pre-treatment CECT images of 50 patients with primary HN carcinoma and known HPV status were retrospectively reviewed. The primary tumour was delineated within a manually drawn volume of interest (VOI). Six first-order and 34 higher order textural features were extracted from each VOI; the latter parameters were derived from analysis of: grey-level co-occurrence matrix (GLCM), neighbourhood grey-level different matrix (NGLDM), grey-level run length matrix (GLRLM) and grey-level zone length matrix (GLZLM). T test was used to evaluate differences in textural features between HPV+ and HPV- lesions. Logistic regression was performed to ascertain the effects of different textural features on the likelihood that a lesion is related or not to HPV.
Results: Of the 50 examined lesions, there were 30 HPV+ and 20 HPV-. Statistically significant ($p<0.05$) differences were seen in, respectively, 5 GLRLM, 2 NGLDM and 4 GLZLM extracted parameters. The logistic regression model was statistically significant for these parameters and correctly classified lesions with accuracies of 77-95%.
Conclusion: HPV+ HN cancers have different textural characteristics than HPV- lesions and are correlated with higher textural coarseness. CT texture analysis of the primary HN carcinoma may be used as a tool for predicting the HPV status.

B-1184 10:42

Estimation of the irradiation dose of children exposed to CBCT for various dental pathologies
M. Marcu, M. Hedesiu; *Cluj-Napoca/RO (marcumaria88@gmail.com)*

Purpose: The aim was to estimate the effective, cumulative and organ doses in children exposed to CBCT.
Methods and Materials: A prospective study was conducted in 561 children aged between 0 and 18 years exposed to CBCT in two European centres, over two years. The radiation doses were estimated for the following dental pathologies: orofacial cleft, impacted teeth, bone pathology, dental anomalies, dentoalveolar trauma, orthognathic surgery, and endodontics. The effective and organ doses were calculated by Monte Carlo simulation in paediatric voxel phantoms. The doses obtained were extrapolated and normalized to age and for the CBCT exposure protocol.
Results: The median of the effective dose was 137.9 µSv and median of cumulative dose was 231.4 µSv. Children with dental anomalies had statistically significant higher radiation doses compared to other pathologies ($p<0.05$). The effective dose was influenced by the field of view (FOV) and age at exposure. The highest doses were found for salivary glands (Q3 was 4.5 mGy) followed by brain (2.4 mGy), thyroid (1.0 mGy) and bone marrow (0.2 mGy). Organ doses were significantly influenced by dental pathology with a lower exposure for brain, thyroid and bone marrow (RBM) in clinical cases that used a small FOV (impacted teeth, endodontic evaluation) compared to cases that required a large FOV (dental anomalies, orofacial cleft and orthognathic surgery). The radiation exposure of salivary glands does not vary with dental pathology.
Conclusion: The results revealed the influence of dental pathology, FOV dimension and age on CBCT doses of children.

B-1185 10:46

Disrupted brain functional network architecture in long-term sensorineural hearing loss patients
X.-M. Xu, G. Teng; *Nanjing/CN (xmxu15@163.com)*

Purpose: Resting-state functional magnetic resonance imaging (fMRI) studies have demonstrated the disruptions of multiple brain networks in sensorineural hearing loss (SHL) patients. Nonetheless, several studies found no differences in network processing between HL patients and healthy controls (HCs). Its neural bases are poorly understood. To identify aberrant brain network architecture involved in long-term hearing loss, we compared the resting-state fMRI (rs-fMRI) patterns of SHL patients and HCs.
Methods and Materials: Long-term SHL patients (n = 22) with abnormal hearing abilities and age-, sex-, education-matched HCs (n = 21) participated in the current study and underwent the rs-fMRI scanning. We used degree centrality (DC) to investigate functional connectivity (FC) strength of the whole-brain network and functional connectivity analysis to explore aspects involved in sensorineural HL.
Results: Compared to HCs, we found significantly increased network centrality in left angular gyrus and left precuneus (GFR corrected, $P<0.025$ for voxel level; $P<0.05$ for cluster level). What's more, the left angular gyrus revealed increased connectivity to the right parietal lobe while the precuneus exhibited enhanced connectivity to the right angular gyrus (GFR corrected, $P<0.025/2$).
Conclusion: Rs-fMRI provides a new and novel method for identifying aberrant brain network architecture. Long-term HL patients have disrupted FC in visual and non-auditory areas. The current findings will provide a new perspective for understanding the neuropathophysiological mechanisms and neural plasticity in long-term SHL.

B-1186 10:50

Elastography shear wave contribution when evaluating thyroid follicular nodules comparing to histological findings
P.H.D. Moraes, M. Chammas, M. Schelini; *São Paulo/BR (pedrohenrique.mmoraes@gmail.com)*

Purpose: Follicular lesion is found in about 10-30% of all FNAB of thyroid nodules. 20% have a diagnosis of follicular carcinoma in the final histological analysis, although 80% of them are benign. Motivated by unnecessary surgeries performed, we studied with shear-wave elastography (SWE) to distinguish benign from malignant nodules (BETHESDA III and IV) before the histological analysis.
Methods and Materials: We included nodules with Bethesda III or IV on cytological analysis. The equipment used was Logic E9, GE, with SWE elastography. We classified follicular nodules according to strain pattern (1-5) - 1: high deformity, lower risk for malignancy and 5: low strain, high risk for malignancy. SWE deformation indexes (SWE index) were defined by two ROIs: one including most of the nodule and the other at pre-thyroid muscles. The arithmetic average of three different SWE indexes of each nodule was calculated. A deformation ratio (RDM) was calculated by dividing the SWE index of the pre-thyroid musculature (sternocleidomastoid) by the SWE index of the nodule, both using Kpa. All patients were submitted to surgical removal, with histological analysis.
Results: 16 patients were studied. 11/16 had histological diagnosis of carcinoma. 7/11 had an elastogram pattern>2. Statistical analysis, however, failed to show a significant association between carcinoma diagnosis and the elastogram pattern ($p=0.611$). RDM>1.32 suggest an increased risk for the diagnosis of carcinoma (sensitivity 81.8% and specificity 80%) ($p=0.015$).
Conclusion: RDM>1.32 is related to increased risk for the histological diagnosis of carcinoma in nodules with follicular pattern at cytology (BETHESDA III and IV).

B-1187 10:54

Metrics and textural features of MRI diffusion to improve classification of common parotid gland tumours
Z. Zhang, J. Cheng; *Zhengzhou/CN (yinierzhang@sina.com)*

Purpose: This study aimed to improve the identification ability of benign and malignant parotid gland tumours using support vector machine classifiers on quantitative MR imaging features.
Methods and Materials: 52 patients with parotid gland tumours (28 pleomorphic adenoma, 16 mucoepidermoid carcinoma, and 8 Warthin tumour) were included in this retrospective study without previous biopsy or surgery. Shape, histogram, and textural features were computed from T2WI and contrast-enhanced T1WI and the apparent diffusion coefficient (ADC) map. Combinations of features were used to train tumour-type-specific classifiers for pleomorphic adenoma, Warthin tumour, and mucoepidermoid carcinoma types in separation and as a joint classifier. The performance of different classifiers was assessed and compared using randomly selected subsets of training and test data.

Results: ADC histogram features (50th and 90th percentiles and skewness) yielded the best classification of tumour type (on average >92.3% of pleomorphic adenoma, >96.1% of Warthin tumour, and >84.7% of mucoepidermoid carcinoma). The resulting joint classifier correctly assigned >90.3% of the parotid gland tumours.
Conclusion: Support vector machine-based classifiers using ADC histogram features yielded very good discrimination among common parotid gland tumour types, and ADC textural features show promise for further subtype discrimination.

The diagnostic value of combination of US < MRI preoperative prediction for the extrathyroidal extension of papillary thyroid carcinoma
S. Hu; *Zhenjiang/CN (hsd2001054@163.com)*

Purpose: The purpose of the present study was to evaluate the diagnostic performance of preoperative ultrasonography (US), magnetic resonance imaging (MRI) and US combined with MRI for the prediction of extrathyroidal extension (ETE) in patients with papillary thyroid carcinoma (PTC).
Methods and Materials: Between January 2013 and December 2016, 83 consecutive patients underwent surgery for pathologically confirmed PTCs with ETE. We analysed all patients with PTC with ETE preoperative combination of US and MRI scan to evaluate ETE.
Results: For T3 (minimal ETE), the accuracy was 92.2% (47/51) for US, 74.5% (38/51) for MRI, and their combination was 98.0% (50/51). The difference in the three methods for T3 was statistically significant (P=0.000). For T4 (extensive ETE), the accuracy was 62.5% (20/32) for US, 87.5% (28/32) for MRI, and their combination was 93.8% (30/32). The difference in the three methods for T4 was statistically significant (P=0.000). For the total accuracy of ETE, US was 80.7% (67/83), MRI was 79.5% (66/83), and their combination was 96.4% (80/83). The difference of the three methods for ETE was statistically significant (P=0.001).
Conclusion: The combination of US and MRI can improve the accuracy of ETE for PTC.

B-1189 11:02

Use of the previously proposed (2013) ultrasound total malignancy score (TMS) in the management of thyroid nodules
S. Zannoni[1], G. Pompili[1], S. Tresoldi[1], G. Di Leo[1], A. Ravelli[1], A. Primolevo[2], G. Spadarella[1], G. Carrafiello[1]; [1]*Milan/IT*, [2]*Altamura/IT (stefaniazannoni@hotmail.com)*

Purpose: To validate the role of the Total Malignancy Score (TMS) previously proposed (Pompili et al.2013) in identifying thyroid nodules suspicious for malignancy by means of the sum of their ultrasound features.
Methods and Materials: The local ethical committee approved this prospective observational study. We examined 231 nodules in 231 consecutive patients (164 females; age range 20-87 years; median age 59 years; IQR 48-70 years) who underwent ultrasound followed by fine needle aspiration cytology (FNAC). Nodules had been further classified using the TMS considering ultrasound features (number, echogenicity, structure, halo, margins, Doppler-signal, calcifications, growth) and the Bethesda System for Reporting Thyroid Cytopathology (TBSRTC) considering cytological features. Patients with nodules considered non-negative (categories III-VI TBSRTC) underwent histological analysis, repeated FNAC or 2 years strict ultrasound follow-up. Association between final diagnosis, each of the ultrasound features and TMS was estimated using the Chi-square test, the Mann Whitney U test and a multivariate logistic regression. A ROC curve was obtained for TMS diagnostic accuracy.
Results: At ultrasound 47%(108/231) of the nodules had TMS<3, 18%(42/231) TMS=3 and 35%(81/231) TMS>3. At FNAC 85%(196/231) of the nodules resulted benign and 15%(35/231) non-negative. Hypoechogenicity, solid structure, presence of microcalcifications and nodule's number resulted independent predictors of the final diagnosis and TMS diagnostic accuracy was good (area under the ROC curve: 0.82).
Conclusion: The TMS system is simple to use, reliable, easy reproducible and strongly relates to malignancy risk. According to our results, FNAC could be limited to nodules with TMS >=3, without missing any carcinoma.

B-1190 11:06

A multivariate analysis combining DCE and IVIM derived parameters to improve parotid tumours differential diagnosis
F. Patella[1], G. Franceschelli[1], M. Petrillo[2], M. Sansone[2], R. Fusco[2], G. Carrafiello[1]; [1]*Milan/IT*, [2]*Naples/IT (battellina@gmail.com)*

Purpose: To evaluate the diagnostic value of a MRI protocol combining dynamic contrast-enhanced(DCE-MRI) and diffusion-weighted imaging (DW-MRI) in patients with parotid tumours.
Methods and Materials: 14 histopathological proven parotid tumours(7 Warthin tumours,WT, and 7 Pleomorphic Adenomas, PA) in 11 patients were included. For both DCE-MRI and DW-MRI model free and model based parameters were computed pixel by pixel on manually segmented regions of interest(ROIs) drawn on entire lesion's volume. Extracted parameters were: Ktrans, kep, vp, MRE, TTP, WIS, WOS, f, D, D*. For each parameter median and standard deviation values on segmented ROIs were calculated for each lesion with a Matlab environment. Statistical evaluations included univariate and multivariate analysis using conventional linear analysis and advanced techniques to separate PA by WT. Furthermore,for the 153 possible couples of parameters specificity, sensibility,PPV and NPV were computed.
Results: No single variable could differentiate WT by PA. Only 4 couples presented AUC = 1: 1) Ktrans(std) and f(std); 2) Ktrans(std) and D(std); 3) Kep(std) and D(std); 4) MRE(av) and TTP(av). The linear combination of these coupled variables provided 4 new parameters: *Y1 = 46.0* Ktrans(std) + 34.7* f(std) ;Y2 = 34.8* Ktrans(std) + 8368* D(std);Y3 = 0.525* kep(std) + 7223* D(std); Y4 = 0.0361 *MRE(av) + 1.5*TTP(av)*-Optimal cut-off resulted 7.2973; 6.8202; 1.0210; 6.0205 respectively.In all cases sensitivity, specificity, PPV e NPV were 100% (misclassification error rate = 0%).
Conclusion: New coupled variables provided by a linear combination of DCE-MRI and IVIM derived parameters potentially could help in differential diagnosis between WT and PA.

B-1191 11:10

Does RFA induce neoplastic change of benign thyroid nodules
S. Ha, J. Shin, J. Baek, D. Song, S. Chung, Y. Choi, J. Lee; *Seoul/KR (su3ha5@hanmail.net)*

Purpose: With increase in detection of thyroid nodules, radiofrequency ablation (RFA) has been investigated for the treatment of symptomatic thyroid nodules, and has been shown to represent acceptable alternative to surgery. Currently, there has been no data whether RFA promote neoplastic transformation of undertreated peripheral portion of the benign nodules through biopsy. The aim of our study was to evaluate during 5-year follow-up, whether RFA treated benign thyroid nodules is associated with malignancy through biopsy, along with clinical efficacy and cytomorphological alteration after treatment.
Methods and Materials: The data were retrospectively collected between April 2008 and June 2013 and core needle biopsy (CNB) was performed on 16 benign thyroid nodules who were treated using RFA . Parameters were compared between the time of each patient's enrollment and the last follow-up examination using a linear mixed model statistical analysis. The slides were reviewed again by two pathologists.
Results: No atypical cells or neoplastic transformation were detected in undertreated peripheral portion of treated benign nodules on CNB specimen. RFA neither altered thyroid capsule nor changed the thyroid tissue adjacent to the treated area. In the histopathological examinations, we observed 82.3% acellular hyalinization, which was the most common finding. After mean follow-up period of more than 5 years, mean volume had decreased to 6.4±4.2 ml, with volume reduction rate of 81.3%±5.8% (p< 0.0001).
Conclusion: RFA is effective for treatment of benign nodules without carcinogenic effect or tissue damage in the normal thyroid tissue adjacent to the RFA treated zone.

B-1192 11:14

Prognostic significance of PET-based radiomic image features in locally advanced laryngeal and hypo-pharyngeal squamous cell carcinoma
H.L. Nelstrop, R. Prestwich, M. Barnfield, G.M. McDermott, A. Scarsbrook; *Leeds/UK (hannah.nelstrop@nhs.net)*

Purpose: To determine whether radiomic features derived from 18F-FDG positron emission tomography (PET) are prognostic predictors in patients with locally advanced laryngeal and hypo-pharyngeal squamous cell carcinoma (SCC) and explore the relationship between radiomic features and tumour volume.
Methods and Materials: Retrospective analysis of 43 consecutive patients with laryngeal and hypo-pharyngeal squamous cell carcinoma (SCC) treated at a single institution was performed. Tumours were segmented using specialised software: RTx Advanced (Mirada Medical) and Advantage workstation (GE Healthcare). Radiomic analysis was performed on tumour and background volumes using Chang-Gung Image Texture Analysis toolbox (CGITA). Entropy derived from the grey-level histogram ($Entropy_{hist}$), entropy and dissimilarity derived from the grey-level co-occurrence matrix and zone percentage derived from the grey-level size zone matrix were assessed. Univariate Cox regression was performed on the results with respect to disease-specific survival (DSS) and progression-free survival (PFS) with significance taken as P<0.05. Spearman's rank correlation was used to assess the correlation between parameters.
Results: None of the radiomic features were prognostic predictors of DSS or PFS following correction for multi-hypothesis testing; however, all texture features were significantly correlated with tumour volume (p<0.002). This correlation reduced for $Entropy_{hist}$ and zone percentage when only the larger tumours (10-15cm^3) were included in the analysis.

Conclusion: Patients with laryngeal/hypopharyngeal tumour sizes greater than 10-15cm³ are more suited for radiomic analysis due to the reduced correlation between texture features and tumour size.

B-1193 11:18

Lateralisation effects on functional connectivity of the auditory network in patients with unilateral pulsatile tinnitus as detected by functional MRI

H. Lv, P. Zhao, Z. Liu, X. Liu, H. Ding, S. Gong, Z. Wang; *Beijing/CN (chrislvhan@126.com)*

Purpose: Unilateral pulsatile tinnitus (PT) was proved to be a kind of disease with brain functional abnormalities within and beyond the auditory network (AN). However, changes in patterns of the lateralisation effects of PT are yet to be established.
Methods and Materials: We recruited 23 left-sided, 23 right-sided PT (LSPT, RSPT) patients and 23 normal controls (NC). We combined applied independent component analysis and seed-based functional connectivity (FC) analysis to investigate alteration feature of the FC of the AN using resting-state functional magnetic resonance imaging (rs-fMRI).
Results: Compared with NC, LSPT patients demonstrated disconnected FC within the AN in both sides. Disrupted network integrity between AN and executive control network, self-perceptual network and limbic network was also demonstrated bilaterally. In contrast, RSPT demonstrated decreased FC within the AN on the left side, but significant increased FC within the AN in the right side (symptomatic side). Enhanced FC between AN and executive control network, self-perceptual network and limbic network was also found mainly on the right side. Positive FC between the auditory network and the limbic network may be a reason to explain why RSPT patients are willing to be in clinic.
Conclusion: LSPT exhibits disrupted network integrity in brain functional networks. But RSPT are featured by enhanced FC within AN and between networks, especially on the right (symptomatic) side. Corroboration of featured FC helps to reveal the pathophysiological changing process of the brain in patients with PT, providing imaging-based biomarker to distinguish PT from other kind of tinnitus.

B-1194 11:22

Shear wave elastography in the evaluation of level VI lymph nodes in papillary thyroid carcinoma

W. Chang, M. Chen; *Shanghai/CN (cwy_jiayou@126.com)*

Purpose: This study aimed at exploring the value of shear wave elastography (SWE) in ultrasound evaluation for level VI lymph nodes in papillary thyroid carcinoma (PTC).
Methods and Materials: 87 level VI lymph nodes from 22 consecutive patients with PTC were evaluated by grey-scale ultrasound and SWE in condition of ex vivo before rapid frozen section. Grey-scale ultrasound and SWE indexes of metastatic and non-metastatic lymph nodes were evaluated by statistical analysis separately in all patients and in patients without Hashimoto's thyroiditis (HT). Indexes included transverse diameter, longitudinal diameter, longitudinal-to-transverse diameter ratio (L/T ratio), E_{mean}, E_{min}, E_{max} and E_{SD}. The rapid frozen section result of each lymph node was used as gold standard to evaluate the diagnostic performance of grey-scale ultrasound and combination method which combined grey-scale ultrasound and SWE.
Results: In all patients, significant indexes included longitudinal diameter ($p=0.009$), L/T ratio ($p=0.003$), E_{max} ($p=0.016$) and E_{SD} ($p=0.006$). In patients without HT, significant indexes included longitudinal diameter ($p=0.002$), L/T ratio ($p=0.003$), E_{mean} ($p=0.030$), E_{max} ($p<0.001$) and E_{SD} ($p=0.001$). Combining grey-scale ultrasound with SWE, combination method had higher AUC than grey-scale ultrasound both in all patients (0.887 vs 0.841) and patients without HT (0.925 vs 0.866). Grey-scale ultrasound had higher AUC in patients without HT than in all patients (0.866 vs 0.841), which was the same with combination method (0.925 vs 0.887).
Conclusion: Shear wave elastography can provide additional information for ultrasound evaluation of level VI lymph nodes in papillary thyroid carcinoma, especially in papillary thyroid carcinoma without Hashimoto's thyroiditis.

B-1195 11:26

Diagnostic value of dual-energy CT imaging for cervical lymph node metastasis in patients with papillary thyroid cancer

M. He; *Fuzhou/CN (hemuzhen@sina.com)*

Purpose: To quantitatively assess the diagnostic value of dual-energy computed tomography(CT) imaging for cervical lymph nodes metastasis in patients with papillary thyroid cancer.
Methods and Materials: Fifty-five consecutive patients with suspected of thyroid cancer were prospectively enrolled and underwent enhanced dual-energy spectral CT scan. The normalised iodine concentration (NIC) and the slope of the spectral Hounsfield unit curve (λ_{HU}) during both arterial and venous phases were measured, respectively, from iodine overlay images and spectral curves. Two-sample t test was performed to compare quantitative parameters at dual-energy CT between the histopathologically proven benign and metastatic lymph nodes. Receiver operating characteristic curves were generated for sensitivity and specificity analyses as well as evaluating the diagnostic value of dual-energy CT imaging and conventional CT features.
Results: Using the conventional CT features for detection of metastatic lymph nodes, sensitivity, specificity and accuracy were 4%-79.0%, 63.6%-100% and 43.9%-72.6%, respectively. Both arterial and venous phase NIC and λ_{HU} were significantly higher in metastatic than in benign lymph nodes (all $p<0.001$). The best quantitative parameter for detection of lymph nodes metastasis was arterial phase NIC with optimal threshold value of 25.8%, sensitivity, specificity were 90.3% and 96.6%. The area under curve (AUC) of arterial phase NIC and λ_{HU} was significantly higher than those of venous phases (all $P<0.001$).
Conclusion: Compared with qualitative conventional CT features, quantitative parameters associated with NIC and λ_{HU} at dual-energy CT showed higher accuracy and better diagnostic performance for cervical lymph node metastasis in patients with papillary thyroid cancer.

B-1196 11:30

Multiphasic CT vs dynamic contrast-enhanced MRI in the characterisation of parotid gland tumours

N. Tharwat Mohammed El-Sayed; *Mansoura/EG (nehaltharwat83@gmail.com)*

Purpose: Salivary gland tumours are challenging with regard to preoperative diagnosis. The aim of our study was to highlight the value of multiphasic CT and contrast-enhanced dynamic MRI in characterisation of benign and malignant parotid tumours as well as to compare the diagnostic accuracy of both modalities.
Methods and Materials: The study group included 45 patients (54 lesions), 26 males and 19 females, and their age ranged from 24 to 78 years. All patients underwent both CT and MRI examinations. The time intensity (or attenuation) curve for each lesion was analysed and compared with the final post-operative pathology.
Results: The type of the curve on dynamic contrast-enhanced MRI had high sensitivity, specificity, positive predictive and negative predictive values, and accuracy in characterisation of benign and malignant parotid tumours (94.4%, 97.2%, 94.4%, 97.2%, and 96.3%, respectively). Also, curve analysis on multiphasic CT revealed similar high sensitivity, specificity, positive predictive and negative predictive values, and accuracy as compared to DCE-MRI (92.6%, 96.3%, 92.6%, 96.3%, and 95.1%, respectively).
Conclusion: Both dynamic contrast-enhanced MRI and multiphasic CT have comparable high accuracy in characterising the different histological types of parotid gland tumours.

B-1197 11:34

An innovative 3D-3D superimposition for assessing anatomical uniqueness of frontal sinuses (FS) through segmentation on CT scans

M. Cellina, D. Gibelli, C. Sforza, G. Oliva; *Milan/IT (m.cellina@yahoo.it)*

Purpose: Uniqueness in shape and size is the most relevant anatomical characteristic of FS and finds a prominent application in personal identification of skeletons and human remains. This study aims at assessing anatomical uniqueness of FS through 3D registration and automatic calculation of point-to-point distances between 2 models.
Methods and Materials: We selected 30 subjects who underwent 2 maxilla CT scans (interval time: 1-5 months; acquisition parameters: kV: 120, mAs: 320, collimation: 40 × 0.6 mm, tube rotation: 1 s; reconstruction thickness: 3 mm; reconstruction filter: H60 sharp). FS were automatically segmented through ITK-SNAP software; the 3D models belonging to the same patient were automatically superimposed according to the least point-to-point difference between the 2 surfaces. Then, we executed the same procedure on 200 randomly selected maxilla CT of other patients to perform 100 superimpositions of FS belonging to different individuals (mismatches). Average root mean square (RMS) point-to-point distances observed in the group of matches and mismatches were assessed through Student's t test. Logistic regression was calculated to provide a diagnostic tool for the recognition of FS.
Results: In the group of matches, RMS value was on average 0.35 mm (SD: 0.25), and 2.90 mm (SD: 1.63) in the group of mismatches, with a statistically significant difference ($p<0.0001$). A logistic formula was developed according to the RMS values from matches and mismatches and was applied to a novel set of 100 superimpositions, with an accuracy of 100%.
Conclusion: This approach to the assessment of anatomical uniqueness provides reliable morphological and quantitative evaluation.

B-1198 11:38

Diagnostic efficacy of dynamic manoeuvres in computed tomographic evaluation of oral cavity lesions

R.V. Mathilakath; *Davangere Karnataka/IN (rajesh.venunath@gmail.com)*

Purpose: To evaluate the diagnostic efficacy of dynamic manoeuvres in CT for better delineation of oral cavity lesions as compared to conventional scans to assess the origin and extent of oral cavity lesions.

Methods and Materials: 52 patients with histologically proven diagnosis of various oral cavity lesions referred for CT evaluation were included in this hospital-based prospective cross-sectional study conducted over a period of two years from December 2013 to November 2015. The consented subjects were subjected to a preliminary conventional plain and contrast study followed by puffed cheek CT scans as described by Weissman and Carrau . The images were compared simultaneously by an experienced radiologist for evaluation of origin and extent of the lesion.
Results: Puffed cheek manoeuvre was highly useful in 71.2% of cases and was not much helpful in 28.8% in evaluation of oral lesions. Puffed cheek CT has a sensitivity of 69% and a specificity of 43% in accurately staging oral malignancies. Puffed cheek CT had a positive predictive value of 36% and a negative predictive value of 81% and an accuracy rate of 51% compared to conventional CT in staging oral malignancies.
Conclusion: Puffed cheek CT scans provide a clearer and more detailed evaluation of mucosal surfaces of the oral cavity than do conventional (non-puffed) images. In selected patients, like those with lesions of retromolar trigone, the puffed cheek technique may serve as a worthy supplement to conventional CT in the evaluation of bony invasion and proper delineation of tumour extent.

B-1199 11:42

Diagnostic value of contrast-enhanced 3D FLAIR sequence in acute optic neuritis

P. Tunlayadechanont, T. Panyaping, P. Cheecharoen, P. Jindahra;
Bangkok/TH (fangpt123@gmail.com)

Purpose: Contrast enhancement and hypersignal T2W of the optic nerve are abnormal findings in acute optic neuritis. Contrast-enhanced FLAIR sequence has both T2W and T1W effects. We aimed to study the diagnostic accuracy of whole-brain CE 3D FLAIR sequence in our routine brain protocol in detecting acute optic neuritis compared with clinical diagnosis.
Methods and Materials: This was retrospective cross-sectional study including optic nerves from twenty-two patients who first-time diagnosis of acute optic neuritis from clinical data and neuro-ophthalmological examination. All patients underwent brain MRI imaging with CE 3D FLAIR imaging at 3T. The hypersignal CE-FLAIR of optic nerve was assessed independently by 2 neuroradiologists. The optic nerve to white matter of the frontal lobe signal intensity ratio was also calculated as maximum SIR and mean SIR.
Results: 30 pathologic nerves of acute optic neuritis from twenty-two patients were diagnosed by neuroophthalologist. 23 hypersignal of optic nerves were found on CE-FLAIR. Interrater agreement was substantial (K=0.73). The consensus optic nerve signal abnormality on CE-FLAIR has 82% accuracy, 77% sensitivity, 93% specificity, 96% positive predictive value and 65% negative predictive value. Optic nerve to frontal white matter SIR of the affected optic nerves showed statistically significant higher than those normal optic nerves. Using a cut-off maximum SIR of 1.24 and cut-off mean SIR of 1.16 with 93% sensitivity and 86% specificity have 89% and 91% accuracy, respectively.
Conclusion: Hypersignal of optic nerve on whole-brain CE 3D FLAIR sequence has diagnostic potential in acute optic neuritis.

B-1200 11:46

Radiological diagnosis of desomorphine-associated osteonecrosis

A. Babkova, N.S. Serova, S.P. Pasha, M. Shariya; *Moscow/RU (an4i1@ya.ru)*

Purpose: Atypical osteonecrosis cases have been noted from 2003 in Russia due to abuse of synthetic drugs, such as desomorphine, which is one of the most widespread drug because of it low cost, quick production process from codeine pills with red phosphorus and other toxic substances.
Methods and Materials: From 2010 to 2017, 165 desomorphine addicts were evaluated at the Sechenov University. Patients underwent skull X-ray, panoramic radiography, multispiral computed (MSCT) and cone-bean computed tomographies (CBCT), radionuclide diagnostics. As a result of this evaluation, 165 patients were diagnosed with “Toxic phosphorus necrosis” of skull bones. Patients underwent different surgical interventions.
Results: Conventional radiography, MSCT, CBCT revealed empty tooth sockets in 165 patients, sclerotic end plates in 76 patients (46%). Massive diffuse periosteal deposits in the lower jaw region were in 97 patients (59%). Alterations in the upper jaw were in 39 subjects (24%). A pathological mandible fracture was observed in 38 cases (23%). Bone scintigraphy and SPECT showed excessive accumulation of the 99mTc-Pyrphotech in the skull bones in 30 cases (100%): in the maxilla, mandible, in the eye-pits (n=11;31%), in the cheekbones (n=8;26%), in the sternum (n=11;31%), in the clavicles and humeral heads (n=7;23%), in the crests of the ilium (n=6;20%), in the knee areas (n=5;17%).
Conclusion: Complex radiological diagnostic technologies used to evaluate the skeletal system in patients taking desomorphine allow full identification of the nature of this disorder, presence of concomitant complications, help in the determination of the surgical strategy and planning of further reconstructive treatments.

Microwave ablation (MWA) in the treatment of colorectal liver metastases (CRLM): an eight-year follow-up study

T.J. Vogl, M. Zitsch, W. Bechstein, J. Trojan; *Frankfurt a. Main/DE (t.vogl@em.uni-frankfurt.de)*

Purpose: To evaluate survival time and the progression-free survival of patients with colorectal liver metastases (CRLM) in curative and palliative intention depending on different parameters.
Methods and Materials: In this retrospective study, 132 patients (59 women, 73 men; mean 61.86; range 35-88) were treated with microwave ablation (MWA) for CRLM between 2010 and 2017. A total of 257 lesions were investigated regarding location of the metastases, technical success, used power, diameter, volume and ablation zone volume. Pre-treatment and follow-up were also documented. Moreover, patients were divided into two different groups based on the indication of the treatment (palliative or curative).
Results: The mean diameter and volume of the intrahepatic metastases were 18.6 mm±10.1 mm and 4.54 cm^3±3.4 cm^3. MWA was performed with an average power of 45 kJ. The follow-up MR images showed a mean post-ablation volume of 38.0 cm^3. Three patients had a local recurrence (3/132; 2.2%) and 13 patients had new intrahepatic metastases (13/132; 9.8%). The average survival was 520 days (1.42 years). In the curative group, mean survival was 637 days (1.74 years) and in the palliative group 250 days (0.68 years), respectively. All MWAs were without any serious complications. Mild side effects were local haematoma and pain symptoms.
Conclusion: MWA for treatment of CRLM is an effective therapeutic treatment procedure with excellent local control rates and improved survival in the curative group.

B-1202 14:08

Comparison between microwave and radiofrequency ablation in local control of colorectal liver metastases

E. Raimondi[1,2], K.N. De Paepe[2], D.-.M. Koh[2], J. McCall[2], N. Fotiadis[2];
[1]*Ferrara/IT*, [2]*London/UK (edoardo.raimondi@unife.it)*

Purpose: To retrospectively analyse the safety and efficacy of radiofrequency ablation (RFA) and microwave ablations (MWA) in the treatment of colorectal cancer liver metastases (CRC-LM).
Methods and Materials: 193 patients with unresectable CRC-LM treated with RFA or MWA in a single centre between March 2006 and December 2016 were retrospectively evaluated. Medical records and imaging studies were reviewed for demographic data, technical deployment, associated complications, tumour recurrence and overall survival. Rate of tumour recurrence, complication rates and patient survival were compared between RFA and MWA treatments.
Results: 456 procedures were performed in 193 patients (123 male, 70 female) with a median age of 66 years (range 32-91 years). Of these, 343/456 (75.2%) were RFA and 113/456 (24.8%) were MWA. The median number of procedures per patient was 2 (range 1-10). Median lesion size was 17mm (range 3-80mm). The local tumour recurrence rate was 45% for RFA and 28% for MWA, with a hazard ratio of 0.6 in favour of MWA (95%CI 0.4-0.9). Two and five year overall survival for RFA vs MWA were 88% vs 89% (p>0.05) and 35% vs 66% (p<0.05) respectively. Complications were reported in 43/456 procedures (9.4%); in 28/343 (8.1%) of RFA and 15/113 (13.3%) of MWA. One patient died due to multi-organ failure post RFA.
Conclusion: MWA achieved better local tumour control compared with RFA in the treatment of CRC-LM, with a slightly higher complication rate.

B-1203 14:16

Risk factor-based prediction algorithm for liver function damage in patients with hepatocellular carcinoma after microwave ablation

Y. Zhou, X. Jing, J. Ding; *Tianjin/CN (dr.jingxiang@aliyun.com)*

Purpose: To investigate the influence of liver function damage in patients with hepatocellular carcinoma (HCC) after microwave ablation (MWA) on prognosis and establish a risk factor-based algorithm to predict liver function damage.
Methods and Materials: A total of 745 patients with HCC undergoing MWA were enrolled in this study and were classified into modelling and validation group. The progression-free survival (PFS) and overall survival (OS) were

analysed using Kaplan-Meier and log-rank tests. The β-coefficients derived from a logistic regression model were used to calculate the risk score.
Results: 69 of 498 patients in modelling group suffered from liver function damage. The 1-, 2- and 3-year OS were 93.7%, 88.0%, 79.8% and 89.2%, 79.6%, 57.8% for patients without and with liver function damage (p=0.043), respectively. A total of five risk factors were filtrated by logistic regression model, namely Child-Pugh classification before treatment, tumour numbers, ablation volumes, relative position between the tumour and portal vein (PV) and APRI. These factors were used to calculate the risk score to predict liver function damage. The AUC of the risk score for predicting liver function damage was 0.798 in modelling group and 0.832 for validation group. The sensitivity and specificity to identify liver function damage were 65.22%, 84.38% in modelling group and 60.61%, 88.32% in validation group, respectively.
Conclusion: Liver function damage after MWA is an unfavourable factor for prognosis. The algorithm based on risk factors is a stabilized assessment model to predict liver function damage in patients with HCC after MWA.

