(yosirad@kobe-u.ac.jp)

Purpose: To directly and prospectively compare the capability for diagnosis of pulmonary nodules between single- and multi-parametric approaches by chemical exchange saturation transfer (CEST) imaging, diffusion-weighted imaging (DWI), and FDG-PET/CT.
Methods and Materials: Fifty-six consecutive patients with 65 pulmonary nodules underwent CEST imaging and DWI at a 3T MR system, FDG-PET/CT, and pathological and/or follow-up examinations. According to final diagnoses, all lesions were divided into lung cancer (n=44) and benign nodule (n=21) groups. Then, magnetization transfer ratio asymmetry (MTR_{asym}) was calculated from z-spectra at 3.5ppm, ADC and SUV_{max} were assessed by ROI measurements. To compare each index between two groups, Student's t test was performed. Multivariate logistic regression analysis was performed to investigate the discriminating factors of malignant lesions from benign lesions. ROC analysis was performed to compare diagnostic performance among all methods. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's test.
Results: Mean MTR_{asym}, ADC and SUV_{max} of malignant group had significant difference with those of benign group ($p<0.05$). Multivariate regression analysis identified MTR_{asym} (odds ratio [OR]: 0.62), ADC (OR: 1.01) and SUV_{max} (OR: 0.15) as a significant differentiator of malignancy. ROC analysis showed area under the curve (Az) of multiparametric method (Az=0.96) was significantly larger than that of SUV_{max} (Az=0.84, $p<0.05$). Sensitivity and accuracy of multiparametric method were significantly higher than those of SUV_{max} ($p<0.05$).
Conclusion: Multiparametric approach by CEST imaging, DWI and PET/CT has a potential to improve diagnosis performance of PET/CT for diagnosis of pulmonary nodules.

Active surveillance of subsoil nodules detected by screening: safe strategy to reduce overtreatment

M. Silva[1], C. Jacobs[2], G. Capretti[1], F. Ciompi[2], B. Van Ginneken[2], C.M. Schaefer-Prokop[3,2], A. Marchianò[4], U. Pastorino[4], N. Sverzellati[1]; [1]*Parma/IT*, [2]*Nijmegen/NL*, [3]*Amersfoort/NL*, [4]*Milan/IT*
(mariosilvamed@gmail.com)

Purpose: Lung cancer derived from subsolid nodule (SSN) can show extremely slow growth rate having no impact on patient outcome. Active surveillance might reduce the rate of overtreatment. The aim of this study was to determine long-term evolution of SSN, survival and cause of death of screenees with SSN, in a large lung cancer screening trial.
Methods and Materials: SSNs underwent active surveillance by low-dose computed tomography. Risk of developing lung cancer, overall mortality, and mortality from lung cancer were calculated by Cox proportional hazards model. Rates of potential overdiagnosis and potential overtreatment were calculated according to the National Comprehensive Cancer network guidelines for lung cancer screening.
Results: SSNs were found in 16.9% (389/2,303) of screenees. During 9.3±1.2 years, the hazard ratio (HR) of developing any lung cancer in subjects with SSN was 6.77, with more cancers not derived from SSN. HR of overall mortality in screenees with SSN was 1.34 and HR of lung cancer mortality was 3.80; no death was associated with lung cancer derived from SSN. Potential overdiagnosis was seen in 28.5% (81/284) and potential overtreatment in 3.5% (10/284). Screenees with a high-risk SSN had an increased risk of lethal lung cancer not derived from SSN compared with screenees with low-intermediate risk (p=0.023).
Conclusion: Active surveillance of SSN does not increase risk of lung cancer mortality due to local progression of the lesion. Active surveillance by long-term annual low-dose computed tomography is a safe strategy to reduce overdiagnosis and overtreatment in lung cancer screening.

Lung cancer screening with MRI: characterisation of nodules with different non-enhanced MRI sequences

M. Meier-Schroers, R. Homsi, H. Schild, D. Thomas; *Bonn/DE*
(michael.meier@ukbonn.de)

Purpose: To analyse MRI characteristics of pulmonary nodules in lung cancer screening.
Methods and Materials: 82 participants of a lung cancer screening were included for this prospective study. MRI datasets of 32 subjects with 46 nodules ≥6 mm were prospectively evaluated together with 50 controls. Acquired MRI sequences were T2-STIR, T2, bSSFP, 3D-T1, and DWI. Each sequence was randomly and separately viewed blinded to low-dose CT (LDCT). Size, shape and contrast of nodules were evaluated on each sequence. Findings were correlated with LDCT and with histopathology if available.
Results: There were eight carcinomas with a size of 7-35 mm. Detection rates for malignant nodules were 100% for T2-STIR, T2 and bSSFP, and 87.5% for 3D-T1. Contrast was significantly higher for malignant nodules on all sequences. Seven of eight carcinomas showed restricted diffusion, positive predictive value of diffusion restriction as an indication of malignancy was 41.2%. Size measurement by MRI significantly correlated with LDCT. Sensitivity/specificity for nodules ≥6 mm was 89.1%/94.2% for T2-STIR, 87.0%/94.2% for T2, 69.9%/98.0% for bSSFP, and 67.4%/96.0% for 3D-T1. Seven of eight subsolid nodules were visible on T2-sequences with lesion contrast being significantly lower compared to solid nodules. Two of eight subsolid nodules were detected by bSFFP and none by 3D-T1. All three calcified nodules were detected by 3D-T1, one by bSSFP, and none by T2-sequences.
Conclusion: Malignant nodules, as well as calcified and subsolid nodules seem to have distinctive characteristics on different MRI sequences. T2-imaging was most suitable for the detection of pulmonary nodules ≥6 mm.

B-1351 11:10

Variation of tube electric current (mA) in lung CT screening for glass ground nodules (GGNs) bigger than 3 mm: phantom study

L. Jin; *Shanghai/CN (BrightDK@126.com)*

Purpose: To explore and assess the feasibility analysis and evaluation for lung mini-nodule thorax CT screening.
Methods and Materials: Two kinds of lung nodules with different distance (3mm, 5mm) and density (-630HU, -800HU), totally four nodules, were randomly placed in phantom. The phantom was scanned under different mA and KV setting by both Lightspeed VCT and Discovery HD750. All the images were scored by 2 experienced radiologists including detection and diagnosis of the lung nodules and image quality. The differences of the inter-observer were determined by kappa statistics.
Results: There was perfect concordance of inter-observers in image quality and diagnostic acceptability (kappa=0.819, kappa=0.847). There was no statistical difference in CT value of the air (P=0.056>0.05). For (3mm, -630HU), under HDCT (120KV, 20mA) for detection, the lowest ED was 0.6mSv; for (120 KV, 40mA) the lowest ED was 1.21mSv; under VCT (120KV, 80mA), the lowest ED was 1.19mSv; for (120 KV, 160 mA), the lowest ED was 3.57mSv. For (3mm, -800HU), under HDCT (80KV, 120mA), the lowest ED was 1.22mSv; for (80 KV, 280mA), the lowest ED was 2.84mSv; under VCT (120KV, 120mA), the lowest ED was 2.37mSv; for (120 KV, 240mA), the lowest ED was 5.95mSv.
Conclusion: In this phantom study, using (120KV, 20mA, HDCT) scanning parameters could be satisfied with the detection for (3mm, -630HU) or over (5mm) lung mini-nodule, but if involving differential diagnosis, the lowest

scanning parameters could be (120KV, 40mA, HDCT). For (3mm, -800HU), detection scanning parameters could be (80KV, 120mA, HDCT), diagnosis scanning parameters could be (80 KV, 280 mA, HDCT).

B-1352 11:18

Semiquantitative visual assessment of sub-solid pulmonary nodules ≦ 3 cm in differentiation of lung adenocarcinoma spectrum

F.-Z. Wu; *Kaohsiung/TW (cmvwu1029@gmail.com)*

Purpose: We aimed to analyze the CT features of persistent subsolid nodules (SSN) ≦ 3 cm diagnosed pathologically as adenocarcinoma spectrum to investigate whether parameters enable distinction between invasive and preinvasive lesions.
Methods and Materials: A total of 129 patients with 141 SSNs confirmed with surgically pathologic proof were retrospectively reviewed. SSNs were classified into three categories: pure ground-glass nodules (pure GGNs), heterogeneous GGNs, and part-solid nodules. Of 141 SSNs, there were 57 pure GGNs, 22 heterogeneous GGNs, and 62 part-solid nodules.
Results: SSN subclassification showed a significant linear trend with the invasive degree of the adenocarcinoma spectrum (pure GGNs 7%; heterogeneous GGNs 36.4%; part-solid nodules 85.5%, *P* for trend <0.0001). For invasive lesions detection in 141 SSNs, a solid part of ≧ 3 mm was the most specificity (sensitivity, 76.9%; specificity, 94.7%), followed by air-bronchogram sign (sensitivity, 53.8%; specificity, 89.5%), SSN subclassification (sensitivity, 81.5%; specificity, 88.2%), and a lesion size ≧ 12 mm (sensitivity, 84.6%; specificity, 76.3%). For invasive lesion detection in 79 pure or heterogeneous GGNs, the heterogeneous GGN sign was the most useful finding, with most specificity (sensitivity, 66.7%; specificity, 79.1%), followed by CT attenuation (HU) of ≧ -493 (sensitivity, 75%; specificity, 74.6%) and a lesion size ≧ 10 mm (sensitivity, 83.3%; specificity, 70.1%).
Conclusion: In conclusion, this simple combined visual and semiquantitative analysis of CT features helps distinguish invasive from preinvasive lesions.

B-1353 11:26

Analysis of pulmonary fibrosis, using an elastic registration technique in a model of fibrosis: systemic sclerosis

C. Martin[1], G. Chassagnon[1], R. Marini[2], A. Regent[1], L. Mouthon[1], N. Paragios[2], M.-P. Revel[1]; [1]*Paris/FR*, [2]*Gif-sur-Yvette/FR (chachmartin@hotmail.com)*

Purpose: To evaluate the feasibility of pulmonary fibrosis detection in scleroderma patients by using magnetic resonance imaging (MRI) and an elastic registration algorithm.
Methods and Materials: Full inspiratory and expiratory spiral VIBE (Volume Interpolated Breath-hold Examination) sequences were performed on a 3T-MRI unit. Depending on High Resolution Computed Tomography results, 3 patient groups were considered: no infiltrative lung disease (ILD), ILD without fibrosis and ILD with fibrosis. A control group of healthy volunteers was also evaluated. An elastic registration algorithm was applied to all examinations in order to get Jacobian maps for each subject. Regions with the most important volume changes between inspiration and expiration were compared in the 3 patient groups and healthy volunteers, using Dice coefficients. Pearson correlation coefficient was calculated between Dice coefficient and Forced Vital Capacity (FVC).
Results: 33 subjects were prospectively evaluated. Jacobian distributions were visually different between subjects with and without ILD. ROC curves analysis was performed for the whole cohort and for a subgroup composed by healthy volunteers and fibrotic patients. The best Dice coefficient cut-off value was 0.44 for both analysis, with sensitivities of 92% and 86% and specificities of 75% and 100% for the presence of fibrosis, respectively. No significant correlation was found between Dice coefficient and FVC (R= 0.12, p=0.6).
Conclusion: Elastic registration of inspiratory and expiratory MR images shows significant differences between subjects with and without ILD. High specificity for the presence of fibrotic changes is reported even though no correlation was found with FVC, in this preliminary study.