B-1204 14:24

CT texture parameters to evaluate outcome after thermal ablation for colorectal liver metastases

E. Klompenhouwer, R.G.H. Beets-Tan, M. De Boer, S. Trebeschi, W. Prevoo, D.M. Lambregts, G.L. Beets, M. Maas; *Amsterdam/NL (l.klompenhouwer@nki.nl)*

Purpose: Early detection of incomplete ablation or local tumour progression (LTP) after thermal ablation is challenging. Aim of this retrospective pilot study is to determine whether liver CT texture is valuable to evaluate the completeness of ablation and to early detect LTP after thermal ablation in patients with colorectal liver metastases.
Methods and Materials: Texture parameters were extracted from CT scans of 27 patients (38 lesions; 23 RFA and15 MWA) 1 month post-ablation. Ablation zones were delineated in 3D-slicer and texture parameters were calculated with an internal tool programmed in Python for the total lesion and for the ablation margin. This ablation margin of 3 mm inwards and outwards was added by the Python tool after delineating the total lesion. Evaluated texture parameters were mean, median, entropy, skewness and kurtosis, which were compared with outcome post-ablation: no LTP, LTP during follow-up or incomplete ablation. Median follow-up was 12 (5-48) months.
Results: 25 lesions were completely ablated, 4 were incompletely ablated and 9 showed LTP during follow-up. In lesions that were incompletely ablated or showed LTP (N=13), the median and mean texture density were significantly higher than in patients without LTP, both for the total lesion texture (p=0.032 and p=0.036, respectively) and the texture of the ablation margin (p=0.026 and p=0.034, respectively).
Conclusion: The mean and median texture density of the total lesion and ablation margin 1 month post-ablation might be valuable non-invasive markers to evaluate incomplete ablation and detect early LTP after thermal ablation for colorectal liver metastasis before they are visible on CT during follow-up.

B-1205 14:32

Microwave ablation (MWA) of liver malignancies: outcomes and prognostic factors of local tumour progression (LTP) with a new generation system

P. Marra, P. Diana, F. Ratti, F. Cipriani, M. Salvioni, S. Gusmini, M. Venturini, L. Aldrighetti, F. De Cobelli; *Milan/IT (marra.paolo@hsr.it)*

Purpose: High-power MWA may present advantages in term of local tumor control, compared with other ablative techniques, but data in the literature are conflictual. We analyzed the outcomes and investigated potential prognostic factors of LTP in the treatment of hepatocellular carcinoma (HCC) and colorectal cancer liver metastases (CRLM), using a new generation MWA system.
Methods and Materials: From November 2014 to June 2017, 50 patients (HCC=30; CRLM=20) underwent percutaneous, laparoscopic or open surgical MWA of 61 liver nodules with a 100W/2450MHz Microwave Generator (Emprint, Medtronic). DCE-CT or MRI were used to assess 1-month complete ablation (CA) and LTP at follow up.
Results: Overall CA rate was 97.3%. Overall LTP in HCC and CRLM metastases was respectively 18% (mean observation time, 15.3 months, interval 6-31 months) and 10% (mean observation time 10.8 months, interval 6-21). For HCC, BCLC-stage >0, multiple nodules, viral etiology and relapsing disease were associated to LTP without statistical significance; LTP was not influenced by age, nodule size and vessels/capsule proximity. For CRLM, a lesion size >20mm was associated to higher LTP (p=0.027). Nodule number >5 showed increased LTP without statistical significance. LTP was not influenced by age, KRAS mutation, synchronous/metachronous metastases and vessels/capsule proximity. LTP did not differ among percutaneous and surgical approaches.
Conclusion: LTP rates after liver MWA for HCC and CRLM are comparable with the literature. CRC mets >20mm are associated with higher LTP. Our initial experience with high-power MWA is promising and further development of this technique will probably provide even better results.

B-1206 14:40

Microwave ablation therapy of giant hepatic cavernous haemangiomas

S. Çakir, M. Baykara Ulusan, I.N. Mutlu, N. Kiliçkesmez, C. Turan Bektas, A. Yardimci; *Istanbul/TR (mehmetsemihcakir@gmail.com)*

Purpose: Endovascular embolisation therapy used as a classical method in the treatment of hepatic giant cavernous haemangiomas does not yield the desired results like dimensional diminution and a decrease in symptoms. It is aimed to demonstrate the effectiveness of treatment with microwave ablation (MWA) therapy.
Methods and Materials: Between October 2016 and April 2017, patients (n=10; 5 female, 5 male) with liver giant cavernous haemangioma underwent MWA therapy and followed for a mean of 6 months. 3 patients presented with gastric complaints, 5 patients had abdominal pain and 2 patients had thrombocytopenia. Patient pain scoring was noted according to the 10-point visual analog scale. MWA therapies were performed by using an 18-gauge electrode (Accu2i pMTA Applicator, AngioDynamics, Inc. Hampshire, UK) under ultrasound guidance in the presence of analgesia and sedation. Mean ablation time was 8.5 minutes.
Results: All ablations were terminated with technical success and there were no major complication. Abdominal pain, especially localised at right upper quadrant, developed after procedure due to ablation therapy and additional analgesia support was given. Average pain score decreased from 5.1 to 1.3 after the first month. Mean tumour volume decreased 66.1% after sixth months.
Conclusion: Therapy of microwave ablation for hepatic haemangiomas with a high-powered microwave device appears to be safe and effective in providing tumour shrinkage, devascularisation and pain relief. While transarterial chemoembolisation alone cannot cause significant tumour shrinkage, the effect of MWA is excellent for haemangioma destruction. Therefore MWA can be used for the treatment of large hepatic haemangiomas.

B-1207 14:48

The effect of oesophageal varices on the outcome of RF ablation in patients with HCC

M. Ahmad; *Sohag/EG (mandw20022002@hotmail.com)*

Purpose: To determine the therapeutic efficacy of radiofrequency ablation and the impact of oesophageal varices on the survival final results.
Methods and Materials: 121 of 168 patients with portal hypertension had oesophgeal varices, underwent RF ablation as a treatment for a single HCC (≤ 5cm). Therapeutic efficacy was evaluated. Logistic regression analyses of risk factors for occurrence of complication and multivariate cox-regression analyses for overall survival were detected.
Results: Patients with HCC and oesophageal varices had a complete ablation rate of 88.4%. Portal vein thrombosis was the most type of complication. By univariate analysis, thrombocytopenia (P= 0.032) was an independent risk factor of complications. By multivariate analysis , left lobe location of HCC (*P* = 0.015) was an independent risk factor of complications and subcapsular location of HCC (*P* = 0.019) was an independent prognostic factor for survival .
Conclusion: This current study has proven that patients with portal hypertension and oesophageal varices can tolerate RF ablation of HCC. Dealing caution as regards correction of thrombocytopenia and professionally as regards location of HCC, we can improve the outcome of RF ablation.

B-1208 14:56

Feasibility, effectiveness and safety of percutaneous MR-guided ablation of small hepatic malignancies

J. Weiß, R. Hoffmann, E. Kessler, H. Rempp, K. Nikolaou, S. Clasen; *Tübingen/DE (jakob.weiss@med.uni-tuebingen.de)*

Purpose: To investigate the feasibility, effectiveness and safety of percutaneous MR-guided ablation of small hepatic malignancies.
Methods and Materials: Between January 2012 and December 2016, 45 patients were included in this IRB-approved retrospective study. All patients were scheduled for percutaneous MR-guided tumour ablation (radiofrequency n=27; microwave n=16) due to primary (HCC n=11; CCC n=2) or secondary hepatic malignancies with a lesion diameter of ≤12mm. A 1.5T MR system was used for planning, targeting and therapy monitoring. Technical success and long-term effectiveness were assessed by dynamic contrast-enhanced MR imaging. Mean follow-up was 17.1±11.6 months (range: 4-42 months).
Results: Tumour ablation was successfully completed in 43 patients. In six patients (13%), planning imaging revealed new, unexpected lesions, which were either treated in the same session (n=4) or changed therapy management (n=2) due to diffuse tumour progress. Thus, incomplete treatment or non-indicated local ablation could be avoided. Planning imaging was

conducted without contrast agent administration in 82% (n=37) of the ablation procedures. In 66% (n=30), target tumours were visible in real-time MR-fluoroscopy during the intervention. Post-procedural imaging revealed a technical success of 100% with no major complications. During follow-up, no local tumour recurrence was observed although twelve patients presented with new tumours distant to the ablation zone.
Conclusion: MR-guided ablation is a feasible approach for effective and safe treatment of small hepatic malignancies. In addition, MR planning imaging is helpful to account for unexpected changes of the oncological situation to avoid inappropriate treatment in favor of patient safety.

B-1209 15:04

A new software for immediate volumetric assessment of tumour ablation completeness: could it allow to spare local retreatments?
R. Muglia[1], M. Solbiati[2], L. Solbiati[3]; [1]*Pieve Emanuele/IT*, [2]*Milano/IT*, [3]*Rozzano (Milano)/IT*

Purpose: To retrospectively evaluate accuracy of a software (AblationFit®, R.A.W. Endosight, Milan, Italy) in assessing complete ablation of tumours with percutaneous thermal ablation.
Methods and Materials: Out of 320 HCCs treated with microwave ablation (AMICA, HS, Aprilia, Italy) from 2010 to 2016, 90 patients in which ablations were technically successful were selected. Imaging follow-up of at least one year was performed. With AblationFit® the ceCT volumes of the 90 HCCs before ablation and the corresponding achieved volumes of necrosis were segmented, co-registered and superimposed, to estimate complete target inclusion into the necrosis volume. Predictions of complete vs partial ablation provided by the software were verified analysing presence or absence of local tumour progression (LTP) on 1-yr follow-up ceCT.
Results: Two experienced radiologists confirmed the ablation in 90/90 cases. With AblationFit® reconstructions, only 73/90 HCCs were entirely included into the volumes of necrosis, while 17/90 were partially included. At 1-yr follow-up, ceCT showed no-LTP in 69/90 and LTP in 21/90. With AblationFit® no-LTP and LTP were correctly predicted, respectively, in 65/73 and 13/17. 8/73 cases of complete ablation according to AblationFit® developed LTP and in 4/17 of partial ablation according to AblationFit® LTP did not develop. Sensitivity of AblationFit® was 62% and specificity 94%. In 13/13 cases of correct prediction of LTP, tumour regrowth in the location where AblationFit® showed residual tumour.
Conclusion: AblationFit® used at the time of ablations, in 13/90 HCCs local re-treatment could have been spared thanks to the immediate detection of non-ablated tumour.

M. Solbiati: Founder; R.A.W., Endosight, Milan, Italy. Shareholder; R.A.W., Endosight, Milan, Italy.

B-1210 15:12

Ablation therapy of non-colorectal cancer lung metastases: retrospective analysis of tumour response post LITT, RFA and MWA
N.-E.A.N. Mohammed, N.N.N. Naguib, T. Gruber-Rouh, I. Burck, T.J. Vogl; *Frankfurt a. Main/DE (nour410@hotmail.com)*

Purpose: To retrospectively compare the local tumour response and survival rates in patients with non-colorectal-cancer-lung-metastases post-ablation-therapy using laser-induced thermotherapy-(LITT), radiofrequency ablation-(RFA) and microwave ablation-(MWA).
Methods and Materials: Retrospective analysis of 175 CT-guided ablation sessions performed on 109 patients (43 males and 66 females,mean age: 56.6years). 17 patients with 22 lesions underwent LITT treatment (tumour size:1.2-4.8 cm),29 patients with 49 lesions underwent RFA (tumour size:0.8-4.5 cm) and 63 patients with 104 lesions underwent MWA treatment (tumour size:0.6-5 cm). CT-scans were performed 24-hours post-therapy and on follow-up at 3,6,12,18 and 24months.
Results: The overall-survival rates at 1-,2-,3- and 4-year were 93.8%,56.3%,50.0% and 31.3% for patients treated with LITT,81.5%,50.0%,45.5% and 24.2% for patients treated with RFA and 97.6%, 79.9%,62.3% and 45.4% for patients treated with MWA respectively. The mean survival-time was 34.14 months for MWA, 34.79 months for RFA and 35.32 months for LITT. In paired comparison a significant difference could be detected between MWA versus RFA (p=0.032). The progression-free survival showed a median of 23.49 ± 0.62 months for MWA,19.88 months ±2.17 months for LITT and 16.66 ± 0.66 months for RFA(p=0.048). The lowest recurrence rate was detected in lesions ablated with MWA (7.7%; 8 of 104 lesions) followed by RFA (20.4%; 10 of 49 lesions) and LITT (27.3%;6 of 22 lesions) p- value of 0.012. Pneumothorax was detected in 22.16% of MWA ablations, 22.73% of LITT ablations and 14.23% of RFA ablations.
Conclusion: LITT, RFA and MWA may provide an effective therapeutic option for non-colorectal cancer lung metastases with an advantage for MWA regarding local tumour control and progression-free survival rate.

B-1211 15:20

Application of contrast-enhanced ultrasound during microwave ablation for large benign thyroid nodules
W. Wang, F. Mao, J.Y. Cao, P. Fan, Y. Dong; *Shanghai/CN (puguang61@126.com)*

Purpose: We aimed to evaluate the value of contrast-enhanced ultrasound (CEUS) during both pre- and post-treatment evaluation of microwave ablation (MWA) for large benign thyroid nodules.
Methods and Materials: Between Jan 2017 and Oct 2017, 65 patients with a total of 65 large benign thyroid nodules admitted to our hospital for MWA treatment were included. Mean diameter of nodules is 54 ± 14 (mm). The generator of microwave system is designed with a frequency of 2450 MHZ and a maximum output power of 100W. The ablation procedures were monitored by real-time ultrasound. Before MWA, dynamic CEUS examinations were performed to make pre-treatment assessment, including blood perfusion of nodules and their relationship with surrounding large vessels. One day and six month after ablation, the post-treatment CEUS were conducted to evaluate whether the original nodules were completely ablated.
Results: During pre-ablation CEUS evaluation, peripheral hyperenhanced rings were detected during arterial phase of all nodules, with mean thickness 1.3 ± 0.5 mm. MWA were conducted successfully in all 65 thyroid nodules. Post-ablation CEUS showed that 62 (95.4%) nodules with complete ablation had no enhancement. The peripheral hyperenhanced ring disappeared in all nodules. The volume reduction of 63 ± 3.1 % was achieved with benign thyroid nodules after six months follow-up. No major complications occurred.
Conclusion: Microwave ablation with real time ultrasound guidance is an effective and safe method in treatment of large benign thyroid nodules. CEUS is a sensitive and effective method to make both pre-treatment evaluation and post-treatment efficacy of MWA.

Proposal of imaging reporting and data system for cervical lymph node based on computed tomography
K. Lee[1], J. Baik[2]; [1]*Ras Al Khaima/AE*, [2]*Busan/KR (lkh770429@naver.com)*

Purpose: To compare computed tomography (CT) features of benign and malignant cervical lymphadenopathy and to propose a CT-based, structural reporting system for cervical lymph node: lymph node reporting and data system on CT (LNRADS-CT).
Methods and Materials: The Institutional Review Board approved and informed patient consent was waived. Between January 2014 and August 2016, a total of 1337 subjects underwent neck CT examination at a single institution. The study included consecutive 407 (malignant lymphadenopathy: 170, benign lymphadenopathy: 237) cases with pathologic diagnosis or sufficient follow-up. CT features of cervical lymph nodes were retrospectively analysed: longest diameter, shortest diameter, shape, necrosis, perinodal fat infiltration, conglomeration, invasion of adjacent structures and enhancement pattern. Regression equation was utilized, and a score was assigned for each significant factor. Risk of malignancy was determined according to the number of suspicious CT features.
Results: Malignant lymphadenopathy revealed larger shortest diameter, round shape, necrosis, conglomeration and well enhancement more frequently ($P < .05$). As the number of suspicious features increased, fitted probability of malignancy increased. Risk stratification of LNRADS-CT was 12.2% in category I (no suspicious features), 38.2% in category II (one suspicious feature), 80.6% in category III (two suspicious features), and 92.4-99.3% in category IV (more than three suspicious features).
Conclusion: LNRADS-CT was proposed based on a 4-point category and can be used to assess the risk of malignancy in cervical lymph nodes.

B-1213 14:17

Diagnostic value of real-time ultrasound image fusion compared to ultrasound-only-guided lymph node fine-needle aspiration in head and neck cancer patients

P. De Koekkoek-Doll, M. van den Brekel, W. Vogel, L. Smit, J.J. van Griethuysen, M. Maas; *Amsterdam/NL (p.doll@nki.nl)*

Purpose: Aim was to evaluate the feasibility of real-time fusion of ultrasound (US) with available tomographic image data for the assessment and guidance of fine-needle aspiration (fused-FNA) for nodal staging in head and neck cancer.
Methods and Materials: 55 patients were prospectively included. Fused-FNA was performed after routine US-FNA, using the electromagnetic navigation system Percunav on a Philips EPIQ-US machine. Live US was fused with PET/CT, MRI, or CT-data. FNA was performed on additional suspicious nodes identified by image fusion. Reference standard consisted of cytological evaluation of the FNAs and histology from node dissection if performed.
Results: Fusion was performed with PET/CT (n=53, 96%), MRI (n=1, 2%) and CT (n=1, 2%). In 6 patients (11%) without suspicious lymph nodes fused-FNA was not performed. On the remaining 49 patients (89%), FNA was performed in 120 nodes. For 97 nodes, FNA was performed based on routine US. Their location was confirmed with accurate image fusion in 88 cases, for the remaining 9 nodes adequate image fusion was not achieved. After US-FNA, 23 additional nodes were identified based on image fusion and fused-FNA was performed. Of all nodes undergoing FNA 46/111 (41%) had malignant cytology, and of the 23 additional fused-FNA nodes 7 were proven malignant (30%). In total, 42% of all PET-positive nodes were malignant.
Conclusion: Real-time US image fusion with FNA is feasible in head and neck cancer, leads to an increased detection of malignant nodes, and allows for more accurate identification of the location of PET-positive nodes.

Computer-aided quantification of intranodal vascularity enhanced the accuracy of ultrasound in distinguishing metastatic and tuberculous cervical lymph nodes

T.-C.M. Ying, S. Cheng, A. Ahuja; *Hong Kong/HK (htmying@polyu.edu.hk)*

Purpose: Ultrasound features of tuberculous nodes are varied and simulated metastatic nodes. This study presents a novel computer-aided method that can quantify intranodal vascularity and enhance the accuracy of ultrasound in distinguishing metastatic and tuberculous cervical lymph nodes.
Methods and Materials: Grey scale and power Doppler sonograms of 100 patients with palpable cervical nodes were reviewed (60 metastases, 40 tuberculous lymphadenitis). Ultrasound images of cervical nodes were evaluated for the shape, echogenic hilus, necrosis and vascular distribution of lymph nodes (conventional assessment). Intranodal vascularity index (VI) was quantified using a customised computer program. The diagnostic accuracy of using conventional assessment and its combination with intranodal VI was evaluated.
Results: Metastatic and tuberculous nodes tended to be round (75% vs 50%), without echogenic hilus (90% vs 72.5%) and have peripheral vascularity (73.3% vs 85%). Intranodal neceosis is more common in tuberculous nodes (27.5%) than metastatic nodes (8.3%). The diagnostic accuracy of conventional assessment in distinguishing metastatic and tuberculous nodes was 59% with sensitivity, specificity, positive predictive value (PPV) and negative predicative value (NPV) of 87%, 18%, 61% and 47% respectively. Results showed that metastatic nodes (23.4±2.1%) tended to have higher VI than tuberculous nodes (12±1.6%) ($p<0.05$). The optimal cut-off of VI was 20%. By combining conventional assessment and intranodal VI quantification, the diagnostic accuracy was 69% with sensitivity, specificity, PPV and NPV of 72%, 65%, 75% and 60% respectively.
Conclusion: Combining intranodal VI quantification and conventional assessment enhances the diagnostic accuracy of ultrasound in distinguishing metastatic and tuberculous cervical lymph nodes.

Cervical adenopathies: diagnostic efficacy of DCMR

L. Aghaghazvini, F. Hashemi, H. Sharifian, B. Rasuli, N. Yazdani; *Tehran/IR (aghaghazvini.leila@gmail.com)*

Purpose: Pre-operative differentiation of benign from malignant cervical adenopathies (CN) remains a challenge. We assessed the efficacy of dynamic contrast MRI (DCEMR) for differentiation between benign and malignant CN.
Methods and Materials: DCEMR were performed in patients with CN who were candidates for surgical resection, before radiotherapy or chemotherapy. In all patients we used 3 Tesla MRI with fast spin echo T2- and T1-weighted images in axial and coronal planes and T1 weighted after contrast medium administration. We recorded dynamic curves and values every 30 seconds up to 10-15 minutes after contrast injection. Data were evaluated in a mixed model analysis and findings were compared with postoperative histopathologic results.
Results: 49 cervical lymph nodes (17 benign and 32 malignant) were included in this study. In time-intensity curves there were significant differences between benign and malignant groups in two parameters: 5-minute washout slope (p value: 0.008) and 5-minute washout ratio (p value: 0.013). For 5-minute washout slope there were 96% sensitivity and 27% specificity at cut-off point: 1.7, 100% specificity and 40% sensitivity at cut-off point: 7.4, 70% sensitivity and 70% specificity at cut-off point: 3. Other DCEMR parameters, lymph nodes sizes and T2w heterogeneity were different but not significant statistically. Also necrosis only was present in malignant lymph nodes.
Conclusion: DCEMR only for washout ratio and slope at 5 minutes after contrast injection could be helpful in differentiation between benign and malignant CN in this study but larger studies are necessary.

Role of RI (resistive index) value as imaging bio marker in differentiating benign and malignant cervical lymphnodes

K.A. Bhagwat; *Davangere/IN (bhagwatkishan@gmail.com)*

Purpose: To assess the role of resistive index , RI value as imaging bio marker in differentiating benign and malignant cervical lymph nodes. To correlate routine ultrasonography features of enlarged nodes with resistive index on Doppler and cytological correlation.
Methods and Materials: Type of study: prospective study. Sample size: 50; Inclusion criteria: patients presenting with clinically palpable cervical lymphadenopathy referred for Ultrasonography. Exclusion criteria: patients who have been treated earlier for cervical lymphadenopathy. Method: all patients underwent high resolution sonography of neck with Colour Doppler and following results were recorded. Only the largest node in each patient was included for study. Morphology: 1. shape of node; 2. size; 3. echotexture; 4. roundness index; 5. necrosis; 6. loss of hilar architecture. Doppler: Hilar flow pattern. Resistivity index of vascularity. The above findings were recorded. Morphologically the nodes were classified as benign and malignant and their RI values were studied. FNAC results were correlated wherever possible.
Results: Out of 50 patients , about 30 patients had benign lymph nodes and 20 patients had malignant secondary nodes. Most of the lymph nodes which were benign on morphological criteria had RI value less than 0.7. All malignant nodes had RI value of 0.8 and above.The unequivocal cases had RI value between 0.7 and 0.8. In these cases FNAC finally concluded that nodes with RI value of 0.75 are malignant.
Conclusion: Thus resistivity index of vascularity of lymph nodes is a reliable cost effective imaging bio marker in differentiating benign and malignant cervical lymphadenopathy.

B-1217 14:49

The use of micro-flow imaging (MFI, Philips Medical Systems) in ultrasound guided tissue sampling of head and neck masses

H. Toghyan, A. Al-Khatib, B. Stenberg, A. McQueen; *Newcastle upon Tyne/UK (hamid.toghyan101@gmail.com)*

Purpose: Ultrasound (US) guided tissue sampling of neck masses is an essential component of a head & neck imaging service. One reason for non-diagnostic US guided lymph node sampling is necrosis of the target lesion (particularly in head & neck squamous cell carcinoma and lymphoma) and this can lead to additional samples being required via repeat percutaneous procedures or surgical excision. Standard Doppler flow is primarily used for diagnostic assessment of vascular architecture within neck masses, but a more detailed perfusion map could enable the ultrasound practitioner to identify and target viable, non-necrotic tissue and reduce the number of samples required to achieve diagnostic sample quality for pathological interpretation.
Methods and Materials: Patients presenting with a neck mass requiring tissue sampling were assessed with MFI, a new technology designed to detect small vessel blood flow with high resolution and minimal artifact, facilitating assessment of lesion perfusion. Samples were obtained from each target lesion, under direct ultrasound guidance using an el18-4 linear US probe and Epiq 7 US machine (Philips Medical Systems). Pathology results, including the pathologist's comments about the adequacy and quality of the samples were obtained from our hospital's intranet.
Results: In this case series/technical evaluation, we present our early experience in utilising MFI and its superiority to standard Doppler flow imaging in depicting vascularity in head and neck masses.
Conclusion: We propose that increased diagnostic confidence in detecting viable regions within abnormal cervical nodes guides tissue sampling, with the potential for fewer procedures and greater adequacy rates.

B-1218 14:57

Higher definition head and neck imaging enabled with digital photon counting PET/CT: an intra-individual comparison with conventional photomultiplier PET/CT

C.L. Wright[1], K. Binzel[1], J. Zhang[1], P. Maniawski[2], M.V. Knopp[1];
[1]*Columbus, OH/US*, [2]*Cleveland, OH/US*

Purpose: To assess the clinical impact and potential clinical benefit of digital photon counting PET (dPET) for higher definition PET/CT imaging in head/neck by intra-individual comparison to conventional photomultipler tube detector (cPET) PET.
Methods and Materials: Thirty oncology patients participated in an intra-individual comparison of FDG PET using pre-commercial release dPET/CT (Vereos) and cPET/CT (Gemini). Standard cPET imaging was performed at ~75 min p.i. of 481 MBq FDG, investigational dPET imaging either at ~55 min or ~95 min p.i. All other aspects of image acquisition were kept identical. Digital PET images were reconstructed using Time-of-Flight with 4mm3 (standard definition/SD), 2mm3 (high definition/HD), and 1mm3 (ultra-high definition/UHD) voxel volumes and compared with SD cPET images. Blinded readers evaluated image sets in regard to overall quality, lesion/tissue characterization, and quality of background in head/neck region.
Results: All cPET/dPET data sets were evaluable. When compared with cPET, higher definition dPET demonstrated improved image quality for qualitative assessment and detection of small FDG-avid head/neck lesions. There was also improved image quality for normal structures/tissues without an appreciable effect on the background FDG activity. FDG activity in lesions and normal tissues/structures were better characterized with HD/UHD dPET. Kappa scores were consistenly higher.
Conclusion: Higher definition dPET improved visualization and characterization of FDG-avid lesions and normal tissues/structures in the head/neck including higher kappa scores for agreement. The improved image quality and lesion/tissue characterization appears to be enabled by the faster timing resolution of dPET (~325ps) compared with cPET (~550ps) and higher definition reconstruction reducing partial volume.

Correlation between apparent diffusion coefficient and standardised uptake values in head and neck carcinomas

S. Türk, S. Bayraktaroğlu, E. Ramo, Ö. Akagündüz, R. Savaş; *Izmir/TR (sevcanturk.ege@hotmail.com)*

Purpose: Head and neck carcinoma may cause a decreased apparent diffusion coefficient (ADC) on diffusion-weighted magnetic resonance imaging (DW MRI) and an increased standardised uptake value (SUV) on fluorodeoxyglucose (FDG) positron emission tomography (PET/CT). We analysed the reproducibility and treatment-related changes of ADC and SUV measurements in head and neck carcinoma and evaluated whether these biomarkers are correlated or independent.
Methods and Materials: This retrospective analysis of DW MRI and FDG PET/CT data series included 36 head and neck carcinoma. Kruskal-Wallis, one-way ANOVA and Mann-Whitney U methods were used to detect any statistical correlation and prognostic significance of ADC and SUV values in responders and non-responders to radiotherapy.
Results: Mean ADCmin, ADCmean and ADCmin/mean in head and neck carcinoma were 0.68±0.17×10–3mm^2/s, 0.82±0.17x10–3 mm^2/s and 0.83 ± 0.10 mm^2/s, respectively. Mean SUVmean and SUVlbm were 14.65±5.5 and 10.96±5.1, respectively. Spearman's correlation analysis showed no significant correlation between ADC and SUV measurements. Although statistically not significant, a trend towards higher SUV and lower ADC was observed in head and neck tumours. Statistically, not significant, a trend towards higher SUV and higher ADC was observed in non-responders to radiotherapy.
Conclusion: Our data suggest that ADC and SUV values are reproducible and independent biomarkers in head and neck carcinomas.

B-1220 15:13

MRI-based surveillance for patients with recurrent head and neck cancer after hypofractionated stereotactic (SBRT) re-irradiation

N. Plakhotina, A. Mikhailov, A.V. Smirnova, D.I. Kuplevatskaya, N. Vorobyov; *St. Petersburg/RU (plahotinadezhda@gmail.com)*

Purpose: To assess MRI value for SBRT treatment response evaluation in patients with recurrent head and neck cancer.
Methods and Materials: 23 patients with head and neck cancer relapse primarily treated by SBRT were enrolled (age range: 33-79 years). Patients were re-radiated with SBRT (35 Gy in 5 fractions). MRI protocol included T2 and T1 WI, with/without FS, axial DWI, T1FS after gadolinium enhancement, with slice thickness 1-3 mm. MRI were performed before initiating SBRT and then each 3 months.
Results: In 86.9% (20 patients) we have found disease stabilization (by RECIST criteria) and the absence of progression during the 24 months. After 3-9 months tumour contours became more uneven, structure became heterogeneous, signs of the necrosis appeared, which were replaced by fibrous tissue after 9-12 months. In all patients in months 3-9 significant oedema at 1 cm margin around tumour focus was revealed. However, after 6 months, the distant oedema signs (mucositis, muscles and fat swelling) were decreasing. In 3 patients (13.1%) we could not assess the long-term results due to death from disease progression.
Conclusion: MRI-based treatment response assessment in head and neck cancer relapse provides adequate information for clinical decision but characterized by some features, demanding multidisciplinary evaluation. Local tissues swelling after SBRT in first months do not allow accurate tumour evaluation and simulate disease increase. To exclude false errors radiologist needs to know RT method, compare MR results with treatment plans and review images in close collaboration with radiation oncologist.

B-1221 15:21

Perineural spread of fungal sinonasal infections: CT scan and MRI findings

M. Mohammadzadeh[1], A. Mohammadzadeh[1], Z. Haghighi[1], H. Sharifian[1], V. Mohammadzadeh[1], S. Kadivar[2]; [1]*Tehran/IR*, [2]*Rasht/IR (mralimohammadzadeh@yahoo.com)*

Purpose: To study imaging features and anatomic pathways of perineural spread(PNS) in head and neck fungal infections.
Methods and Materials: Imaging findings of 25 patients diagnosed with sinonasal fungal infection evaluated. Perineural tumour spread was defined as foraminal enlargement, foraminal destruction, nerve enlargement, abnormal enhancement of the evaluated nerves and obliteration of the perineural fat pad.
Results: 52% of patients revealed definitive signs of perineural spread. All of patients with PNS had Infra Orbital Fissure and pterygopalathine obliteration. Maxillay branch of trigeminal nerve was involved in 100% of PNS cases. Sinus covernous involvement in 69% and Meckels cave in 30% of these cases were identified.
Conclusion: Perineural spread is a common mechanism of extension in sinonasal fungal infections and the most common pathway is spread along mandibular division of trigeminal nerve.

3D-assessment of RVOT dimensions prior to percutaneous pulmonary valve implantation

S. Ebel[1], S. Gottschling[2], M.T.A. Buzan[3], M. Grothoff[1], I. Dähnert[1], R. Wagner[1], D. Gräfe[1], M. Gutberlet[1], C. Lücke[1]; *1Leipzig/DE, 2Halle/DE, 3Cluj-Napoca/RO (sebastian.ebel@icloud.com)*

Purpose: To evaluate which cardiacMRI technique allows for better assessment of the RVOT in patients with pulmonary valve disease after tetralogy of Fallot (TOF) repair: contrast-enhanced MR-angiography (ceMRA) or 3D steady-state free precession (SSFP) during systole and/or diastole.
Methods and Materials: We retrospectively evaluated 89 patients (male:female:45:44 mean age 19 ± 8 years), who underwent cardiac-MRI (1.5 T) after surgical TOF repair. Data sets covering the whole heart in systole and diastole were obtained using a ECG-gated 3D SSFP and a non-gated ceMRA. Measurements were performed in the narrowest diameter of the RVOT and MPA to obtain the mean minimal, maximal and effective diameter.
Results: The mean minimal diameters in diastolic SSFP, systolic SSFP and ceMRA were 21.4 mm (± 6.1 mm), 22.6 mm (± 6.2 mm) and 22.6 mm (± 5.96 mm), respectively. The mean maximal diameters were 29.9 mm (± 9.5 mm), 29.98 mm (± 6.98 mm) and 28. mm (± 8.1 mm) respectively. The mean effective diameter was 23.2 mm (± 5.7 mm), 27.4 mm (± 6.7 mm) and 24.4 mm (± 6.2 mm), with a significant difference between diastole and systole ($p<0.0001$). Measurements in ECG-gated SSFP showed a better inter- and intraobserver variability compared to measurements in ungated ceMRA sequences.
Conclusion: Patients with TOF repair who could benefit from PPVI should undergo non-invasive CMR for preprocedural assessment. There are significant differences regarding the size of the RVOT and pulmonary trunk between systole and diastole; therefore, it is essential to obtain ECG-gated

sequences for precise measurements. We show that 3D SSFP sequences acquired during systole are best to identify a potential landing zone for PPVI.

3D-printed heart model to guide LAA closure: preliminary results
A.-L. Hachulla, S. Noble, G. Guglielmi, D. Agulleiro, H. Muller, J.-P. Vallee; *Geneva/CH (anne-lise.hachullalemaire@hcuge.ch)*

Purpose: Percutaneous left atrial appendage (LAA) occlusion is as an alternative therapeutic approach to medical therapy for stroke prevention in patients with atrial fibrillation. The correct sizing of the occluding device remains challenging due to the variable LAA shape. We investigated the use of personalised 3D-printed model to guide the selection of the device size.
Methods and Materials: Fifteen patients scheduled for an occlusion of the LAA underwent a cardiac CT. The left atrium was segmented by semiautomatic algorithms and a 1.5 mm thick shell of the left atrium was exported in STL format and printed using a flexible material. A new CT scan of the 3D-printed model with and without inserted Amplazer® Amulet cardiac plugs was acquired. The size of the Amulet predicted with CT, transechocardiography (TEE) and 3D-printed model was compared to the size of the device implanted in the patient.
Results: The segmentation process was fast (less than 15 min). The device size was correctly predicted in 8/15 cases with TEE, in 10/15 cases with Cardiac CT, in all of the 15 cases with 3D-model. On the 3D-printed model CT, the proximal disc sealing the ostium of the LAA and the close contact of the distal lobe with the LAA wall could be seen very well. In case of incorrect sizing, absence of contact with the LAA wall or device deformation was easily identified.
Conclusion: We introduced a fast and robust protocol using personalized 3D-printed LAA model to select the correct size of the occluding device.

B-1224 14:16

Left atrial appendage closure guided by 3D-printed patient-specific models
M. Guglielmo[1], A. Guaricci[2], D. Andreini[1], M. Conti[1], S. Marconi[1], F. Auricchio[3], M. Pepi[1], C. Tondo[1], G. Pontone[1]; [1]*Milan/IT*, [2]*Bari/IT*, [3]*Pavia/IT*
(marco.guglielmo@ccfm.it)

Purpose: Percutaneous left atrial appendage (LAA) occlusion has been proposed as an alternative therapeutic approach for stroke prevention in patients affected by atrial fibrillation. 3D printing allows reconstruction of patient-specific models of the heart using computed tomography angiography (CTA). We sought to assess whether the sizing of the implanted occluder device is in accordance with the sizing obtained using the 3D printing models.
Methods and Materials: We used 3D printing to create patient-specific LAA models, reconstructed by CTA, as supporting tool of the pre-operative stage of the LAA occlusion procedure with endovascular devices, such as the Wave Crest device (Coherex Medical, Inc, USA) and the Amplatzer Amulet device (St Jude Medical, St Paul, MN).
Results: 13 patients, undergoing percutaneous LAA occlusion, were retrospectively analysed; for each of them a patient-specific 3D LAA-printed model was manufactured using pre-operative CTA images. We observed that: i) in 54% of the cases (n=7) the actual sizing was underestimated when compared to the 3D-printed model; ii)in 38% of the cases (n=5) the two sizing approaches matched; iii) only in 1 case (8%) an overestimation of the actual size compared to the 3D-printed model was detected. In all underestimated cases a drawback, such as leakage or device migration was observed.
Conclusion: This report demonstrates that 3D printing LAA model may contribute in sizing the device, finding its correct position and guiding the choice of the device, providing additional data to angiography and TEE.

B-1225 14:24

3D printing of the aortic root based on cardiac computed tomography and cardiac magnetic resonance imaging: preliminary experience on pre-procedural planning for aortic valve sizing
M. Gatti, R. Faletti, A. Cosentino, G. Pennisi, A. De Paoli, A. Di Chio, S. Fiore, L. Pavan, P. Fonio; *Turin/IT (marcogatti17@hotmail.it)*

Purpose: To determine the feasibility of using CCT and CMRI to print individual models of the aortic root complex for aortic annulus measurement.
Methods and Materials: Retrospective study on 20 patients who underwent aortic valve replacement with available records of pre-surgery annulus assessment by CCT and CMRI and of intra-operative assessment by Hegar dilators. The imaging DICOM data were loaded into an imaging processing software (OsirixMD) to obtain Standard Tessellation Language (STL) files that were exported to a model-editing software (Meshmixer®) and edited to retain only the aortic root from the left ventricular outflow tract to the sinotubular junction. 40 aortic annuli were printed using a fusion deposition modelling printer (Ultimaker 2 Extended+®) with flexible polylactic acid filaments. The same cardiac surgeon performed both the intra-operative and the 3D model measurements. A time-cost analysis was performed. Data were analysed using Wilcoxon signed-rank test.
Results: There were no significant differences when compared the annulus dimensions measured by 3D models derived from CCT (p=0.33) and CMRI (p=0.44) to the surgical reference of intra-operative sizing. Valve sizing for CoreValve® by intra-operative measurement had the same good agreement with 3D model-based measurement, with a 95% match rate; for SAPIEN XT® the agreement was slightly better (95%) for CMR-derived model than for CCT (90%). Time and cost per model were: STL creation ~30min; printing time ~30min; post-processing ~5min; material cost <1€.
Conclusion: The 3D models performed well when compared to the surgical reference of intraoperative sizing. This approach may be a reliable, not expensive, patient-specific pre-operative planning opportunity.

B-1226 14:32

Fusion of coronary CT angiography and whole-heart 3D CMR myocardial perfusion: building a framework for comprehensive 3D cardiac imaging
J. von Spiczak, R. Manka, A. Gotschy, S. Oebel, S. Hamada, H. Alkadhi; *Zurich/CH*

Purpose: To develop a high-quality framework for hybrid three-dimensional imaging of coronary CT angiography (CCTA) and dynamic whole-heart 3D cardiovascular magnetic resonance stress perfusion (CMR-Perf) image data to correlate coronary artery stenoses to stress-induced myocardial perfusion deficits.
Methods and Materials: 23 patients underwent CCTA and CMR-Perf. For CCTA, image quality and stenoses >50% were documented. For CMR-Perf, image quality and stress-induced perfusion deficits were noted. A new software framework was developed to allow for three-dimensional image fusion of patient data revealing relevant stenoses and corresponding perfusion deficits. Computation steps included: 1) automated segmentation of CT coronary arteries and heart contours; 2) manual segmentation of the left ventricle in CMR-Perf images; 3) automatic co-registration of CT and CMR datasets; 4) projection of the CMR-Perf values on the CT left ventricle. A dedicated algorithm for high-quality interpolation and co-registration was developed to avoid frequently occurring image artefacts. Results of the hybrid 3D analysis were compared to separate readouts from CCTA and CMR-Perf data.
Results: CT and CMR image quality was rated as good to excellent (scores 3.5±0.5 and 3.7±0.4, respectively, scale 1-4, 1=poor, 4=excellent). Multimodal three-dimensional image fusion was feasible in all patients. Perfusion deficits could be correlated to culprit coronary lesions in all cases.
Conclusion: Three-dimensional fusion of morphological high-resolution CCTA and functional CMR-Perf image data is feasible using the imaging framework presented in this work. Hybrid imaging can ease the anatomic correlation of stress induced myocardial perfusion deficits and their culprit lesions.

B-1227 14:40

3D image fusion of whole-heart dynamic cardiac MR perfusion and late gadolinium enhancement: identifying areas for revascularisation
J. von Spiczak, M. Mannil, H. Alkadhi, R. Manka; *Zurich/CH*

Purpose: To develop a framework for three-dimensional image fusion of whole-heart dynamic 3D cardiac MR perfusion (3D-PERF) and 3D late gadolinium enhancement (3D-SCAR) to delineate stress-induced myocardial perfusion deficits and areas of scar.
Methods and Materials: Five patients with coronary artery disease (54±20 years) undergoing cardiac MR were included. A software framework was developed for 3D fusion of 3D-PERF and 3D-SCAR data revealing perfusion deficits along with myocardial scar. Computation steps included: 1) manual segmentation of the left ventricle in 3D-PERF and 3D-SCAR images; 2) semi-automatic thresholding of perfusion and scar data; 3) automatic calculation of ischaemic and scar burden; 4) projection of perfusion and scar values on an artificial template of the left ventricle; 5) semi-automatic co-registration to an exemplary heart contour easing 3D orientation; 6) 3D rendering of the combined datasets using automatically defined color tables. All tasks were performed by two independent, blinded readers. Interreader agreement was determined by calculating intraclass correlation coefficients.
Results: Image acquisition, post-processing, and 3D fusion was feasible in all cases. All patients showed stress-induced perfusion deficits in 3D-PERF; three patients showed late gadolinium enhancement in 3D-SCAR. Average ischaemic burden was 16% and average scar burden was 8%. Interreader agreement was excellent for both 3D-PERF (ICC=0.95) and 3D-SCAR (ICC=0.99). 3D fusion allowed intuitive visual assessment of perfusion deficits, scar, their overlap, and areas possibly accessible to revascularisation.
Conclusion: 3D fusion of 3D-PERF and 3D-SCAR facilitates anatomic correlation of stress-induced myocardial perfusion deficits and scar tissue for identifying areas for potential revascularisation.

B-1228 14:48

Prognostic impact of myocardial perfusion single-photon-emission computed tomography in patients with major extracardiac findings by computed tomography for attenuation correction

Z.C. Charline; *Toulouse/FR (charline.zadro@gmail.com)*

Purpose: Attenuation correction computed tomography (CT) contributes to an improvement in the diagnostic accuracy of myocardial perfusion imaging (MPI) by single-photon-emission tomography (SPECT). The aim of this study was to explore the prognosis of patients with major findings by CT according to the results of MPI.
Methods and Materials: 1506 patients who underwent MPI by SPECT between January 2010 and June 2011 in the CHU of Toulouse Rangueil were retrospectively included. Attenuation correction CT images were systematically analysed for major and minor abnormalities.
Results: 830 (55.1%) and 212 (14.1%) patients had minor and major extracardiac findings, respectively. Among patients with major extracardiac findings, the abnormality was previously unknown in 113 (53.3%) patients. 90 (41.9%) had abnormal MPI, 73 (34.4%) had a myocardial infarction scar, 55 (25.9%) had myocardial ischaemia, and 38 (17.7%) patients had both myocardial infarction scar and myocardial ischaemia. Among the 201 patients available for survival analysis, there were 67 (31.2%) deaths over a follow-up period of 3.2±1.3 years. There was no significant impact on survival arising from MPI, whatever the result. The results were the same among the 103 patients with previously unknown major extracardiac findings.
Conclusion: Extracardiac findings by CT during MPI are frequent. Patients with major extracardiac findings have a poor mid-term outcome, whatever the results of the myocardial perfusion imaging. Extracardiac findings should be systematically checked when attenuation correction CT is performed.

B-1229 14:56

3D analysis and planning of septal reduction therapy basedon CT coronary angiography in patient with hypertrophic cardiomyopathy

B. Batsak; *Kiev/UA (dr.batsak@gmail.com)*

Purpose: The aim of our study was to develop non-invasive method for preoperative 3D analysis and planning of septal reduction therapy .
Methods and Materials: Were performed CT coronary angiography with 320-MDCT (Aquilion ONE) in 45 patients with obstructive form of hypertrophic cardiomyopathy (mean age- 41±7,3, mean weight-70±13,2). We performed reconstruction of the 3D anatomy of coronary artery and myocardium of interventricular septum with the help of a post processing software package. For alcohol septal ablation we define the area of blood supply by septal branch of LCA. For planning surgical myectomy we perform 3d anatomical reconstruction of LV myocardium and zone of obstruction for determine level and amount of myocardium resection. Obtained data was analyzed.
Results: We found that septal branch supply the hypertrophic region of interventricular septum which caused obstruction in 21 patients. In 15 patient, no septal branches larger than 1 mm. In 9 patient, the 1st septal branch supplies area below site of obstruction. In patients with an appropriate anatomy of septal branches we performed alcohol ablation. During procedure we confirm area of blood supply by contrast echocardiography with perftoran. In patients with a non-appropriate anatomy of septal branches we performed myectomy after preoperative 3D planning
Conclusion: 3D analysis and planning of septal reduction therapy based on CT coronary angiography helps in choosing optimal methods of treatment in patient with obstructive form of hypertrophic cardiomyopathy.

B-1230 15:04

Assessment of post-operative pulmonary regurigitation by pre-operative RV and pulmonart artery imaging characteristics in pediatric TOF repaired with trans-valve surgert

Y. Gao, Z. Yang, K. Shi, K. Diao; *Chengdu/CN (304789161@qq.com)*

Purpose: Pulmonary regurgitation (PR) is most common complications after tetralogy of Fallot (TOF) surgical repair, the long-term PR might result in cardiovascular events. The aim of this study was to assess the influence of pre-operative right ventricle(RV) and pulmonary artery(PA) parameters on post-operative PR by dual-source computed tomography(DSCT).
Methods and Materials: A total of 41 patients had TOF repaired with trans-valve surgery were retrospectively recruited. All diameters were measured using the computer caliper during systole. The RV and PA parameters evaluated by pre-operative DSCT were compared between the PR and non-PR groups used non-parametric test and Spearman test.
Results: The result showed that the PA parameters (McGoon ratio, Nakata index and LPA diameter) and RV parameters (RV length diameter and RV short diameter) all had significant differences between the two groups (all $p<0.05$). There was a significant correlation between PR and LPA diameter ($r = 0.35$), McGoon ratio ($r = 0.32$), and Nakata index ($r = 0.43$), and the same as PR between RV length diameter ($r =-0.46$) and RV short diameter ($r =-0.34$). ROC analysis also revealed that moderate sensitivity and specificity were obtained for predicting the occurrence of PR with LPA (66.33%; 82.60%), McGoon ratio (83.33%,56.52%), Nakata index (83.33%; 60.87%), RV length diameter 66.67%; 82.61%)and RV short diameter (77.78%; 60.87%).
Conclusion: This study indicated that these pre-operative indexes by DSCT are associated with post-operative PR, and these pre-operative PA and RV parameters could be new predictive factors for the occurrence of PR.

B-1231 15:12

Modified myocardial performance index for evaluation of foetal cardiac function in small for gestational age foetuses

A. Taori; *Indore/IN (abhijittaori@gmail.com)*

Purpose: To test the validity of modified myocardial performance index for foetal cardiac function assessment and explore the sequence of changes in modified MPI, umbilical artery and ductus venosus flow in SGA foetuses.
Methods and Materials: Singleton pregnancies between 24 and 36 weeks gestation with 'small for gestational age foetuses' as assessed by foetal biometry were included. Umbilical artery and ductus venosus waveforms were obtained. Myocardial performance index was calculated as MPI = (ICT+IRT)/ET with appropriate placement of Doppler gate to include both the lateral wall of the ascending aorta and the mitral valve, where the clicks corresponding to the opening and closing of the two valves could be clearly visualised.
Results: All foetuses with early-onset IUGR and abnormal umbilical artery indices had abnormal MPI values. Significant percentage of foetuses with late-onset IUGR and normal umbilical artery PI also had an elevated MPI. In IUGR foetuses, MPI is one of the earliest parameters affected and remains elevated throughout the different stages of IUGR. MPI is a direct measurement of myocardial performance while DV flow patterns are an indirect reflection, thus abnormal myocardial function becomes evident in DV only in advanced stage of deterioration.
Conclusion: Modified MPI is the earliest and reliable marker for global cardiac dysfunction in response to hypoxia. It can detect true growth-restricted foetuses amongst SGA foetuses with normal UA flow velocities. It has immense potential in late-onset IUGR foetuses where even a short period of hypoxia can cause severe morbidity.

B-1232 15:20

Diagnostic accuracy of non-contrast self-navigated free-breathing MRA in paediatric patients with coronary anomalies using CTA as reference standard

M. Albrecht[1], A. Varga-Szemes[2], C.N. De Cecco[2], T.J. Vogl[1], J.W. Nance[2], D. De Santis[3], M. Eid[2], D. Piccini[4], U.J. Schoepf[2]; [1]*Frankfurt a. Main/DE*, [2]*Charleston, SC/US*, [3]*Rome/IT*, [4]*Lausanne/CH (MoritzAlbrecht@gmx.net)*

Purpose: To evaluate the diagnostic accuracy of a non-contrast, free-breathing, self-navigated 3D (SN3D) coronary MR angiography (cMRA) technique for coronary artery (CA) anatomy assessment in children with coronary abnormalities, using coronary CT angiography (cCTA) as the reference standard.
Methods and Materials: We prospectively enrolled 21 pediatric patients (15 male, 12.3±2.6 years) undergoing same-day unenhanced SN3D cMRA and contrast-enhanced cCTA. Two radiologists scored the depiction of CA segments and reader confidence using a 3-point scale: 1=insufficient, 2=moderate, and 3=excellent. Readers assessed CAs for anomalies, high CA origin, and both inter-arterial and intra-mural CA course. Sensitivity, specificity, positive and negative predictive values (PPV, NPV) were calculated to evaluate diagnostic accuracy. Inter-observer agreement was assessed using Intra-class Correlation Coefficients (ICC).
Results: Fourteen children showed CA anomalies or pathologies on cCTA images. Depiction of CA segments was scored higher for cCTA compared to cMRA ($P<0.015$), except regarding the left main CA ($P=0.301$), with good ($ICC=0.62$) to excellent ($ICC=0.94$) inter-observer agreement. Diagnostic confidence was higher for cCTA evaluation ($P=0.046$). Sensitivity, specificity, PPV and NPV of cMRA were 92%, 92%, 96% and 87% for the detection of CA anomalies, 85%, 85%, 74% and 92% for high CA origin, 71%, 92%, 82% and 87% for inter-arterial course, and 41%, 96%, 87% and 80% for intra-mural course.
Conclusion: SN3D cMRA is highly accurate for the detection of CA anomalies and inter-arterial course in children without radiation exposure, contrast administration, or need for breathing commands. Diagnostic confidence and CA visualisation, however, are still inferior in comparison with cCTA.

MR imaging of the Parkinson's syndrome: a pictorial essay

E.D. Alves, C.d.F. Zorzenon, G.H.A.A. Bienes, H.B. Ferraz, H. Carrete Jr; *Sao Paulo/BR (ealves23@hotmail.com)*

Purpose: The Parkinson syndrome is a worldwide condition that affects millions of people. This syndrome has a broad aetiology, but mostly are caused by unknown neurodegenerative process. Some of these diseases, including the most common one, the Parkinson disease, have been a usual challenge diagnosis to radiologist around the world. We intend to show that this situation can change under the new MRI sequences that have been developed and applied to the diagnosis of these conditions.
Methods and Materials: 40 patients suffering from Parkinson's syndromes underwent brain MRI non-contrast studies in a 3 Tesla system. We have applied the usual T1 and T2 images associated with a T1-weighted neuromelanin-sensitive image and to a multiecho susceptibility image to evaluate the substantia nigra and nigrosome-1. These patients all have already a clinical diagnosis, with a diverse aetiology. Among these group of aetiologies are Parkinson disease, Parkinson plus syndromes, vascular diseases, medicament-related conditions and Parkinson-like processes (essential tremor). It was also done studies of 15 voluntary healthy control patients.
Results: Some of the diseases that cause Parkinson syndrome have presented typical findings in regular MRI studies. Others, like Parkinson disease, that a few years ago would have presented no conclusive MRI signs, have showed reliable findings in the T1 neuromelanin-sensitive images and in multiecho susceptibility images.
Conclusion: The use of the new developed sequences to evaluate the morphology and signal of the *substantia nigra* can provide reliable information for the differential diagnosis of the conditions that causes the Parkinson syndromes.

Phase value assessment reveals iron accumulatin in Parkinson disease

A.N. Sirin Özcan, E.B. Dirik; *Ankara/TR (aysenursirinozcan@gmail.com)*

Purpose: As a progressive neurodegenerative disorder Parkinson disease demonstrated iron accumulation in substantia nigra. İn daily neuroradiology practice neuroimaging still have supplied limited information and used particularly only to exclude parkinson plus sydromes. İron accumulation prediction was made with different methods and phase value assesment from susceptibility weighted imaging phase data is one of them.
Methods and Materials: 20 parkinson and 21 healty control group patient included in the prospective study. MRI examination consisted Susceptibility weighted imaging with phase and magnitude imaging. Phase value quantified via SPIN software. Phase value evaulated from substantia nigra from three level at axial section for each side as right and left. Parkinson disease clinically effected and non efected side analyzed individually .Both side of Parkinson group compared with control group and also with each other. Statistical analysis was performed on SPSS with ANOVA test.
Results: Phase values were statically different in Parkinson and control group. But inside the Parkinson group although clinically effected side demonstrated higher phase values than non effected side it didn't showed statically significant difference.
Conclusion: Phase value asesment is useful to demonstrate iron accumulation effect at substantia nigra in Parkinson disease.

Within- and across-network alterations of the sensorimotor network in Parkinson's disease

J. Caspers[1], S.B. Eickhoff[2], F. Hoffstaedter[2], C. Rubbert[1], J. Aissa[1], M. Südmeyer[3], B. Turowski[1], A. Schnitzler[1], C. Mathys[4]; [1]*Düsseldorf/DE*, [2]*Jülich/DE*, [3]*Potsdam/DE*, [4]*Oldenburg/DE*
(Julian.Caspers@med.uni-duesseldorf.de)

Purpose: Neuroimaging studies repeatedly demonstrated alterations in sensorimotor areas related to Parkinson's disease (PD). As a systematic evaluation of the sensorimotor network (SMN) in PD is yet missing, we investigate the within- and across-network functional connectivity (FC) of the SMN in PD based on independent component analysis (ICA) of resting-state fMRI.
Methods and Materials: Resting-state fMRI (3T, EPI, TR=2.2s, TE=30ms, flip-angle=90°, resolution=3.1x3.1x3.1mm, acquisition time=11min) was evaluated in 38 PD patients, acquired under regular medication (ON) and after withdrawal of dopaminergic drugs (OFF), and 43 age-, gender-, and movement-matched healthy controls. Preprocessed fMRI time series were decomposed into 20 intrinsic connectivity networks using ICA in FSL. We tested for group differences in FC between patients and controls within the SMN using dual regression ($p<0.05$, FWE corrected), and between SMN and the remaining 19 networks using FSLNets ($p<0.05$, FDR corrected).
Results: Within the SMN, PD patients (OFF) showed decreased connectivity in left inferior parietal lobule compared to controls and, additionally, in left postcentral gyrus compared to their ON scan. There were no group differences between patients (ON) and controls. Across networks, SMN was decoupled from (primary) motor and visual networks in PD OFF, which partially normalized in medical ON.
Conclusion: PD is associated with SMN connectivity impairments, both, within and across networks. These dysfunctions in short- and long-range sensorimotor connections are at least partially alleviated by dopaminergic treatment. Connectivity decrease within the network and to primary motor networks is directly linked to PD-related motor symptoms. Decoupling from visual networks hints to deficits in visuospatial integration for motor planning.

B-1236 14:24

Peculiarities of brain activation during dominant-hand tactile perception in lateralised Parkinson's disease

O. Omelchenko, Z. Rozhkova, M. Makarchuk, I. Karaban; *Kiev/UA (Ol.Omelchenko@Gmail.Com)*

Purpose: We propose brain activation and connectivity analysis during the unilateral tactile stimulation in primary and non-primary hand motor symptom lateralised Parkinson's disease (PD) patients for the motor PD symptom asymmetry impact study on the somatosensory processing in PD.
Methods and Materials: Three groups of right-handed subjects (G1/G2/G3) were studied with 1.5T Signa MR scanner (GE, USA). G1 consisted of 7 healthy subjects (4F, 51-83y.o.). G2 consisted of 6 PD patients with left-side (non-primary hand) motor symptoms (2F, 53-74y.o.). G3 consisted of 6 PD patients with right-side (primary hand) motor symptoms (2F, 56-74y.o.). Index finger tactile stimulation successively alternating for right and left hand was used for somatosensory fMRI activation. Data processing was made by FSL.
Results: For G1/G2/G3 activation of contralateral postcentral gyrus was shown. In G2/G3 primary (right) hand stimulation evoked more activation in bilateral postcentral gyri, contralateral superior parietal lobule, supramarginal gyrus, inferior part of pre/postcentral gyri. In G3 activation of contralateral ventral premotor area was found. Increased functional connectivity was shown for left globus pallidus, right dorsal premotor cortex, right dorsolateral prefrontal cortex in G2 and bilateral premotor, right prefrontal, bilateral superior parietal lobule in G3.
Conclusion: Primary somatosensory cortex remains steadily active during tactile stimulation in PD, while primary hand tactile stimulation in primary hand lateralised PD patients also evoke activation of primary and associative sensory, motor and executive nodes of the cortex. Tactile stimuli processing evokes increased connectivity of globus pallidus, premotor, prefrontal and parietal cortex, which might reveal tactile-evoked motion suppression in PD.

B-1237 14:32

Detection of Parkinson's disease based on resting-state inter-network functional connectivity using machine learning

C. Rubbert[1], C. Mathys[1,2], S.B. Eickhoff[3,1], F. Hoffstaedter[3,1], M. Südmeyer[4], C.J. Hartmann[1,1], B. Turowski[1], A. Schnitzler[1,1], J. Caspers[1,3]; [1]*Düsseldorf/DE*, [2]*Oldenburg/DE*, [3]*Jülich/DE*, [4]*Potsdam/DE*
(christian.rubbert@med.uni-duesseldorf.de)

Purpose: Parkinson's disease (PD) is a clinical diagnosis, which may be challenging in certain cases. Resting-state functional connectivity has been reported to show alterations in PD and may prove to be a valuable biomarker in those cases. We evaluated an unsupervised, data-driven classification approach to identify PD patients based on between-network connectivity in whole-brain resting-state fMRI (rs-fMRI).
Methods and Materials: Whole-brain rs-fMRI (Siemens Trio 3T, EPI/TR=2.2s/TE=30ms/flip angle=90°/resolution=3.1x3.1x3.1mm/acquisition time=11min) was assessed in 42 PD patients (medical OFF) and 47 healthy controls (HC) matched for age and gender. Between-network connectivity based on full and partial correlation measures were computed for each subject based on a canonical functional network architecture at different levels of granularity (Human Connectome Project, "recon2" subjects, 03/2017 dataset). A boosted logistic regression model was trained on the correlation matrices using 20 repeats of 10-fold cross-validation. The number of iterations was fixed

at 100, then optimized for the best set of components. Accuracy was averaged over the validation folds to evaluate model performance.
Results: The median accuracy over the different granularities was as following: 15 components = 61.9% (full correlations)/66.4% (partial correlations), 25=75.8%/73.1%, 50=71.4%/65.6%, 100=66.0%/62.5%, and 200=67.0%/52.5%. 160 iterations were found to be optimal for the best model (25 components), yielding a median accuracy of 75.9% (SD=3.5) for full correlations and 74.5% (SD=3.9) for partial correlations.
Conclusion: The accuracy for predicting PD in rs-fMRI is overall acceptable. It is varying with the number of components and better at a lower number of components, which should be explored in more detail.

B-1238 14:40

Volumetric analysis of the pattern of brain atrophy in Wilson's disease
J.P. Chu, Y. Song, X. Tang, L. Zou; *Guangzhou/CN (15692009037@163.com)*

Purpose: To quantitatively evaluate brain atrophy pattern in Wilson's disease (WD) using a novel and validated fully automated whole brain segmentation method.
Methods and Materials: 3D-T1-weighted MRI scans were obtained from 27 WD patients (M: 17, F: 10, median: 31.3y) with neurological manifestations and 25 health controls (M: 8, F: 17, median: 25.1y). The volumetric segmentations of each structure were obtained automatically by using a multi-atlas processing pipeline to segment T1-weighted images into 289 anatomical regions of interest (ROI). In the volumetric group difference analyses, multiple comparison correction was carried out by controlling the family-wise error rate (FWER) at 0.05.
Results: In WD patients, significant volumetric decrease was found in 59 ROIs. Deep nuclei including bilateral putamen, substantia nigra, red nucleus, globus pallidus, caudate nucleus and thalamus showed obvious atrophy. For neuroanatomically defined white matter, we found significant atrophy of bilateral superior fronto-occipital fasciculus, external capsule in the claustrum, subcortical white matter of the subgenual anterior cingulate cortex, corticospinal tract, then followed by anterior corona radiate and cerebral peduncle ($P<0.001$). More notably, volumetric reduction detected in deep nuclei was more severe than white matter. Among basal ganglia, the putamen showed the most obvious atrophy. Moreover, eight ROIs including lateral and third ventricles had volumetric increase, which indicated a larger ventricular system secondary to brain atrophy.
Conclusion: Volumetric data obtained with automated segmentation of cerebral regions showed a significant atrophy of different brain structures in WD. Our study demonstrated that the atrophy of deep nuclei was more obvious than whiter matter.

A 3 Tesla MRI brain atlas for Parkinson's disease as diagnostic and interventional tool
I. Papageorgiou[1,2], L. Angelidakis[3], C. Damianou[3], M.-N. Psychogios[2], P. Lingor[2], K. von Eckardstein[2], A. Malich[1], S. Hadjidemetriou[3]; [1]*Nordhausen/DE*, [2]*Goettingen/DE*, [3]*Limassol/CY* *(ismini.e.papageorgiou@gmail.com)*

Purpose: Parkinson's disease (PD) is a chronic degenerative disorder of the central nervous system. The aim of this work is to develop an MRI-based brain atlas representative of the PD-brain alterations for diagnostic and interventional medical applications.
Methods and Materials: The data were 3.0 T MRI brain images from 16 PD patients and 10 matched controls. The brain atlases with multiple contrasts have been computed with the open platform 3D Slicer® using T1-weighted (T1w), T2-weighted (T2w) images, as well as susceptibility weighted images (SWI). Anatomic co-registration with a labeled atlas in BrainSuite® was done, refined with the level-set segmentation method by ITK-Snap®. Target structures were analysed for their volume and signal intensity.
Results: Comparison with the control group unravels a significant PD-related T1w signal loss in the caudate nucleus (CN) and putamen (Put) compared to age-matched controls (CTL). The T1w signal intensity is significantly reduced in PD patients in the CN/Put by approximately 8%/4% on the average CTL value ($p < 0.001$, rank-sum test), albeit without associated volume loss. The diagnostic efficacy of the T1w signal intensity is high according to the ROC analysis with an AUC 0.93/0.88. T1w, T2w and SWI atlas data, as well as average 3D volume rendering reconstructions for the substantia nigra, red nucleus, subthalamic nucleus and thalamus, are provided in detail.
Conclusion: We establish a disease-specific, PD MRI brain atlas for the midbrain structures and the striatum using the 3D Slicer®. T1w signal loss in the striatum may be a promising PD imaging biomarker.

B-1240 14:56

Asymptomatic T1 pallidal hyper intensity in patients with chronic liver disease
F. Costa, J.P. Filipe, C. Reis; *Porto/PT*

Purpose: T1 pallidal hyperintensity is believed to be caused by the deposits of neuroactive substances in the brain, particularly manganese. These changes may precipitate Acquired Hepatocerebral Degeneration (AHD), a rare chronic encephalopathy that may follow any form of chronic liver disease (CLD). Its clinical spectrum comprises motor signs, cognitive impairment, short term memory loss and in some cases mielopathy. It is believed that its prevalence is approximately from 1 to 2% in patients with CLD. Little is known about the prevalence of T1 pallidal hyperintensity in chronic liver patients population that bare no symptoms and may therefore be wrongfully labeled as AHD.
Methods and Materials: We retrospectively analyzed the medical records and imaging studies of CLD patients, for whom brain MRI data was available. The presence of T1 hyperintensity, its location and signal intensity was registered. We used non-parametric tests and Fisher's exact test to evaluate the association between symptomatic and asymptomatic patient and T1 signal intensity, hyperintensity location and Child-Pugh scores.
Results: We identified 250 patients, of which 16 (6,4%) had T1 pallidal hyperintensity, and among them only 7 (2,8%) presented with AHD clinical spectrum symptoms, meaning that 56% of patients with T1 pallidal hyperintensity showed no symptomatology whatsoever. Comparing symptomatic and asymptomatic patients, we observed no significant univariate association between the two groups and Child-Pugh score, signal intensity or location.
Conclusion: The T1 hyperintense pallidal signal is not predictive of AHD in this exploratory study, raising the question of its exact role in the clinical diagnosis of AHD.

B-1242 15:04

T2* hypointensity of the bulbar segment of the primary motor cortex in ALS patients with bulbar impairment
G. Donatelli, E. Caldarazzo Ienco, G. Migaleddu, P. Cecchi, G. Aringhieri, G. Siciliano, M. Cosottini; *Pisa/IT*

Purpose: In amyotrophic lateral sclerosis (ALS) the disruption of bulbar function as speech and swallowing is a possible clinical manifestation and to distinguish between the contribution of UMN and LMN degeneration to bulbar impairment is difficult. Recent 7T-MR studies suggested T2*-hypointensity as a possible marker of UMN impairment in ALS patients. We assessed the cortical T2* signal intensity of the bulbar segment of the primary motor cortex (fM1) in ALS patients, and its relationship with bulbar impairment.
Methods and Materials: Forty-seven ALS patients underwent 3D multi-echo T2*-weighted sequence at 3T-MR. Two neuro-radiologists visually assessed fM1 signal intensity using a score system (0=signal intensity similar to that of the postcentral gyrus; 1=mild hypointensity; 2=marked hypointensity). The bulbar impairment was evaluated using the items I-III of ALSFRS-R.
Results: Thirteen patients had bulbar impairment. In 15 patients fM1 was rated bilaterally hypointense: 10 patients received score=2 and had bulbar impairment; 5 patients received score=1 and have not bulbar impairment. fM1 of two patients without bulbar symptoms had score=1 only in one side. Thirty patients received score=0; three of them had bulbar impairment. Considering score=2 as pathological, sensitivity, specificity, PPV, NPV and accuracy of fM1 hypointensity were 0.77, 1, 1, 0.92 and 0.94. Considering bilateral score>0 as pathological, they were 0.77, 0.85, 0.67, 0.90 and 0.83. The interobserver agreement was 0.78.
Conclusion: The marked bilateral fM1 hypointensity seems the typical finding in ALS patients with bulbar impairment. The follow-up of patients without bulbar symptoms could provide information about the prognostic role of fM1 hypointensity.

B-1243 15:12

Role of qualitative and quantitative parameters in differentiation of PSA from other atypical parkinsonian syndromes in MRI
P. Hota[1], T. Dhibar[2], A. Biswas[2]; [1]*Bangalore/IN*, [2]*Kolkata/IN* *(meparamitahota@gmail.com)*

Purpose: Overlapping atrophic features without specific radiological signs complicate the diagnosis of various atypical parkinsonian syndromes. A method of differentiating progressive supranuclear palsy from other atypical Parkinsonian syndromes with qualitative and quantitative measurement of midbrain volume loss is introduced.
Methods and Materials: T1 mid-sagittal MRI image of 35 patients with clinically diagnosed PSP (n=6), MSA (n=4), DLB (n=2), CBD (n=3) and IPD (n=20) were acquired and measurements were taken as depicted below. Elliptical region of interest was placed over the pons and the midbrain in mid-sagittal slice. Two lines were drawn to define the major axes of the ellipses, corresponding to superior - inferior axis . The maximum measurement

perpendicular to the major axis was taken as the absolute pons and midbrain diameter for calculation.
Results: The absolute midbrain diameter and the midbrain to pons ratio were measured. Statistical significance of midbrain measurement < 9.35mm calculated from two columns and rows contingency table by Fisher's exact probability test gives the P value that is <0.001. 100% of clinically diagnosed MSA and PSP cases had a midbrain diameter measured as previously shown <9.35mm. 100% of clinically diagnosed PSP cases showed midbrain to pons ratio as described before < or =0.52.
Conclusion: Midbrain to pons ratio < or =0.52 is 100% specific for detection and differentiation of PSP from other atypical parkinsonian syndromes. This sign is reproducible, simple and correlates with other previously published results.