Finding the right spot: where to measure airway parameters in patients with COPD?

J.F.M. Gawlitza, A.M. Fischer, I. Akin, M. Borggrefe, S.O. Schönberg, H. Haubenreisser, T. Henzler, F. Trinkmann; *Mannheim/DE (joshua_gawlitza@yahoo.de)*

Purpose: The importance of spirometry for diagnosing and treating COPD was reduced in the 2017 revision of the GOLD report. While spirometry does not reflect the complexity of the disease, quantified computed tomography (qCT) may gain further relevance. Airway measurements show strong correlations with lung function tests and symptoms. However, these correlations are specific to the airway localization, and currently there is no evidence for the ideal spot. Therefore, the aim of this prospective study was to systematically correlate airway measurements with extensive lung function testing.
Methods and Materials: 65 patients with diagnosed COPD underwent body plethysmography, impulse oscillometry and dose-optimized qCT examination (Somatom Force, Healthineers, Germany) in inspiration and expiration. Eight airway parameters were acquired for both scans in every lobe for the third- to fifth-generation bronchus and correlated with the lung function tests.
Results: The most significant correlations between airway parameters were found for the third-generation bronchus of the upper left lobe during expiration (25 out of 48 correlation pairs, mean r = -0.39) and for the third-generation bronchus of the upper right lobe during inspiration (9 out of 48 correlation pairs, mean r = -0.25). No significant correlations were for example found for the upper right lobe in expiration.
Conclusion: Correlations between airway parameters and lung function tests vary widely between lobes, bronchus generations and breathing states. Our work suggests that the third-generation bronchus of the upper left lobe in expiration could be the preferred localization for airway quantification in future studies.

B-1355 11:42

Prospective quantification of respiratory mechanics in COPD patients before and after lung volume reduction surgery on dynamic MRI

K. Martini, C. Caviezel, G. Milanese, W. Weder, T. Frauenfelder; *Zurich/CH*

Purpose: To prospectively evaluate respiratory mechanics in chronic obstructive pulmonary disease (COPD) patients pre- and post-lung volume reduction surgery (LVRS) on dynamic magnetic resonance imaging (MRI).
Methods and Materials: 24 patients (11 female, median age 63y) suffering from COPD and scheduled for LVRS were included. MRI was performed on a 3T MR-scanner and dynamic sequences of the lung were acquired in a sagittal plane during two breath-cycles for both lungs the day before and 3 months after LVRS, herein termed as pre- and post-LVRS-MRI. Quantitative measurements were performed on sagittal planes for left and right lung in pre- and post-LVRS-MRI: lung height, anteroposterior (AP) diameter, hemidiaphragm height and lung area as well as hemidiaphragm area were measured. Additionally, lung areas during one breath cycle were measured. Student's t test was used to test for statistically significant differences between pre- and post-LVRS-MRIs. A p value<0.05 was considered as statistically significant.
Results: In expiration, mean lung and hemidiaphragmatic area on both sides (p_{right}=0.002 and p_{left}=0.043) as well AP diameter of both lungs (p_{right}=0.003 and p_{left}<0.001) improved significantly in patients undergoing LVRS. Dynamic measurements showed significant differences pre- and post-LVRS on the right lung, but not on the left (p_{right}=0.032 and p_{left}=0.606). There were no significant changes in lung and hemidiaphragmatic high pre- and post-LVRS. Additionally, there was no difference of the measured variables in inspiration.
Conclusion: By increasing the elastic recoil of the lung LVRS improves significantly impaired respiratory mechanics caused by increased airflow resistance and reduces pulmonary compliance in patients with COPD.

B-1356 11:50

MR-based lung volume segmentation in population-based whole-body MR imaging: correlation with clinical characteristics, pulmonary function testing and obstructive lung disease

J. Mueller[1], R. Lorbeer[2], R. von Krüchten[1], A. Pomschar[3], H.-U. Kauczor[1], F. Bamberg[4], H. Schulz[5], S. Karrasch[5], C.L. Schlett[1]; [1]*Heidelberg/DE*, [2]*Munich/DE*, [3]*München/DE*, [4]*Tuebingen/DE*, [5]*Neuherberg/DE (Ricarda.vonKruechten@med.uni-heidelberg.de)*

Purpose: Whole-body magnetic resonance imaging (MRI) is increasingly performed as part of clinical service and research. The value of lung volume derived from non-dedicated MRI sequences is unknown.
Methods and Materials: As part of a population-based KORA FF4 study, 400 subjects aged 56.4 (±9.2) years underwent whole-body MRI. Lung volumes were derived semi-automated and related to common predictors, pulmonary function tests (PFT, available in n=214) and obstructive lung disease (FEV1/FVC<70% or self-reported physician diagnosis of COPD/emphysema).
Results: The average MRI-based lung volume (MRLV) was 4.0±1.1L, which was 64.8±14.9% of the predicted total lung capacity (TLC) and 124.4±27.9% of the predicted functional residual capacity. In multivariate analysis, MRLV was positively associated with age, male gender, current smoking, and height. Among PFT indices, MRLV correlated best with TLC, alveolar volume (VA), and residual volume (RV; r=0.57 each), while it was negatively correlated to FEV1/FVC (r=-0.36) and lung diffusing capacity (TLCO/VA; r=-0.16). Combining the most strongly associated PFT parameters in a multivariate model, RV and FEV1/FVC remained independently associated with MRLV (β=0.50, p=0.04, and β=-0.02, p=0.02, respectively) explaining up to 45% of the variability of the MRI data. In subjects with obstructive lung disease, higher MRLVs were observed yielding an AUC of 0.673 for a FEV1/FVC below 0.7 and of 0.654 for a diagnosis of COPD/emphysema.

Conclusion: Lung volumes derived from non-dedicated whole-body MRI were independently associated with RV and FEV1/FVC after accounting for well-known predictors and typical risk factors of respiratory function and show moderate accuracy for detection of obstructive lung disease.

Learning the language of PI-RADS version 2: correlation between prostate MRI lexicon terms and malignancy
M. Rudolph, A. Baur, M. Haas, S. Mahjoub, H. Cash, P. Asbach, B. Hamm, T. Penzkofer; *Berlin/DE*

Purpose: To assess the value of PI-RADS 2 lexicon terms for predicting prostate cancer using lesion shape, border and diffusion characteristics.
Methods and Materials: Prostate lesions of 160 patients that received multiparametric prostate MRI and subsequent MRI/TRUS-biopsy including systematic biopsy were examined in a blinded and randomized setting by two experienced radiologists. Every lesion was examined with regard to imaging characteristics as defined by PI-RADS v2 lexicon terms. The histopathological result of the respective lesion was correlated to the assigned morphological features and positive and negative predictive values (PPV and NPV) were calculated.
Results: 174 lesions were identified of which 102 (58.6%) were histopathologically confirmed malignant. Predictive values of lexicon terms describing lesion characteristics were reported as follows (PPV/NPV): “restricted diffusion” (76%/74%), “DWI hyperintensity” (80%/86%), “ADC hypointense” (74%/90%), “round” (53%/40%), “oval” (66%/43%), “lenticular” (83%/43%), “lobulated” (71%/43%), “water drop shaped” (91%/44%), “wedge shaped” (29%/37%), “linear” (7%/37%), “irregular shape” (63%/43%), “circumscribed” (57%/40%), “non-circumscribed” (83%/43%), “indistinct” (63%/42%), “obscured” (85%/49%), “irregular border” (71%/43%), “spiculated” (100%/42%), “encapsulated” (12%/36%), “organized chaos” (31%/30%), “erased charcoal sign” (86%/45%).
Conclusion: Out of 20 examined PI-RADS lexicon items, the terms associated with restricted diffusion had a favorable combination of both high PPV and NPV to correctly predict and exclude malignant lesions. The shape and border terms associated with inflammation or BPH “wedge shaped”, “linear”, “encapsulated” and “organized chaos” showed a potential to predict benign lesions with low PPV/NPV. The remaining lexicon terms had mediocre predictive values indicating potential for refinement in further iterations of the PI-RADS lexicon.

Diagnostic performance of PI-RADS version 2 in detecting prostate cancer using whole-mount histology after radical prostatectomy as the standard of reference
R. Girometti[1], S. Bednarova[1], S. Sioletic[1], V. Ficarra[2], F. Greco[1], A. Crestani[1], C. Zuiani[1]; [1]*Udine/IT*, [2]*Messina/IT (rgirometti@sirm.org)*

Purpose: To assess the accuracy of prostate imaging reporting and data system version 2 (PI-RADS v2) in detecting prostate cancer (PCa) on multiparametric magnetic resonance imaging (mpMRI).
Methods and Materials: During May 2016-February 2017 we prospectively included patients with PCa undergoing staging 3.0T mpMRI before radical prostatectomy. One experienced pathologist performed whole-mount histology on prostate specimens. mpMRI images were analysed independently by three radiologists (2-8 years of experience) who detected, mapped and scored imaging findings following PI-RADS v2. After an mpMRI-to-whole-mount histology matching, we calculated sensitivity and specificity in detecting PCa and clinical significant PCa (csPCa) using PI-RADS ≥3 and ≥4 thresholds. Inter-reader agreement in attributing the PI-RADS score was calculated with Cohen’s weighted-kappa statistic.
Results: Included were forty-eight patients (median iPSA 7.2 ng/ml) with 71 cancers on final histology (median size 16 mm, median Gleason score 6, stage ≥T3 in 19/48 cases). On a per-lesion basis, sensitivity was slightly higher with PI-RADS ≥3 vs. ≥4 threshold (range 0.55-0.62 vs. 0.48-0.60 for all PCas, and 0.67-0.74 vs. 0.61-0.72 for csPCas, respectively), at expenses of lower specificity (range 0.11-0.30 vs. 0.56-0.71 for all PCas, and 0.28-0.30 vs. 0.55-0.71 for csPCas, respectively). Accuracy improved on a per-patient basis, with 0.64-0.77 sensitivity and 0.73-0.83 specificity for csPCa with a PI-RADS ≥4 threshold. Inter-reader agreement was moderate to substantial (k=0.47-0.72 vs. 0.51-0.71 for PI-RADs thresholds ≥3 and ≥4, respectively).
Conclusion: PI-RADS v2 showed good diagnostic performance in detecting PCa, with acceptable inter-reader agreement. PI-RADS ≥4 threshold offered a better balance between sensitivity and specificity.