Radiological Wheeler staging system: a valid tool to improve the local staging of organ-confined prostate cancer with mp-MRI
E. Tabone[1], V.M. Doronzio[1], E. Appendino[1], V. Romano[1], S. Pedalino[1], M. Manfredi[2], S. Mazzetti[1], D. Regge[1], F. Russo[1]; [1]*Candiolo/IT*, [2]*Orbassano/IT*
(emanuele.tabone@gmail.com)

Purpose: To determine a new multiparametric-MRI staging system based on pathology for the assessment of capsular invasion in PCa.
Methods and Materials: This retrospective single center multi-reader study included consecutive patients with preoperative mp-MRI who underwent non nerve-sparing radical prostatectomy. Three radiologists with different experience and blinded to pathology, reported all examinations, classifying lesions according to a 5-point score based on radiological Wheeler (rW), derived from the pathological Wheeler (pW). Whole-mount histological sections were used as the reference standard and the pathologist defined the extent of capsular invasion using pW. PCa classified as L0,L1,L2 (respectively without contact, with contact or with infiltration of fibrous capsule) were grouped in the T2 stage class, while L3F and L3E (respectively with radial extracapsular infiltration ≤0.7mm and >0.7mm) in the T3 stage class. The accuracy of mp-MRI in predicting the pathological group T2 or T3 was assessed and AUC analysis was performed for each and overall readers.
Results: 105 patients were included for a total of 130 PCas. Sensitivity of the most experienced reader was 49% (17/35 T3 PCas), specificity 95.8% (91/95 T2 PCas), PPV 81% (17/21), and NPV 83% (91/109). Overall sensitivity was 60%, specificity 77%, PPV 50%, and NPV 84%. The AUC of the two most experienced readers in the detection of capsular invasion was 0.72-0.74.
Conclusion: In experienced hands organ-confined PCa is well recognized by mp-MRI and allows pre-treatment decision to tailor surgical approach (i.e., nerve-sparing radical prostatectomy). The understaging of T3 tumours remains a limitation, independently of radiologist expertise.

B-1246 14:08

Comparison of prostate cancer detection rates between MR-targeted and saturation TRUS-guided biopsy
V. Romano[1], E. Tabone[1], E. Appendino[1], S. Mazzetti[1], V. Giannini[1], A. Giacobbe[2], G. Muto[2], F. Russo[1], D. Regge[1]; [1]*Candiolo/IT*, [2]*Milan/IT*
(vittorio.romano@ircc.it)

Purpose: To compare PCa detection rate of in-bore MR-targeted biopsy and of saturation TRUS-guided biopsy in men with clinical suspicion of PCa and a positive MRI finding.
Methods and Materials: Diagnostic mp-MRI was performed using a 1.5T magnet and a phased-array coil combined with an endorectal coil. Acquisition protocol included T1- and T2-weighted, diffusion-weighted, and dynamic contrast-enhanced imaging. Subjects with at least one region with suspicion of PCa were considered positive at MRI, and randomly allocated (ratio 1:1) to MR-targeted biopsy (arm A) or saturation TRUS-guided biopsy (arm B). In MR-targeted biopsy only index lesions were sampled, using at least 2 cores, while in saturation TRUS-guided biopsy at least 28 cores were retrieved. Biopsy Gleason score (bGS) was used as the reference standard.
Results: PCa detection rate was 71% and 76% in arm A and arm B, respectively. No statistical significant difference was observed between the detection rates of the two study arms (p=0.58). In arm B, we observed higher overall PCa detection rate in the biopsy-naïve group than in patients with at least one previous negative biopsy (88% vs 62%, p=0.03). Sampling efficiency was in favour of arm A with 59.7% of core detecting PCa versus 22.3% of the arm B (p < 0.0001).
Conclusion: In-bore MR-targeted biopsy has a comparable PCa detection rate to TRUS-guided saturation biopsy, but reached a significant higher positivity rate of biopsy cores. Using a lower number of sampling cores could reduce pain perceived by patients, increasing acceptance and tolerability of the targeted procedure.

B-1247 14:16

Targeted MRI/TRUS fusion-guided biopsy in patients with suspicious pararectal lymph nodes after radical prostatectomy
V. Kapustin, A. Gromov, V. Shirokorad, Y. Subbotin; *Moscow/RU*
(wwkapustin@yandex.ru)

Purpose: To determine a possibility of simultaneous transrectal ultrasound and MR imaging technique (sensor-based MR-TRUS Fusion) for biopsy guidance in patients with biochemical recurrence (BR) after radical prostatectomy when metastatic involvement of pararectal LN is suspected.
Methods and Materials: 18 patients with BR after radical prostatectomy (RP) and suspicious pararectal LN were included in this study. Multiparametric 1.5T MRI with a surface coil were performed. Initial MR examinations showed suspicious prararectal LN in 16 cases. In 2 cases pararectal LN-mts were primarily suspected by PET-CT findings and subsequent retrospective MRI data review. Simultaneous MR and TRUS image formations were performed. High accuracy level (0.3-0.4 cm) of "Fusion" images superposition was achieved in 11 cases. In these cases core-needle targeted biopsies (TB) of suspicious LN were performed. In 3 cases achieved accuracy level was too low, however areas of suspicious LN localization for further TRUS-guided TB were detected. Eventually, in 2 cases LN-mts were localized at the level of rectosigmoid junction, thus they were unachievable for TRUS approach. In these cases fine-needle aspiration biopsies (FNAB) were performed with cognitive Fusion navigation under endosonoscopic control.
Results: Use of MRI/TRUS-Fusion technique allowed us to verify metastatic involvement of pararectal LN in 13 out of 18 cases. In the remaining 5 cases fragments of pelvic fat with no evidence of tumor growth or LN tissue were histologically revealed.
Conclusion: MRI/TRUS-Fusion proves to be a promising technique for targeted core-needle biopsies in patients after RP when a pararectal lymph nodes mts-involvement is suspected.

B-1248 14:24

Could mpMRI really improve the detection of clinical recurrence of prostate cancer with low PSA value and efficacy of radiation treatment?
F. Kossov, P. Bulychkin, D. Romanov, M.A. Shorikov, E. Tarachkova, V. Panov, S. Tkachev, B. Dolgushin, G. Hagverdiyeva; *Moscow/RU*
(fil-doc@yandex.ru)

Purpose: Salvage radiation therapy (SRT) is the main treatment modality for patients with prostate cancer recurrence (PCaR) after radical prostatectomy (RP). Clinical PCaR (tumour substrate appearance at area of prostate bed or regional lymph nodes metastasis) early detection improves SRT efficiency. Medical imaging plays minor role in clinical PCaR diagnostic due to low accuracy of routine radiological approaches (TRUS-CT-MRI). Multiparametric MRI (mpMRI) would significantly improve clinical PCaR detection even in patients with low PSA values and small sizes of tumour substrate.
Methods and Materials: 142 men (54-71 years, median - 62) with biochemical recurrence (PSA>0.2 ng/ml) after RP were examined by mpMRI before and 6 months after SRT with every 3 months PSA control. There were 2 groups of patients with clinical PCaR: 1) PCaR size>5 mm (PSA 0.9 ng/ml); 2) PCaR size<5 mm (PSA 0.5 ng/ml). Prescribed dose of SRT to regional lymphatic nodes was 44 Gy, to prostate bed - 66 Gy (72 Gy - if region of clinical PCaR was identified).
Results: Clinical PCaR was found in 121 cases. 8 patients had distant metastasis. 13 patients had no significant mpMRI data of clinical PCaR. mpMRI sensitivity/specificity for clinical PCaR at I group were 89%/96%; at II group - 78%/87%, respectively. In all cases, PSA progression decreases after SRT was evaluated. Size of clinical PCaR significantly correlated with PSA level (p<0.001). Higher SRT doses to PCaR areas associated with fast PSA level decrease (p<0.004).
Conclusion: mpMRI showed high sensitivity and specificity in clinical PCaR detection. SRT escalation dose to area of clinical PCaR effected to more progressive PSA reduction.

B-1249 14:32

11C-Choline PET/CT in the detection of oligometastatic prostate cancer recurrence

D. Pursanova, I. Aslanidis, O. Mukhortova, I. Ekaeva, T.A. Trifonova, V.I. Shirokorad, D.A. Roshchin; *Moscow/RU (dipoursanidou@gmail.com)*

Purpose: To investigate the diagnostic value of 11C-Choline PET/CT in the detection of oligometastatic prostate cancer (PCa) recurrence, which is essential in determining the personalized therapeutic approach.
Methods and Materials: This retrospective analysis included results of 11C-Choline PET/CT examinations performed in 217 PCa patients with rising PSA after radical treatment. The mean PSA value in the group was 2.1±2.5 (0.2-9.7) ng/ml. Examinations were done on PET/CT scanner (Biograph-64, Siemens) 10 min after 11C-Choline injection (400-550Mbq).
Results: Overall, PET/CT detected PCa relapse in 56% (121/217) patients, of which 68% (82/121) had oligometastatic process (1-3 lesions). Local relapse was revealed in 62% (51/82) patients, distant oligometastatic lesions were identified in 33% (27/82), both local and distant metastases in 5% (4/82) cases. Oligometastases to lymph nodes were diagnosed in 35 patients, of which 71% (25/35) had single foci, and of these 57% (20/35) were presented by normal-size lymph nodes (median 6 mm). Oligometastases to skeleton were revealed in 23 patients, of which 78% (18/23) had single foci, and the rest had several - two (n=4) and three (n=1) foci. Importantly, that 5 of 23 PET-positive patients with bone metastases had no structural abnormalities on CT images, corresponding to isolated involvement of bone marrow.
Conclusion: 11C-Choline PET/CT has been shown to be a noninvasive accurate technique for detection of recurrent PCa in patients with rising PSA after radical treatment, which allows to differentiate patients with local and distant metastases in one study, as well as identify oligometastatic process and, therefore, is useful in determining the further personalized therapeutic approach.

Comparisons of imaging biomarkers on simultaneous choline PET and multiparametric MRI between TNM staging in high-risk prostate cancer patients

L.-J. Wang, J.-R. Tseng, Y.-C. Lin; *Taoyuan/TW (lijenwang0918@gmail.com)*

Purpose: To compare imaging biomarkers between TNM staging on simultaneous C11 choline PET (chPET) and multiparametric prostate MRI (mpMRI) in high-risk prostate cancer (PCA) patients.
Methods and Materials: From January 2015 to December 2016, we prospectively enrolled 31 PCA patients undergoing simultaneous chPET and mpMRI. Of each patient, total lesion glycolysis and metabolic tumour volume of standardized uptake values (SUV_{TLG} and SUV_{MTV}), maximum values of perfusion parameters ($ktrans_{max}$ and kep_{max}), and minimum value of apparent diffusion coefficient (ADC_{min}) of PCA were recorded. The presence or absence of extra-prostate or adjacent organ extension (T3-4), regional lymph node metastasis (N1) and distant metastasis (M1) of each patient was determined by histological results, imaging findings, clinical examinations and follow-up. Imaging biomarkers between patients with and without T3-4, N1 and M1 were compared using Mann-Whitney U test.
Results: Of the 31 patients, there were 27 patients (87.1%) with T3-4, 13 patients (41.9%) with N1, and 17 patients (54.8%) with M1 diseases. Significant differences of SUV_{TLG}, SUV_{MTV}, $ktrans_{max}$, kep_{max} and ADC_{min} between patients without and with T3-4 as well as of SUV_{TLG} and SUV_{MTV} between patients without and with M1 were shown (all $p < 0.05$). Nonetheless, there were no significant differences of all 5 imaging biomarkers between patients without and with N1 as well as of $ktrans_{max}$, Kep_{max} and ADC_{min} between patients without and with M1 diseases.
Conclusion: Imaging biomarkers on chPET and mpMRI are good indicators of primary tumour status of PCA.

Prospective evaluation of extent of disease in prostate cancer biochemical relapse by [^{68}Ga]PSMA-HBED-CC PET/CT

G. Chong, D. Barahona Z., A. Balcells, D. Hasson, G. Schiappacasse, A. Labra Weitzler; *Santiago de Chile/CL (danibarahona@gmail.com)*

Purpose: Accurately determining the extent of disease on biochemical relapse of prostate cancer (PCa) can have important therapeutic implications. The lesion detection rate of [^{68}Ga]PSMA-HBED-CC-PET/CT and its relation to prostate-specific antigen (PSA) level and Gleason score is evaluated.
Methods and Materials: All patients subjected to [^{68}Ga]PSMA-HBED-CC-PET/CT with PCa biochemical relapse, from November 2014 to December 2016 were included. Laboratory exams performed prior to PSMA-PET-CT were retrieved from electronic medical records, and histopathology results were extracted from surgical specimens. All high-uptake regions were identified by two experienced readers. Regional involvement was defined as urethrovesical anastomosis lesions or pelvic lymphadenopathies.
Results: 102 patients were recruited. Mean age was 70.3 years (SD: 9.2), and median PSA Score was 2.52 ng/ml (IQR: 7.1), with a minimum value of 0.04 ng/ml, and 35% of PSA values under 1 ng/ml. PSMA-PET/CT was positive for 70% of patients. Among PSMA-PET/CT positive cases, 55% had regional involvement and 2.5% had suprapelvic lymphadenopathies without regional involvement. PSMA-PET/CT was positive in 43% of studies with PSA levels of <1 ng/ml. The lowest PSA level related to a positive finding was 0.11 ng/ml. 16% of lymphadenopathies detected were under 0.5 cm, and 69% were under 1 cm. 28% of studies showed bone metastases. A high Gleason score (9-10) was non-significatively associated with a higher number of pelvic metastases.
Conclusion: [^{68}Ga]PSMA-HBED-CC-PET/CT can identify secondary lesions in PCa biochemical relapse even in patients with very low PSA levels and can accurately identify small intra- and extra-pelvic lymphadenopathies, which can substantially influence treatment planning.

B-1252 14:56

The impact of [^{68}Ga]PSMA I&T PET/CT on radiotherapy planning in patients with biochemical cancer relapse after radical prostatectomy in prostate cancer.

C. Berliner, T. Frenzel, M. Tienken, M. Abdel, S. Klutmann, D. Beyersdorff, G. Adam, A. Krüll, P. Bannas; *Hamburg/DE (caberliner@gmail.com)*

Purpose: To determine the impact of [^{68}Ga]PSMA I&T PET/CT on radiotherapy planning of biochemical cancer relapse of prostate cancer.
Methods and Materials: We performed a retrospective analysis of 75 patients who underwent [^{68}Ga]PSMA I&T PET/CT scans prior to scheduled radiotherapy treatment. All patients had a documented biochemical relapse after radical prostatectomy. The age distribution was median 69 (range 52-86) years. The PSA level was median 0.2 (range 0.02-653.2) ng/ml. We compared the impact of [^{68}Ga]PSMA I&T PET/CT on lesion detection and treatment decision.
Results: [^{68}Ga]PSMA I&T PET/CT revealed a total of 47 positive lesions, whereas CT detected 18 lesions. The therapeutic regimen was changed in 32 of 75 cases (43%) based on the [^{68}Ga]PSMA I&T PET/CT. In 31 cases (41%) it upstaged to an enhanced tumour extension. Twenty-five cases (33%) received an additional boost to the [^{68}Ga]PSMA I&T PET/CT-positive findings.
Conclusion: [^{68}Ga]PSMA I&T PET/CT is an advanced hybrid imaging technique prior radiotherapy treatment for prostate cancer patients with proven biochemical relapse. It is significantly impacting the radiotherapy planning and enables individualized therapy for prostate cancer patients.

B-1253 15:04

Clinical utility of ^{18}F-NaFand ^{68}Ga-PSMA PET-CT as prognostic marker in patients with metastatic prostate cancer treated with Radium-223

S.S. Medina-Ornelas, F. Garcia-Perez; *Mexico City/MX (dr.sevastian@outlook.com)*

Purpose: Determine if ^{18}F-NaF and ^{68}Ga-PSMA PET/CT can predict response to ^{223}Ra treatment in patients with metastatic prostate cancer (mPC).
Methods and Materials: Twenty patients with metastatic castration-resistant PC (mCRPC), and seven patients with high-grade PC (hgPC), were evaluated with ^{18}F-NaF and ^{68}Ga-PSMA PET-CT prior to receipt ^{223}Ra therapy a standard dose (55kBq/kg), and 4-6 weeks after the last dose, with simultaneous measurements of PSA and alkaline phosphatase (AP). A semiquantitative bayesian analysis of each patient allowed to establish 3 study groups based on the molecularly active volume: low-burden (<1000 cm³), medium-burden (1001-3000 cm³); and high burden (>3001 cm³). Ten patients were classified as high-burden, 7 patients as medium-burden and 10 patients as low-burden.
Results: Fifteen patients completed 6 cycles (7-hgPC, 8-mCRPC). Nine were of low burden and six of medium-burden, which showed a decrease in PSA and AP levels ($p < 0.05$); the rest of patients according to the number of doses variable results was obteined; the value of ^{18}F-NaF and ^{68}Ga-PSMA as a predictive tool in response therapy according to the degree of tumour burden. Patients with low-burden treated with ^{223}Ra showed to be a predictor of good prognosis in response to treatment ($p < 0.05$); while patients with high-burden have a high probability of do not complete 6 cycles.
Conclusion: The PET-CT in the evaluation of response to ^{223}Ra is useful tool in the selection of those patients who are likely to improve according to their degree of overall tumour burden, in addition to timely evaluation of therapeutic efficacy.

B-1254 15:12

Assessment of response to therapy in bone metastases from prostatic malignancy beyond mono-exponential diffusion imaging

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: To evaluate performance of intra-voxel incoherent motion model of diffusion imaging in monitoring treatment response in bone metastases from prostatic malignancy and possible identification of early androgen resistance.
Methods and Materials: 36 patients with histologically proven prostatic malignancy with bone metastases on whole body diffusion imaging (using

DWIBS sequence) with no prior treatment with anti-androgens were included in the study. Imaging was performed on Achieva 1.5 Tesla scanner (Philips Healthcare, Best, The Netherlands) the day after commencement of antiandrogen therapy and thereafter at 3 time points: 2 weeks, 3 months and 6 months. Lesions in iliac bones or sacrum were analysed. Images were acquired in an axial plane with 11 b values. IVIM parameters (perfusion fraction [*f*], molecular diffusion coefficient [*D*], and perfusion-related *D* [*D**]) and apparent diffusion coefficient (ADC) were obtained.
Results: D values (P 0.001) were the most sensitive, robust and reproducible indicator for response. D values increased in the first 2 weeks of therapy and continued to rise and plateaued off after 3 months. f values increased after one month and remained stable till 3 months but showed further increase at 6 months. ADC values derived from mono-exponential equation also showed elevation after therapy.
Conclusion: D values derived from IVIM model demonstrated very good measurement repeatability and sensitive to treatment response. f values provide complimentary data to identify tumour response. Thus, a combination of ADC, D and f values would provide non-invasive monitoring of therapy and possibly predict early resistance to treatment.

The efficacy of MRI in the diagnostic work-up of cystic fibrosis-associated liver disease
S. Pötter-Lang, K. Staufer, P.A.T. Baltzer, D. Tamandl, D. Muin, N. Bastati-Huber, E. Halilbasic, L. Kazemi-Shirazi, A. Ba-Ssalamah; *Vienna/AT (sarah.poetter-lang@meduniwien.ac.at)*

Purpose: To identify independent imaging features and establish a diagnostic algorithm for early diagnosis of cystic fibrosis-associated liver disease (CFLD) in CF patients as compared with a control group (CG) on gadoxetic acid-enhanced MRI.
Methods and Materials: 90 adult patients were enrolled, 50 with CF and 40 of the CG. The CF group was divided in two subgroups, the retrospective or test subgroup (n = 33) and the prospective or validation subgroup (n = 17). The CG (patients with normal liver enzymes, but no more than benign focal liver lesions) was divided also accordingly (27:13). MRI variables including quantitative and qualitative parameters were used to distinguish those with CFLD from the CG using the clinical criteria by Debray. Fifteen qualitative single-lesion CF descriptors were defined. Two readers independently evaluated the images. Univariate statistical analysis was performed to obtain the significant imaging features that differentiate CF patients from the CG. Subsequently, a multivariate classification analysis using the chi-squared automatic interaction detector (CHAID) methodology was performed to identify the most important descriptors. Diagnostic performance was assessed by receiver-operating characteristic (ROC) analysis.
Results: Three independent imaging descriptors distinguished CFLD from CG: a) the presence of altered gallbladder morphology (GBAM); b) periportal tracking (PPT) and c) periportal fat deposition (PPFD). Prospective validation of the classification algorithm demonstrated a sensitivity of 94.1 % and specificity of 84.6 % for discriminating CFLD from the control cohort.
Conclusion: We identified 3 independent imaging features that could potentially diagnose early-stage CFLD on unenhanced MRI.

B-1256 14:04

T_1 mapping on gadoxetic acid-enhanced MR imaging potentially predicts recurrence of HCC after hepatectomy
W.T. Wang, S. Zhu, Y. Ding, L. Yang, C.-Z. Chen, Q.-H. Ye, M.-S. Zeng, S.-X. Rao; *Shanghai/CN (787356268@qq.com)*

Purpose: The enhancement on hepatobiliary phase on gadoxetic acid-enhanced magnetic resonance imaging (MRI) could reflect biological properties of hepatocellular carcinoma (HCC). The retrospective study aimed to evaluate the prognostic significance of T_1 mapping on gadoxetic acid-enhanced MRI in prediction of recurrence of single nodular HCC (≤ 3cm) after hepatectomy.
Methods and Materials: A total of 107 patients with single nodular HCC (≤ 3cm) who underwent preoperative gadoxetic acid-enhanced MRI followed by hepatectomy was included retrospectively. Independent prognostic MR imaging findings were identified on multivariate analysis. Based on the optimal cut-off value of the receiver operating characteristic (ROC) curve analysis, cumulative recurrence rates were compared between groups of low and high reduction rate of T_1 relaxation time.
Results: Reduction rate of T_1 relaxation time (*P* =0.001; hazard ratio = 0.08; 95% confidence interval [CI]: 0.02-0.38) and non-hypervascular hypointense nodules (*P* =0.042; hazard ratio = 2.21; 95% CI: 1.03-4.77) in preoperative gadoxetic acid-enhanced MRI were independently related to recurrence of HCC after hepatectomy. The area under ROC curve analysis of reduction rate of T_1 relaxation time was 0.802. Patients with lower reduction rates (≤ 44.8%) group had higher cumulative recurrence rates. A combination of these two risk factors in patients with single HCC had significantly higher recurrence rates compared to those with either or none of the two risk factors during the years of follow-up.
Conclusion: Reduction rate of T_1 relaxation time in combination with the presence of non-hypervascular hypointense nodules can potentially predict recurrence of HCC after hepatectomy.

B-1257 14:08

Magnetic resonance imaging of hepatitis B virus-related hepatocellular carcinoma: correlations with imaging features and molecular marker glypican-3
S. Wang, J.H. Li; *Beijing/CN (wangsudan815@163.com)*

Purpose: To investigate whether imaging features from dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) could aid in the prediction of pathological grading of hepatocellular carcinoma (HCC) related to hepatitis B virus (HBV) cirrhosis, by correlation analysis between lesion signal intensity variation in MRI and glypican (GPC)-3 immunohistochemistry.
Methods and Materials: Seventy-four patients with HBV-related HCC (22 cases well-differentiated HCC, 33 cases moderately differentiated, and 19 poorly differentiated) underwent DCE-MRI and biopsy before any targeted therapy. Signal intensity variance ratio was used to assess the image contrast between the region of interest (ROI) of tumours and liver parenchyma, by two radiologists who independently drew the ROI and calculated signal variance ratio on MRI images. GPC-3 expression grading was evaluated with immunohistochemistry.
Results: Low GPC-3 expression level was observed predominantly in well-differentiated HCC, whereas high GPC-3 expression level was observed predominantly in poorly and moderately differentiated HCC ($p<0.05$). We observed a significant correlation between GPC-3 expression and lesion signal intensity variance ratio in the arterial enhancement phase ($r=0.323$, $p=0.005$), as well as between GPC-3 expression and lesion signal intensity variance ratio from T2-weighted images ($r=0.276$, $p=0.017$). However, no correlation was found between GPC-3 grade and signal variance ratio in hepatic portal venous and late phases.
Conclusion: GPC-3 expression level of HCC showed a favorable diagnostic performance in differentiating well-differentiated from poorly differentiated HCC. Signal intensities in arterial phase and T2WI were well correlated with the degree of GPC-3 expression in HBV-cirrhosis-related HCC. Consequently, some MRI parameters are expected to non-invasively predict differentiation stages of HCC before biopsy or surgery.

B-1258 14:12

Differentiation of inflammatory pseudo-tumour from colorectal liver metastases on gadoxetic acid-enhanced magnetic resonance imaging
S. Ichikawa, U. Motosugi, T. Suzuki, T. Shimizu, H. Onishi; *Chuo-shi/JP*

Purpose: To determine the differential features of inflammatory pseudo-tumour (IPT) from colorectal liver metastases (CLM) on gadoxetic acid-enhanced magnetic resonance imaging (MRI).
Methods and Materials: This retrospective study was approved by the institutional review board, and waived informed patient consent. One hundred and thirty-four patients with pathologically proven or clinically diagnosed IPT (*n* = 25) and CLM (*n* = 109) who had undergone gadoxetic acid-enhanced MRI were enrolled. Images were analysed for the shape, enhancement pattern on hepatic arterial phase (HAP), persistent rim-enhancement during HAP to late phase, blood vessel penetration, peri-tumoural enhancement on HAP, peri-tumoural hypointensity on hepatobiliary phase (HBP), peri-tumoural hyperintensity on T2-weighted imaging (T2WI), biliary dilatation, target appearance (central hypointense area with peripheral hyperintense rim) on HBP, signal pattern of diffusion-weighted imaging (DWI) and T2WI, and lesion-to-liver signal intensity ratio (LLR) on HBP and DWI. Univariate and multivariate analyses were performed to identify relevant differentiating features between ITP and CLM.
Results: Univariate analysis revealed that the following significant parameters favour IPT over CLM: irregular shape, hyperenhancement on HAP, blood vessel penetration, target appearance on HBP, peri-tumoural hyperintensity on T2WI, absence of persistent rim-enhancement, high LLR on HBP, and low LLR on DWI (*P* < 0.0001-0.0361). Multivariate analysis revealed that target appearance on HBP, high LLR on HBP, and low LLR on DWI were predictive of IPT (*P* = 0.0220-0.0330).

Conclusion: Target appearance on HBP and LLR on HBP and DWI were the reliable imaging features for distinguishing IPT from CLM on gadoxetic acid-enhanced MRI.

B-1259 14:16

Dynamic-enhanced CT of multiple solid pancreatic lesions: prevalence and features of non-malignancies

L. Zhu, J. Li, Z.-y. Sun, H.-d. Xue, Z.-y. Jin; *Beijing/CN (zhuliang_pumc@163.com)*

Purpose: To determine the prevalence of multiple solid pancreatic lesions on dynamic enhanced CT in a large cohort of patients with suspected pancreatic diseases, and to describe CT features of non-malignant disease entities.
Methods and Materials: We investigated 8096 consecutive patients who underwent dynamic enhanced CT pancreas protocol at a tertiary pancreatic disease center (June 2014 to August 2017). The final clinical diagnosis was used to determine the prevalence of malignant and non-malignant courses. The diagnostic accuracy of dynamic enhanced CT for non-malignancies was calculated. Univariate and multivariate analyses were conducted to identify clinical and CT findings (age, gender, symptoms, serum biomarkers and CT morphological and enhancement features) that predict non-malignancy.
Results: Multiple solid pancreatic lesions were seen in 1.5% of patients with suspected pancreatic diseases (121/8096). The prevalence of non-malignancies was 19.8%(24/121). The most common non-malignancy was autoimmune pancreatitis (17.4%, 21/121). The most common malignancies were neuroendocrine tumours (51.2%, 62/121), pancreatic adenocarcinoma (as the dominant lesion, 12.4%, 15/121), metastases (7.4%, 9/121) and lymphoma (5.8%, 7/121). In patients with multiple solid pancreatic lesions, dynamic enhanced CT had a sensitivity of 79.2% and a specificity of 92.8% for diagnosing non-malignancies. Elevated serum IgG4 level ($p<0.001$), hypoenhancement in arterial phase ($p=0.001$), non-hypoenhancement in later phases ($p=0.009$) and location in both proximal and distal pancreas ($p=0.036$) were found to be predictors of non-malignancies.
Conclusion: Multiple solid pancreatic lesions were rare, with a wide disease spectrum. Dynamic enhanced CT provides clues for determining disease nature.

B-1260 14:20

Diagnostic accuracy and interobserver agreement: CEUS-LI-RADS vs MRI-LI-RADS

B. Schellhaas, M. Hammon, D. Strobel, R. Görtz, A. Cavallaro, R. Janka, M.F. Neurath, M. Uder, H. Seuss; *Erlangen/DE (hannes.seuss@uk-erlangen.de)*

Purpose: We compared diagnostic accuracy and interobserver-agreement for the recently introduced contrast-enhanced ultrasound (CEUS)-based algorithm CEUS-LI-RADS (liver imaging reporting and data system) versus the well-established magnetic resonance imaging (MRI)-LI-RADS for non-invasive diagnosis of hepatocellular carcinoma (HCC) in high-risk patients.
Methods and Materials: Focal liver lesions in 50 high-risk patients (mean age 66.2 ±11.8 years; 39 male) were assessed retrospectively with CEUS and MRI. Two independent observers reviewed CEUS and MRI examinations, respectively, classifying observations according to CEUS-LI-RADSv.2016 and MRI-LI-RADSv.2014. Interobserver agreement was assessed with Cohen's Kappa. Diagnostic accuracy for histologically proven lesions (n=36) was compared between CEUS-LI-RADS and MRI-LI-RADS.
Results: 43 lesions were HCCs; two were ICCs; five were benign lesions. Diagnostic accuracy was 64%/50% (observer 1/2) for CEUS-LI-RADS and 81%/75% (observer 1/2) for MRI-LI-RADS. Washout was observed more frequently with MRI. Interobserver-agreement for arterial hyperenhancement was κ=0.511/0.565 (CEUS/MRI), for washout it was κ=0.490/0.582 (CEUS/MRI), and for CEUS-LI-RADS category it was 0.309/0.609 (CEUS/MRI).
Conclusion: CEUS-LI-RADS in its current form is inferior to MRI-LI-RADS for definite diagnosis of HCC (LR-5). Arterial hyperenhancement is the key feature for diagnosis of HCC with CEUS. Combining the LR-4 and LR-5 categories in CEUS-LI-RADS would improve diagnostic accuracy, sensitivity and interreader agreement.

B-1261 14:24

Evaluating autoimmune pancreatitis under corticosteroid treatment with T1 mapping

L. Zhu[1], H.-D. Xue[1], Z.-Y. Sun[1], D. Nickel[2], T.-Y. Qian[1], Z.-Y. Jin[1]; [1]*Beijing/CN*, [2]*Erlangen/DE (zhuliang_pumc@163.com)*

Purpose: To evaluate the T1 relaxation time of autoimmune pancreatitis (AIP) in the native state and its change after corticosteroid treatment (CST).
Methods and Materials: The institutional review board approved this prospective study and all patients provided written informed consent. Twelve patients with focal AIP and 22 patients with diffuse AIP received pancreatic MR including T1 mapping on a 3T scanner, both before and after steroid treatment. Twenty patients without pancreatic diseases who received T1 mapping of the pancreas served as control. In each patient, T1 relaxation time of pancreatic parenchyma in the head, body and tail was measured.
Results: The T1 relaxation time of normal pancreatic parenchyma was 785.4±49.5 msec. For both focal and diffuse AIP, the T1 relaxation time was significantly elongated compared to the control (both $p<0.001$). After 4-12 weeks of CST, the T1 relaxation time of the pancreas shortened significantly towards normalization, compared to the baseline value (for focal AIP: from 1220.7±139.3 msec to 931.7±86.4 msec; and for diffuse AIP: from 1104.5±121.8 msec to 893.8.4±108.4 msec, both $p<0.01$). The visually uninvolved parenchyma in focal AIP had longer T1 relaxation time compared to normal pancreas ($p<0.01$), which also shortened significantly after steroid treatment (from 918.7±128.9 msec to 831.1±94.3 msec, $p<0.01$).
Conclusion: T1 mapping could accurately depict the inflammatory state and extent in patients with AIP, and monitor parenchyma change with treatment. T1 mapping detects more extensive parenchyma involvement in focal AIP, compared to visual inspection.

B-1262 14:28

Non-hypervascular pancreatic neuroendocrine tumours: spectrum of MDCT imaging findings and differentiation from pancreaticductal adenocarcinoma

E. Belousova, G. Karmazanovsky; *Moscow/RU (mestre@inbox.ru)*

Purpose: To determine contrast-enhanced MDCT features to differentiate nonhypervascular pancreatic neuroendocrine tumors (PNETs) from pancreatic ductal adenocarcinomas (PDACs).
Methods and Materials: We included 74 patients with PNETs and 80 patients with PDACs who underwent preoperative MDCT. Two radiologists evaluated the morphologic characteristic and enhancement patterns of the tumors. Tumor-to-pancreas enhancement ratio was defined as the HU value of the tumor divided by the HU value of the pancreas. The possibilities of PNET or PDAC were estimated for nonhypervascular PNETs.
Results: On the basis of arterial enhancement, 43 PNETs were hypervascular and 31 were nonhypervascular. When compared to PDAC, nonhypervascular PNETs more frequently had well-defined tumor margins, intratumoral cystic components, calcifications and blood vessels and less frequently had main pancreatic duct dilatation, peripancreatic infiltration and vascular invasion ($p<0.01$ for all). Nonhypervascular PNETs had higher tumor-to-pancreas enhancement ratio in venous phase (1.02vs.0.78,$p<0.05$). Nonhypervascular PNETs more often had portal-venous hyperenhancement or persistent isoenhancement, while PDAC more often had persistent hypoenhancement or gradual delayed enhancement ($p<0.001$). The most accurate MDCT-findings to predict nonhypervascular PNET were the absence of MPD dilatation and peripancreatic infiltration (79% and 92% accuracy), portal-venous phase hyperenhancement or persistent isoenhancement (77%), the presence of intratumoral blood vessels (77%) and relative enhancement intensity in venous phase >0.9(76%). Using these criteria, the area under curve for differentiation of PNET from PDAC was 0.906-0.846.
Conclusion: Combined assessment of the enhancement and morphologic characteristics can improve the diagnosing of nonhypervascular PNETs at contrast-enhanced MDCT, reducing the rate of false diagnoses of nonhypervascular PNETs as PDAC.