B-1359 10:55

Diagnostic yield of prostate biopsies and PI RADS version 2 scoring of MRI prostates
G. Chilvers, U. Udeshi; *Worcester/UK (geoffreyschilvers@gmail.com)*

Purpose: Current literature assessing the accuracy of PI-RADS v2 scoring of MRI prostates demonstrates variable outcomes. This study investigates this further with the largest reported population to date. We also determine if the addition of cognitive targeted biopsies to systematic biopsies of the prostate improves diagnostic yield for prostate cancer.
Methods and Materials: A retrospective study was performed comparing all prostate biopsy results in 2016 with PI-RADS v2 score on the pre-biopsy MRI. Two populations were identified: those with PI-RADS v2 score of 4 or 5 (significant cancer identified) and those with PI-RADS v2 score of 1, 2 or 3. A significant cancer was defined histologically as a Gleason score ≥7. The histology results were analysed to determine whether the diagnosis of prostate cancer was made via systematic biopsies or cognitively targeted biopsies.
Results: 464 patients were included. 166 scored PI-RADS 4 or 5. 63% of these had histologically proven significant cancer, whilst 90% of 298 patients scored 1, 2 or 3 had no histologically proven significant cancer. Overall, sensitivity 77%, specificity 81%, positive predictive value 63% and negative predictive value 90%. 49.4% of systematic prostate biopsies demonstrated prostate cancer, whilst 51.1% of systematic plus cognitively targeted prostate biopsies demonstrated prostate cancer.
Conclusion: This study demonstrates that PI-RADS v2 scoring can help identify which patients require further investigation with prostate biopsy. PI-RADS v2 scores of 1, 2 or 3 correlate well with histologically non-significant biopsy results. Cognitively targeted biopsies in addition to systematic prostate biopsies slightly improve the diagnostic yield for prostate cancer.

B-1360 11:03

Clinical value of the PIRADS score in predicting benign and malignant conditions at MRI-guided prostate biopsy: a correlation of 54 patients with suspicion of prostate cancer
K. Engelhard, K. Bogner, F. Schneider; *Nürnberg/DE (karl.engelhard@martha-maria.de)*

Purpose: To evaluate the sensitivity and positive predictive value of the PIRADS score 4 and 5 (version 2) in determining positive histological tumour results and the impact of PIRADS score 3 score in differentiating these nondistinctive lesions as benign or malignant at MRI-guided prostate biopsy in patients with the suspicion of prostate cancer.
Methods and Materials: 54 patients with an elevated PSA value >4 ng/ml and a cancer suspicious region in multiparametric MRI underwent MRI-guided biopsy in a standard 1.5T magnet. 34 men were biopsy naïve, 20 patients had prior tumour-negative biopsies. A mean of 2.2 cores were taken from each tumour-suspected lesion. The PIRADS scores of the tumour-suspected lesions were compared with the histological results of the biopsy.
Results: Applying the PIRADS system 54% of cancers were detected by MRI-guided biopsy with a rate of 90% significant tumours. The sensitivity of PIRADS score 4, 5 was 90%, by a positive predictive value of 70%. In 25 men with PIRADS score 3 no cancerous tissue was found at histology. In one of these lesions a high-grade PIN was detected.
Conclusion: In this study the PIRADS score system was highly sensitive and shows a fair positive predictive value in detecting significant prostate cancers at MRI-guided biopsy. Including PIRADS 3 lesions into the biopsy procedure in our population the score can be helpful as a predictive tool in the estimating whether a PIRADS 3 lesion should undergo a targeted biopsy.

B-1361 11:11

Audit of diagnostic yields of prostate cancer in biopsy naive patients at high risk of cancer on the London Cancer Alliance Best Practice Prostate Pathway (LCABPPP)

H.K. Sokhi[1], S. Patel[1], A. Padhani[2], A. Pope[1]; [1]*London/UK*, [2]*Northwood/UK*

Purpose: To document multiparametric MRI (mpMRI) diagnostic yields of the 2013 LCABPPP involving pre-biopsy mpMRI followed by TRUS biopsies in patients at higher risk of prostate cancer (PCa).
Methods and Materials: 214 pre-biopsy PI-RADS compliant mpMRI studies performed between April 2014 & April 2017. 195 (91%) patients had PSA >10ng/mL and/or abnormal digital rectal examination. 180 scans evaluated with the PI-RADS scoring systems. mpMRI findings were correlated with TRUS +/- targeted biopsy histology.
Results: Prevalence of all PCa and clinically significant cancer (csPCa: Gleason>3+3) was 72% and 58% respectively in 199 of 214 patients. Of 180 PI-RADS assessed mpMRIs, 121 contained focal index lesions (PI-RADS 3-5); 33 demonstrated non-measurable extensive/diffuse changes (PI-RADS 3-5); 26 were negative (PI-RADS 1-2). Overall diagnostic yield of all PCa and csPCa was 4/26 (15%) & 1/26 (4%) for PI-RADS 1/2; 6/19 (32%) & 3/19 (16%) for PI-RADS 3; 20/27 (74%) & 14/27 (52%) for PI-RADS 4 and 102/108 (94%) & 87/108 (81%) for PI-RADS 5 categories respectively. Rule out ability (Sen 99%, NPV 96%, LR-ve 0.03) was better than rule in performance (Spec 33%, PPV 68%, LR+ve 1.49) for csPCa.
Conclusion: There is a high prevalence of positive mpMRI (PI-RADS 3-5) in higher risk biopsy naïve patients. Positive mpMRI (PIRADS 3-5) is associated with all PCa and csPCa detection rate of 83% & 68% respectively using TRUS +/- targeted biopsy. Systematic TRUS biopsy has negligible yields in mpMRI negative patients.

B-1362 11:19

PI-RADS version 2-based assessment of prostate in patients with borderline-elevated prostate-specific antigen levels: a prospective study

A. Yadav, M. Bagarhatta, U. Jaipal; *Jaipur/IN (arushiy403@gmail.com)*

Purpose: To predict clinically significant prostate cancer (CSPca) in patients with borderline-elevated prostate-specific antigen (PSA) levels.
Methods and Materials: Fifty patients with PSA levels of 4-10 ng/ml were prospectively evaluated by 3.0 T multiparametric MRI (mp-MRI). Evaluation was done by 2 independent radiologists using PI-RADS v2 scoring system. Region-based analysis with sectoral mapping followed by 12 core systematic biopsy was done. CSPca was defined as Gleason score ≥ 3+4 or tumour volume ≥ 0.5 ml. Histopathology by expert uropathologist was considered gold standard. Statistical analysis was done with SPSS 20 and diagnostic accuracy was calculated separately for PI-RADS score 3 and 4 as cutoff. Youden index was used for best diagnostic cutoff. Kappa test was used for diagnostic concordance among radiologists.
Results: 95% cores of biopsy specimen were reported satisfactory. Mean age was 62 ± 1 years, with mean PSA of 7.86 ± 2.79 ng/ml. The diagnostic accuracy (95% CI) of PI-RADS v2 with score of 3 as cutoff in diagnosing CSPca was: sensitivity, 0.93 (0.77-0.99); specificity, 0.94 (0.92-0.96); LR+, 17.40 (12.05-25.13); LR-, 0.07 (0.02-0.28), respectively. The PPV were from 0.39 to 0.57 and NPV from 0.98 to 0.99. ROC curve showed a score of 3 as the best diagnostic cutoff (AUC - 0.949). The diagnostic concordance among two radiologists was good (kappa=0.719).
Conclusion: PI-RADS v2 has very high NPV in predicting CSPca in patients with borderline PSA, reducing the number of useless biopsy and morbidity. A score of 3 seems to be the best cutoff to diagnose CSPca.

B-1363 11:27

When does biopsy make sense in patients with an overall PI-RADS score of 3?

T. Ullrich, L. Schimmöller, M. Quentin, N. Laqua, D. Blondin, C. Arsov, R. Rabenalt, P. Albers, G. Antoch; *Düsseldorf/DE (Tim.Ullrich@med.uni-duesseldorf.de)*

Purpose: To systematically analyse patients with 'equivocal' (PI-RADS-3) lesions in multiparametric prostate MRI (mp-MRI) and MR-targeted plus systematic transrectal ultrasound-guided (TRUS-GB) biopsies as reference standard and define conditions under which biopsy is recommended.
Methods and Materials: One hundred and twenty consecutive patients with a PI-RADS overall score of 3 after mp-MRI (T2WI, DWI, DCE-MRI) at 3T and subsequent targeted MRI/US fusion-guided (FUS-GB) plus systematic 12-core TRUS-GB were retrospectively included in this study. Endpoints were prostate cancer (PCa) detection rates, distribution of Gleason scores and location of PCa.
Results: PCa was detected in 13 of 118 patients (detection rate 11%) including five patients with a Gleason score (GS) of ≥3+4=7 (4.2%). 1.4% (3/212) of the transitional lesions and 9.4% (6/64) of the peripheral zone lesions were positive for PCa. 54% of the PCa patients showed MRI patterns of peripheral prostatitis combined with diffuse stromal hyperplasia. Prostate volume was significantly lower in PCa patients (p=0.015), whereas differences in PSA levels were not statistically significant (p=0.87). PSA density (PSAD) was higher in patients with PCa (0.19 vs 0.12ng/ml/ml).
Conclusion: In patients with PI-RADS overall score of 3 low-grade PCa (GS 3+3=6) can occur. PCa with a GS ≥3+4=7 can reliably be detected in mp-MRI. GS ≥4+3=7 PCa is very unlikely in PI-RADS-3-lesions. Therefore, these patients primarily should receive follow-up MRI. In patients with a combination of MRI aspects of extensive prostatitis and diffuse stromal hyperplasia, low prostate volume, and high PSA density a combination of targeted and systematic biopsy might be considered.

B-1364 11:35

How to prevent patients with a false-positive overall score of PI-RADS 4

T. Ullrich, L. Schimmöller, M. Quentin, N. Laqua, F. Dietzel, C. Arsov, R. Rabenalt, P. Albers, G. Antoch; *Düsseldorf/DE (Tim.Ullrich@med.uni-duesseldorf.de)*

Purpose: To characterize patients with an overall PI-RADS score of 4 in mp-MRI of the prostate and negative histology after combined targeted and systematic biopsy in a large cohort based on clinical conditions and PI-RADS decision rules.
Methods and Materials: 170 consecutive patients with a PI-RADS v2 overall score of 4 after multi-parametric MRI (T2WI, DWI, DCE) at 3T and subsequent targeted MR/US fusion-guided plus systematic transrectal ultrasound-guided biopsy were retrospectively included in this study. Endpoints were detection rates and subgroup analyses.
Results: PCa detection rate was 62% (106/170) including 87 patients (51%) with a Gleason score (GS) of ≥3+4=7 (csPCA). PSA density (PSAD) was significantly higher in PCa patients (0.22±0.12ng/ml/ml; p<0.01). 135/287 (47%) index lesions in the peripheral zone (PZ) were positive for PCa whereas 28/143 (20%) transitional lesions revealed PCa. 58/107 (54%) PZ lesions with PI-RADS single score of 3 in DWI and upgrade to overall PI-RADS 4 due to positive DCE contained PCa. 4/10 (40%) transitional lesions with upgrade to overall PI-RADS 4 due to positive DWI (score 4 or 5) contained PCa.
Conclusion: Patients with an overall PI-RADS score of 4 possess a high likelihood of PCa/csPCa and index lesions need (additional) targeted biopsy. In case of negative histology results, targeted re-biopsy should be considered in patients with high PSAD and index lesion located in the PZ. Existing PI-RADS decision rules for upgrading lesions from 3 to 4 reveal PCa in many cases. DCE is essential not to miss significant PCa, especially in the peripheral zone.