B-1264 14:32

Application of CT texture analysis in evaluating histologic grade of pancreatic neuroendocrine tumours

S.-h. Cheng[1,2], L. Zhu[1], H. Xue[1], Z. Jin[1]; [1]*Beijing/CN*, [2]*Chengdu/CN (1025518057@qq.com)*

Purpose: To explore the application of CT texture analysis (CTTA) to differentiate between G1 versus G2 and G3 pancreatic neuroendocrine tumours (PanNETs).
Methods and Materials: A total of 36 patients with G1 PanNETs (n = 18) and G2+G3 PanNETs (n = 18) were included in this retrospective study. Both unenhanced and enhanced CT images were chosen for CTTA. Texture parameters including mean grey-level intensity (mean), standard deviation (SD), entropy, mean of positive pixels (MPP), skewness, and kurtosis were compared between G1 and G2+3 PanNETs. Receiver operating characteristic (ROC) analysis was performed and the area under the ROC curve (AUC) was calculated. Sensitivity (Se), specificity (Sp), positive predictive value (PPV), negative predictive value (NPV), and accuracy were calculated using the cut-off value of texture parameter with the highest AUC.
Results: Compared to G2+G3 PanNETs, G1 PanNETs had significantly lower skewness ($P = 0.031$) on unenhanced images and lower skewness ($P < 0.05$), higher mean ($P = 0.047$) and MPP ($P < 0.05$) on enhanced images. A skewness <0.23 at medium texture scale on enhanced images identified G1 PanNETs from G2+G3 PanNETs with the highest AUC of 0.724 ± 0.091 (Se = 61.1%, Sp = 94.4%, PPV = 91.6%, NPV = 70.8%, and accuracy = 77.8%).

Conclusion: CTTA proved to be a feasible tool for differentiating G1 PanNETs from G2+G3 PanNETs. Skewness quantified from medium texture scale on enhanced images was the optimal diagnostic parameter for estimating histologic grade of PanNETs.

B-1265 14:36

The efficacy of superb microvascular imaging for diagnosing acute cholecystitis: comparison with conventional ultrasonography

J. Ra, E. Lee, H. Park, J. Lee, S. Park, B. Choi; *Seoul/KR (joonbi89@naver.com)*

Purpose: To evaluate the diagnostic performance of ultrasonography (US) plus superb microvascular imaging (SMI) compared to conventional US alone for diagnosing acute cholecystitis.
Methods and Materials: We retrospectively investigated 54 patients with right upper quadrant abdominal pain who underwent US with SMI. The pixel count of SMI showing flow signal was measured in the region of interest of the gallbladder bed of the liver. Two radiologists independently evaluated the imaging features and rated the five-point diagnostic likelihood level before versus after the addition of SMI using the optimal cut-off SMI pixel count obtained by the receiver operating characteristic (ROC) curve. Multivariate logistic regression analysis identified predictive factors for acute cholecystitis. Pairwise comparison of ROC was performed to compare the diagnostic performance of US before versus after the addition of SMI.
Results: Of the 54 patients, 29 had acute cholecystitis confirmed by cholecystectomy or percutaneous cholecystostomy. The SMI pixel count was significantly higher in acute than in non-acute cholecystitis (169.84 versus 27.48, $p < 0.001$). The optimal SMI cut-off pixel count for predicting acute cholecystitis was 56.67 with 82.8% sensitivity and 92.0% specificity. In multivariate analysis, SMI pixel count and gallbladder wall thickening were significant predictive factors ($p < 0.05$). Area under the curve values were significantly higher after the addition of SMI than before (0.850 versus 0.729, $p = 0.022$).
Conclusion: Quantitative SMI values were significantly higher in acute than in non-acute cholecystitis. US plus SMI could objectively improve diagnostic performance compared with conventional US alone for acute cholecystitis.

B-1266 14:40

MR T2 mapping of hepatocellular carcinoma: sequence parameters optimisation and its correlation with Ki-67 proliferation status, histological grades and microvascular density

L. Cao, B. Song; *Chengdu/CN (clk2089@icloud.com)*

Purpose: To optimise T2 mapping imaging parameters in liver and explore the relationship between T2 relaxation time of HCC and histological results.
Methods and Materials: (I) Ten healthy volunteers were examined to optimise T2-prepared TrueFISP parameters to acquire the best quality of T2 map. (II) Thirty-five HCC patients were included. T2 map was acquired through T2-prepared TrueFISP on a 3T scanner. Freehand ROI was placed in HCC solid regions to measure T2 value. The relationship between Ki67 indices, microvascular density (MVD) and T2 was determined by correlation analysis. ANOVA was used to evaluate the statistical differences of T2 among histopathological groups. ROC analysis of discriminating well-differentiated (grade I) from moderately-(grade II) and poorly-differentiated (grade III and IV) HCC was performed for T2.
Results: (I) Three T2-prepared images with length of 0, 25 ms, 55 ms could provide the best quality of T2 map and meanwhile the shortest breath-holding time. (II) T2 value of poorly-, moderately- and well-differentiated HCC were (40.6±3.2) ms, (42.9±2.8) ms and (49.6±3.9) ms, respectively, and there were significant differences among them ($p < 0.001$). T2 value demonstrated good diagnostic performance (AUC = 0.94) for discriminating well-differentiated HCC from the others, with sensitivity of 83.3% and specificity of 72.4% respectively. T2 value were significant negatively correlated with Ki67 indices (rho = -0.546 ,p=0.037) and MVD (rho = -0.679 ,p= 0.009).
Conclusion: T2 value demonstrated moderate correlations with tumour proliferation status and neovascularisation. Quantitative measurement of T2 value offers a potential way for non-invasive evaluation of HCC malignancy.

Readout-segmented echo-planar diffusion-weighted MR for the evaluation of aggressive characteristics of rectal cancer

X. Chunchao, Z.-L. Li; *Chengdu/CN (xiachunchao@126.com)*

Purpose: To evaluate whether aggressive characteristics of rectal cancer can be predicted by the apparent diffusion coefficient (ADC) obtained using readout-segmented echo-planar imaging (rs-EPI) diffusion-weighted magnetic resonance.
Methods and Materials: One hundred and fifteen patients were enrolled. The image quality of ADC maps obtained using rs-EPI was compared with that using traditional single-shot echo-planar imaging (ss-EPI), and ADC measurement was performed on the rs-EPI based ADC maps. Differences in ADC values of tumors grouped according to differentiation grade, clinical T stage and plasmatic carcinoembryonic antigen (CEA) level were tested. The correlation between each aggressive characteristic and the corresponding ADC values was evaluated.
Results: The image quality of ADC maps obtained by rs-EPI was superior to that of ss-EPI ($P < 0.05$). The ADC values of tumor were categorized based on the following differentiation grades: poor ($0.89 \pm 0.12 \times 10^{-3}$ mm^2/s), moderate ($1.13 \pm 0.25 \times 10^{-3}$ mm^2/s), and good ($1.31 \pm 0.19 \times 10^{-3}$ mm^2/s); $P < 0.001$. Tumors with lower differentiation grades corresponded to lower ADC values ($r = 0.59$, $P < 0.001$). However, significant differences were not observed in different clinical T stage ($1.16 \pm 0.19 \times 10^{-3}$ mm^2/s vs. $1.15 \pm 0.28 \times 10^{-3}$ mm^2/s vs. $1.08 \pm 0.21 \times 10^{-3}$ mm^2/s vs. 1.15 ± 0.20; $P = 0.47$) and plasmatic CEA level ($1.14 \pm 0.26 \times 10^{-3}$ mm^2/s, vs. $1.03 \pm 0.35 \times 10^{-3}$ mm^2/s, $P = 0.06$).
Conclusion: rs-EPI sequence-based ADC values represent a potential imaging marker for the assessment of aggressive rectal cancer characteristics.

B-1269 14:48

Comparison of liver stiffness measurements between point shear wave elastography (ElastPQ) and two-dimensional shear wave elastography (ElastQ Imaging) equipped on a same machine

W. Hong[1], S.M. Lee[1], M.J. Kim[1], H. Ha[1], K. Lee[1], D. Lee[2], S. Lee[1]; [1]*Anyang/KR*, [2]*Seoul/KR (wj.jenny29@gmail.com)*

Purpose: To prospectively compare applicability rate between point shear wave elastography (pSWE, ElastPQ) and a new two-dimensional shear wave imaging (2D-SWE, ElastQ Imaging) and to correlate liver stiffness (LS) values measured by the two elastographic techniques equipped on a same machine in the same population.
Methods and Materials: We prospectively enrolled 152 patients (82 men, 70 women; age 20-83 years) , 62 of whom were previously diagnosed with chronic liver disease. LS values were measured in the same session using two techniques equipped on a same ultrasound machine (EPIQ7G). The applicability rates of the two techniques were compared by Chi square test. LS values obtained by the two techniques were correlated and compared using Spearman correlation coefficient and Wilcoxon signed-rank test. For the assessment of agreement of LS value measurement, we used 95% Bland-Altman limit of agreement.
Results: The applicability rate of ElastQ Imaging (139/152, 91.4%) was significantly higher than that of ElastPQ (115/152, 75.7%) ($P=0.001$). The LS values obtained by the two techniques showed strong correlation ($r=0.866$, $P<0.001$). The 95% limit of agreement of the two techniques was ranged from -53.7% to 36.2%. The mean LS value of ElastQ Imaging (6.49 ± 3.95 kPa) was significantly higher than that of ElastPQ (5.88 ± 3.29 kPa) ($P<0.001$).
Conclusion: ElastQ Imaging showed better applicability rate than ElastPQ. However, LS values obtained by ElastQ Imaging was significantly higher than those obtained by ElastPQ. In addition, the two techniques are not interchangeable due to the large limit of agreement.

B-1270 14:52

MRI-detected extramural vascular invasion is one of the strongest risk factors in predicting distant metastasis in rectal cancer

P. Tripathi[1], S. Rao[1], W. Guo[1], B. Rai[2], M.-S. Zeng[1]; [1]*Shanghai/CN*, [2]*Wuhan/CN (pratik9_band@hotmail.com)*

Purpose: Extramural vascular invasion (EMVI) has been recommended as an independent prognostic factor for poor overall survival rate in rectal cancer. We aimed to evaluate the MRI-detected extramural vascular invasion (mrEMVI) in predicting distant metastasis in T3 rectal cancer.
Methods and Materials: Post-operative histopathologically confirmed T3 rectal cancer patients without previous treatment from July 2014 to December 2016 were enrolled for this study. Two blinded radiologists evaluated location of the tumour, the degree of mesorectal extension and MRI detected extramural vascular invasion (mrEMVI). mrEMVI was further categorized into EMVI positive and EMVI negative in T2-weighted image using mrEMVI scoring system. The results along with other clinical characteristics (age, sex, tumour location, MRI detected distance of mesorectal extension, lymphatic invasion, perineural invasion, mrEMVI score and CEA) were then correlated with synchronous metastases to determine the risk factors using univariate and multivariate analyses.
Results: In 180 patients, 38 patients were confirmed to be mrEMVI positive, 142 patients mrEMVI negative. There were totally 34 patients with synchronous metastasis in which 25 were mrEMVI positive and 9 were mrEMVI negative. Three factors were significantly associated with synchronous metastasis: mrEMVI ($p=0.001$; odds ratio=8.665), histopathological lymphatic invasion ($p=0.001$; odds ratio=12.940) and preoperative CEA ($p =0.026$; odds ratio=4.124). mrEMVI score 4 was more liable for synchronous metastasis ($p=0.044$; odds ratio=9.429) than mrEMVI score 3 in rectal cancer.
Conclusion: mrEMVI positive is an independent risk factor for synchronous distant metastasis in rectal cancer. mrEMVI score 4 is a strong risk factor for synchronous metastasis than mrEMVI score 3 in rectal cancer.

B-1271 14:56

Radiomics analysis for preoperative prediction of synchronous distant metastasis in patients with rectal cancer

H. Liu, C. Zhang, J. Li, D. Wang; *Shanghai/CN (liuhuanhuan0117@163.com)*

Purpose: To investigate the value of radiomics analysis for preoperative prediction of synchronous distant metastasis in patients with rectal cancer.
Methods and Materials: A total of 177 patients with histopathologically confirmed rectal cancer who underwent high-resolution MR imaging before any treatment were divided into the primary cohort (n=123) and the validation cohort (n=54). Radiomics features were extracted from oblique axial T2-weighted images of each patient. The independent two-sample t test, Kruskal-Wallis test, and Pearson correlation analysis were used for feature selection. A radiomics signature was built and multivariable logistic regression analysis was used to develop the radiomics model including radiomics features and independent clinico-radiologic risk factors. The performance of the radiomics model was assessed by its calibration, discrimination, and clinical usefulness.
Results: A total of 385 radiomic features were extracted from each patient, and 9 radiomics features were selected for the radiomics signature. The radiomics model included radiomics signature, MR-reported lymph node status, and CA199. The model showed good discrimination and moderate calibration in the primary cohort and validation cohort, with a C-index of 0.840 (95% confidence interval (CI), 0.768-0.912) and 0.782 (95% CI, 0.648-0.916), respectively. Decision curve analysis confirmed the clinical utility of the radiomics model.
Conclusion: We developed a radiomics model based on the MR radiomics features in combination with independent clinico-radiologic risk factors. The model could be used to predict synchronous distant metastasis in patients with rectal cancer, which could be helpful for individual treatment strategy.

B-1272 15:00

CT-based radiomics for prediction of neoadjuvant chemotherapy outcomes in locally advanced gastric cancer: a pilot study

Z. Li; *Kunming/CN (lizhenhui621@qq.com)*

Purpose: To investigate the wealth of radiomics for pretreatment CT in prediction of pathological response of locally advanced gastric cancer with preoperative chemotherapy.
Methods and Materials: Thirty consecutive patients with CT-staged II/III gastric cancer receiving neoadjuvant chemotherapy were enrolled. All patients underwent unenhanced, late arterial phase (AP) and portal venous phase (PP) of the abdomen CT scans. In total, 19,985 radiomic features were extracted in AP and PP for each patient, respectively. Four methods were adopted in feature selection and 6 methods were used in the process of building the classifier model. Twenty-four combinations of feature selection and classification methods were examined. ROC curves were used to evaluate the capability of each combination of feature selection and classification method to predict non-good response evaluated with tumour regression grade.
Results: The mean AUC ranged from 0.760 to 0.954 in AP and from 0.671 to 0.925 in PP according to different combinations of feature selection and the classification method. For both AP and PP, the feature selection method of lasso + classifier of lasso achieved the highest prognostic performance (AUC, 0.954 ± 0.064 and 0.925 ± 0.073, respectively). For the combination of AP and PP (AP+PP), the AUC was 0.965. There was no statistical difference between AP and PP, AP and AP+PP, PP and AP+PP in the highest prognostic performance (all P>0.05).
Conclusion: It is possible to predict non-GR after neoadjuvant chemotherapy in locally advanced gastric cancers based on the radiomics of CT.

B-1273 15:04

Can emergency CT reliably detect significant blunt bowel and mesenteric injury?

N. Keller, T. Zingg, F. Agri, J.-F. Knebel, S. Schmidt Kobbe; *Lausanne/CH (keller.nathalie@chuv.ch)*

Purpose: To evaluate and compare two previously validated imaging-based scoring systems for the detection of significant blunt bowel and mesenteric injury (sBBMI) by emergency computed tomography (CT).
Methods and Materials: We consecutively included all our polytrauma patients addressed from 2008 to 2015 to our emergency department (trauma registry cohort) following a road traffic accident provided that they had undergone abdominal CT before surgery. In consensus, two radiologists, blinded to patients' outcome, reviewed all the CT examinations in view of 6 mesenteric, 4 intestinal and 9 other abdominal trauma CT findings. The latter were then correlated with patients' surgical outcome or clinical follow-up (>24h). Furthermore, two previously validated imaging-based bowel-injury scoring systems were compared with each other by applying them on our cohort (t test, Chi-square test).
Results: Among 681 analysed patients 21 (3.1%) had sBBMI, confirmed by emergency laparotomy. Pneumoperitoneum, small hemoperitoneum, diffuse bowel wall thickening, mesenteric or pericolic stranding, vascular extravasation, and anterior abdominal wall injury were significantly correlated with sBBMI, as were each of the two scoring systems, the Faget and Mc Nutt score (p<0.001).
Conclusion: The prevalence of sBBMI among polytrauma patients is low; however, early diagnosis is necessary. Certain CT-features are pathognomic; thus, they must not be overlooked. Scoring systems may be helpful, but do not seem mandatory for the detection of significant blunt bowel and mesenteric injury.

B-1274 15:08

MRI vs FDG PET-CT for response assessment after neoadjuvant chemoradiotherapy in oesophageal cancer

S.E. Vollenbrock, F.E.M. Voncken, D.M. Lambregts, M. Maas, E. Vegt, L.C. ter Beek, B.M.P. Aleman, R.G.H. Beets-Tan, A. Bartels-Rutten; *Amsterdam/NL (s.vollenbrock@nki.nl)*

Purpose: The debate nowadays is whether patients with oesophageal cancer who show clinical complete response (cCR) after neoadjuvant chemoradiotherapy (nCRT) could be deferred from resection. Critical is an accurate response assessment tool. FDG-PET-CT is current clinical routine to rule out distant metastases, but is suboptimal for local tumour restaging. We determined the performance of MRI compared with FDG-PET-CT for response assessment after nCRT.
Methods and Materials: Twenty-three patients with locally advanced oesophageal cancer underwent FDG-PET-CT and MRI (1.5T; T2W&DWI;b-values=0,200,800s/mm^2) before and after nCRT with a maximum of 21 days between imaging and surgery. One radiologist scored MRIs and one nuclear medicine physician scored FDG-PET-CTs, both using a 5-point score (1=definite cCR, 3=inconclusive/equivocal, 5=definite residual tumour). Histopathology of the resection specimen was the reference standard (Mandard tumour regression grade 1=pCR,2-5=residual tumour). Areas under the ROC (AUROC), sensitivity and specificity were calculated considering imaging scores 3-5 tumour-positive.
Results: Two patients were excluded due to poor image quality. Six (29%) of 21 patients achieved a pCR. AUROC was 0.58 on PET-CT versus 0.80 on MRI (p = 0.056). Sensitivity for residual tumour was 67% on FDG-PET-CT and 93% on MRI, whereas specificity was 50% on FDG-PET-CT versus 57% on MRI. The number of equivocal scores was 6 on FDG-PET-CT and 3 on MRI.
Conclusion: MRI shows a tendency towards higher accuracy than FDG-PET-CT for the local assessment of tumour response. MRI shows a lower number of equivocal scores than FDG-PET-CT which may be because of better discrimination between treatment-related effects and residual tumour.

Comparison of double-reading of mammography-2D with single-reading of tomosynthesis plus synthesised mammography: is it time to change the way we work in breast-screening programme?

S. Romero, J.L. Raya Povedano, M. Cara Garcia, A.L. Santos, M. Pedrosa Garriguet; *Cordoba/ES*

Purpose: To evaluate single reading of tomosynthesis plus synthesised mammography compared with double-reading of mammography-2D as new screening strategy.
Methods and Materials: Women (50-69) were invited to participate in this prospective study between January 2015 and December 2016, written informed consent was provided. Those who agreed underwent combined mammography plus tomosynthesis at the same time. The reading models were: 1) double-reading of mammography-2D (double-2D); 2) single-reading of tomosynthesis + synthesised mammography (single-3D). Each participant had three blind and independent readings. Five radiologists with exclusive dedication to breast imaging participated.
Results: 16067 women participated. 98 cancers were detected in 97 participants (one bilateral cancer), because we present data for 16068 screens. 69 cancers were detected with both techniques (double-2D and single-3D), 7 cancers detected only at double-2D (4.7/1000) and 18 cancers only at single-3D (5.4/1000), showing a significant increase of 12.6% (95%IC: 7.2%-21.2%, p=0.043). 1196 women were recalled, 250 recalls occurred with both techniques, 560 only at double-2D (5.0%) and 232 only at single-3D

(2.9%), significant decrease of 40.5% (95%IC: 37.2-43.9%, p<.001). Both techniques detected similar cancer number in 3341 women baseline screened (23 double-2D and 22 single-3D). In 12727 women previously screened, 53 cancers were detected at double-2D (4.2/1000) and 65 cancers at single-3D (5.1/1000), a significant increase in 18.5% (95%IC: 10.9-29.5%, p=.004).
Conclusion: Single reading of tomosynthesis plus synthesised mammography allows a significant increase in cancer detection and decrease in recalls compared to double reading of mammography-2D, so it could be considered as new screening strategy.

B-1276 16:04

Radiomics signature from enhanced T1-weighted MR image helps to improve the differential diagnosis performance of sub-1cm breast mass

L. Wang[1], D. Wang[1], X. Li[2]; [1]*Shanghai/CN*, [2]*Guangzhou/CN (wanglijun@xinhuamed.com.cn)*

Purpose: To investigate the value of magnetic resonance imaging (MRI)-based radiomics signature for differentiation of malignant from benign masses that manifest as sub-1cm breast masses.
Methods and Materials: We enrolled 130 patients with 130 pathologically confirmed solitary and solid sub-1cm breast masses (training cohort: n=90; validation cohort: n=40) on MRI. The 130 masses included 94 benignities and 36 malignancies. A total of 388 radiomic features were extracted from the second post-contrast enhanced T1-weighted MR image. A model 1 including the clinical and conventional MRI features was established. A model 2, which incorporated model 1 with radiomic features was constructed. Feature selection and model building were performed by logistic regression.
Results: The radiomics signature, which consisted of seven selected features, was a significant diagnostic indicator in the differential diagnosis of the sub-1cm breast mass in the training cohort (p=0.016). The model 2 yielded a C-index of 0.885 in the training cohort and 0.862 in the validation cohort. The model 2 had a higher accuracy in differential diagnosis of sub-1cm masses than the model 1 both in the training cohort (80% vs. 75.6%) and the validation cohort(85% vs. 70%). Decision curve analysis demonstrated that the model 2 had a higher overall net benefit than the model 1 with a significant difference (p=0.001).
Conclusion: The radiomics signature is an independent diagnostic factor for the differential diagnosis of sub-1cm breast masses. Incorporating radiomics signature into clinical and conventional MRI features performed better in the differential diagnosis of sub-1cm breast masses.

B-1277 16:08

Correlation between optoacoustic imaging and molecular subtypes of malignant breast masses

G. Menezes[1], R.M. Pijnappel[1], C. Meeuwis[2], B. Bisschops[3], J. Veltman[4], P. Lavin[5], M. van de Vijver[6], R.M. Mann[7]; [1]*Utrecht/NL*, [2]*Arnhem/NL*, [3]*Dordrecht/NL*, [4]*Almelo/NL*, [5]*Framingham, MA/US*, [6]*Amsterdam/NL*, [7]*Nijmegen/NL (giselalgm@gmail.com)*

Purpose: OA/US fuses real time gray-scale ultrasound imaging with optoacoustic imaging using laser light. This enables simultaneous functional (relative de-oxygenation of hemoglobin) and morphologic imaging of breast masses using a hand-held duplex OA/US probe. In this study we assessed the correlation between OA/US features and histopathological findings of malignant breast lesions.
Methods and Materials: For OA/US 3 internal and 2 external features were scored per lesion. Spearman correlation was used to analyze the relationship between these OA/US features and mitotic index. Pearson correlation coefficient was used to evaluate the correlation with percentages of ER, PR and Ki-67. One-way ANOVA was used to evaluate the correlation between the OA/US features and molecular subtypes.
Results: Of 215 breast masses included in this prospective multicenter study, 67 were malignant. A significant correlation was observed between the sum of 3 OA/US internal feature scores and the mitotic index (p= 0.0352). There was a significant correlation between summed OA/US internal feature scores and KI-67 percentages (p= 0.0250), and between summed OA/US internal feature scores and ER percentages (p= 0.0307). OA/US Internal Vessel Scores significantly distinguished Luminal A from Luminal B masses (p= 0.0221) and triple negative from HER-2 positive masses (p= 0.0440). Both summed internal and external OA/US Features helped to differentiate between Luminal A and triple negative masses (p= 0.0134).
Conclusion: OA/US features may be used to differentiate among breast cancer molecular subtypes. They may also help to identify triple negative breast cancers.

Diagnostic values of magnetic resonance imaging in mammography detected BI-RADS 4 category calcifications

Y. Jiang, H.-U. Kauczor; *Heidelberg/DE (peggy_jiang@hotmail.com)*

Purpose: To assess the diagnostic value of magnetic resonance imaging (MRI) in suspicious calcification which were negative on ultrasound.
Methods and Materials: A total of 338 suspicious calcification lesions were included in the study. Those calcifications were classified above BI-RADS 4 category and negative on ultrasound between January 2013 and June 2016. 277 lesions were sent to breast magnetic resonance imaging (MRI). Then evaluate mammography (MG) and MRI features of suspicious calcification lesions and correlate with pathologic results.
Results: A total of 338 lesions, benign lesions 284 (84.0%), malignant lesions 54 (16.0%). Benign calcifications were most presented as amorphous calcifications 74.3% (211/284), while malignant calcifications were most presented as fine pleomorphic calcifications 40.7% (22/54). In malignant calcifications 67.4% lesions were presented as non-mass enhancement, and mass enhancement were more common in malignant lesions than in benign lesions, (20.9% VS 3.4%, P<0.001). 11.6% lesions were presented as non enhancement while 75.2% benign calcifications were presented as non enhancement, (P<0.001). Persistent time-signal intensity curve (TIC) suggest benign lesions (82.8% VS 34.2%, P<0.001) while wash-out curve suggest malignant lesions (57.9% VS 13.8%, P<0.001). The detect sensitivity for ultrasound negative calcifications were 60.5% for MG and 88.4% for MRI, (P=0.003). The negative predictive value were 92.3% for MG and 97.5% for MRI, (P=0.015).
Conclusion: MRI has higher sensitivity and negative predictive value (NPV) than MG. For ultrasound negative suspicious calcifications, the combination of MRI could improve the diagnostic efficiency.

B-1279 16:16

Characterising mammographic calcification as a prognostic biomarker for breast tumour phenotypes

J. Li, Y. Song, Y. Wu, H. Cai, L. Li; *Guangzhou/CN (lijiao@sysucc.org.cn)*

Purpose: To identify the relationship between histological types and calcification characteristics on mammography in breast carcinomas.
Methods and Materials: Between January 2012 and January 2016, 755 consecutive patients with calcified lesions on mammography were recruited, including 160 (21.2%) with ductal carcinoma in situ (DCIS), 272 (36.0%) with DCIS with invasion component (DCIS-I), and 323 (42.8%) with pure invasive ductal carcinoma (IDC). 568 features were extracted from microcalcification clusters. We applied the 10-fold cross-validation as the criterion for feature selection and classification. We compared the performance of seven classification methods based on clinical features alone. For radiomics alone or combined clinical features and radiomics signatures, five feature selection methods and the same seven classification methods were evaluated in terms of their performance. Probability estimates for the three prediction models in test cohort were compared by multivariate analysis of variance (MANOVA).
Results: The mean age of pure-IDC patients was statistically older than DCIS-I and pure-IDC ($P < .001$); the proportion of dense breast in DCIS-I was higher than for other histological types ($P < .001$); mass prevalence was most frequent in pure IDC ($P < .001$). ROC curve analysis showed that clinical variables combined with radiomics signatures (AUC, 0.8463) was superior to clinical variables alone (AUC, 0.8161) and to radiomics signatures (AUC, 0.7060) ($P < .001$) in discrimination pure-DCIS from pure-IDC. The combination methods XGBoost + logistic regression gave the highest prognostic performance.
Conclusion: Microcalcifications on mammograms can help predict histopathological phenotypes.

B-1280 16:20

Intravoxel incoherent motion diffusion-weighted magnetic resonance imaging in characterisation of axillary lymph nodes: preliminary animal experience

Y. Zhu, X. Li, F. Wang, Z. Ye; *Tianjin/CN (zhuyueqiang1985@126.com)*

Purpose: To investigate the diagnostic value of intravoxel incoherent motion (IVIM) diffusion-weighted imaging (DWI) for discriminating axillary metastatic from non-metastatic lymph nodes (LNs) in rabbit models.
Methods and Materials: The institutional animal care and use committee approved this study. Forty New Zealand white rabbits were randomly divided into two groups. The axillary LN models were created by inoculating VX2 cell suspension and complete Freund's adjuvant in the mammary glands of 20 female rabbits of each group, respectively. Conventional MRI and IVIM DWI were performed after animal models were successfully established. Images of axillary LNs were analysed with regard to long-axis diameter (L), short-axis diameter (S), apparent diffusion coefficient (ADC) and IVIM parameters (D, D*,

f). Receiver operating characteristic analyses were conducted to determine the diagnostic performance of aforementioned criteria.
Results: A total of 42 metastatic and 30 non-metastatic LNs were successfully isolated. ADC and D of metastatic LNs were significantly lower than those of non-metastatic ones (all $P < 0.001$), whereas D* was statistically higher ($P = 0.033$). L, S, and f showed no significant difference between the two groups ($P = 0.089$, 0.058, 0.054, respectively). Optimal cutoff values, area under the curve, sensitivity, and specificity for differentiation were as follows: ADC=1.101 × 10^{-3} mm^2/s, 0.886, 78.6%, 90.0%; D = 0.938 × 10^{-3} mm^2/s, 0.927, 83.3%, 93.3%; and D* = 12.635 × 10^{-3} mm^2/s, 0.657, 52.4%, 80.0%.
Conclusion: IVIM DWI is useful to distinguish metastatic from non-metastatic LNs in axilla. D was the most discriminative variable for predicting metastatic LNs.

B-1281 16:24

Radiomics with MRI for early prediction of the response to neo-adjuvant chemotherapy in breast cancer patients
A. Tahmassebi[1], A. Meyer-Baese[1], G.J. Wengert[2], T.H. Helbich[2], K. Pinker-Domenig[2]; [1]*Tallahassee, FL/US*, [2]*Vienna/AT (katja.pinker-domenig@meduniwien.ac.at)*

Purpose: In patients undergoing neoadjuvant chemotherapy for breast cancer, the achievement of a pathological complete response (pCR) is associated with a significantly improved disease-free and overall survival. The aim of this study was to assess radiomics with dynamic contrast-enhanced (DCE) MRI for the early prediction of pathological complete response (pCR) in breast cancer patients undergoing neoadjuvant chemotherapy.
Methods and Materials: In this IRB-approved prospective study, 41 women (median age 50 years; range 25-80 years) with breast cancer scheduled for NAC were included and underwent mpMRI using DCE MRI prior to and after two cycles of NAC. For each lesion a total of 14 features were extracted ranging from morphological, enhancement and ADC parameters. Recursive feature elimination method along with five different classifiers including linear support vector machine (SVM), linear discriminant analysis (LDA), logistic regression (LR), random forest (RF), and stochastic gradient descent (SGD) was employed to rank the features.
Results: Radiomics analysis and classification accuracy of mpMRI achieved AUCs for residual cancer burden (RCB) score (AUC 0.85), metastases (AUC 0.89) based on RF and death (AUC 0.95) based on SVM. The most relevant parameters for prediction of RCB score were mass internal enhancement, shape and margins with DCE, for metastasis peritumoural oedema, mass margins and internal enhancement, and for death high signal intensity on T2-weighted imaging, mass margins, and internal enhancement.
Conclusion: Radiomics with DCE-MRI enables prediction of response to NAC with high accuracy and thus can provide predictive information and guide treatment decisions.

B-1282 16:28

The role of arterial spin labelling (ASL) and diffusion tensor Imaging (DTI) and to differentiate between malignant and benign breast lesions
A.N. Kamble[1], A. Kamble[2], M. Popli[1]; [1]*New Delhi/IN*, [2]*Mumbai/IN (akshaykumar.kamble92@gmail.com)*

Purpose: Diffusion tensor imaging picks up the architectural distortions. Arterial spin labelling give perfusion maps by utilising the water as a contrast medium itself. Both of these techniques do not require contrast, therefore, clinically significant where contrast is contraindicated. We applied these techniques to differentiate between malignant and benign breast lesions.
Methods and Materials: 44 women with breast lesion detected on mammography, USG or MR underwent advanced MR imaging. DTI was performed at 3Telsa (Skyra Siemens) in 12 directions using a diffusion-weighted echo planar sequence. 2D ASL (Arterial Spin Labelling) protocol was modified with TI of 1800ms and TR of 4000. Analysis of DTI and ASL data was done by dedicated post processing team using MATLAB-2017a, FSL and ASL 2.0 toolbox. Taking histopathology as Gold Standard, ROC curves were plotted.
Results: Total of 44 lesions were detected on MRI. ROC curve showed ASL has 72% sensitivity, 89.5% specificity, 79.5% accuracy, 10% FPR. The blood flow to the malignant lesions was significantly higher (350 ml/100gm tissue/sec, SD: 100ml) compared to benign lesions (150ml/100gm tissue/sec, SD: 90ml) (p value<0.05). ROC curve for DTI showed 80% sensitivity, 78% specificity, 79% accuracy, 21 % FPR. Combined DTI and ASL had increased sensitivity of 84%.
Conclusion: This study demonstrates advanced MR imaging using ASL and DTI has good specificity for differentiating breast cancer from benign lesions. With ASL quantification of blood flow to malignant and benign lesion is possible. The sensitivity of combined ASL and DTI method is better that the sensitivity of both independently.

B-1283 16:32

Earlier detection of breast cancer using artificial intelligence
A. Watanabe[1], W. Bradley[2], V.D. Lim[2], C.Y.R. Chim[2]; [1]*Manhattan Beach, CA/US*, [2]*San Diego, CA/US (alyssa90266@gmail.com)*

Purpose: It is known that up to 50% of breast cancers may be seen on previous mammograms. The purpose of this study was to evaluate the potential benefit of using a deep learning based breast CAD in earlier detection of breast cancer.
Methods and Materials: A 3 year retrospective audit was performed of an archive of mammograms obtained from a community based practice. 125 cases of confirmed breast cancers with prior studies were identified. All of the mammograms were processed using a deep learning based CAD (cmAssist, CureMetrix, La Jolla, CA. The cancer cases were evaluated by 2 radiologists who identified retrospective findings and then classified them as actionable vs nonactionable. The type of lesion (calcification, density, or mass) was also tabulated. The ROC and AUC of the entire data base was calculated as well as the false positive per image rate to demonstrate overall accuracy of the CAD.
Results: The artificial intelligence trained CAD flagged 100% of the breast cancers that were detected by the original interpreting radiologists. In addition, the CAD flagged actionable findings on prior mammograms in 76% of the cases. The true negative rate for the CAD also showed high accuracy. There were few false flags.
Conclusion: This deep learning based CAD flagged a majority (76%) of breast cancers on prior studies that showed retrospective findings. This CAD could be a powerful tool in enhancing earlier detection of cancer on mammography and reducing false negative mammography.