B-1365 11:43

Is it possible to reduce the number of false positive cases of PI-RADS v.2 classification? Role of quantitative analysis of DCE-MRI in prostate lesions' characterisation

G. Cristel, A. Esposito, A. Damascelli, S. Antunes, G. Brembilla, A. Briganti, A. Del Maschio, F. De Cobelli; *Milan/IT (cristel.giulia@hsr.it)*

Purpose: To test the potential impact of pharmacokinetic dynamic contrast-enhanced MRI parameters on the multiparametric MRI (mpMRI) diagnostic performance, using PI-RADSv.2 as standard of reference.
Methods and Materials: From our Data-Base of 666 prostate mpMRI (1.5T) acquired between January 2016 and July 2017, we retrospectively evaluated a group of 103 patients, with available corresponding histological specimen obtained through target biopsies. Perfusion study included multiple flip-angle T1W-images (5°,8°,12°,15°) for T1-mapping and contrast enhanced 3D-FFE-T1W sequence. Images were evaluated using PI-RADS score v.2 and pharmacokinetic parameters (Ktrans, Kep, Ve, Vp) were calculated with commercially available permeability software (population-based AIF). We evaluated the diagnostic performance of MRI for Gleason Score (GS)>=7 tumours, considering PI-RADS>=3 as pathological.
Results: The 103 lesions were classified as follow: 8 PI-RADS2, 23 PI-RADS3, 57 PI-RADS4 and 15 PI-RADS5. 59 lesions presented GS≥7 at histological evaluation. Sensitivity and PPV of mpMRI using PI-RADSv.2, were 98% and 61%, respectively. GS≥7 lesions showed higher Ktrans (p<0.01) and Kep (p=0.01) compared to GS<7. ROC curve analysis was used to identify a Ktrans cut-off value of 191×10^{-3}/min (AUC 0.75) that predicted the presence of GS≥7 with sensitivity of 95% and specificity of 61%. Considering only PI-RADS≥3 lesions, the application of Ktrans cut-off shifted 22 false positives to true negatives with 3 false negative findings, resulting in an increase of PPV (79%) without a significant drop of sensitivity (93%,p=0.25).
Conclusion: DCE-MRI pharmacokinetic parameters, especially Ktrans, may improve PI-RADSv.2 diagnostic performance and its capability in prostate lesions' characterisation, decreasing the number of false positive results.

B-1366 11:51

Chronic prostatitis: distinction from prostate cancer and benign prostatic hyperplasia by means of PIRADS version-2 descriptors

U.G. Mueller-Lisse[1], M. Kuhn[1], M. Scherr[2], U.L. Mueller-Lisse[1], S. Murer[1], M.F. Reiser[1], J. Scheidler[1]; [1]*Munich/DE*, [2]*Murnau a. Staffelsee/DE (ullrich.mueller-lisse@med.uni-muenchen.de)*

Purpose: Chronic prostatitis (CP) is common and potentially difficult to distinguish from both benign prostatic hyperplasia (BPH) and prostate cancer (PCA) in mpMRI of the prostate. We hypothesized that prostate imaging reporting and data system-version-2 (PIRADSv2) descriptors for T2-weighted magnetic resonance imaging (T2WI) and diffusion-weighted magnetic resonance imaging (DWI) would not distinguish CP from BPH or PCA.
Methods and Materials: With ethics committee approval, consecutive 3.0T-multi-channel surface coil mpMRIs of 19 CP patients (previous clinical and MRI diagnosis, negative prostate biopsy, NBX), 17 BPH patients (NBX), and 16 patients with high-grade PCA (biopsy Gleason scores 4+3 to 4+5, n=7) or low-grade PCA (biopsy Gleason scores 3+3 and 3+4, n=9) were independently scored by two blinded observers (O1, O2) applying respective PIRADSv2 descriptors for T2WI and DWI. Two-tailed Fisher's exact tests assessed scoring contingency tables and two-tailed Student's T tests potential confounders (significance, $p<0.05$).
Results: Both observers distinguished BPH and high-grade-PCA. Despite significant statistical differences, PIRADSv2 scores implying malignancy overlapped between CP patients versus low-grade PCA patients in T2WI (O1: 1/19 versus 5/9; O2: 4/19 versus 6/9), standard pelvic DWI (O1: 0/19 versus 3/9; O2: 3/19 versus 5/9), and optimized DWI zoomed to the prostate (O1: 0/19 versus 4/9; O2: 4/19 versus 6/9), respectively. Between CP and low-grade PCA, prostate-specific antigen levels (PSA, 9.4±2.6 versus 8.4±5.2 ng/ml), PSA density (0.13±0.06 versus 0.17±0.10 ng/ml/ccm), and age (64±7 versus 65±9 years) did not differ significantly, while prostate volume differed (88.9±60.2 versus 48.4±10.0 ccm, $p=0.01$).
Conclusion: PIRADSv2 descriptors for T2WI and DWI of PIRADSv2 peripheral or central zone regions appear to overlap between CP and low-grade PCA.

Whole-body tumour staging of cervical cancer patients using 18F-FDG PET/MRI: does it change therapeutic decisions when compared to MRI alone?

J. Grueneisen[1], T. Sarabhai[1], B.M. Schaarschmidt[2], A. Wetter[1], M. Forsting[1], K. Herrmann[1], L. Umutlu[1]; [1]*Essen/DE*, [2]*Dusseldorf/DE (johannes.grueneisen@uk-essen.de)*

Purpose: To investigate whether differences in local and whole-body tumour staging between integrated PET/MRI and MRI alone lead to different therapeutic decisions in patients with primary cervical cancer.
Methods and Materials: 53 consecutive patients with a primary cervical cancer were prospectively enrolled for a whole-body 18F-FDG PET/MRI examination. A radiologist and nuclear medicine physician analysed the MRI data, in consensus, followed by a second reading session of the PET/MR datasets. The readers were asked to perform a dedicated TNM staging (7th edition of the AJCC staging manual). Subsequently, the results of MRI and PET/MRI were discussed in a simulated interdisciplinary tumour board and therapeutic decisions based on both imaging modalities were recorded.
Results: Staging results of MRI and PET/MRI revealed discrepant findings in 17/53 (32%) cases, which led to differences in treatment recommendations for 11 patients (21%). PET/MRI over- (n=1) and underestimated (n=1) the actual tumour stage in two patients, which affected therapy decisions. Conversely, MR readings led to incorrect staging results in 9 patients (n=3, upstaging; n=6 downstaging). PET/MRI enabled determination of the correct tumour stage in 7 of those 9 patients. In the two other cases, false ratings in PET/MRI did not result in changes in therapy management. In the remaining 6 patients (11%), different imaging findings in MRI and PET/MRI did not lead to changes in therapeutic decisions.
Conclusion: Our results demonstrate the successful application and diagnostic advantage of integrated PET/MRI imaging over MRI alone for whole-body tumour staging of cervical cancer patients, enabling more accurate treatment planning.

B-1368 10:38

The prognostic value of pre-treatment FDG-PET/CT metabolic parameters in cervical cancer patients

V. Bollineni[1,2], S. Ytre-Hauge[2], A. Gulati[2], M. Halle[2], K. Woie[2], Ø. Salvesen[3], C. Krakstad[2], J. Trovik[2], I. Haldorsen[2]; [1]*Brussels/BE*, [2]*Bergen/NO*, [3]*Trondheim/NO (bollinenivr@yahoo.com)*

Purpose: To explore quantitative metabolic and microstructural primary tumour parameters at pre-treatment FDG-PET/CT and diffusion-weighted MRI (DW-MRI) in relation to clinical FIGO stage and outcome in cervical cancer patients.
Methods and Materials: Fifty-three patients with histopathologically verified cervical carcinoma with clinical FIGO stage IB1-IV were subjected to FDG-PET/CT and for a subgroup also DW-MRI (n=30) prior-to-treatment. Maximum standardized uptake value (SUV_{max}), total lesion glycolysis (TLG) and metabolic tumour volume (MTV) were estimated from the entire primary tumour at FDG-PET/CT. On MRI, longest tumour diameter (MRI-LD), tumour volume (MRI-TV) and mean tumour apparent diffusion coefficient (ADC_{mean}) values were measured. FDG-PET/CT-parameters were explored in relation to clinical prognostic factors at diagnosis and progression/recurrence-free survival and compared to MRI parameters.
Results: The metabolic tumour parameters TLG and MTV were highly positively correlated to MRI-LD and MRI-TV ($r=0.72$-0.82; $p<0.001$ for all), whereas tumour SUV_{max} was only moderately correlated ($r=0.29$-0.36; $p\leq0.04$). High tumour TLG, MTV, MRI-LD and MRI-TV predict advanced-FIGO-stage, whereas high tumour-SUV_{max} does not. No significant correlations were observed between tumour-ADC_{mean} and the other imaging parameters or FIGO-stage. High primary tumour-MTV (> 56.7 cm^3), high-TLG (> 412) and large MRI-TV (>36 cm^3) as well as advanced FIGO-stage (> IIIA) predicted reduced progression/recurrence-free survival yielding corresponding hazard ratios [HR]of 7.8 ($P=0.002$), 6.9 ($P=0.004$), 4.6 ($P=0.022$) and 6.9 ($P=0.004$), respectively. In multivariate analysis, advanced FIGO-stage (> IIIA) and high-MTV (> 56.7 cm^3) both had an independent unfavourable impact on progression/recurrence-free survival with adjusted HRs of 5.5 ($P=0.02$) and 7.8 ($P=0.025$), respectively.
Conclusion: High MTV at pre-treatment FDG-PET/CT and high clinical FIGO stage independently predict reduced progression/recurrence-free survival in cervical cancer patients.

B-1369 10:46

Quantitative MRI analysis of cervical cancer parametrium invasion

M. Shorikov, E. Tarachkova, V. Panov, I. Tyurin; *Moscow/RU (vopanov@gmail.com)*

Purpose: It is well known that MRI is a good method for evaluation of cervical cancer (CC) extent to parametrium. However, in the literature mostly the evaluation was qualitative and it was pointed out that MRI tends to overestimate the extent due to peritumoural inflammation. The purpose of the study is to correlate quantitatively measured on different MR-images the extent of the CC to parametrium to the results of the histological analysis performed after surgery.
Methods and Materials: 40 patients with histologically verified CC were enrolled in the study. The parametrium invasion maximal distance was measured in mm by two radiologists on different MR images (axial images, thickness=3mm): T2w/T2wfs, DWI+ADC-maps, contrast-enhanced T1TWISTfs at 90-120sec after i.v. injection of the MRCA (1.0mmol/ml solution of Gd-DO3A-butrol in standard dose). All the patients underwent surgery and the parametrium invasion of the tumour was measured in mm by a histologist.
Results: The MR measurements were significantly different to the histological findings ($p<0.05$) and tended to overestimate the invasion. The sen/sp for actual presence of the invasion and not peritumoural inflammation was estimated, the best results were on: T1WI+CE with sen/sp=0.96/0.92 for a 3mm distance on MRI and DWI sen/sp=0.91/0.92 for 4mm. MR results showed high correlation to histological measurements for all images ($r^2=0.79$-0.93, $p<0.05$) with the best results for T1WI+CE and DWI. The actual distance can be calculated as: invasion (histology) = 0.8*invasion (T1WI+CE) - 0.8 or invasion (histology) = 0.7*invasion (DWI) - 1.0.
Conclusion: The critical distances to detect the presence of invasion with high sen/sp are determined in this study (best results for T1WI+CE and DWI). The actual distance can be calculated using our results.