Sensitivity of contrast-enhanced spectral mammography (CESM) versus digital mammography (DM) for detecting breast cancer in dense or extremely dense breasts
E. Gioutlaki, C. Tzimas, E. Feida, A.N. Chalazonitis; *Athens/GR (egiou@hotmail.gr)*

Purpose: Contrast-enhanced spectral mammography (CESM) is a quite new imaging method for neo-angiogenesis detection by tracking iodinated contrast agent uptake and washout in suspicious breast lesions. Our aim was to compare mammography findings of CESM and DM, in dense or extremely dense breasts.
Methods and Materials: From October 2012 to May 2017, 283 women, aged from 24 to 88 years, (mean age 54.6 years) with dense or extremely dense breasts, underwent CESM examination. Evaluation of CESM examination was based on enhancement intensity of the lesion according to a qualitative scale categorized into 4 steps as follows: type -1 (negative enhancement), type 0 (no enhancement), type 1 (moderate enhancement), type 2 (intense enhancement). Histopathology reports were compared with imaging assessment.
Results: Out of 283 women, 20 of them had bilateral lesions. From a total sample of 189 breasts positive in CESM, 164 were diagnosed with breast cancer at histopathology. According to our study, the sensitivity of this method was 91%, specificity 71.4%, and accuracy 82%. On the contrary, conventional MMG had a sensitivity of 73%, a specificity of 62%, and diagnostic accuracy 67%. As a result, sensitivity, specificity and accuracy were significantly higher on CESM compared to MMG.
Conclusion: Many factors may affect the diagnostic accuracy of DM. One of them is breast density. Cancer may be occult in dense breast. It seems that CESM is superior to DM in detecting breast cancer with high accuracy, especially in dense breasts.

MRI analysis after neoadjuvant chemotherapy on breast cancer: correlation between radiological and pathological response
E.M.S. Negrao, A. Bitencourt, J.A. Souza, E. Ferreira Marques, C. Souza Guatelli, L. Graziano, M.L.L. Albuquerque; *São Paulo/BR (brenda_kika@yahoo.com.br)*

Purpose: Breast cancer is classified into molecular subtypes (MS), which differ in clinical presentation, response to treatment and survival. Triple-negative (TN) and HER2 expression (HER2+) are known to be more aggressive and potentially metastatic. Complete pathological response (pCR) after neo-adjuvant systemic treatment (NST) is considered predictor of clinical benefit. The aim of this study was to compare radiological response at magnetic resonance imaging (MRI) and pathological response after NST.

Methods and Materials: 310 breast tumours were analyased retrospectively in a cancer centre between October 2014 and July 2017. Radiological response (MRI after NST) was compared to the pathological response (surgical specimen) and stratified the different MS to define the ability of MRI to predict the pCR.
Results: Patients' age ranged between 27 and 85 years (mean age 47 years). The predominant Luminal B in 189 cases (of these, 55 cases hybrid Luminal B: HER2+). TN in 90 cases and HER2+ (hormone negative) in 31 cases. There were 126 cases (41%) of pCR (10 cases had only residual CDIS). The sensitivity, specificity and accuracy of the MRI was 82%, 74% and 79%, respectively. Stratifying by MS, the highest indexes were HER2+ (89%, 82% and 83%) and the TN subtype (78%, 78% and 70%). The Luminal B subtype presented specificity of 56% (Luminal B hybrid obtained 78%).
Conclusion: MRI has remained a good method to investigate the pCR, especially in the HER2+, TN and Luminal B hybrid subtypes, demonstrating greater accuracy in the pCR in the more aggressive subtypes.

B-1286 16:44

Screen-detected breast cancer: differences in mammographic tumour features between agreement and disagreement recall

M. Orsi, M. Cellina, F. Leone, D. Mariani, A. Presazzi, C. Floridi, G. Oliva; *Milan/IT (marcello.orsi@asst-fbf-sacco.it)*

Purpose: To analyse how radiological features of breast cancer are correlated with agreement and disagreement recall, in a single-centre independent double reading population-based screening program.
Methods and Materials: Between November 2014 and February 2017, screening mammograms positive for breast cancer were retrospectively evaluated by two radiologists, in consensus, to assess the tumoural imaging features (mass, calcifications, asymmetric density or architectural distortion). We evaluated two different groups according to agreement recall (AR) or disagreement recall (DR). We compared the differences among tumoural imaging features between the two groups.
Results: 113 consecutive screen-detected histologically proved breast cancer mammograms were reviewed, there were 76 AR and 37 DR. In the AR group, we found, as single or part of multiple features in a suspicious lesion, 51 (67%) mass, 24 (32%) calcifications, 24 (32%) architectural distortion and 18 (23%) asymmetric density; in the DR group, we depicted 20 (54%) architectural distortion, 11 (30%) mass, 9 (24%) calcifications, 7 (19%) asymmetric density. Differences in tumour imaging features between the two groups were statistically significant ($p<0.05$).
Conclusion: Our results show that architectural distortion is the most frequent tumour imaging feature in the DR group, which includes a false-negative result; the detection of architectural distortion requires a good practice of mammography and any technical improvements focused on depicting architectural distortion could increase the overall sensitivity of mammographic screening.

B-1287 16:48

Interpretation of patterns of enhancement on contrast-enhanced digital mammography: an approach to a standardised scheme

S. Gareer, Y. Mounir, M.H. Helal, O. Mokhtar, A. Abdel Aziz, H. Kassas, L. Bassam; *Cairo/EG (sherihangareer@gmail.com)*

Purpose: Applying the morphological descriptors described in the MRI breast imaging and reporting data system (BIRADS) in characterising enhancing breast lesions seen on CESM.
Methods and Materials: Methods: 178 breast lesions in patients with mean age 46 years in a prospective study were included. Morphological categorisation of the included lesions was presented into focus, mass and non-mass forms. Furthermore classifications included the margin, enhancement intensity for “focus”, the shape, margin and internal enhancement for “mass” and the distribution and internal enhancement for “non-mass”. Each morphology descriptor was evaluated separately (irrespective of the other descriptors) by calculating its sensitivity, specificity, (PPV) and (NPV)
Results: This study included 104 malignant lesions versus 74 benign. Diagnostic accuracy parameters for CEDM were sensitivity 98 % (102/104) and specificity 76% (56/74). Irregular margin intense enhancement focus (1/8) was diagnosed malignant, (7/8) while regular margin faint enhancing foci were benign.Irregular shape, spiculated margin and heterogenous internal enhancement descriptors of mass lesion descriptors conformed to malignancy (PPV 92.5% of the former and 88.7% of the latter, p value ≤ 0.001).Asymmetry with segmental distribution, (17/27) (70.8%) heterogeneous and clumped internal enhancement patterns were indicative for malignancy in non mass enhancement (PPV <0.001)
Conclusion: MRI lexicon morphology descriptors can be applied (yet with few exceptions) in the characterization of enhancing breast lesions on CESM.The most sensitive descriptors for malignant lesions regarding masses are irregular, margins yet for NME the focal, ductal and segmental distribution with heterogeneous or clumped enhancing patterns. Foci are still controversial.

B-1288 16:52

Screen-detected breast cancer: an argument for starting screening mammography at age 40 in the community-based setting

R. Benjamin[1], M. Aujero[1], K.S. Traylor[1], M. Gerges[2], J. Holt[1]; [1]*Newark, DE/US*, [2]*Philadelphia, PA/US (Rbenjamin@christianacare.org)*

Purpose: Current screening guidelines are contradicting. An argument for starting screening mammography at age 40 is introduced.
Methods and Materials: A total of 38,393 screening mammograms, additional imaging studies, and relevant biopsy results were compiled and analysed at our institution from August 2015 to December 2016. 72.5% of the studies were performed with tomosynthesis. No stratification was based on imaging modality, race, breast density, or risk assessment.
Results: 38,393 patients were stratified into different age ranges including 40-49, 50-64, and over 65. 10,267 patients were within the 40-49 age range and 31 cancers were detected, 20 invasive. 16,735 patients were within the 50-64 age range and 97 cancers were detected, 64 invasive. 10,680 patients were within the greater than 65 age range and 93 cancers were detected, 75 invasive.
Conclusion: In our screening populations, 14% of all screen-detected cancers were found in women aged 40-49 and 65% of these (21/30) were invasive. Although, the USPSTF agrees that there is a “net benefit” to screening women age 40-49, it gives a “C” recommendation for screening in this age group. Data obtained by the task force come predominantly from randomised and observational studies and trials which date as far back as 1963. Furthermore, film mammography, not digital mammography or tomosynthesis (DBT), was the basis for their recommendations. With growing research on the benefits of DBT, the USPSTF recommendations should be updated according to current data. This study supports the ACR and ACOG recommendation that annual screening mammography begin at age 40.

B-1289 16:56

Abbreviated breast MRI: do we still need contrast media?

A. D'Angelo[1], J. Al Mohanna[2], P. Clauser[3], P. Kapetas[3], P. Rinaldi[1], C. Zuiani[4], T.H. Helbich[3], K. Preidler[3], P.A.T. Baltzer[3]; [1]*Rome/IT*, [2]*Riyadh/SA*, [3]*Vienna/AT*, [4]*Udine/IT (anna.dangelo05@gmail.com)*

Purpose: To compare the diagnostic performance of two abbreviated breast MRI protocols for the characterisation of breast lesions: Diffusion Weighted Imaging (Non-contrast MRI, NC-MRI) and early enhanced T1w (first contrast enhanced measurement, CE-MRI).
Methods and Materials: IRB-approved retrospective single-center study. 57 consecutive patients (median age 55, range 29-84 years) were eligible, who underwent biopsy of BI-RADS 4/5 findings after full diagnostic workup including mammography, ultrasound and MRI. The MRI protocol (3T Siemens Magnetom Skyra; 16-channel coil) included a readout-segmented DWI (b 0, 800 and calculated b1400 s/mm^2) and Dynamic-Contrast-Enhanced (DCE) images (T1w VIBE with fatsat; single-dose Gadoteridol (ProHance), temporal resolution 72 seconds). Two fellowship-trained breast radiologists (R1, R2) independently assigned a BI-RADS and visibility score (ordinal 5-point scale) to NC-MRI and CE-MRI using MIP reconstructions and original acquisitions. Receiver Operating Characteristics (ROC) and Visual Grading Characteristics (VGC) analysis were applied.
Results: Histopathology revealed 36 malignant and 21 benign lesions. Areas under the ROC curves were similar: CE-MRI: 0.825 (95%-CI: 0.702-0.913), R1 and 0.810 (95%-CI: 0.684-0.901), R2; NC-MRI: 0.721 (95%-CI: 0.573-0.841), R1 and 0.730 (95%-CI: 0.582-0.847), R2. The lower AUC in NC-MRI was mainly due to a lower sensitivity. In both readers, NC-MRI could not rule-out malignancy while CE-MRI could. VGC analysis revealed a superior lesion conspicuity by CE-MRI ($P<0.001$, R1, R2).
Conclusion: The comparison of abbreviated NC-MRI and CE-MRI revealed a superiority of CE-MRI for characterisation of breast lesions. NC-MRI readings could not rule-out malignancy, stressing the necessity of contrast media in breast MRI for breast cancer diagnosis.

B-1290 17:00

Mammography, breast MRI and histopathological features of pure ductal carcinoma in situ

Y. Jiang, H.-U. Kauczor; *Heidelberg/DE (peggy_jiang@hotmail.com)*

Purpose: To analyze the imaging and histopathological features of pure ductal carcinoma in situ (DCIS). To evaluate the sensitivity of breast MRI and mammography (MG) in the detection of pure DCIS.
Methods and Materials: A total of 131 pure DCIS lesions between January 2013 and June 2016 were included. According to 2013 BI-RADS to evaluate MG and MRI features of calcified and non-calcified DCIS. All lesions were divided into different cancer subtypes determined by immunohistochemistry (IHC) and fluorescence in situ hybridization (FISH). Correlate molecular subtypes and nuclear grade of pure DCIS with MG and MRI features.

Results: Most pure DCIS (68.0%) presented with suspicious calcifications (including other abnormal expression: mass, FAD and architectural distortion). 32.0% presented without suspicious calcifications. For DCIS presented with suspicious calcifications on MG, diagnostic accuracy for MRI was 95.1% (P=0.001). Diagnostic accuracy of MG and MRI for DCIS without suspicious calcifications on MG were 62.2% and 91.9% (P=0.002). On MRI, 69.7% pure DCIS presented as non-mass enhancement. HER2 positive DCIS were more commonly associated with calcifications than ER positive and triple negative DCIS (54.0%, 45.5% VS 81.4%, P-0.002). High nuclear grade DCIS more presented with calcification compared to middle and low grade DCIS (42.1%, 67.2% VS 77.8%, P=0.015). The diagnostic accuracy for MG and MRI were 80.6% and 94.1% (P=0.002).
Conclusion: The most typical MG and MRI features of pure DCIS were suspicious calcification and non mass-like enhancement. MG was better than MRI in diagnosing calcified DCIS, while MRI was better in diagnosing non-calcified DCIS

B-1291 17:04

Molecular subtypes of invasive breast cancer: correlation between PET/CT and MRI findings

M. Akin, I.S. Örgüc, F. Aras, A. Kandiloglu; *Manisa/TR (meloakin@gmail.com)*

Purpose: In our study, we investigated the diagnostic value of F18-FDG PET/CT and MRI findings in determining molecular subtypes of invasive breast cancer. In addition, the relationships between the volume measurements in PET/CT and MRI and the pathological volume of the mass were evaluated.
Methods and Materials: A total of 55 primary invasive breast cancer masses in 51 female patients who had histopathological diagnosis and underwent FDG PET/CT and MRI before therapy were retrospectively analysed. The correlations between molecular subtypes and SUVmax, SUVmean, MImean, MTV and HU values from FDG PET/CT findings; shape, margin, intratumoral enhancement, kinetic curve type and ADC values (based on 2013 BI-RADS MRI classification) from MRI findings were evaluated. In addition, the relationships between the pathologic tumor volume and the tumor volume measured by MRI and PET/CT were evaluated.
Results: The SUVmax and SUVmean values of the luminal B subtype of invasive breast cancer were higher than the luminal subtype A ($p = 0.002$, $p = 0.017$, respectively); the triple negative subtype had a higher SUVmax value than the luminal subtype A ($p = 0.028$). There were statistically significant strong positive correlations between MTV and FTV (p= 0,000; r= 0,857); MTV and the pathologic tumor volume (p= 0,006, r= 0,796); FTV and the pathologic tumor volume (p= 0,006, r= 0,921).
Conclusion: Our findings suggested that SUVmax value was superior to MRI findings in predicting molecular subtypes. In addition, we determined that MRI was superior to PET/CT in predicting the pathologic tumor volume.

B-1292 17:08

Focal breast categorisation according to the BI-RADS-US lexicon: role of a computer-aided decision-making support

A. Orlando, F. Amato, M. Di Vittorio, C. Lupo, L. Spatafora, M. Safina, F. Ienzi, R. Ienzi, T.V. Bartolotta; *Palermo/IT (orlandoalessiamed@hotmail.it)*

Purpose: To assess a computer-guided decision-making software (S-Detect) in the sonographic characterisation of focal breast lesions (FBLs).
Methods and Materials: According to BI-RADS-US lexicon, 300 FBLs (size: 2.6-47.2mm) in 255 patients were prospectively assessed in consensus by two experienced radiologists without and with S-Detect. To evaluate intra and inter-observer agreement, two residents assessed independently the same 300 FBLs at baseline and after 3 months. All the FBLs classified as BI-RADS-4 or 5 underwent core-biopsy, all the lesions classified as BI-RADS-3 were followed-up.
Results: 120/300 FBLs were malignant, 2/300 high-risk and 178/300 benign. Experts reviewers showed higher Sensitivity, Specificity, PPV and NPV with S-Detect (97.5%, 86.5%, 83.2%, 98.1%) than without (91.8%, 81.5%, 77.2%, 93.6%) (p>0.05), as confirmed by ROC curve analysis (0.95 with and 0.92 without [p=0.0735]. A significant higher area under the ROC curve was found for Resident#1 (0.85 without and 0.88 with S-Detect [p=0.0067]) and Resident#2 (0.83 without and 0.87 with S-Detect [0.0302]). Intra-observer agreement (k score) improved with S-Detect from 0.69 to 0.78 for Resident#1 (p>0.05) and from 0.69 to 0.81 for Resident#2 (p>0.05). Inter-observer agreement improved with S-Detect from 0.67 to 0.7 (baseline; p>0.05) and from 0.63 to 0.77 (after 3 months; p>0.05). According to S-Detect-guided re-classification, 25/64 (39.1%; 95%CI=[25.1;51.0] FBLs underwent no change in clinical management (CM), 27/64(42.2%; 95%CI=[30.0;52.3]) and 12/68(18.7%; 95%CI=[27.1; 51.1]) underwent respectively a positive and a negative change in CM.
Conclusion: S-Detect is an effective tool for the classification of FBLs according to BI-RADS-US lexicon, improving cancer detection rate, especially for less experienced physicians.

B-1293 17:12

Comparison of automated vs bilateral handheld whole-breast US in screening patients regarding efficacy and patient preferance

B. Tutar, G. Esen, H. Kara, N. Guldogan, C. Uras; *Istanbul/TR (gulesenicten@gmail.com)*

Purpose: To evaluate the efficacy and patient satisfaction for automated breast volumetric scanning (ABVS) compared to handheld breast US (HHUS).
Methods and Materials: From May 2014 to July 2015, 338 screening patients underwent bilateral technician performed ABVS followed by physician performed HHUS (ACUSON S2000™; Siemens, Germany). Acquisition and evaluation time, patient satisfaction,image interpretability, lesion number and BIRADS scores were recorded. Chi square test was used for statistical analysis.
Results: Mean examination time was 20 minutes for ABVS and 10 minutes for HHUS. Mean interpretation time for ABVS was 8 minutes. The ratio of patients who experienced severe pain during the procedure was 8% for ABVS and 3% for HHUS. With ABVS, 19 patients (5.6%) were recalled because of areas of shadowing (BIRADS 0) but were normal on second look US. ABVS detected more solid lesions in 10 patients, while HHUS detected more in 4. The difference was statistically significant. The final category for ABVS was BIRADS 4 in 11 and BIRADS 5 in 1 patient. With HHUS, there were 2 BIRADS 4 and 2 BIRADS 5 results. US guided biopsy was performed in 4 patients and cancer was diagnosed in 2.
Conclusion: ABVS is superior to HHUS in lesion detection with no false negative results. Patient satisfaction is good and physician time is shorter. It can be an alternative to HHUS in breast clinics. It should be kept in mind that the recall rate is higher and positive predictive value is lower with ABVS as stated in previous reports.

B-1294 17:16

Breast cancer staging with automated breast volume scanner (ABVS) and digital breast tomosynthesis (DBT): a comparison with magnetic resonance imaging (MRI)

R. Girometti, L. Tomkova, M. Zanotel, M. Lorenzon, A. Linda, V. Londero, C. Zuiani; *Udine/IT (rgirometti@sirm.org)*

Purpose: To investigate whether the combination of ABVS and DBT (ABVS+DBT) is comparable to MRI in staging breast cancer.
Methods and Materials: We retrospectively included seventy-three patients with histologically proven breast cancer who underwent preoperative ABVS, DBT and 1,5T MRI in the period July 2015-January 2017. Two radiologists in consensus recorded the number, site and BI-RADS category of breast findings during two independent reading strategies, namely using DBT+ABVS or MRI (complemented with hand held ultrasound second look images, if indicated). Using histology or 1-year follow up as the standard of reference, we calculated sensitivity and specificity for breast cancer of both imaging strategies.
Results: Patients showed a total of 160 lesions (109 malignant and 51 benign). Malignant lesions were monofocal, multifocal, multicentric and biltateral in 53, 16, 3 and 1 cases, respectively. Sensitivity and specificity of ABVS+DBT versus MRI were 88.1% and 86.2% vs. 94.5% and 88.2%, respectively, with no significant differences in cancer detection (p>0.05; McNemar's test). Compared to MRI, ABVS+DBT missed 9 lesions, including 5/9 DCIS or DCI with DCIS, 3 DCI and 1 Paget disease. Compared to ABVS+DBT, MRI missed 2 lesions (DCIS).
Conclusion: ABVS+DBT approaches MRI in staging breast cancer, and might represent a diagnostic alternative in selected cases.

Clinical value of dynamic contrast-enhanced MRI and diffusion-weighted imaging on diagnosis of central gland prostate carcinoma
W. Jing, X. Zhang; *Shenyang/CN*

Purpose: To study the clinical value of dynamic contrast-enhanced MRI (DCE-MRI) and diffusion-weighted imaging (DWI) on diagnosis of central gland prostate cancer(CG-PCa).
Methods and Materials: A retrospective analysis was performed based on the clinical data of 63 patients who were admitted in the Hospital and confirmed to have central gland diease through pathological diagnosis.There were 34 cases of CG-PCa and 29 of CG-BPH.According to the pathological Gleason scores,the 34 patients with PCa were divided into three groups:the low(GS 3+3),moderate(GS 3+4)and high(GS 4+3,4+4,4+5,5+4,5+5)malignancy groups.The DCE-MRI semi-quantitative parameters (TTP, MSI), quantitative parameters (Ktrans, Kep and Ve) and ADC of the PCa and the BPH were measured and compared.These parameters were used for ROC curve analysis to calculate the PCa diagnosis susceptibility and specificity.The correlations between the ADC value and Gleason score grouping were assessed.
Results: The TTP and MSI values of the BPH patients were both higher than those of the PCa ones (P<0.05).Meanwhile,statistically significant differences were found in the Ktrans,Kep and ADC values between the PCa and the BPH whereas the differences in the Ve values showed no statistical significance.The largest area of Ktrans under the ROC curve reached 0.82 with the susceptibility and specificity of 82.4% and 67.6%.There were significant differences in the ADC values among the three groupings(F=14.04, P>0.05).The ADC values of the low and the moderate malignancy groups showed no significant differences (P>0.05).The results suggested negative correlations between the ADC value and the Gleason score grouping.
Conclusion: Hence,DCE-MRI and DWI have important clinical value on CG-PCa identification.

Development and validation of a low-cost paediatric pelvic phantom for digital radiography dose optimisation
A.H. Mohammed Ali[1], P.H. Hogg[1], A. England[2]; [1]*Salford/UK*, [2]*Manchester/UK (p.hogg.@salford.ac.uk)*

Purpose: Imaging phantoms can be cost prohibitive and a need, therefore, exists to produce low-cost alternatives which are fit for purpose. Consequently, this paper outlines the development and validation of a low-cost dose/image-quality pelvis phantom for a 5-year-old child.
Methods and Materials: Tissue equivalent materials representing paediatric bone (plaster) and soft tissue (PMMA) were used. PMMA was machined to match the bony anatomy identified from a CT scan of a 5-year-old child and cavities were created for plaster infusion. Phantom validation comprised physical and visual measures. Physical included CT density (HU) comparison between a CT scan of a 5-year-old male one of the phantom, a signal to noise ratio (SNR) comparative analysis of AP DR phantom X-ray images against a commercially anthropomorphic phantom. Visual analysis used a psychometric image quality scale.
Results: For HUs, the percentage difference between cortical bone and soft tissue and the equivalent tissue phantom substitutes were 88.4% and 86.1%, respectively. For SNR (mAs response) there was a strong positive correlation between the two phantoms (r>0.95 for all kVps). For kVp response, there was a strong positive correlation (1-8mAs (r>0.85)), this decreased as mAs increased (r=-0.21 at 20 mAs). Psychometric scale results produced a Cronbach's alpha of almost 0.8.
Conclusion: Physical and visual measures suggest the low-cost phantom has suitable anatomical characteristics for X-ray imaging. Our method produces a low-cost phantom which could have utility in dose and image quality optimisation studies.

B-1297 08:38

80kV vs 100kV in the CT pulmonary angiography protocol: an evaluation of the impact on patient dose and image quality on two CT machines
A. Rusandu[1,2], A. Ødegård[1], G.C. Engh[1], H.M. Olerud[2]; [1]*Trondheim/NO*, [2]*Kongsberg/NO (albertina.rusandu@ntnu.no)*

Purpose: The aim of this study was to analyse the dose reduction and image quality achieved using 80kV instead of 100kV in CT protocols for pulmonary arteries.
Methods and Materials: 80 examinations of non-obese patients were analysed (40 consecutive patients for each protocol, equally distributed on two CT scanners). Objective image quality was assessed by measurements of HU values (average and standard deviation) in five ROIs in pulmonary arteries and calculations of signal-to-noise (SNR) and contrast-to-noise ratio (CNR). Subjective image quality was independently evaluated by two radiologists in terms of perceived noise, sharp reproduction of pulmonary arteries and overall diagnostic quality. Radiation dose parameters (CTDIvol, DLP, SSDE and effective dose) were compared. Differences in dose and objective image quality for the two protocols were assessed using the independent t test; comparison of subjective grading of image quality was performed with Mann-Whitney U test.
Results: Use of 80kV significantly increased arterial contrast enhancement. Both measured and subjectively rated image noise was higher at 80 kV. Differences in SNR, CNR and subjective diagnostic image quality between protocols were not statistically significant (p = 0.177, p=0.88, p=0,703). The dose reduction achieved by using 80kV was significant on both scanners (SSDE reduction 33% and 45%, p<0.001; effective dose reduction 40% and 52%, p<0.001).
Conclusion: Use of 80kV protocols for CT examinations of pulmonary arteries in non-obese patients with body weight below 80 kg results in significant reduction of patient doses without compromising diagnostic image quality.

B-1298 08:42

Atypical functional connectivity between cerebral and cerebellar resting state networks in autism spectrum disorder
Y. Wang, W. Zhang, S. Lui; *Chengdu/CN (970805975@qq.com)*

Purpose: Motor impairment has been repeatedly documented in autism spectrum disorder (ASD). However, it is unclear what brain mechanisms contribute to this impairment. Our purpose is to examine the correlation between motor data and brain resting-state functional imaging and identify the functional connectivity(FC)alteration in ASD individuals using seed-driven approach.
Methods and Materials: We acquired resting-state functional magnetic resonance imaging scans from 43 subjects (24 ASD)10-33 years old. ROIs were identified by examining the correlations between motor data and whole brain ALFF in control and ASD separately. Whatever correlation of motor data with brain ALFF showed statistical significance, its specific brain region was selected as one of the ROIs and further used for FC analysis. Brain-behaviour relationships were assessed by regressing FC measures with social deficit severity and repetitive behaviours.
Results: Relative to typically developing control participants,individuals with ASD showed a mixed pattern of both over- and under-connectivity in the cerebral-cerebellar network, including increased connectivity of posterior cerebellum with left superior parietal ,bilateral superior occipital and left middle occipital gyrus but decreased connectivity with prefrontal cortex and superior temporal gyrus. Decreased connectivity was also identified within cerebellar network, and was negatively correlated with repetitive behaviour score (P<0.05, uncorrected).
Conclusion: Individuals with ASD showed a mixed pattern of over- and under-connectivity with cerebral-cerebellar network and decreased connectivity within cerebellar network, these findings are consistent with emerging evidence of disrupted network segregation and integration in ASD. Further, abnormal decreased connectivity within cerebellar network implicates relation with restricted and repetitive behaviours in ASD.

B-1299 08:46

Morphological characteristics of carotid atherosclerotic plaques: comparison based on CTA and MRI
N. Giannotti, J. McNulty, S.J. Foley, P. Kelly; *Dublin/IE (nicola.giannotti@ucd.ie)*

Purpose: Risk stratification of atherosclerotic plaque is based on the degree of stenosis. However, classification of plaque components (fibrous tissue, lipid, and calcium) can be associated with plaque vulnerability and may be used as a predictor of cerebrovascular events.
Methods and Materials: CT Angiography (CTA) and High-resolution MRI (HRMRI) datasets of 30 patients with confirmed internal carotid artery stenosis were analysed by a single observer using two software tools (TeraRecon iNtuition™ and MRI-Plaque View2.1) to measure the volume of plaque components. Plaque volume was assessed through semi-automatic

segmentation of the vessel wall from the lumen. Three Hounsfield unit ranges were defined in the CTA analysis, while an algorithm based on morphology enhanced probabilistic plaque segmentation was used for the HRMRI analysis. The Wilcoxon signed-ranked test assessed whether statistical differences exist between CTA and HRMRI plaque components measurements and Spearman's correlation test investigated their level of agreement. Bland-Altman plots assessed proportional bias.
Results: Although a significant difference was found between fibrous tissue measurements; measurements of lipid and calcium did not statistically change (Z=-2.026, p=0.43) (Z=-2.448, p=0.14) and Spearman's tests showed moderate agreement rs=0.446 (p=0.013), 0.444 (p=0.014). Bland-Altman plot confirmed no proportional bias between lipid and calcium measurements (t=0.359, p=0.722) (t=1.354, p=0.187).
Conclusion: Lipid and calcium measurements did not statistically differ between CTA and HRMRI. Although limitations affect these analyses, further investigations are necessary in order to validate these approaches since the presence of certain components within atherosclerotic lesions can lead to plaque vulnerability and cerebrovascular events.

B-1300 08:50

The impact of the smartphone application (app) on MR radiographers' knowledge and confidence in relation to MR image-quality-related errors
W. Alsharif, M. Davis, L.A. Rainford, A. McGee; *Dublin/IE (walaa.alsharif@ucdconnect.ie)*

Purpose: This study aimed to evaluate the impact of a smartphone app prototype on the level of MR radiographers' knowledge and confidence in recognising and rectifying MR image-quality-related errors.
Methods and Materials: The study used the comparison-experimental approach (pre- and post-test). Thirty-five MR radiographers independently reviewed a prepared series of MR images (n=25). The participants were requested to identify image-quality-related errors, to specify error-correction strategies and score how confident they were in relation to their responses. Participants were then divided into experimental (n=19) and control cohorts (n=16). The app was provided to the experimental cohort for three months, after this period both cohorts re-reviewed the MR images and retested.
Results: During pre-test, a low level of MR radiographer knowledge was noted in terms of correct identification of the type of image quality error and specification of an appropriate error-correction strategy ($p<0.05$). The confidence level of radiographers in their ability to name the types of error varied significantly ($p<0.05$). During post-test, the results showed a statistically significant difference between control and experimental cohorts relative to participants' pre- to post-test knowledge level. For the experimental cohort, years of experience, qualification and type of hospital were not associated with radiographer knowledge level and confidence in recognising the presence of an image quality error, naming the error and specifying appropriate correction strategies ($p>0.05$).
Conclusion: The study identified the potential of the smartphone app as an effective educational tool to support MR radiographers' knowledge in recognising and characterising MR image quality errors.

B-1301 08:54

Role of renal ultrasound in pelvic imaging: to scan or not to scan?
K. Cronin, S.J. Foley, S. Simpson, A. Kelly; *Dublin/IE (kevin.cronin@ucd.ie)*

Purpose: Ultrasound is a highly sought after imaging tool with consequent resource pressures. Kidneys are often routinely scanned when female patients present for pelvic imaging. The objective of this audit was to identify the frequency of abnormal renal findings when imaged following pelvic examinations and determine the clinical significance of the patient. The results would be used to inform the local imaging protocol.
Methods and Materials: A retrospective study was carried out over a four-month period in a single university teaching hospital. Radiology reports were reviewed from the hospital radiology information system. Renal findings were recorded as normal/abnormal based on local double reporting system and clinical significance recorded according to pre-agreed criteria reached via consensus between two sonographers. The average kidney scan time was estimated based on all departmental sonographers' input (n=10).
Results: The results for 286 scans were analysed, and 31 (11%) abnormal scans were identified, most of which were benign cysts (n=15). Just 16 (6%) were deemed clinically significant (13 complicated cysts, 1 carcinoma, 1 calculus, 1 mild hydronephrosis). The estimated mean time to scan the kidneys was 20 min, which equates to 98 hours and 40 min of scanning kidneys where findings were normal during this period.
Conclusion: Routine scanning of the kidneys with pelvic examinations is not recommended and significant time/resources can be saved from an evidence-based scanning protocol.

B-1302 08:58

Implementing mobile radiography services: a qualitative study of managers' experiences of success criteria and barriers to overcome
E. Kjelle, K.B. Lysdahl, H.M. Olerud, A. Myklebust; *Kongsberg/NO (elin.kjelle@usn.no)*

Purpose: The objective of this qualitative study was to evaluate success criteria and barriers in the process of implementing mobile radiography services, from managers' point of view.
Methods and Materials: 11 semi-structured interviews were conducted with managers from five hospitals and six municipalities in Norway with mobile radiography services. Core issues in the interview guide were barriers and facilitators in the different implementation phases. The framework method of thematic analysis was used for inductive data analysis.
Results: Five main categories were developed: national health policy, regional and municipal policy and conditions, inter-organizational implementation projects, experienced outcome, and professional skills and personal characteristics. These categories were allocated into three higher order classifications macro-, meso- and micro-level. The main barriers experienced by the managers were financial, structural and procedural. In particular, the reimbursement system, crossing of healthcare levels and incompatible information systems. The main facilitators were external funding, collaboration and enthusiastic individuals.
Conclusion: The main success criteria were external funding and the support and engagement from individuals in the collaborating organizations. To facilitate mobile services and services across healthcare levels, changes in management and the financial system are needed. In addition, there is a need for compatible information systems across healthcare levels. This study have been submitted to BMC health services research.

B-1303 09:02

Paediatric lifetime cancer risk for head CT protocols of a 1-year-old child
M.R. Benhalim, P.H. Hogg, A. England, L.A. Walton, K. Szczepura; *Salford/UK (P.Hogg@salford.ac.uk)*

Purpose: To compare effective risk (ER) for a range of paediatric CT brain scanning protocols.
Methods and Materials: An ATOM phantom representing a one-year-old child was implanted with MOSFET radiation detectors. Helical CT scans were undertaken using 162 protocols. Protocols included changes in rotation times, gantry angulation, pitch, mA and detector configuration. Absorbed tissue doses were read from MOSFET and used to estimate ER, using BEIR VII report, for males and females aged 0-5years.
Results: ER ranged from 20-102 and 8-46 for females and males, respectively. ER increased consistently by approximately 38% for females and 17% for males when the pitch factor changed from fast to detail (mean ER 102 versus 64 and 46 versus 29, respectively). Changing mA modulation from high to low dose resulted in a 48% risk reduction for both female and male (mean ER 102 versus 36 and 46 versus 16, respectively). Changing detector configuration from 0.5x16 to 1.0x16 resulted in approximately 33% reduction for both female and male, respectively. The gantry angulation and rotation time had no effect on ER. When CT gantry angle changed from 0^o to 27^o and the rotation time from 0.5 to 0.75 (S), the percentage change in effective risk was 0.03% and 0.0% for female and male, respectively.
Conclusion: CT protocol selection has a significant effect on ER and it is important to consider this when implementing protocols. Risks are lower for older children and males.

B-1304 09:06

How can we improve the patient experience of nuclear medicine hybrid imaging procedures? A systematic review of the evidence
S. King; *Bristol/UK (simon5.king@uwe.ac.uk)*

Purpose: Patients attending complex imaging examinations may suffer from anxiety and discomfort resulting in reduced satisfaction and perceptions of a suboptimal experience. A systematic literature review was performed on the patient experience of nuclear medicine hybrid imaging procedures.
Methods and Materials: A systematic search of relevant databases including MEDLINE, EMBASE, AMED and CINAHL was conducted. Articles identified during the search process as meeting pre-determined inclusion criteria were then subjected to quality appraisal. A process of narrative synthesis followed in which key themes were identified and could be used to inform any recommendations for practice.
Results: Five studies were identified that met the predetermined inclusion criteria. The studies were evaluated within two separate strands: the quantifiable evidence relating to the effectiveness of an intervention in improving patient experience, and a thematic analysis of the qualitative evidence. Four key themes were identified relating to: prior knowledge of the procedure, anxiety levels, standards of care and physical comfort levels. The review demonstrates some promising areas for further investigation and early

evidence to show which interventions may have a positive impact on patient experience.
Conclusion: The findings of the review highlight the diverse and challenging ways that patients experience nuclear medicine hybrid imaging. All health professionals involved in this type of imaging need to be aware of the experiences of their patients and provide them with ongoing support. This could be through the use of accurate patient information resources and/or ensuring that staff-patient communication is able to reduce feelings of isolation and anxiety.