B-1370 10:54

MRI findings of post-IGBT-treated cervical tumour

E. Wong[1], T. Chang[2], F. Cho[1], M. Lai[1], S. Soong[1], L. Law[1], M. Yeung[1], K. Tang[1]; [1]*Chai Wan/HK*, [2]*Pok Fu Lam/HK (esthermfwong@gmail.com)*

Purpose: To study the accuracy of MRI as surveillance tool in locally advanced cervical cancer who has received MRI-image-guided brachytherapy (IGBT).
Methods and Materials: Consecutive cases of locally advanced cervical tumour receiving concurrent chemoradiation with whole pelvic radiotherapy were included. Pelvic MRI was performed 3-6 months post-radiotherapy.

Cervical biopsies were performed near the time of MRI. Images on post-radiotherapy MRI were retrospectively reviewed by 2 radiologists and scored as 1 = frank residual tumour signal, 2 = equivocal residual tumour signal, 3 = mainly fibrotic signal, no residual disease. The resulting scores were compared with the biopsy findings.
Results: 29 patients were retrospectively reviewed. The mean time interval between the last fraction of brachytherapy and post-treatment MRI was 20 weeks. Three cases were subsequently proven to have residual/recurrent disease at cervix or upper vagina. Out of the 15 cases rated as MRI negative (score 1) by both reviewers, none of their respective biopsies were positive. The other 14 cases were rated as either indeterminate (score 2) or frank residual disease (score 3) by either or both of the two reviewers. Three out of these are subsequently proven positive recurrent disease. Overall good interobserver agreement was found (k=0.75). Using residual disease detection as endpoint, MRI reached 100% for sensitivity and negative predictive value. Specificity was 73%.
Conclusion: MRI is highly sensitive in detection and ruling out of residual disease. It guides biopsy in dubious case.

B-1371 11:02

Simultaneous multiparametric PET/MRI for the assessment of therapeutic response to chemotherapy or concurrent radiochemotherapy of cervical cancer patients: preliminary results

T. Sarabhai, V. Stebner, A. Wetter, R. Kimmig, M. Forsting, L. Umutlu, J. Grueneisen; *Essen/DE (theresia-catharina.sarabhai@uk-essen.de)*

Purpose: To assess the response to chemotherapy or chemoradiotherapy in patients with primary cervical cancer, using simultaneous multiparametric PET/MR analysis.
Methods and Materials: 8 patients with a histopathologically confirmed primary cervical cancer were prospectively enrolled for a simultaneous 18F-FDG PET/MRI examination prior and after initial treatment strategy (chemotherapy, n=6; chemoradiotherapy, n=2). For the assessment of therapeutic response several morphological, functional and metabolic parameters of the primary tumors were determined in pre- and post-treatment PET/MR examinations. Histopathological correlation after subsequent tumor resection (n=7) or biopsy (n=1) served as the reference standard for the determination of therapeutic response.
Results: In accordance with the RECIST- and PERCIST-criteria, 7 of the 8 patients were classified as therapy responders (RECIST: CR=1, PR=6; PERCIST: CR=2; PR=5), while one patient showed stable disease. The responder group showed a significant reduction in tumor size (60%) and metabolic activity (SUVmax: 64%; SUVmean: 62%). Furthermore, a valuable increase of ADC values (ADCmin: 38%; ADCmean: 39%) and a significant decrease of certain perfusion parameters (Ktrans: 39%, Kep: 47%, iAUC: 57%) was found. Conversely, the non-responder revealed a slight decrease in tumor size (9%) and metabolic activity (SUVmax: 6%; SUVmean: 15%), accompanied with an increase of post-treatment perfusion parameters (Ktrans: 15%, Kep: 22%, iAUC: 22%). In addition, ADC values showed a slight (ADCmean: 24%) to moderate (ADCmin: 35%) increase during treatment.
Conclusion: These preliminary results demonstrate the feasibility of simultaneous multiparametric PET/MR analysis, which may function as a useful diagnostic tool for response assessment of initial treatment strategies in cervical cancer patients.

B-1372 11:10

Predicting early response in cervical malignancies to concurrent chemoradiation using intravoxel incoherent motion (IVIM) MRI

R. Balaji; *Chennai/IN (ravikanthbalaji@gmail.com)*

Purpose: To evaluate the use of intravoxel incoherent imaging diffusion MRI in assessing early response of cervical malignancies treated with concurrent chemoradiation.
Methods and Materials: 36 patients with cervical malignancies decided by the tumour board for concurrent chemoradiation were included in the study. Patients underwent routine diagnostic pelvic MRI for staging purpose in a 1.5T scanner. IVIM imaging was also performed with 11 *b* values 0 to 1000 s/mm^2. Follow-up imaging was then performed a week after start of treatment, 3 weeks later and within 3 days of completing therapy. The apparent diffusion coefficient (ADC) maps were derived from the mono-exponential model, while the diffusion coefficient (D), perfusion fraction (*f*) and pseudo-diffusion coefficient (D*) maps were calculated from the bi-exponential model. Changes in ADC, D, *f* and D* in cervical cancers were investigated as bio-imaging markers for treatment response.
Results: ADC and D values showed progressive elevation after commencing treatment which persisted after completion. Mean D values after completion of therapy were 1.4 ± 0.16 x 10^{-3} mm^2/s. f values, however, increased in the first week of treatment, started to decline by third week with significant fall in post-treatment scans (0.14% ± 0.67).
Conclusion: IVIM-derived D and f parameter values have significant potential in assessing treatment response non-invasively without use of contrast and without use of radionuclides.

B-1373 11:18

Evaluating the MR scoring system (“ADNEX MR score”) for characterisation of sonographically indeterminate adnexal masses

H. Rajani, S.B. Grover, P. Mittal, G. Khanna; *New Delhi/IN (heena.rajani@gmail.com)*

Purpose: The critical role of imaging in adnexal masses is to differentiate between benign and malignant pathologies, as it has a crucial role in deciding the management: radical surgery versus fertility preserving laparoscopic surgery. Although ultrasound is the primary modality for evaluation of adnexal masses, the results are often inconclusive. The present study aimed to evaluate the “ADNEX MR score” for classification of sonographically indeterminate adnexal masses as benign or malignant.
Methods and Materials: MR imaging (1.5 T) was performed in 34 adnexal masses in 30 patients, presenting with sonographically indeterminate adnexal masses. Routine sequences were followed by Dynamic contrast enhanced study.The adnexal masses were assigned an “ADNEX MR score” between 1 to 5, as devised by Thomassin-Naggara et al. ROC curve analysis was done to determine the cut- off ADNEX MR Score for prediction of malignancy. All patients underwent laparoscopic or surgical excision. Statistical analysis was done using histopathology as gold standard.
Results: Using ROC analysis, we obtained the optimal “ADNEX MR score” cut-off value of 4. The sensitivity, specificity, NPV, PPV and accuracy of “ADNEX MR score”, using cut off score ≥4 for prediction of malignancy was 100%, 90%, 100% , 87.5% and 94.% respectively with area under curve being 0.96.
Conclusion: In the present study, the “ADNEX MR score” value of 4 was found to have good sensitivity and specificity for malignancy prediction in sonographically indeterminate adnexal masses. Hence, “ADNEX MR score” should be included in the standardised MRI reporting format for adnexal masses.

B-1374 11:26

Adnexal masses: diagnostic value of DCE-MRI

S. Parviz; *Tehran/IR (srparviz@gmail.com)*

Purpose: To evaluate the utility of the dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) parameters in differentiating the malignant adnexal masses from the benign ones.
Methods and Materials: 43 patients with 49 complex adnexal masses (27 benign, 3 borderline, and 19 malignant) underwent preoperative DCE-MRI examinations, on a 3 Tesla MRI. Using extended Tofts' model, quantitative analysis was done in the solid parts of all tumours. Three PK parameters were defined as volume transfer coefficient (Ktrans), the rate constant (Kep) ,and the plasma volume (Vp). Semi-quantitative analysis was also performed and the values of relative signal intensity (SI_{rel}) , wash-in-rate (WIR) , the initial area under the curve ($iAUC_{60}$), time-to-peak (TTP) and wash-out-rate (WOR) were calculated. Using logistic regression and receiver operating characteristic (ROC) curve, we compared the mean values of individual parameters between the two groups.
Results: The mean value of Ktrans and the plasma volume (Vp) were significantly higher in malignant adnexal masses (P value<0.0001 and P value = 0.001, respectively). Semi-quantitative analysis showed that SI_{rel} (P value <0.0001), WIR (P value <0.0001) and $iAUC_{60}$ (P value = 0.001) had higher values in malignant adnexal tumours compared to the benign ones. The pairwise comparison among the receiver operating characteristic (ROC) curves showed that the area under the curve (AUC) of Ktrans was significantly larger than the AUCs of all the other DCE-MRI parameters.
Conclusion: DCE-MRI is a relevant tool for differentiating benign from malignant adnexal masses. Among all pharmacokinetic and semi-quantitative parameters, Ktrans is the most accurate discriminator.

MR-imaging of neoplastic and non-neoplastic lesions of the vagina

S. Aksenova, N. Nudnov, J. Kreynina; *Moscow/RU (fabella@mail.ru)*

Purpose: Capabilities of MRI in detecting tumour lesions of the vagina using of the whole panel of modern features of MRI: DWI, DCE. Identify difficult moments in the diagnostic assessment of the vagina in operated patients with gynaecologic cancer.
Methods and Materials: 196 MRI examinations of pelvic with contrast enhancement were done in 137 patients. Complex MRI pelvic examinations with contrast enhancement were evaluated in 83 (60.6%) patients aged 34–82 (mean age 58±4.7) with vagina neoplastic lesion suspicion, consisted of native

scanning, diffusion-weighted imaging, dynamic contrast enhanced examination with additional endovaginal MR suitable applicator introduction.
Results: Neoplastic lesions in vagina were found during MRI in 83 (60.6%) patients, at lower third – in 8 (9,7%), as endometrial and vulvar cancer progression, at middle third – in 20 (24.1%) patients, at upper third – in 55 (66.2%), included 30 (36.1%) patients with vaginal cuff relapse. It was revealed as a zone with increasing signal in T2WI and contrast accumulation in the arterial and venous phases. Non-tumour changes were observed in 54 patients. The greatest difficulty was to make the differentiation of early manifestations vaginal cuff relapse with residual fibrotic changes after radiation therapy. Differential diagnosis with post-radiation fibrosis demanded image fusion of T2WI fat sat, DWI and DCE with endovaginal MR-suitable applicator, which created conditions for better visualisation of vaginal wall structure and tumour localisation because of fold smoothing.
Conclusion: MRI allows a good visualisation of the tumour, as well as the differential diagnosis of neoplastic and non-neoplastic lesion.

B-1376 11:42

Diagnostic value of imaging for the detection of peritoneal metastases: a meta-analysis
I. van't Sant-Jansen, M. Engbersen, D.M. Lambregts, A.G. Aalbers, W. van Driel, R.G.H. Beets-Tan, M.J. Lahaye; *Amsterdam/NL (M.Lahaye@nki.nl)*

Purpose: To determine the diagnostic value of imaging in detecting peritoneal carcinomatosis (PC) in staging cancer patients.
Methods and Materials: A literature search in Pubmed, Embase (Ovid) and Scopus was performed (January 1997- July 2017) to identify studies reporting on the accuracy of imaging of PC in newly diagnosed primary gastrointestinal or ovarian cancers. Data extraction was performed by two observers in consensus. The sensitivity, specificity, and diagnostic odds ratio (DOR) were calculated using a bivariate random effects model and hierarchical summary operating curves (HSROC) were generated.
Results: The original search resulted in 4177 articles. Twenty relevant studies fulfilled all the required inclusion criteria of > 15 patients and surgery/histology/radiological follow-up as reference standard. From these articles 30 datasets could be extracted for analysis; 18 for CT, 8 for PET(CT) and 4 for MRI. The pooled sensitivity, specificity, DOR for detection of PC were 71% (CI:58-81%) ; 94% (CI:88-97%); 35.1 (CI:15.7-78.5) for CT. For PET(CT): 80% (CI:56-93%); 89% (CI:79-94%); 31.7(CI: 16.2-130.4). Due to the limited amount of MRI studies these datasets could not be analysed.
Conclusion: This meta-analysis shows that CT and PET(CT) demonstrate almost similar results in detecting peritoneal metastasis. More research is needed to investigate the diagnostic performance of MRI for peritoneal metastasis.

Ovarian cancer staging: prospective comparison among ultrasound, CT and whole-body-MRI
V. Buscarino[1], S. Rizzo[1], A. Colarieti[2], M. Femia[1], E. Pagan[1], V. Bagnardi[1], M. Bellomi[1]; [1]*Milan/IT*, [2]*Rome/IT (valentinabuscarino@gmail.com)*

Purpose: The standard treatment of OC is primary cytoreductive surgery with resection of macroscopic disease; although, according to recent studies, interval debulking surgery after neoadjuvant chemotherapy allows comparable outcomes in advanced OC. The role of pre-operative staging is to select patients who may undergo up-front cytoreduction or may benefit from a neoadjuvant treatment. The objective of this study is a prospective comparison of diagnostic performance among WB-DW-MRI, US and CT.
Methods and Materials: All patients included underwent to US, CT and WB-DW-MRI as pre-surgical imaging evaluation before diagnostic or therapeutic surgery. Every imaging reader and the surgeon, reported on a specific report site of disease. Diagnostic performance of WB-DW-MRI, TC and US was calculated for each site, using the surgical evaluation as gold standard. The accuracy of WB-DWI-MR and CT were compared using the McNemar's test.
Results: Thirty-eight patients met the inclusion criteria. Imaging studies included for evaluation were: 31 CT, 36 US, 38 MRI examinations. WB-DWI-MR showed higher values of sensitivity, specificity and accuracy for crucial sites such as peritoneal carcinosis, mesenteric involvement and retraction, lombo-aortic and celiac nodes, although there was no significant statistical difference among WB-DWI-MRI and CT.
Conclusion: WB-DW-MRI is able to assess OC staging in satisfactory concordance with surgical findings, especially for sites considered crucial to indicate optimal resectability.

Identifying pulmonary consolidation in chest x rays using deep learning
T.R. Nimmada, P. Putha, M. Tadepalli, S. Jain, P. Rao, P. Warier; *Mumbai/IN (tarun.raj@qure.ai)*

Purpose: Chest x-rays are widely used to identify pulmonary consolidation because they are highly accessible, cheap and sensitive. Automating the diagnosis in chest x-rays can reduce diagnostic delay, especially in resource limited settings.
Methods and Materials: Anonymised dataset of 423,218 chest x-rays with corresponding reports (collected from 166 centres across India spanning 22 x-ray machine variants from 9 manufacturers) is used for training and validation. x-rays with consolidation are identified from their reports using natural language processing techniques. Images are preprocessed to a standard size and normalised to remove source dependency. These images are trained using deep residual neural networks. Multiple models are trained on various selective subsets of the dataset along with one model trained on entire data set. Scores yielded by each of these models is passed through a 2-layer neural network to generate final probabilities for presence of consolidation in an x-ray.
Results: The model is validated and tested on a test dataset that is uniformly sampled from the parent dataset without any exclusion criteria. Sensitivity and specificity for the tag has been observed as 0.81 and 0.80, respectively. Area under the Receiver Operating Curve (AUC-ROC) was observed as 0.88.
Conclusion: Deep learning can be used to diagnose pulmonary consolidation in chest x-rays with models trained on a generalised dataset with samples from multiple demographics. This model performs better than a model trained on controlled dataset and is suited for a real world setting where x-ray quality may not be consistent.

B-1379 10:47

Efficacy of deep learning for screening pulmonary tuberculosis
P. Putha, M. Tadepalli, S. Jain, J. Chiramal, T.R. Nimmada, P. Warier; *Mumbai/IN (preetham.putha@qure.ai)*

Purpose: Chest X-rays(CXR), being highly sensitive, serve as a Screening tool in TB diagnosis. Though there are no classical features diagnostic of TB on CXR, there are a few patterns that can be used as supportive evidence. In Resource limited settings, developing Deep Learning algorithms for CXR based TB screening, could reduce diagnostic delay. Our algorithm screens for 8 abnormal patterns(TB tags)- Pleural effusion, blunted CP, Atelectasis, Fibrosis, Opacity, Nodules, Calcification and Cavity. It reports 'No Abnormality Detected' if none of these patterns are present on CXR.
Methods and Materials: An anonymized dataset of 423,218 CXRs with matched radiologist reports across (22 models, 9 manufacturers, 166 centres in India) was used to generate training data for the deep learning models. Natural Language Processing techniques were used to extract TB tags from these reports. Deep learning systems were trained to predict the probability of the presence/absence of each TB tag along with heat-maps that highlight abnormal regions in the CXR for each positive result.
Results: We validated the screening algorithm on 3 datasets external to our training set- two public datasets maintained by NIH(from Montgomery and Shenzen) and a third from NIRT, India. The Area under the Receiver Operating Curve (AUC-ROC) for TB prediction was 0.91, 0.87 and 0.83 respectively.
Conclusion: Training on a diversified dataset enabled good performance on samples from completely different demographics. After further validation of it's robustness against variation, the system can be deployed at scale to improve the current systems for TB screening significantly

Automatic localisation and identification of vertebrae in spine CT scans by combining Deep Learning with morphological image processing techniques

A. Jiménez-Pastor, A. Alberich-Bayarri, B. Fos Guarinos, F. Garcia-Castro, L. Marti-Bonmati; *Valencia/ES (anajimenez@quibim.com)*

Purpose: In spine pathologies, the proper detection and identification of vertebrae is a need to perform diagnosis. This is a manual task that delays radiologists' workflow. The main goal of this work is to assist radiologists by detecting and identifying automatically vertebrae in spine CT scans.
Methods and Materials: To locate the spine centerline, a detection of the spinal canal was done by using a thresholding and a dilation using a cylindrical structuring element. Once the spine was located, the position of each vertebral body was detected and identified. This procedure was divided into 4 steps. First each axial 2D image was classified into 4 different regions: upper-thoracic, lower-thoracic, lumbar or sacrum. Thereafter, for each region, axial 2D images were classified into vertebra or non-vertebra. All these classifiers were designed using a pre-trained Convolutional Neural Network (CNN) to extract characteristics of each image followed by a Support-Vector-Machine (SVM) classifier and distribute them into the different groups. Finally, the centroid of each vertebra was calculated and identified.
Results: The mean localization error (distance between the estimated and real vertebra position) obtained was 7,37±8,69mm on the thoracic region and 9,21±8,70mm in the lumbar region; and the identification rate obtained was 89,20% in the thoracic region and 92,90% in the lumbar zone.
Conclusion: By combining deep learning with image processing techniques it is possible to automatically locate and identify vertebrae in spine CT scans. CNN are a good candidate to extract complex characteristics from the images in order to classify radiological images.

B-1381 11:03

Fully automatically staging of lung cancer using deep neural networks

K.S. Mader[1], A.W. Sauter[2], G. Sommer[2], T. Weikert[2], F. Trolese[1], J. Hagger[1], B. Stieltjes[2]; [1]*Zurich/CH*, [2]*Basel/CH (kevinmader@4quant.com)*

Purpose: The standard diagnostic protocol for Lung Cancer involves an FDG-PET/CT to stage the patient. Both over- and undertreating the stage lead to drastic consequences for the patient's health and comfort. The full examination of these images takes up to 90 minutes per patient and requires the expertise of both a radiologist and a nuclear medicine physician. We aim to support physicians by automatically and quantitatively evaluating this reading and interpretation process.
Methods and Materials: Using a retrospective study with 179 patients, we collect the first PET-CT scan, manually annotate the suspicious lesions, and record the radiological TNM stage. We train a deep neural network using augmentation including transformed versions of the original images to avoid overfitting.
Results: The accuracy of the network was evaluated by using a validation group. The accuracy of the network was for very high: over 90% of lesions area was overlapping and a misclassification rate of 20%.Once the network was trained, detecting the suspicious lesions and computation of stage for a new patient can be done in a few seconds.
Conclusion: Staging and reading PET-CT images is a challenging task with large degrees of heterogeneity in both the patients and images. Given this heterogeneity, this initial study shows great promise in terms of speed and accuracy of the proposed set-up and could make this a valuable asset in the clinical environment and clinical trials.

Discrimination between distal ureteral stones and pelvic phleboliths in CT using a deep neural network: more than local features needed

M. Lidén, J.K. Jendeberg, M. Längkvist, A. Loutfi, P. Thunberg; *Örebro/SE (matsliden@yahoo.com)*

Purpose: To develop a deep learning method for assisting radiologists in the discrimination between distal ureteral stones and pelvic phleboliths in thin slice CT images, and to evaluate whether this differentiation is possible using only local features.
Methods and Materials: A limited field-of-view image data bank was retrospectively created, consisting of 5x5x5cm selections from 1-mm-thick unenhanced CT images centred around 218 pelvis phleboliths and 267 distal ureteral stones in 336 patients. 50 stones and 50 phleboliths formed a validation cohort and the remainder a training cohort. Ground truth was established by a radiologist using the complete CT examination during inclusion. The limited field-of-view CT stacks were independently reviewed and classified as containing a distal ureteral stone or a phlebolith by seven radiologists. Each cropped stack consisted of 50 slices (5x5cm field-of-view) and was displayed in a standard PACS reading environment. A convolutional neural network using three perpendicular images (2.5D-CNN) from the limited field-of-view CT stacks was trained for classification.
Results: The 2.5D-CNN obtained 89% accuracy (95% confidence interval 81%-94%) for the classification in the unseen validation cohort while the accuracy of radiologists reviewing the same cohort was 86% (range 76%-91%). There was no statistically significant difference between 2.5D-CNN and radiologists.
Conclusion: The 2.5D-CNN achieved radiologist level classification accuracy between distal ureteral stones and pelvic phleboliths when only using the local features. The mean accuracy of 86% for radiologists using limited field-of-view indicates that distant anatomical information that helps identifying the ureter's course is needed.