B-1306 09:10

Air embolism on coronary computed tomography angiography: its incidence associated with the preparation of intravenous infusion

S. Kayano[1], K. Ono[1], T. Yamaguchi[2], H. Ota[1]; [1]*Sendai/JP*, [2]*Sapporo/JP*
(skayano.ism@gmail.com)

Purpose: Air embolism can be observed in the right heart system following injection of contrast media with power injector system on coronary CT angiography. Although almost all air embolism is asymptomatic, it has potential risks of paradoxical embolism. The study aimed was to evaluate whether its incidence on coronary CT angiography was associated with the process of preparation for intravenous infusion.
Methods and Materials: We retrospectively evaluated a total of 693 coronary CT examinations in three institutions. Trained CT nurses placed an intravenous cannula in the forearm. Tubes connected to the cannula were prepared in the following ways: A, an interposed three-way cock and 20-ml syringe filled with normal saline to collect air contamination in the tube; B, direct connection to the power injector system without interposed three-way cock; C, an interposed three-way cock and 50-ml normal saline drip infusion bottle system to keep the tube patency. The incidence and location of air emboli and preparation of intravenous injection were assessed.
Results: The overall incidence of air embolism was 54.9% (381/693), most frequently observed in the right atrium (81.9%, 312/381). Its incidence was significantly different among the three methods of preparation (A, 21% (34/162), B: 62.9% (237/376) and C, 71% (110/155), respectively, $p < 0.05$). No patient demonstrated any symptom associated with air embolism.
Conclusion: Using a three-way cock with syringe demonstrated the lowest incidence of air embolism on coronary CT angiography. It is recommended to reduce the potential risks of complications related to intravenous contrast medium injection.

B-1308 09:14

Evaluating the roles of CT radiographers in the UK

M.A. Harris[1], M. Hardy[2]; [1]*Wakefield/UK*, [2]*Bradford/UK*
(martine.harris@midyorks.nhs.uk)

Purpose: Computed tomography (CT) technologies have advanced significantly over the last decade resulting in faster patient throughput and greater utility. However, threshold radiographer competencies, as defined by the UK Health and Care Professions Council (HCPC), are limited and no certification and registration requirements for operating CT exist. Instead, generic person and professional skills and knowledge frameworks have been published but these are inconsistent in their role expectations. As a result, a unified knowledge and skills analysis tool has been developed. This study reports the application of this tool to UK CT radiographer role descriptors to compare current clinical roles with theoretical framework standards.
Methods and Materials: A convenience sample of UK advertised radiographer role descriptors requiring participation in CT were surveyed and analysed using systematic structured content analysis to determine correlation with themes within the unified framework tool.
Results: A total of 114 radiographer role descriptors were analysed. Role grades and experience required, as well as type of recruiting organization, were varied. While key knowledge, skills and behaviors were evident across all roles, we noted discrepancies in role expectations. Further, the language used to describe role characteristics was inconsistent and open to interpretation.
Conclusion: Small changes in language were identified between recognized levels of radiography practice and these have a significant impact on expected radiographer decision-making, responsibility and autonomy of clinical practice. However, the majority of these competencies reflect generic professional standards and CT clinical task competencies remain largely undefined potentially placing patients at risk of inconsistent CT imaging practice.

B-1309 09:18

Digital radiography: impact of a lower tube voltages on image quality and radiation dose in chest phantom radiography

I. Hauge[1], I.-J. Aandahl[1], J.-P. Baranzelli[2], P.M. Coelho[3], L. Eriksen[1], N. Hadebe[4], G. Kahl[5], S. van Schagen[6], M. O`Connor[7]; [1]*Oslo/NO*, [2]*Lausanne/CH*, [3]*Lisbon/PT*, [4]*Bloemfontein, Free State/ZA*, [5]*Santa Catarina/BR*, [6]*Groningen/NL*, [7]*Dublin/IE (vs_steven@hotmail.com)*

Purpose: A tube voltage of 120 kVp is the standard in chest radiography. However, three studies have found that a lower kVp (e.g. 80 kVp) may provide better image quality for visualizing lung tissue and the cardiac silhouette. The aim of this study is to investigate the impact of tube voltage reduction on dose and image quality of DR chest phantom radiographs.
Methods and Materials: An anthropomorphic chest phantom, without and with additional plates, to simulate a normal and large person, was imaged in PA and lateral projections using stepwise increases of 10 kVp, from 60 to 130 kVp. Subjective image analysis was conducted by doing visual grading analysis (VGA). Six observers rated the image quality score (IQS). In addition, objective image analysis was performed by using ImageJ analysis software by finding the contrast-to-noise ratio for six and 3 regions of interest (ROI) in the image, for the PA and lateral view, respectively. To optimize with regard to both image quality and dose, the figure of merit (FOM) = (contrast-to-noise- ratio squared/DAP) was estimated at each selected kVp.
Results: 91 kVp had highest IQS for PA without plates and 110 kVp for the PA with plates, lateral without plates and lateral with plates. However, 130 kVp had the best FOM.
Conclusion: The VGA analysis showed that it is possible to reduce the kVp and still get good image quality. However, more extensive VGA is needed to come to a definite conclusion.

Patient doses in plain chest x-ray compared to national DRLs

A. Henner, K. Paalimäki-Paakki; *Oulu/FI (anja.henner@oamk.fi)*

Purpose: Finnish Radiation and Nuclear Safety Authority set updated diagnostic reference levels (DRLs) in 2017 (both ESD and DAP) for adult's plain chest x-ray. These DRLs are: pa projection 0.12mGy (0.1Gy*cm^2) and lateral projection 0.5mGy (0.2Gy*cm^2). There is also achievable level for DR: pa 0.05mGy (0.07Gy*cm^2) and lateral 0.14Gy*cm^2. Purpose of this study was to find out doses of chest examination and compare them to updated national DRLs.
Methods and Materials: The data (526 patients) was collected by student radiographers during their clinical practice in spring 2016 and 2017 all over Finland. Imaging protocols, equipment and doses/parameters were documented. Entrance surface doses were calculated with formula $ESD=Y(U,F) \cdot (FDD/FSD)^2 \cdot Q \cdot BSF$. Measurements of radiation output were done by vendors or hospital engineers. DAP meter was available only in few places and, therefore, is not included in data.
Results: Source to image distance 200cm, focal spot size 1mm or 1.2mm, grid 10:1 ; 12:1, 17:1, kV 125 and AEC were used. Added filtration varied according to the manufacturer. Mean ESD was 0.08mGy in pa and 0.31mGy in lateral projection.
Conclusion: The mean ESD 0.08mGy in pa projection compared to DRL 0.12mGy and in lateral ESD 0.31mGy compared to 0.5mGy are below DRLs. Both CR and DR detectors are included in the mean. With DR the mean ESD in pa was 0.05mGy which is same as the achievable level.

B-1311 09:26

Radiography on wheels for nursing home residents may reduce healthcare costs

E. Kjelle[1], L. Kleven[2], H. Olerud[1], H. Melberg[2,2]; [1]*Kongsberg/NO*, [2]*Oslo/NO*
(elin.kjelle@usn.no)

Purpose: To determine whether mobile radiography service for nursing home residents reduce cost from a societal perspective.
Methods and Materials: To do the cost analyses a model was constructed based on current knowledge of organization of radiology services for nursing home residents. The model included two different organizational alternatives, hospital-based services alone and hospital-based services combined with a mobile radiography service. In addition to the x-ray examination, the model included the immediate treatment given based on the results of the examination. The treatment could be given either in the hospital (in or outpatient) or at the nursing home. Transition probabilities in the model are based on data collected from hospitals in southeast Norway and earlier research. Cost data have been collected in reports, Norwegian regulations and Statistics Norway. Costs are presented in Euro (annual average of daily rates in 2016).
Results: The preliminary analysis indicates that the mean cost of examining and treating one resident in the case of hospital-based services would be approximately € 2 116 (95% CI: 1 908 - 2 313). In the case of combination of

hospital-based and mobile services the mean cost would be € 1 378 (95% CI: 1 342-1 410).
Conclusion: Mobile radiography services reduce costs by approximately 35% when x-ray examining and treating nursing home residents in southeast Norway.

B-1312 09:30

Evidence-based practice in diagnostic imaging departments - involving the patients in procedure-developement
L. Hammerstrøm; *Sarpsborg/NO (linda.hammerstrom@hioa.no)*

Purpose: In an effort to increase patient safety and reduce adverse events in health care, there is a strong focus on developing and utilising evidence-based clinical guidelines or protocols. The purpose of this study has been to investigate radiographers' views on involving the patients in developing procedures in imaging departments.
Methods and Materials: The study has a qualitative inductive design with phenomenological approach. Data collection took place in individual, semi-structured interviews. Inclusion criteria: Radiographers with experience in developing guidelines or protocols in imaging departments. Managers in eight imaging departments received information about the study and inclusion criteria by email, to help in recruitment by suggesting participants. Fourteen suggested participants received information about the study by email. Seven radiographers in five different imaging departments who met the inclusion criteria choose to participate in the study. The author transcribed and analysed all interviews.
Results: The study suggests that brief encounters with patients and complex high-tech equipment are factors that can complicate patient involvement in procedure development in imaging diagnostics. The study shows that radiographers perceive patient involvement in developing procedures difficult and confusing, due to few guidelines on how to involve the patients.
Conclusion: The findings suggests that further training and research on EBP must be a focus in future procedure development. New ways of thinking is in order to involve the patients according to the governments' intentions

B-1313 09:34

Relationship between body fat by DEXA and cardiovascular risk factors
R.A.M. Santos, A.C. Girão, J.P. Figueiredo; *Coimbra/PT (rutemartinssantos@gmail.com)*

Purpose: To evaluate the relationship between % body fat (%BF) and % abdominal fat (%ABDF) evaluated by bone densitometry (DEXA) and risk factors for cardiovascular diseases in young adult's students.
Methods and Materials: 214 individuals (aged between 18-25 years), were submitted to a DEXA for the determination of %BF and android fat (AF) classified in four groups 9using the Bray criteria (1998); and submitted to blood sampling for biochemical analyses: glycemia, triglycerides, total cholesterol and HDL, and insulin resistance. Correlation was assessed by the Pearson coefficient. Fat parameters and biochemical analysis were compared by Student's t-test. The association between anthropometric variables and cardiovascular risk factors was analysed by gender using the $\chi 2$ test. The multivariate linear regression allowed to identify the predictors of %BF and AF.
Results: The prevalence of obesity was 9.09% in boys and 16.6% in girls, with the average of the ABDF (AF) respectively of 17.49% and 29.27% (p=0.000). There was a positive correlation of insulin resistance with BF (p=0.023), with total cholesterol (p=0.001) and triglycerides (p=0.019) only in girls. Also in girls, a positive correlation was observed between TF and triglycerides (p=0.030). With the multivariate linear regression, we verified that both predictive models of BF and AF expressed a modest explanatory model (R2≈0.4) associated to predictors gender and BF (p<0.05).
Conclusion: This study shows that gender and triglycerides are one of the predictors for BF and AF, in girls.

B-1314 09:38

Exposure to electromagnetic fields during a gradient echo sequence in a 3T MRI scanner along z-axis
V.M.F. Silva, I. Ramos, M. Marques, J. Moreira; *Porto/PT (vitorsoft@gmail.com)*

Purpose: Occupational staff, volunteers and patients' accompanying sometimes are exposed to electromagnetic fields (EMF) during magnetic resonance imaging (MRI) procedures, inside MRI room. This study aims at evaluating the propagation of the electromagnetic field associated with a T2 gradient echo brain sequence along the z-axis from the magnet entrance up to the room limits in a 3T scanner.
Methods and Materials: A well 200 MHz oscilloscope (Agilent DS01024A), that was positioned outside the MRI room, was used with a receiving rectangular loop connected through a double-shielded coaxial cable, allowing measurements of the induced voltage due to RF-magnetic field. Six independent measurements of induced voltage were taken at different fixed points in the MRI room along the z-axis from the bore, using a T2 gradient echo brain sequence.
Results: Values obtained ranged from 55 mV to 382 mV and a sinusoidal z-dependence of the induced voltage was ascertained, due to interference of the income and wall reflected RF-wave. Lowest values were reached at the bore entrance (0 cm) and at 150 cm from the entrance. Highest values were reached at 105, 210, 225, 240 and 255 cm from the bore entrance. Values measured on the back of the equipment were at 380 mV range at different points.
Conclusion: Values measured from all six measurements showed a "sinusoidal" waveform shape, demonstrating that highest values are not located in points closer to the magnet isocenter. Professionals must be aware to that for better practices in terms of exposure to EMF in MRI.

Diagnostic performance in the stage of liver fibrosis: comparison of magnetic resonance T1 rho and acoustic radiation force impulse
J. Li, C. Zhang, H. Liu, S. Yang, Y. Wang, W. Chen, D. Wang; *Shanghai/CN (lijinning117@163.com)*

Purpose: To compare the diagnostic performance of magnetic resonance (MR) T1 relaxation time in rotating frame (T1 rho) and ultrasound-based elastography (acoustic radiation force impulse imaging, ARFI) for staging liver fibrosis in rat models.
Methods and Materials: Thirty-two rats were injected with carbon tetrachloride (CCl_4) to induce liver fibrosis and fifteen rats were injected without CCl_4 as control. Both T1 rho and ARFI imaging were performed for all rats, and T1 rho values and ARFI velocities were measured. The stage of liver fibrosis was identified based on METAVIR scoring system (F0-4). The Pearson correlation coefficient was obtained between the two imaging techniques and pathological staging. Diagnostic performance was determined by calculating areas under receiver operating characteristic curves (AUCs).
Results: There is moderate correlation between T1 rho values and ARFI velocities (r = 0.624, P < 0.001). T1 rho values showed stronger correlation with the stage of liver fibrosis (r = 0.82, P < 0.001) than that of ARFI velocities (r = 0.618, P < 0.001). AUCs of diagnosing fibrosis of ≥ F1, ≥ F2, ≥ F3, ≥ F4 for T1 rho imaging was 0.923, 0.901, 0.898, 0.961, respectively, which was higher than 0.862, 0.825, 0.815, 0.860 of ARFI imaging, and there is significant difference of AUCs between two imaging techniques for detecting fibrosis of ≥ F3 (P = 0.046) and ≥ F4 (P = 0.019).
Conclusion: MR T1 rho value is a better biomarker than ultrasound ARFI velocity for staging liver fibrosis, especially for diagnosing obvious fibrosis (≥ F3).

B-1315 10:38

Evaluation of T1 measurement methods of the liver in chronic liver disease
A. Yamada, T. Nonaka, M. Nakamura, T. Suzuki, D. Komatsu, S. Fujita, Y. Fujinaga, M. Kadoya; *Matsumoto/JP (a_yamada@shinshu-u.ac.jp)*

Purpose: The purpose of study is to validate reproducibility and clinical usefulness of T1 measurement by variable flip angle method (VFA) and saturation recovery method (SR) in chronic liver disease.
Methods and Materials: Consecutive sixty-four patients with chronic liver diseases who underwent MR elastography (MRE) and T1 measurement of the liver from April 2015 to April 2016 in our institution were included in this IRB approved prospective study. Plastic bottle phantoms filled with various concentration of Gd-EOB-DTPA (0, 0.1, 0.2 mmol/mL) were scanned together with patients. T1 of the liver and phantoms were measured by VFA in 43 patients, by SR in 21 patients, before and 20 minutes after contrast media administration. Correlation coefficient between Gd-EOB-DTPA concentration and measured 1/T1 in phantoms (rC), normalized absolute difference in repeated measurement of T1 in phantoms (dT1), correlation coefficient between liver stiffness obtained by MRE and native T1 of the liver (rLS) were statistically analyzed between VFA and SR.
Results: Mean and standard deviation (SD) of rC and dT1 were 0.9084±0.3103 and 0.3058±1.0881 for VFA, 0.9997±0.0006 and 0.0379±0.0201 for SR, respectively (P = 0.0105 and 0.0262). Mean and 95%

confidence intervals of rLS were 0.0658 (-0.3531, 0.4848) for VFA, -0.7779 (-0.9461, -0.6098) for SR, respectively.
Conclusion: T1 measurement by SR is more reproducible and well correlated to Gd-EOB-DTPA concentration and liver stiffness than that by VFA.

B-1317 10:46

Assessment of histological stage of fibrosis using relative liver enhancement in patients with primary sclerosing cholangitis
J. Yamamura, A. Aigner, C. Schramm, R. Zenouzi, G. Adam, S. Keller;
Hamburg/DE (j.yamamura@uke.de)

Purpose: To assess if relative liver enhancement (RLE) of extracellular gadolinium-based contrast agent (GBCA) enhanced magnetic resonance imaging (MRI) could be used as a marker of hepatic fibrosis and inflammation in patients with PSC.
Methods and Materials: 40 patients (41.2±7.1 years) underwent 3-tesla (T) MRI examination of the liver as well as liver biopsies in a mean time of 54±55 days between liver biopsy and MRI. Ishak modified hepatic activity index (mHAI) and Scheuer grading/staging of inflammation/fibrosis were used to categorize the specimen. T2wI and multiphase T1wI were performed, where T2 signal intensities, contrast enhancement and RLE were assessed. Interobserver agreement tests, and mixed effects regression models were applied to derive effect estimates for the association between histopathology and MRI parameters.
Results: A fibrosis stage >2/4 was found in n=26/66 of liver histologies**.** Regression models revealed a significant positive correlation of delayed-phase RLE and fibrosis staging (e.g. 69.2 times (95%-CI: 45.8-92.8) higher RLE for fibrosis 3 or 4 compared to 0. Interobserver agreement for quantification of RLE was excellent (portalvenous RLE R=0.93; delayed RLE R=0.97). Interobserver agreement was good both for detection of T2 signal alterations and contrast enhancement **(**Cohen´s Kappa T2 >0.77; contrast enhancement >0.92). No significant association between portalvenous/delayed RLE and mHAI was observed.
Conclusion: Delayed RLE of multiphase MRI may provide a reproducible and accessible evaluation of hepatic fibrosis in patients with PSC.

B-1318 10:54

Assessing liver fibrosis with diffusion-weighted MRI: comparison between conventional and kurtosis models
L. Yang, M. Zeng, S. Rao; *Shanghai/CN*

Purpose: To assess liver fibrosis in patients with chronic liver disease using diffusion kurtosis imaging (DKI), in comparison with conventional diffusion-weighted Imaging.
Methods and Materials: This prospective study was conducted with a 1.5T MR scanner. DKI with b-values of 0, 200, 500, 1000, 1500 and 2000 sec/mm^2 was performed in 81 patients with chronic liver disease. Mean diffusivity (MD), mean kurtosis (MK) and apparent diffusion coefficient (ADC) maps were calculated. Correlations of MK and MD with fibrosis stages and ADC were computed. The diagnostic efficacy of MD, MK and ADC for predicting stage 2 fibrosis or greater, and stage 3 fibrosis or greater was compared.
Results: The MD (rho=-0.475, *P*<0.001), MK (rho=0.526, *P*<0.001) and ADC (rho=-0.480, *P*<0.001) correlated significantly with fibrosis stages, and ADC exhibited a strong negative correlation with MK (rho=-0.967; *P*<0.001) and a moderate association with MD (rho=0.601, *P*<0.001). Areas under the curves (AUCs) for predicting stage 2 fibrosis or greater were not significantly different (*P*>0.05) between MK (0.809,95%CI: 0.709-0.909) and ADC (0.797,95%CI: 695-0.899) as well as between MD (0.715,95%CI: 0.598-0.832) and ADC. AUCs were also similar for MD (0.710,95%CI: 0.599-0.822), MK (0.768,95%CI: 0.665-0.870) and ADC (0.747,95%CI: 0.641-0.853) for predicting stage 3 fibrosis or greater.
Conclusion: DKI is feasible for predicting liver fibrosis in patients with chronic liver disease, but MD and MK offer similar diagnostic performance to ADC values.

B-1319 11:02

The potential role of Gadoxetate disodium (Gd-EOB-DTPA) and diffusion-weighted magnetic resonance imaging in primary sclerosing cholangitis
J. Yamamura[1], J. Sedlacik[1], T. Schuler[1], R. Buchert[2], H. Kooijman-Kurfuerst[1], C. Schramm[1], J. Fiehler[1], G. Adam[1], S. Keller[1]; [1]*Hamburg/DE*, [2]*Berlin/DE (s.keller@uke.de)*

Purpose: To assess the diagnostic effectiveness of both dynamic contrast-enhanced (DCE) and diffusion-weighted (DWI) magnetic resonance imaging (MRI) in patients with primary sclerosing cholangitis (PSC).
Methods and Materials: After measuring the hepatic fibrosis classified according to METAVIR fibrosis score with ultrasound-elastography within an interval of 0±6 months, 47 patients (43.4 ± 14.5 years) with known PSC were examined by DCE-MRI using Gd-EOB-DTPA and by DWI on a 3.0-tesla scanner. DCE-parameters were calculated using a dual-inlet two-compartment uptake model. ROI covering the right liver lobe were drawn by two observers independently. Pearson correlation and univariate analysis of variance was used to test quantitative ADC and DCE-parameters for differences between the fibrosis stages.
Results: Both ADC and hepatocellular uptake rate (Ki) correlated significantly to hepatic fibrosis (r=-0.610; P<0.001 and r=-0.368; P=0.01). Multiple comparison testing of ADC confirmed significant difference in discrimination of F0/1 from F2 (p=0.02), F3 (p=0.008), and F4 (p=0.001). The optimal cut-off value of ADC=1.17 mm^2/sx10^{-3} for discrimination of F0/1 from F3 showed a sensitivity 0.1 and specificity of 0.826. The cut-off value ADC=1.13 mm^2/sx10^{-3} discriminated F0/1 from F4 with a sensitivity of 0.875 and specificity of 0.87. Ki only discriminates F0/1 from F4 (p=0.034), but not F2 or F3. The cut-off value Ki=0.353/100/min and Ki=0.355/100/min showed a sensitivity of 0.857 and specificity of 0.5 to discriminate F0/1 from F3 and F4, respectively.
Conclusion: DWI showed a higher sensitivity to differentiate several stages of fibrosis and might be more preferable than DCE-MRI for diagnosis and staging of fibrosis in PSC.

B-1320 11:10

Tumour response to preoperative chemotherapy in patients with colorectal liver metastases: can ADC values evaluated at 3T MRI replace RECIST criteria?
F. Donati, P. Boraschi, R. Cervelli, F. Pacciardi, G. Tarantini, M. Castagna, L. Urbani, D. Caramella, F. Falaschi; *Pisa/IT (francescamaria69@gmail.com)*

Purpose: To evaluate tumour treatment response in colorectal liver metastases (CRLM) after preoperative chemotherapy (pCT) at 3T MRI, focusing on the role of ADC values.
Methods and Materials: Twenty-five patients with CRLM, who underwent 3T MRI before and after fluorouracil-based pCT and subsequently treated by parenchymal-sparing liver surgery, were retrospectively included in our study. Diffusion weighted-MRI (DW-MRI) was performed using a spin-echo echo-planar sequence with multiple *b*-values, obtaining an ADC map. Fitted ADC values were calculated by two radiologists in conference for each lesion before and after pCT, by drawing on the ADC map a ROI around the tumour burden of the lesion. Maximum diameter of each lesion in both examinations was recorded. Diameter variations and RECIST 1.1 criteria were assessed. All MRI findings were histopathologically related to Tumour Regression Grading (TRG) of resected liver metastases. Statistical analysis was performed on a per-lesion basis.
Results: A total of 58 CRLM were analyzed. According to RECIST 1.1, 8 lesions were classified as CR, 24 as PR and 25 as SD. In only one lesion PD was found. In 8 lesions both ADC and TRG was not evaluated due to the lesion disappearance. TRG 1, TRG 2, TRG 3, TRG 4 and TRG 5 were observed in 6, 12, 12, 13 and 7 lesions, respectively. ADC_{post}, Δ ADC values (both p<0.0001), RECIST 1.1 criteria (p=0.0009) were significantly different based on TRG classes.
Conclusion: 3T DW-MRI, using ADC values, can be a reliable tool to assess tumour treatment response after pCT in CRLM.

B-1321 11:18

Liver function estimation using gadoxetic acid-enhanced liver MRI
J.-H. Yoon[1], E. Kim[1], T. Okuaki[2], J. Lee[1]; [1]*Seoul/KR*, [2]*Tokyo/JP*

Purpose: To determine whether hepatocyte fraction derived from gadoxetic acid-enhanced liver MRI can estimate liver function.
Methods and Materials: In this IRB approved prospective study analysed 50 patients who underwent gadoxetic acid MRI at 3T and ICG R_{15}. T1 maps of the liver using Look-Locker sequence were obtained before contrast (preT1 map) media injection and 10 minutes (post T1 map) after a standard dose of gadoxetic acid (0.025mmol/kg). Hepatocyte fraction and liver volume were calculated. The relationships were evaluated between MR parameters and ICG R_{15}. The parameters were also compared between patients with different Child-Pugh class, and with different ICG R_{15} results (≥15% or <15%).
Results: Hepatocyte fraction (*r*=-0.78) and liver volume (*r*=-0.42) showed a negative correlation with ICG R_{15}. Compared with patients with chronic liver disease (CLD) or Child A (88%, 44/50), hepatocyte fraction (238.6±106.3%, 77.0±34.6%, *P*<0.0001) was significantly lower in Child B patients (12%, 6/50). In 44 patients with CLD or Child A, hepatocyte fraction (298.17±69.81% vs. 160.12±95.28%, *P*<0.0001) was significantly higher in patients with ICG R_{15}<15% (n=25), compared with patients with ICG R_{15}≥15% (n=19), whereas liver volume did not (1059.7±129.8mL vs. 991.7±207.0mL, *P*=0.19). Compared with liver volume, hepatocyte fraction showed a better performance to detect patients with ICG R_{15}> 20%, which is a contraindication of major hepatectomy (area under the curves were 0.70, and 0.98).
Conclusion: Hepatocyte fraction derived from gadoxetic acid-enhanced liver MRI showed a significantly negative correlation with ICG R_{15}, and showed a better performance to identify contraindicative patients of major hepatectomy than liver volumetry.

Pathologic alterations in hepatic vasculature in primary sclerosing cholangitis: correlation with morphologic spectrum and abnormal hyperintensity in T2-weighted MR images

M. Kul, D. Kuru Öz, A. Erden; *Ankara/TR (melahatkul@yahoo.com)*

Purpose: To correlate both the spectrum of hepatic morphology and abnormally high signal intensity in T2-weighted (T2w) MR images in primary sclerosing cholangitis (PSC)with pathologic alterations in major hepatic vessels.
Methods and Materials: A total of 34 patients with PSC were included in this study. Two radiologists retrospectively analyzed the image sets in consensus regarding the presence of any pathologic finding in portal and hepatic veins, abnormally T2-hyperintense areas, and spectrum of hepatic morphologic changes. Patients were divided into hepatic vascular pathology group (HPG) and control group (CG). Hepatic morphology and T2-hyperintensity were correlated between both groups. In HPG, correlation was also made in terms of location between affected vessel and both morphologic changes and T2-hyperintensity. Additionally, time since diagnosis and total bilirubin levels were compared between both groups.
Results: In 12 out of 34 patients (35%) at least in one of the hepatic vessels pathologic alteration was present (HPG). No significant difference was detected between HPG and CG in terms of abnormal morphologic spectrum and T2-hyperintensity ($p>0.05$). Total bilirubin levels, time since diagnosis did not differ between HPG and CG ($p>0.05$). No significant correlation was found between hepatic vascular pathology and both hepatic morphologic changes and T2-hyperintensity in terms of location ($p>0.05$).
Conclusion: Abnormal hepatic morphology and T2-hyperintensity do not appear to be primarily affected by pathologic alterations of hepatic and portal veins in PSC. Thus, the heterogenous spectrum of hepatic morphology/T2-hyperintensity in PSC seems rather to derive from heterogenity in microperfusional alterations due to periductal inflammatory and fibrotic changes.

B-1324 11:34

The possitive effects of bariatric surgery on NAFLD at early postoperative period: proof with ideal IQ sequences obtained by 3.0 Tesla MRI

Y. Metin[1], N. Orhan Metin[1], S. Kalcan[1], O. Ozdemir[1], M. Çolakoğlu[1], A. Küpeli[2]; [1]*Rize/TR*, [2]*Mus/TR (ymetin53@gmail.com)*

Purpose: To investigate the early effects of bariatric surgery on liver fat fraction (LFF), pancreas fat fraction (PFF) and liver length at 3T MRI using ideal IQ sequences.
Methods and Materials: Body mass index (BMI), body weight, liver fat fraction, pancreas fat fraction and craniocaudal length of liver were measured preoperatively (one week before surgery) and postoperatively (one month after surgery) in 39 consecutive patients (25 female, 14 male; age range, 25-60 years; mean age, 41 years) who underwent bariatric surgery [laparoscopic Roux-Y-gastric-bypass (4) or laparoscopic sleeve gastrectomy (35)] between May 2016 and April 2017.
Results: At the end of first month of bariatric surgery a significant decrease in mean values of pancreas and liver fat fraction has been observed along with a decrease of body weight and BMI. A moderate positive linear correlation was observed between LFF and PFF, liver length while a weak positive linear correlation was noticed between LFF, BMI and body weight.
Conclusion: Ideal IQ MRI sequences enables quantitative analysis of fatty infiltration within the liver and pancreas, and thus may be use as a non-invasive tool to monitor the positive effects of the surgery on fatty infiltration of these organs.

B-1325 11:42

Contrast-enhanced MR imaging 3D texture analysis as a potential tool for preoperative prediction of microvascular invasion in hepatocellular carcinoma

Y. Zhu, X. Ma, X. Zhao; *Beijing/CN (zhuyj04@126.com)*

Purpose: To explore the value of contrast-enhanced MR imaging (MRI) texture analysis in predicting the microvascular invasion (MVI) status of hepatocellular carcinoma (HCC) preoperatively.
Methods and Materials: A retrospective study of 90 pathologically confirmed cases was conducted. Studies were divided into two groups: the MVI-positive group (n=45) and MVI-negative group (n=45) based on pathology. 58 texture parameters of HCC were extracted using baseline MRI on both arterial phase (AP) and portal phase (PP) by a 3D method. The clinical radiological features were also included. Univariable logistic regression identified potentially predictive parameters, which were tested in multivariable logistic regression together with clinical features to predict development of MVI.
Results: In the clinical features, only max tumour diameter (MTD) showed significant difference between the two groups (P=0.001). Multivariable logistic regression revealed that MTD, 3 MR texture features in AP model and 3 in PP model might be predictors to MVI. AP model showed a better diagnostic performance than PP model using ROC analysis, with area under the curve (AUC) 0.921 (0.864-0.977) vs 0.815 (0.727-0.904), sensitivity 88.9% vs 80.0%, specificity 84.4% vs 71.1%.
Conclusion: The contrast-enhanced MRI 3D texture analysis can predict MVI of HCC preoperatively and noninvasively; the arterial phase showed better performance.

Virtual monoenergetic image reconstruction from spectral detector CT improves objective image quality and subjective assessment of pulmonary emboli

N. Grosse Hokamp[1,2], R. Kessner[2], R. Gilkeson[2], A. Gupta[2]; [1]*Cologne/DE*, [2]*Cleveland, OH/US (nils.grosse-hokamp@uk-koeln.de)*

Purpose: To investigate objective and subjective image quality of virtual monoenergetic images (VMI) provided by spectral detector computed tomography (SDCT) for assessment of pulmonary vessels regarding emboli (PE).
Methods and Materials: 40 consecutive patients that underwent contrast-enhanced SDCT (IQon, Philips Healthcare) with PE-protocol were included in this IRB-approved study. Two regions of interest were placed in each of the following regions in conventional images (CI) and copied to VMI (40-200keV; 10keV increment): pulmonary trunk and arteries, lobar arteries, and segmental arteries. Attenuation (HU) and standard deviation (SD) were recorded, SDMuscle was considered representative of image noise. Signal- [SNR = HU(x) / SD(x)] was calculated. Subjectively, 40keV, 70keV, 110keV and CI images were assessed using 5-point Likert scale regarding large/intermediate/small vessel assessment and diagnostic confidence. ANOVA and Wilcoxon test were used for statistical assessment.
Results: Attenuation in vessels was higher in low-keV images ($p\leq0.05$) while image noise remained constant throughout all reconstructions ($p\leq0.05$); this resulted in a significant increase of SNR in VMI40-70keV compared to CI (e.g. lobar arteries, 40keV/CI: 40.7±14.6/13.9±4.8; $p\leq0.05$). Segmental arteries' SNR in VMI40keV was equivalent to the SNR of the pulmonary arteries in CI (15.1±9.8 and 15.3±5.2, respectively). Subjectively, 40keV images significantly improved the assessment of vessels (e.g. intermediate, 4(4-5) vs 4(2-5), $p\leq0.05$) resulting in a higher diagnostic confidence regarding PE (4.5(3-5) vs 4(2-4), $p\leq0.05$).
Conclusion: Low-keV VMI from SDCT yields a significant increase in SNR of pulmonary vessels while maintaining low image noise. Accordingly, subjective vessel assessment and diagnostic confidence is improved in these reconstructions.

B-1327 10:47

CT pulmonary angiography at reduced radiation exposure and contrast material volume in obese patients using IMR and iDose^4 in comparison to FBP

A. Quitzke, J. Schmidt-Holtz, C. Behzadi, G. Adam, M. Regier; *Hamburg/DE (a.laqmani@uke.de)*

Purpose: To intraindividually assess the image quality of CT pulmonary angiography (CTPA) in obese patients at reduced radiation exposure (RD-CTPA) and contrast medium (CM) volume using two different iterative reconstruction (IR) algorithms (iDose^4 and iterative model image reconstruction (IMR)) in comparison to filtered back projection (FBP).
Methods and Materials: 17 obese patients (mean BMI: 37.6) with suspected pulmonary embolism (PE) underwent RD-CTPA (tube voltage: 100 kV; mean CTDIvol: 6.15 mGy; mean effective dose: 2.94 mSv) using 60 ml CM. The raw data were reconstructed using FBP and two different IR algorithms, iDose4 (levels 4 and 6) and IMR (levels 1-3) (Philips Healthcare). Subjective and objective image quality, image appearance and conspicuity of PE were

assessed in central, segmental, and subsegmental arteries. The objective image noise (OIN) was measured; contrast-to-noise ratio (CNR) was calculated.
Results: Noise reduction of up to 65% was achieved with iDose^4 level 3 and of 85% with IMR level 3. CNR significantly increased with iDose^4 and IMR compared to FBP (p<0.05). Subjective image quality was rated significantly higher at IMR reconstructions in comparison with iDose^4 and FBP. Moderate blotchy image appearance was observed when the highest strength of IMR was obtained, mildly limiting the diagnostic confidence. The conspicuity of central and segmental PE improved with the use of IMR. In subsegmental arteries, IMR was inferior to iDose^4.
Conclusion: IMR enables CTPA at reduced radiation exposure and contrast medium volume in obese patients by the superior reduction of image noise and improvement of conspicuity of pulmonary embolism compared to FBP and iDose4.