B-1383 11:19

Deep learning for liver segmentation and volumetry in late phase MRI

A. Schenk[1], G. Chlebus[1], H. Meine[1], S. Thoduka[2], N. Abolmaali[2]; [1]*Bremen/DE*, [2]*Dresden/DE (andrea.schenk@mevis.fraunhofer.de)*

Purpose: Radioembolisation in the liver requires the computation of organ and tumor volumes for dosimetry planning. The purpose of this study was to investigate the accuracy of a new, fully-automated deep learning approach for liver segmentation in MRI data.
Methods and Materials: Images of 70 patients who underwent MRI to evaluate liver tumors were retrospectively analyzed. Data was acquired on two different scanners (Signa HDxt or Discovery 750, GE) applying a volume sequence and Gd-EOB-DTPA as contrast agent. Segmentation was performed on late phase images with a slice thickness of 2-3 mm.
Ground truth liver contours were accurately defined by experienced technicians using contouring and interpolation software and checked by a radiologist. Additionally, one radiologist and two residents defined routine segmentations for 28 patients scheduled for radioembolisation. A deep learning network was trained on the remaining 42 data sets and automatic organ boundaries were computed for the radioembolisation cases.
Results: Compared to the ground truth, relative volume error was 5.37%±4.38%, 3.63%±4.57% and 4.33%±4.62% for the three clinical users, and 6.95%±5.73% for the deep learning approach. DICE coefficient was 0.94±0.02, 0.95±0.02, 0.95±0.02, and 0.92±0.04 for the automatic method. Interactive ground truth segmentation took 24±8 minutes compared to approximately 10±4 minutes by the clinicians, and 20±7 seconds for the deep learning method.
Conclusion: Automated deep learning based liver segmentation in MRI data of radioembolisation patients was much faster with sufficient accuracy compared to interactive contouring and interpolation. The new method will support automated tumor load computation based on MRI in the future.

B-1384 11:27

Evaluation of a multiparametric deep learning model for glioblastoma segmentation

M. Perkuhn[1,2], F. Thiele[1,2], G. Shakirin[1,2], D. Garmpis[1], P. Stavrinou[1], J. Borggrefe[1]; [1]*Cologne/DE*, [2]*Aachen/DE (michael.perkuhn@uk-koeln.de)*

Purpose: MRI is commonly used to non-invasively evaluate location, size, spread, oedema and the biological status of glioblastoma (GBM). Automatic, reliable and reproducible tumour segmentation can enable volumetric response assessment and effective integration of volumetric multimodal tumour characterization. The objective of this study was to apply a state-of-the-art deep learning algorithm for fully automatic GBM-compartment segmentation on clinical routine data from multiple centres, and to compare the results to ground truth manual expert segmentation.
Methods and Materials: 64 patients from 15 institutions with newly diagnosed, primary GBM were included. T1, T2, FLAIR and contrast-enhanced (CE) T1 sequences (Philips and Siemens scanners) underwent preprocessing and were fed to a deep-learning model based on DeepMedic. This model was trained on 220 cases of the BRATS database. Acquired segmentations were compared to manual segmentations of whole tumour (WT), necrosis (NC), and contrast-enhanced tumour (CET) performed by experienced radiologists as part of this study.
Results: The CET and WT were automatically detected in all patients. The automatic/manual segmentation dice similarity coefficients (DSC) were 0.86±0.09 (WT), 0.78±0.15 (CET), 0.62±0.30 (NC). For NC we found a correlation (R=-0.622, p<0.01) between surface-to-volume ratio and DSC. No correlation was found between resolution and DSC.
Conclusion: The proposed approach is robust on routine clinical data and has high accuracy comparable to interrater variability. This makes it a suitable building block for automatic tumour segmentation reviewed by the radiologist in pre-operative characterisation of GBM. Training the network on data with small/complex shape tumours might further increase the NC segmentation accuracy.

Peering into the darkness: visualising what neural networks learn through generative deep learning

J.C.Y. Seah, J.S.N. Tang, F. Gaillard; *Melbourne/AU (J.Seah@alfred.org.au)*

Purpose: To demonstrate the application of generative deep learning in visually representing what neural networks learn. The specific example explored is the prediction of B-type natriuretic peptide (BNP) levels as a marker of heart failure from chest radiographs.
Methods and Materials: 106,290 chest radiographs from 48,532 unique patients were extracted from a PACS database for this ethics approved study. 7,390 radiographs had a corresponding BNP result within 36 hours.The remainder 98,900 did not have a corresponding BNP result and formed the unlabelled dataset. The unlabelled dataset was used to create a generative model to convert radiographs to and from a low dimensional latent space. Simulated reconstructions for chest radiographs with high BNPs were then performed to visualise the same radiograph if it had a normal BNP. These were used to obtain a visual rationale which represent features the model has identified as important in this specific predictive task.
Results: A linear regression shows that the latent representations are logarithmically correlated with the accompanying BNP result. At a cut-off BNP value of 100 ng/L, the linear classifier obtained an AUC of 0.82. Qualitative assessment of the generated visual rationales confirms that the algorithm learns radiographic findings compatible with traditional human teaching. It also allows identification of unexpected features.
Conclusion: Generative learning can be applied to create visual representations of features learned by an algorithm. These visual representations could improve radiologists' understanding of deep learning algorithms and help enable the safe and appropriate application of deep learning in medicine.

B-1386 11:43

Automated detection of intra- and extra-axial haemorrhages on CT brain images using deep neural networks

S. Chilamkurthy[1], R. Ghosh[1], P. Rao[1], M. Biviji[2]; [1]*Mumbai/IN*, [2]*Nagpur/IN (rohit.ghosh@qure.ai)*

Purpose: To develop and validate a deep neural network-based algorithm for automated, rapid and accurate detection from head CT for the following haemorrhages: intracerebral (ICH), subdural (SDH), extradural (EDH) and subarachnoid (SAH).
Methods and Materials: An anonymised database of head CTs was searched for non-contrast scans which were reported with any of ICH, SDH, EDH, SAH and those which were reported with neither of these. Each slice of these scans is manually tagged with the haemorrhages that are visible in that slice. In all, 3040 scans (116227 slices) were annotated, of which number of scans(slices) with ICH, SDH, EDH, SAH and neither of these are 781(6957), 493(6593), 742(6880), 561(5609) and 944(92999), respectively. Our deep learning model is a modified ResNet18 with 4 parallel final fully connected layers for each of the haemorrhages. This model is trained on the slices from the annotated dataset to make slice-level decisions. Random forests are trained with ResNet's softmax outputs for all the slices in a scan as features to make scan-level decisions.
Results: A different set of 2993 scans, uniformly sampled from the database without any exclusion criterion, is used for testing the scan-level decisions. Number of scans with ICH, SDH, EDH and SAH in this set are 123, 58, 41 and 62, respectively. Area under the receiver operating curve (AUC) for scan-level decisions for ICH, SDH, EDH and SAH are 0.91, 0.90, 0.90 and 0.90, respectively. Algorithm takes <1s to produce the decision for a scan.
Conclusion: Deep learning can accurately detect intra- and extra-axial haemorrhages from head CTs.

Automatic detection of generalised cerebral atrophy using deep neural networks from head CT scans

S. Tanamala[1], R. Ghosh[1], S. Chilamkurthy[1], P. Rao[1], M. Biviji[2]; [1]*Mumbai/IN*, [2]*Nagpur/IN (rohit.ghosh@qure.ai)*

Purpose: Features of generalised cerebral atrophy on brain CT images are the marker of neurodegenerative diseases of the brain. Our study aims at automated diagnosis of generalised cerebral atrophy on brain CT images using deep neural networks thereby offering an objective early diagnosis.
Methods and Materials: An anonymised dataset containing 78 head CT scans (1608 slices) was used to train and validate a skull-stripping algorithm. The intracranial region was marked out slice by slice in each scan. Then a U-Net-based deep neural network was trained on these annotations to strip the skull from each slice. A second anonymised dataset containing 2189 CT scans (231 scans with atrophy) was used to train and validate an atrophy detection algorithm. First, an image registration technique was applied on the predicted intracranial region to align all scans to a standard head CT scan. The parenchymal and CSF volume was calculated by thresholding Hounsfield units from the intracranial region. The ratio of CSF volume to parenchymal volume from each slice of the aligned CT scan and the age of the patient were used as features to train a random forest algorithm that decides if the scan shows generalised cerebral atrophy.
Results: An independent set of 3000 head CT scans (347 scans with atrophy) was used to test the algorithm. Area under the receiver operating curve (AUC) for scan-level decisions is 0.86. Predictions on each patient takes time < 45s.
Conclusion: Deep convolutional networks can accurately detect generalised cerebral atrophy given a CT scan.

Features of MRI after cryoablation of primary breast cancer without surgical resection

Y. Machida[1], A. Shimauchi[1], T. Igarashi[2], H. Okuma[2], E. Fukuma[3]; [1]*Chuo/JP*, [2]*Tokyo/JP*, [3]*Kamogawa/JP (machida.yoichi@kameda.jp)*

Purpose: To retrospectively evaluate the features of serial magnetic resonance imaging (MRI) after cryoablation for breast cancer lesions without subsequent surgical resection.
Methods and Materials: This study was approved by the institutional review board. Requirement to obtain informed consent was waived. Ductal carcinoma in situ or invasive carcinoma ≤ 15mm, nuclear grade 1 or 2, estrogen receptor positive/human epidermal growth factor 2 negative without lymph node metastasis were treated with cryoablation without subsequent excision. Two observers independently reviewed the first and second post-cryoablation MRI for shape (none, linear, or nodular) and suspicion for residual disease (positive or negative). Fisher's exact test or the Mann-Whitney U test was performed for variables. Interobserver agreement of findings was evaluated by calculating κ values.
Results: Fifty-four cases were enrolled. The first and second post-cryoablation MRIs were performed 22-171 days and 82-487 days after cryoablation, respectively. The interobserver agreement for descriptor ranged fair to moderate (κ = 0.331 - 0.434). There were 7 cases (13.0%) for which either observer 1 or 2 evaluated positive suspicion on the first post-cryoablation MRI. There was a significant association between nodular shape compared to non-nodular (linear or none) and positive suspicion for residual disease or recurrence in both two observers' results ($p < 0.001$). On the second post-cryoablation, there were no cases with suspicious findings based on both of the two observers.
Conclusion: There were some cases with suspicious findings within treated area at the first post-cryoablation MRI, which can resolve during subsequent adjuvant therapies and follow-up management.

Combined ultrasound-guided high-intensity focused ultrasound and vacuum assisted biopsy for treatment of large sized breast fibroadenoma

N.M. Abdel Razek, M. Hamed; *Cairo/EG (naglaabdelrazek@yahoo.com)*

Purpose: To assess the efficiency of ultrasound guided HIFU & VAB as non surgical technique for compete excision of large sized breast fibroadenoma
Methods and Materials: The study is a prospective one conduced in a single center during the period from February 2017 to September 2017.The ethical committee approval and patients written consents were obtained. The study included 20 patients with large sized breast fibroadenomas in one or both breasts were selected for treatment with US guided HIFU followed by VAB excision after 2 months. Patients' age ranged from 16 to 52 years ;mean 32 years. All patients with FA underwent core needle biopsy with histological confirmation. HIFU treatment was performed as an outpatient procedure under conscious sedation. After the treatment, follow up US with volume evaluation

was performed at 1 &2 months and then percutaneous ultrasound guided VAB was performed to the residual lesion after HIFU
Results: The FA mean baseline size ranged between 3.5-6 cm diameter. At 1 month follow up, the mean volume reduction was 33.2% ± 19.1% and achieved significance at 2 month ;49.2% ± 16.2%, $p < 0.001$. After 2 months, the residual part was then excised using ultrasound guided VAB thus achieving complete excision .
Conclusion: Combined Ultrasound guided HIFU followed by VAB is an efficient well tolerated non invasive two step procedure for non-surgical complete excision of large fibroadenoma, Preliminary results are encouraging and show that the combined HIFU & VAB could be an alternative to surgery for large breast fibroadenoma. further work is still on progress .