B-1328 10:55

Model-based iterative reconstruction on low-dose CT pulmonary angiography: image quality and radiation dose saving compared with hybrid iterative reconstruction CTPA
A. de Vito[1], D. Ippolito[1], C.R. Talei Franzesi[2], L. Riva[2], S. Drago[1], S. Sironi[1]; [1]*Monza/IT*, [2]*Milan/IT (a.devito@campus.unimib.it)*

Purpose: To evaluate the dose reduction and image quality of low-dose pulmonary angiography (CTPA) reconstructed with model-based iterative reconstruction (IMR), and compared with standard CTPA with hybrid iterative reconstruction (iDose4).
Methods and Materials: 139 patients were prospectively enrolled and investigated for pulmonary embolism; a study group of 75 patients underwent low kV setting (80 kV, automated mAs) CTPA study, while a control group of 64 patients underwent standard CTPA protocol (100 kV; automated mAs); all patients were examined on 256 MDCT scanner (Philips iCT elite). In the study group, images were reconstructed using IMR technique, while in the control group we used iDose4 technique. CTDIvol, DLP and ED were evaluated in both groups. Region of interests were drawn in the three main pulmonary vessels to evaluate vascular enhancement (HU); signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were also calculated.
Results: Compared to iDose4-CTPA, low kV IMR-CTPA presented lower CTDIvol (6.41±0.84 vs 9.68±3.5 mGy) and DLP (248.24±3.2 vs 352.4±3.59 mGy*cm), with ED of 3.48±1.,2 vs 4.93±1.8 mSv. Moreover, IMR-CTPA showed higher attenuation values (670.91±9.09HU vs 292.61±15.5HU) and a significantly higher SNR and CNR. The subjective image quality of low kV IMR-CTPA was also higher compared with iDose4-CTPA.
Conclusion: Low-dose CTPA (80 kV and automated mAs modulation) reconstructed with model-based algorithm represents a feasible protocol for the diagnosis of pulmonary embolism in the emergency setting, achieving high image quality with extremely low noise and a significant dose reduction within adequate reconstruction times (less than 120 seconds).

B-1329 11:03

High temporal resolution dynamic CE MRA in detection of reperfused pulmonary arteriovenos malformations (PAVMs) in HHT-patients
G. Schneider, A. Bücker, A. Massmann; *Homburg/DE (dr.guenther.schneider@uks.eu)*

Purpose: The recommended treatment of PAVMs in HHT patients (Hereditary Hemorrhagic Telangiectasia / Osler disease) is catheter embolization. Although immediate postinterventional imaging may show complete success of therapy, reperfusion may occur. We evaluated time-resolved contrast-enhanced MR-Angiography for detection of reperfused PAVMs.
Methods and Materials: 65 patients post embolization of PAVMS with platinum-coils or Amplatzer-vascular-plugs underwent follow-up studies for detection of reperfused PAVM. First, a time-resolved MRA-study was performed with injection of a small contrast medium bolus (0.025 mmol/kg BW (Gd-BOPTA) MultiHance, Bracco). The temporal resolution of the sequence was 3 sec/dataset with a total number of 72 slices. Thereafter a high resolution CE-MRA (0.075 mmol/kg BW MultiHance) with a timing based on the findings from the time-resolved study was performed. Images were evaluated regarding simultaneous enhancement of feeding artery and draining vein on dynamic CE-MRA.
Results: Time-resolved MR-Angiography was technically adequate in 61/65 cases. In 26/61 patients 32 reperfused PAVMs were detected. In those cases in which diagnosis of reperfused PAVM was unclear on high resolution images, evaluation of the enhancement kinetics of the draining vein on dynamic CE-MRA was used for diagnosis and could confirm 14 reperfused PAVM. All reperfused PAVM diagnosed on CE-MRA were confirmed by DSA and underwent reembolization.
Conclusion: Time resolved CE-MRA is a helpful adjunct to standard high resolution anatomic imaging, allowing for the evaluation of the enhancement kinetics of the draining vein as an indicator of recanalization of PAVM. Compared with CT imaging of embolized PAVM, this is an important advantage of CE-MRA.

The frequency of coexistence of renal artery and vein variations on abdominal CT
S. Gurel, Ö. Yılmaz, A. Kiyan; *Bolu/TR (safiyegurel@gmail.com)*

Purpose: Our aim is to determine the frequency of coexistence of renal artery and vein variations.
Methods and Materials: Abdominal CT examinations of 505 patients(217 female and 288 male) were evaluated for the presence of renal artery variations [early branching, multiple renal arteries (hilar-polar-supplementary artery)], right renal vein variations (multiple right renal vein, split of right renal vein, gonadal vein connected to right renal vein) and left renal vein variations (circumaortic left renal vein, retroaortic left renal vein, multiple left renal vein). Presence of accompanying IVC anomaly (duplication and transposition) was evaluated as well. The frequency of renal artery and vein variations were calculated in percentages.
Results: The frequency of uni- or bilateral early branching of main renal artery were found to be 0.6% and 2.97% whereas uni- or bilateral multiple renal arteries were found to be 12.3% and 2.97% respectively. On the right side, the frequency of multiple renal veins, split renal vein and gonadal vein draining to renal vein were found to be 20.4%, 0.2%, 8.9% respectively. On the left side,the frequency of circumaortic renal vein and retroaortic renal vein were 6% and 3.96% respectively. No left-sided multiple renal veins and accompanying IVC anomaly were detected.
Conclusion: The frequency of coexistence of renal artery and vein variations were found to be 7.5%. Within this group, presence of left hilar artery and double renal vein on the right side in nine (1.78%) of 38 patients were found to be the most frequent coexistent variations.

B-1331 11:19

Evaluation of pelvic congestion syndrome with time-resolved MR angiography
S. Wassef, A. Stolpen; *Iowa City, IA/US (shafik.wassef@gmail.com)*

Purpose: The purpose of this educational exhibit is to review the role of time-resolved MR angiography (TR-MRA) in evaluation of pelvic venous congestion.
Methods and Materials: Although non-invasive imaging techniques, such as ultrasound and static CT and MRI, can be helpful, they cannot accurately determine the timing and direction of venous blood flow, which is essential for accurate diagnosis and treatment planning. Conventional angiography has been considered the gold standard for diagnosis and potential embolisation therapy. Recently, TR-MRA has proved to be a useful tool for the assessment of ovarian vein reflux eliminating the invasiveness and ionising radiation of conventional angiography.
Results: TR-MRA is a useful sequence for the assessment of ovarian vein reflux, which may aid the evaluation of pelvic congestion syndrome. Pelvic congestion syndrome (PCS), the female counterpart of male varicocele, is caused by incompetence of the left ovarian vein, often in combination with left renal vein compression. This results in venous reflux, pelvic venous engorgement, and chronic pelvic pain.
Conclusion: TR-MRA has been proven to be a quick and non-invasive technique that allows evaluation of the physiological blood flow. It can be useful in detecting ovarian vein reflux which help evaluating PCS. MRI also provides details of the anatomy and can evaluate for other possible causes of pelvic pain in addition to providing dynamic imaging of the pelvic vasculature.

B-1332 11:27

Determination of inferior vena caval diameter: is it true on cavography?
C. Ma; *Changsha/CN (mcismc@126.com)*

Purpose: The geometries and the orientations of IVC are various and variable, which may lead to an inaccurate diameter measurement. The purpose of this study was to (a) type the geometries and the orientations of IVC on cross-sectional CT imaging; (b)compare the discrepancy between anteroposterior projection diameter(PD) on cross-sectional CT imaging and hypothetical diameter based on caval circumferences calculation (CD); (c) if difference between PD and CD exists, how often it can affect IVC filter selection.
Methods and Materials: 1619 patients who underwent abdominal contrast-enhanced CT were included. The following parameters were measured on cross-sectional CT: (a) the anteroposterior PD and (b) the caval circumference. PD and CD were compared using Mann-Whitney U test. Cohen's kappa test was used to evaluate the agreement of measurement consistency between PD

and CD, where one yielded a diameter of >28mm and the other yielded a diameter of <28mm.
Results: PD was significantly larger than CD (22.3±3.5 vs 20.4±2.8, P<0.05) in the entire study population. With the PD rule, the prevalence of megacava was 5.5% in our study,but only 0.67% patients in our series had an IVC diameter greater than 28 mm according to the CD rule. When performing a Cohen's kappa test, an agreement of consistency for the diameter of 28 mm was poor with a kappa coefficient of 0.186.
Conclusion: As the geometry of IVC may not be circular, HD calculation based on circumference may be a more appropriate approach for IVC diameter determination.

B-1333 11:35

Evaluation of radiation dose and image quality of dual-detector spectral CT portal venography of swine using a low-concentration iodinated contrast agent and low tube current
C. Chen, X. Lu, H. Liu, Z. Lu; *Shenyang/CN (475395751@qq.com)*

Purpose: To investigate image quality and radiation dose of the low-iodine-load contrast agents for portal venography by dual-detector spectral CT.
Methods and Materials: Five swines (weighing 42.5± 3.1 kg) underwent portal venography by dual-detector spectral CT (120 kVp; current: dose right index 22) with the following four different contrast media injection protocols: total iodine dose 40ml, 50ml, 60ml for 270 mg I/ml and 80ml for 350 mg I/ml (control group). The data were reconstructed in monochromatic images at 40, 50, 60, 70 keV (spectral iterative reconstruction level 3). The image noise (IN) (standard deviation, SD) of portal vein (PV) and the contrast-to-noise-ratio (CNR) of PV-to-liver parenchyma were measured. Subjective score of the sharpness of PV boundaries and the diagnostic acceptability (DA) were performed by two radiologists independently using a 5-point scale (1 very poor to 5 excellent).
Results: The radiation dose (CTDIvol) for low-iodine-load contrast groups was 60% lower than for control group (7.4mGy vs 18.4mGy, P < 0.05) . The IN, CNR, DA and sharpness of PV of all groups were statistically different (P < 0.05). For each low-iodine-load contrast group, the IN decreased and CNR increased from 40 keV to 70 keV, respectively. Compared with control group, monochromatic images 50 keV + 50 ml contrast dose combination demonstrated the acceptance image quality.
Conclusion: At less than 40% of the conventional radiation dose, by the dual-layer detector spectral CT, 50ml isotonic iodine contrast agents still clearly show the portal vein, at the same time, to meet the diagnostic needs.

B-1334 11:43

Treatment of varicose veins with endovenous laser ablation using low linear endogenous density
S. Sangma[1], U. Gorsi[1], M. Yadav[2], T. Yadav[1], N. Khandelwal[1]; [1]*Chandigarh/IN*, [2]*New Delhi/IN (ujjwalgorsi@gmail.com)*

Purpose: To assess the efficacy of EVLA with 1470 nm laser using low linear energy density (LEED) less than 80 J/cm
Methods and Materials: A prospective study was conducted in a total of 58 limbs with GSV incompetence using low LEED below 80 J/cm. The occlusion rate, improvement in CEAP and VCSS, ulcer healing rate, improvement in symptoms were assessed . The complication rate and recurrence of disease were also assessed
Results: The occlusion rate was 96.1%; there was up gradation of CEAP score by one or two grades by a period of one month in 75 % cases and rest by a maximum period of 3 months. Ulcer healing rate was seen in more than 91 % patients. Over 95 % confirmed improvement of symptoms . The post procedure pain was minimal and less than 50 % requiring NSAIDS immediately post procedure. DVT was encountered in 2% of patients. No major complications like pulmonary embolism and arterio-venous fistula were encountered. Two patients had segmental recanalisation of GSV after a period of 18 months. One patient had recurrence of symptoms and down gradation of CEAP score
Conclusion: EVLA with 1470 nm using low LEED is an effective mode of treatment for varicose veins with lesser complications and similar venous occlusion rate with higher LEED>90 J/cm. No significant recanalisation of GSV was encountered; however a longer period of follow up will be required to determine incidence of recanalisation and recurrence of disease.

Multiparameter ultrasound in the diagnosis of deep vein thrombosis of the lower extremities
A. Demidova, I. Rychkova, N. Krivosheeva, E.A. Zubareva, A. Kuznecova; *Moscow/RU*

Purpose: With the advent of the latest visualisation technologies such as acoustic structure quantification (ASQ), ultrasound elastography (USEG) and superb microvascular imaging (SMI), we get an opportunity to detect hypoechoic thrombotic masses in the deep veins of the lower extremities, hardly visualised in B-mode and colour duplex or power Doppler imaging modes. The combined use of new technologies, based on different variants of echo signal processing, allowed us to qualitatively assess the ageing of deep vein thrombosis (DVT).
Methods and Materials: 32 patients aged 43 to 85 years with DVT underwent ultrasound examination (B-mode, CD, PD) and additional examination using ASQ, USEG and SMI. All examinations were provided with Toshiba Aplio 500 ultrasound systems with high-frequency linear transducers.
Results: Visualisation of thrombi with USEG had advantages over B-mode in the acute phase of thrombus formation. Thrombi were coded as homogeneous hard elastic structure in the vein lumen. Thrombi after the retraction phase were coded as soft elastic structure; later, the stiffness of the structure increased and the signs of elastic inhomogeneity appeared. Within the zone of recanalisation, we detected soft elastic parts. Using SMI allowed us to detect early signs of the recanalisation process (before appearance of classic color Doppler signs). ASQ technology determines inhomogeneity of thrombi which were homogeny hypoechoic structures in the B-mode.
Conclusion: New ultrasound technologies allow us to reliably assess the echo structure of thrombi within different DVT stages and determine early signs of the recanalisation processes. Moreover, these technologies are simple to use and can be provided within a short time.

Percutaneous combined treatment for lumbar disc herniation: how we do it
G. Galvano[1], M. Raciti[2], G. Scavone[1], S. De Luca[1], A. Cannella[1], C. Di Lorenzo[1], G. Tigano[1], A. Scavone[1]; [1]*Catania/IT*, [2]*Pavia/IT (mariavittoria.raciti@libero.it)*

Purpose: To show percutaneous combined treatment, coblation and oxygen-ozone nucleus pulposus ablation, for lumbar disc decompression under fluoroscopic guidance and local anaesthesia.
Methods and Materials: Retrospective single-centre study has been performed. Inclusion criteria included patients with back pain (visual analogue scales VAS > 6), unsuccessful conservative treatments at least six weeks and protruded disc without calcifications. Main exclusion criteria were extruded disc herniation, black disc, spinal stenosis, spondylolisthesis, instability, neoplastic disease, metabolic bone disease, infection and haemorrhagic diathesis. Since July 2015, 150 patients (82 male, 68 female, from 26 to 69 years) were enrolled. Disc disease was studied with MR or TC and electromyography in doubt cases. Interventions have been performed with postero-lateral access under fluoroscopic guidance in local anaesthesia. All patients were treated with coblation and oxygen-ozone nucleus pulposus ablation, and simultaneously with transforaminal periganglionic steroid injection. The clinical outcomes were evaluated using VAS score at 1, 6 and 12 months of follow-up.
Results: There was a significant reduction of back pain in 80% of patients. The average preoperative VAS score was 7.1±0.3; VAS score was decreased down to 2.1±0.3 1 months after the procedure; the final follow-up VAS score was 2.6±0.1. The treatment showed a complication rate <1%. Only 1 patient showed an early complication, extruded disc herniation.
Conclusion: The advantage of percutaneous combined treatment, coblation and oxygen-ozone nucleus pulposus ablation, is that it is a single minimally invasive procedure which allows for a double treatment with a synergistic effect. Combination treatment is more effective than single procedures without increasing complications.

B-1337 10:47

CT-guided pulsed radiofrequency treatment of the lumbar dorsal root ganglion in patients with acute radicular low back pain

A. Napoli, S. Dababou, H.-P. Erasmus, C. Marrocchio, R. Scipione, C. Catalano; *Rome/IT (alessandro.napoli@uniroma1.it)*

Purpose: To determine the clinical impact of CT-guided Pulsed Radiofrequency (PR) in the management of patients with acute or sub-acute neuro-radicular pain from lumbar disc herniation, refractory to usual therapeutic strategies.
Methods and Materials: Patients were eligible for this single-center prospective study if they presented acute or sub-acute neuro-radicular low back pain (EMG confirmed),refractory to usual treatments(drugs and injections),and if they could safely undergo PR-procedures.Treatment was performed using a 22-20G needle-electrode with probe tip directed to the symptomatic DRG under CT-guidance;E-pulsed radiofrequency(Cosman G4) was administered for 10min at 45V with constant local temperature of 42°C.Clinical evaluation was conducted with Visual Analogue Scale(VAS),Owestry Disability Index(ODI) and Roland-Morris score(RM) for quality of life assessment; all questionnaires were obtained at baseline and at 1-week,1-month and 3-month follow-up.Analyses were performed on a per-protocol basis.
Results: Over a 3-year period,80 patients were treated with PR.Median VAS decreased from 7.8 to 3.5 to 2.6 to 1.3, median ODI from 78.0 to 12.5 to 6.0 to 5.5 at baseline, 1week, 1month and 3 months,respectively; RM decreased from 16 to 3 to 1.5 at baseline, 1month and 3 months,respectively($p<0.001$).Overall,90.0% of patients reached a 0 VAS score within the first month after treatment;97.5% had a decrease of ≥20 points in ODI score in the same interval.6 patients were considered partial responders requiring a second PR session.
Conclusion: CT-guided PR has shown to be a minimally invasive, effective and repeatable percutaneous treatment option for patients with acute or sub-acute neuro-radicular low back pain.

B-1338 10:55

Clinical outcome of rotational angiography in percutaneous laser disc decompression

D.N. Srivastava, V. Ha, A. Monga, R. Malhotra; *Ansari Nagar/IN (drdeepsrivastava@gmail.com)*

Purpose: 1. To evaluate the use of 3D rotational angiography technique in the percutaneous laser disc decompression (PLDD) treatment. 2. To evaluate the role of PLDD in patients with low back pain due to disc herniation.
Methods and Materials: We performed a prospective study of 46 patients who underwent PLDD for chronic discogenic low back pain. The PLDD procedure was performed under fluoroscopic guidance using flat panel DSA unit with 3D rotational x-ray imaging facility. For PLDD 980-nm diode laser was used. Follow-up clinical outcomes were assessed by the modified MacNab criteria.
Results: Excellent to fair response was seen in 30 out of 46 patients with overall success rate of 65%. In a group of patients with disc herniation smaller than 1/3 of the spinal canal diameter (34/46), success rate was 73.9% and in patients with disc herniation more than 1/3 of the spinal canal diameter (12/46), success rate was 26%.
Conclusion: Preoperative imaging studies and selection of patients with disc herniation smaller than 1/3 of the spinal canal diameter predict the clinical outcome of PLDD. 3D rotational angiography technique with Dyna CT is useful in target selection to maximise the efficacy of the technique. PLDD is a valid alternative for those selected patients with contained lumbar disc herniation, who do not respond to conservative treatment.

B-1339 11:03

Evaluation of magnetic resonance guided focused ultrasound (MRgFUS) as a first-line treatment of bone metastases with the intention of local treatment and pain palliation

H.-P. Erasmus, A. Napoli, S. Dababou, C. Marrocchio, R. Scipione, C. Catalano; *Rome/IT (hansperasmus@gmail.com)*

Purpose: To evaluate MRgFUS as a first-line treatment of metastatic bone disease for the purpose of tumor control and pain palliation.
Methods and Materials: 40 patients with naïve (no previous treatment) symptomatic skeletal metastases, suitable for MRgFUS, were enrolled. Imaging (CT/MRI) was performed before and 3, 6 and 12 months after treatment. The primary endpoint was the number of lesions with partial or complete response at 3 months according to MD Anderson criteria. Clinical outcomes were evaluated over the same time period using a VAS score.
Results: Out of 40 patients, 7 were lost and missed the 3-month imaging check. 33 patients with 41 lesions were evaluated. The procedure was successful in terms of local control at 3 months in 20 lesions (49%) - complete in 12, partial in 8. Stable disease was observed in 5 lesions and a progression in 2. VAS score dropped from an average of 9 to 6 to 3 to 1,5 to 1 before, immediately after and 3, 6 and 12 months after treatment. Results were statistically independent of histology (primary cancer). The only element influencing the outcome was the size of the lesion (up to 16 cm), with 7 cm as a reasonable cutoff for successful ablation - $p<0.01$. BMI, age and sex did not play a role in the final outcome. No major adverse events occurred.
Conclusion: MRgFUS for painful bone metastases appears to achieve a local control of the lesion and satisfactory pain control.

B-1340 11:11

Drill-assisted bone tissue sampling: do we need to care about heat?

S. Niehues, J.L. Vahldiek, B. Geyer, B. Hamm, F. Poch, K.S. Lehmann; *Berlin/DE*

Purpose: Battery-powered drill-assisted bone tissue sampling has become a value alternative to manual drilling. Due to enhanced rotation speed and improved material, sampling of bone lesions has become more comfortable in lesser time. The question if enhanced drilling results in an increased heating of the system and the bone sample, leading to temperature-related sample affection, remains unclear.
Methods and Materials: Eight experimental drillings using a battery-powered drilling system (Arrow OnControl, Teleflex, Shavano Park, TX, USA) were carried out in an in vivo model using large pigs (15 sec. drilling time) with a temperature probe placed adjacent to the drilling canal. Continuous temperature measurements during the drilling was recorded to identify possible heating of the tissue.
Results: During the drilling process, we encountered a slight heating effect of median 0.65 degrees Celsius (SD 0.33, min. 0.1, max. 1.4 degrees Celsius). Initial heating reached a plateau phase during the drilling process.
Conclusion: Battery-powered drilling causes a slight heating of the tissue not exceeding 1.4 degrees Celsius. Initial heating is limited mainly due to the heat-sink effect preventing from thermal damage of the bone probe.

The clinical impact of a novel low-dose protocol for minimal-invasive CT-guided musculoskeletal interventions

Z. Alagic, H. Alagic, R. Bujila, M.C. Wick; *Stockholm/SE (zlatan.alagic@sll.se)*

Purpose: CT-guided biopsies are important to establish the diagnoses of musculoskeletal lesions. They have a low morbidity and high cost-effectiveness but high levels of radiation. This prospective study compares our low-dose protocol for CT-guided musculoskeletal biopsies on a latest generation 16-cm detector 258-slice multi-detector CT (MDCT) scanner with advanced dose-reduction techniques to a protocol on a 64-slice MDCT scanner.
Methods and Materials: Between October 2016 and April 2017, 115 patients met the inclusion criteria and 58 of these underwent a CT-guided intervention utilising our novel low-dose protocol on a 258-slice MDCT (group A). The remainders underwent CT-guided intervention on a 64-slice MDCT without modern radiation-dose reduction (group B). Between-group comparisons comprised radiation dose, success rate, image quality parameters and workflow.
Results: In group A, the mean total DLP was 41.2±2.9 mGy*cm and statistically significantly lower than of group B (257.4±22.0 mGy*cm), corresponding to a mean dose reduction of 84% ($p<0.001$). For group A, the mean $CTDI_{vol}$ for the localizer scan was 1.34±0.08 mGy and for the puncture scan 1.88±0.09 mGy. Corresponding values for group B were 5.88±0.14 mGy and 13.16±0.40 mGy and statistically significantly higher than for group A ($p<0.001$, respectively). The success rate in group A was 91.2% and in group B 87.9% (p=N.S.). No negative effect on quantitative- and qualitative image-quality parameters, time of intervention and number of biopsy scans was found.
Conclusion: We developed and successfully utilised a low-dose protocol for CT-guided musculoskeletal biopsies on a 258-slice MDCT that markedly reduces the radiation dose without affecting success rate, image quality and workflow.

B-1342 11:27

MR-guided high-intensity focused ultrasound (MRgFUS) for the treatment of oligometastatic prostate cancer bone metastases: can sound waves downstage cancer spread?

C. Marrocchio, A. Napoli, R. Scipione, S. Dababou, H.-P. Erasmus, C. Catalano; *Rome/IT (cristinamarrocchio@gmail.com)*

Purpose: With improvements in diagnostic modalities such as functional imaging, oligometastatic prostate cancer is being diagnosed with greater frequency than ever before. Our aim was to determine MRgFUS ability to downstage patients with oligometastatic bone disease with a single session of non-invasive metastasis-directed therapy.
Methods and Materials: The study was designed with intention-to-treat metastatic bone lesions. Patients were enrolled if they had accessible bone metastasis and could safely undergo MRgFUS (InSightec, Israel). Baseline measurable characteristics included dynamic contrast-enhanced MRI study

(Gd-BOPTA, Bracco; GE 750 3T magnet) with semiquantitative perfusion analysis, PSA level (ng/ml) and choline PET (SUV). Measurable variables were obtained at treatment time, and 3 months, 12 months and 24 months follow-up.
Results: 18 patients fulfilled the inclusion criteria and safely underwent MRgFUS procedure of metastatic bone ablations. Lesions were located in the pelvis (11), scapula (3) and long bones (4). At baseline, all lesions showed a significant DCE perfusion (highly vascular) with a mean perfusion reduction of 88% at the 3 months follow-up (CI:100-50; p<0.001) and stable at subsequent follow-up scans. Similarly, PSA levels decreased from a mean baseline of 19 (ng/ml) to 7.1, 2.9 and 2.1, at 3-12 and 24 months, respectively. SUV values showed a similar trend with reduction from baseline (mean 8.9 to 3.0, 2.3 and 1.7; p<0.001). In all patients, a single MRgFUS session was appropriate without any major or minor adverse events reported.
Conclusion: MRgFUS is a totally non-invasive procedure that can obtain nearly complete bone ablation in patients with oligometastatic prostate disease. The technique features a radiation-free approach that can be of incremental value in the long-survivor subset of oncological patients, significantly reducing the risk of toxic effects.

B-1343 11:35

Focused ultrasounds for the treatment of bone metastases: efficacy and feasibility
A. Iannessi, A.-S. Bertrand, H. Beaumont, R. Natale, G. Baudin, A. Thyss; *Nice/FR (asbertrand3@hotmail.com)*

Purpose: To evaluate the efficacy and feasibility of high intensity focused ultrasounds (HIFU) for the treatment of bone metastases.
Methods and Materials: A single-centre prospective study involving 11 consecutive patients with symptomatic bone metastases were done (8 women, 3 men). Patients were treated by Focused Ultrasounds performed with MR-guidance applied to bone metastases. Surgical treatment or radiotherapy treatment were not indicated for the patients who underwent FUs. The lesions were located in the appendicular and axial skeleton, consisting of secondary symptomatic lesions resulting from metastatic disease. The clinical course of pain was evaluated using the Visual Analog Scale (VAS) before treatment, at one week, and one month after treatment. We used Wilcoxon signed rank test to assess change in patient's pain (R CRAN software V 3.1.1).
Results: Patient follow-ups in our series show supportive results: within 11 patients, 10 patients were satisfied with a long-lasting result after the procedure had been performed, and would recommend the intervention to relatives. The average evaluation of pain was 7.9/10 (SD: 1.3) before treatment, 2.8/10 (SD: 1.7) one week after treatment, and 2.3/10 (SD: 2.1) one month after treatment. Our results show a significant decrease of the pain felt by patients between -before procedure and one week after the procedure- (p= 0.003), -before procedure and one month after the procedure- (p=0.004).
Conclusion: HIFU under MR-guidance seems to be an effective and safe procedure in the treatment of symptomatic bone lesions for patients suffering from metastatic disease with a significant decrease of patient's pain.

B-1344 11:43

How to carry out follow-up studies in patients with osteoid osteoma treated with minimally invasive procedures (MRgFUS and RFA). Evaluation of imaging findings and clinical outcome
C. Giannneramo[1], S. Quarchioni[2], P. Palumbo[1], F. Arrigoni[1], S. Mariani[1], L. Zugaro[1], A. Barile[1], C. Masciocchi[1]; [1]*L'Aquila/IT*, [2]*Teramo/IT (camillagianneramo@gmail.com)*

Purpose: To evaluate the main diagnostic CT and MRI findings after treatment of osteoid osteoma (OO) with radiofrequency ablation (RFA) or MRgFUS, and their relationship with clinical outcome with a follow-up period that lasted up to 24 months
Methods and Materials: We retrospectively evaluated follow-up CT and MRI examinations of 35 patients treated with minimally invasive procedures (MRgFUS and RFA) (23 and 12 patients respectively).We analysed imaging findings that proved the good clinical outcome, in particular bone marrow oedema, perilesional flogistic reaction, disappearance of the nidus, "needle signs", periosteal reaction and "ring signs". We identified the follow-up period when this imaging signs disappeared, according to clinical improvement (evaluated by VAS score).
Results: Clinical improvement was exhibited by VAS reduction (from 8 to 1) after 6 months from treatment.Imaging analysis showed decrease of bone marrow oedema in 65% of patients and decrease of perilesional flogistic reaction in 50% of cases in the 6 months follow-up. After one year from treatment, resolution of bone marrow oedema and perilesional flogistic reaction, was observed in 86% and 70% of cases respectively. We also noted significant decrease of periosteal reaction in 60% of patients.Two-years control was important to evaluate the disappearance of the nidus (80% of cases).
Conclusion: According to our results, follow-up CT and MRI examinations after treatment of OO should be performed at 6, 12 and 24 months , since in this time we have statistically significant correlations between clinical outcome and variations in imaging findings.

B-1345 11:51

Ablation zones after radiofrequency ablation in 16 patients with atypical cartilaginous tumours
R. Rivas Loya, J. Overbosch, J. Kraeima, R.A.J.O. Dierckx, P.C. Jutte, P.M. Van Ooijen; *Groningen/NL (r.rivas.loya@umcg.nl)*

Purpose: Local bone tumour treatment using Radiofrequency Ablation (RFA) is increasing, but mostly clinical outcomes are reported. There is a lack of radiology data regarding ablation zones in bone, needed for reliable planning and predictability. The purpose is to report ablation zones in 16 RFA procedures in Atypical Cartilaginous Tumours (ACT).
Methods and Materials: A retrospective study of 16 patients with ACT in long bones underwent a single placement CT-guided temperature controlled RFA. Tumours <10 mm (n=1) were treated with 10 mm needles; tumours 10-20 mm (n=9) with 20 mm needles, and tumours 20-30 mm (n=6) with 30 mm needles. The ablation zone was measured three months later in a follow-up MRI scan.
Results: All ablations were successful and without complications. Mean total ablation time was 9.25 minutes (range 8-12 minutes), in which the tip of the needle was at 90°C for a mean time of 7.62 minutes (range 6-10 minutes). Mean ablation zone diameters and standard deviations (SD) were: 24 mm for 10 mm needles, 41.37 mm (range 35-48 mm and SD 3.9 mm) for 20 mm needles, and 46.66 (range 42-64 mm and SD 7.88 mm) for 30 mm needles.
Conclusion: Clinical success obtained reaffirm that RFA can be effectively performed in the treatment of ACT. Ablation zones are ellipsoids 10-20 mm larger than the tip of the needle, with a SD <10 mm. However, there were outliers. Thus, stressing the need for better real-time monitoring techniques and better planning to develop safe and effective bone tumour ablations.

High-resolution lung MRI: 1.5 or 3 Tesla?
G. Chassagnon[1], C. Martin[1], W. Ben Hassen[2], A. Stemmer[3], S. Bennani[1], M.-P. Revel-Dubois[1]; [1]*Paris/FR*, [2]*Saint-Denis/FR*, [3]*Erlangen/DE (gchassagnon@gmail.com)*

Purpose: To compare high-resolution lung MR images acquired at 1.5 and 3 Tesla.
Methods and Materials: 3D spiral VIBE sequences were performed in 10 healthy volunteers on a 1.5 Tesla unit with an isotropic resolution of 1.2 mm3 and then at 3 Tesla with isotropic resolutions of 1.0 and 1.2 mm3. Assessment of bronchi up to the subsegmental level and signal measurements were performed. Signal and contrast-to-noise ratios (SNR, CNR) were calculated. Images acquired with the 1.2 mm3 resolution at 1.5 and 3 Tesla were compared to assess the effect of the magnetic field strength on image quality. Images with 1mm3 and 1.2mm3 resolution acquired at 3 Tesla were also compared to assess the effect of image resolution. Comparisons were performed using paired t-tests.
Results: Mean acquisition and reconstruction times respectively ranged from 4.9 ±0.4 to 6.1 ±3.1 minutes and from 9.1 ±2.1 to 14.3 ±7.5 minutes. They were significantly longer for the 1mm3 resolution. Ninety-five to 99% and 33 to 45% of the segmental and subsegmental bronchi were detected, respectively. The number of visible subsegmental bronchi was significantly higher with the 1mm3 resolution (p=0.04) and significantly lower at 3 Tesla (p=0.04). Mean SNR and CNR ranged from 133 to 165% and from 5.7 to 9.6%, respectively. Both were significantly lower at 3 Tesla (p=0.016 and 0.003, respectively).
Conclusion: High-resolution lung MRI is feasible at 1.5 and 3 Tesla. However, bronchial visibility as well as SNR and CNR are significantly better at 1.5 Tesla.

Preliminary application of PETRA sequence in lung nodule screening
H. Feng; *Shijiazhuang/CN (helloth1984@163.com)*

Purpose: To assess lung MRI with a respiratory-gated pointwise encoding time reduction with radial acquisition (PETRA) sequence at 3T and compare it with computed tomography (CT) on the visibility of lung nodules.

Methods and Materials: Patients were imaged with PETRA sequence,T2-haste sequence,T2-blade sequence,T1-vibe and CT. Taking the image of CT as the gold standard, the total detectable rate of nodules, the detection rate of solid nodules, the detection rate of glass nodule and the difference of CNR and maximum diameter were compared. SPSS21.0 software was used for statistical analysis. Comparisons were made using the Wilcoxon-signed rank test for means and the McNemar test for ratios. Agreement between CT and MR imaging was assessed using the k test.
Results: Good agreement was found between CT and PETRA image (k = 1.0).Compared with other sequences, Petra sequence has a higher detection rate, the total detection rate is 85%, the detection rate of solid nodules, glass nodules and some solid nodules are 80%, 74% and 100%, respectively. For nodules with diameter greater than 5mm, the detection rate was 85%, and the CT value was higher than that of 600HU. The detection rate was 83%, and the nodules located in the middle and upper lung fields were better than those in the lower lung fields.
Conclusion: PETRA enables free-breathing and submillimeter imaging of lung nodules with high CNR and may be an alternative to CT for patients with lung nodules .