Digital breast tomosynthesis-guided vacuum-assisted biopsy (DBT-guided VAB): initial experience with patients positioned on a dedicated armchair

E. Venturini, M. Panzeri, C. Losio, M. Rodighiero, S. Tacchini, E. Schiani, P. Panizza; *Milan/IT (venturini.elena@hsr.it)*

Purpose: To evaluate the success rate and the tolerability of DBT-guided VAB with patients positioned on a dedicated armchair.
Methods and Materials: Sixty-four women with a suspicious breast finding (BIRADS 4) detectable only by mammography or DBT underwent DBT-guided VAB (Selenia Dimensions, Hologic). Patients were positioned in lateral decubitus or in sitting position on a dedicated armchair. DBT was acquired to determine lesion coordinates. Pre and post fire images were acquired with 2D-full field digital mammography to limit artifacts related to the needle (9G vacuum device). At least 12 biopsy specimens were obtained. Mammography of biopsy specimens was performed to verify the presence of microcalcifications.
Results: From 10/2016 and 09/2017 64 women (mean age 52 years; 39-81 years) with 66 suspicious (BI-RADS 4) mammographic findings underwent DBT-VAB. Overall, 66 DBT-guided biopsies were performed: 37 procedures with patient in sitting position, 29 in lateral decubitus. The technical success rate was 98.5% (65/66). Twenty-five breast carcinomas were diagnosed (4 invasive, 21 in situ) and 2 high-risk lesions were found at histological examination on biopsy specimens. Fifteen women underwent surgery at our Institution. One case of upgrade at final pathology was registered (from DCIS to 5 mm CDI with extensive in situ component). No serious complications were observed; 4 patients developed a small hematoma and 5 women a slight vasovagal reaction, which resolved spontaneously.
Conclusion: DBT-VAB with patients positioned on a dedicated armchair are a procedure with high success rate and well-tolerated.

Impact of MRI/ultrasound fusion-guided biopsy for breast lesions detected on MRI alone

S. Nakano[1], K. Fujii[2], J. Kousaka[2], Y. Mouri[2], T. Ando[1], M. Ido[1], M. Goto[1], Y. Ito[1], T. Ishiguchi[1]; [1]*Aichi/JP*, [2]*Nagakute/JP (snakano1@aichi-med-u.ac.jp)*

Purpose: When MRI-detected breast lesion can be identified by second-look US, US-guided biopsy is recommended. However, the detection rate of second-US is very heterogeneous because of the lack of reproducibility. The aim of this study was to examine the safety and outcomes of MRI/ultrasound fusion-guided biopsy using real-time virtual sonography (RVS) for breast lesions detected on MRI alone.
Methods and Materials: 39 lesions in 39 consecutive patients who underwent second-look US to identify MRI-detected lesions on prone MRI were enrolled in this retrospective study. For MRI-detected lesions that were not identified using conventional B-mode, second-look US using RVS and RVS-guided biopsy were performed after an additional supine MRI. The detection rate, lesion characteristics, and complication were assessed.
Results: The mean lesion size on MRI was 8.0 mm (3-46mm). Of the 39 lesions, 33 (85%) were detected and subjected to biopsy with second-look US using RVS. The MRI morphology types of these lesions were as follows: mass, 16; non-mass, 5; and focus, 12. 25 (76%) were benign and 8 (24%) were malignant. Of the 33 lesions, those with non-circumscribed margins and hypoechogenicity were significantly more likely to be malignant ($p < 0.05$). The remaining 6 (15%) US-occult lesions could be judged to be benign after 24 months follow-up under RVS. There were no procedure-related complications.
Conclusion: Our results suggest that RVS-guided biopsy is a useful modality for the tissue sampling of breast lesions detected on MRI alone and may contribute to identifying cases in which MRI-guided biopsy is absolutely necessary.

B-1392 11:02

What can affect tomosynthesis-guided vacuum-assisted breast biopsy (TVAB) procedures? Clinical and technical challenges

G. Negro, M. Durando, G. Mariscotti, B. Desana, E. Regini, P. Isoardi, M. Garolla, P. Fonio, G. Gandini; *Turin/IT (giulietta.negro@gmail.com)*

Purpose: To evaluate clinical and technical performances of tomosynthesis-guided vacuum-assisted breast biopsy (TVAB), considering different breast compositions and mammographic lesion features.
Methods and Materials: All TVABs performed at our Breast Service between June 2016-July 2017 with an upright system and using VAB 9G-needles were retrospectively reviewed. We recorded all data about patient age, breast density, lesion type, dimension and localization, histhology, breast thickness, breast positioning, number of projections, procedure time, average glandular dose(AGD), entrance surface dose(ESD). TVAB procedures were classified according to the number of performed projections(≤8 or ≥9), as less or more difficult proceedings. Uni- and multi-varied analyses of data were performed (significant p values<0.05).
Results: 145 TVABs were included. Mammographic findings were: microcalcifications(115;79%), architectural distortions(14;10%), focal asymmetries(6;4%) and masses(11;7%). At microhistological examination, lesions were classified as B1(1;1%), B2(74;51%), B3(38;26%), B4(3;2%), B5(29;20%). Average procedure time was 17±4minutes. Average number of projections per procedure was 8±2. TVAB with ≤8 projections were 95(66%) and 50(34%) with ≥9. No associations were observed(p>0.05) between easier technical feasibility (procedures ≤8 projections) and breast density or thickness, lesion dimension or localisation. Considering lesion type, microcalcifications correlated with a higher number of projections(p=0,01). Median total AGD for TVAB with ≤8 projections was 10.8 mGy and 14.3 mGy with ≥9 (p<0.0001) and correlated with median total ESD (35.6 mGy and 45.2 mGy respectively; p<0,0001).
Conclusion: TVAB, in our experience, is a rapid, safe and accurate technique. The evaluation of microcalcifications correlated with a greater number of projections, as they can represent a more difficult target in tomosynthesis-images.

B-1393 11:10

Digital breast tomosynthesis (DBT) guided biopsy of thin breast patients: how tomosynthesis and special maneuvers contribute to the technical success

L.H.Y. Sinn, J.C.M. Sitt, C.Y. Fong, C.Y. Lui; *Central/HK (lorriesinn@gmail.com)*

Purpose: To evaluate how rapid target depths identification by DBT contribute to the improvement in workflow and successful rate in performing biopsies in thin breast patients, which minimize the need for open surgical biopsy.
Methods and Materials: Patients referred to our centre for tomosynthesis guided biopsies (core biopsy with 14G needle or vacuum assisted biopsy (VAB) with 9G/10G needle) from January 2016 to July 2017 with compressed thickness </= 30mm were included. All biopsies were carried out under DBT guidance in upright position or with prone table system by dedicated radiologists. The compressed breast thicknesses, z value of the target co-ordinates, microcalcifications retrieval, histological diagnosis, and special maneuvers during the procedure were recorded.
Results: 33 patients (6 VAB, 27 core biopsies) were included, compressed breast thickness ranged 17-30mm. All (100%) biopsies were technically successful with target lesions (31 microcalcifications group: confirmed by specimen radiographs, 2 architectural distortions) removed. Different maneuvers including air-gap technique (n=4), lateral approach with lateral arm (n=1, VAB), petite needle (n=1, VAB) and application with peripheral pressure to increase breast thickness (ring technique, n=1, VAB) were used. No significant complications developed. 6 DCIS and 1 invasive ductal carcinoma were identified. No pathological discordance with final pathology identified in operated cases. Mean time of procedure was 22 (range 8-42) minutes.
Conclusion: DBT guided biopsies in thin breast patients provided better planning of approach before and during the procedures, with known anticipated target depths which allowed optimal positioning and special manipulations for successful lesion retrieval in short time.

B-1394 11:18

Diagnosis and treatment of suspected high-grade lesions using ultrasound-guided vacuum-assisted breast biopsy

J. Vucetic, J. Palao Errando, C. Barber Hueso, J.S. Cárdenas Herrán, M. Ortega Millán, R. Garcia Garcia; *Valencia/ES (vucetic_jelena@yahoo.com)*

Purpose: The purpose is to share our two-year experience in performing vacuum-assisted breast biopsy (VABB) for diagnosis and treatment of benign and potentially malignant breast lesions.
Methods and Materials: We received patients from outpatient clinics (68%), primary care (17%) and screening centers (15%). Eligible for VABB are considered lesions BI-RADS 4A and higher, high risk histology (B3 and

higher), radio-pathologic discordance (benign histology but suspicious lesion on image), and special cases such as patients with confirmed cancer and high anesthetic risk or BI-RADS 3 lesions at patient´s request. We use Bard Encord vacuum system with 7G and 10 G needles. Biopsies are performed in supine position. We do follow up ultrasound and mammogram the next day for possible complications.
Results: A total of 76 lesions were biopsied from March 2015 to September 2017. The most of the lesions were BI-RADS 4A (63 lesions, 83%). Regarding histological classification, there were 35 (46%) of B3 lesions (papillary and/or atypical lesions on core needle biopsy). Five cancers were diagnosed (6.6%), three of them corresponding to BI-RADS 4A lesions, one 4B lesion and one BI-RADS 3 lesion BRCA+ patient.
Conclusion: Although longitudinal studies are still needed, the excision of high-risk lesions and lesions with radio-pathologic discordance is possible with VABB system. There is generally a very good tolerance among patients with a low complication rate. The surgical intervention is avoided in 95% of the cases in our series. It is essential to have multidisciplinary collaboration for the selection of cases.

B-1395 11:26

Design, development and validation of the first 3D PET manual breast-guided biopsy system

M. Herranz[1], G. Abou-Jaoude[2], W. Liang[3], P. Aguiar[1], A. Ruibal[1];
[1]*Santiago de Compostela/ES*, [2]*Lausanne/CH*, [3]*Shanghai/CN*
(michel.herranz.carnero@sergas.es)

Purpose: Some of the problems reported with breast-specific PET imaging technology lies in those lesions able to detect but invisible to other techniques, or those that, because of their heterogeneity, are difficult to characterize, or tumours with functional resistance to chemotherapy. How we can be able to validate or demonstrate the correct diagnosis of these lesions?
Methods and Materials: The PROne BIOpsy Sistem: ProBioS™ consists 1. a resistive resin adapter with fixed or mobile grids of 1, 3 or 6 racks. 2. A disposable holding system with receptacle for blood and other fluids, sterile and detachable. 3. A specific software. The system is adapted to be able to be used with any type of manual biopsy system.
Results: Test with PROBioS: 1. calibration of the 3D positioning. 2. Checking the theoretical calibration values. 3. Verification of empirical calibration values using point sources. Accuracy definition. 4. Verification of empirical calibration values using sources mimicking tumours. 5. Verification of empirical calibration values using breast phantoms. 6. Comparison with stereotaxic biopsy. 7.- Mathematical study of correlation between the values of biopsy in stereotaxic and MAMMI corrections. 8. Compression software studies. 9. Compression hardware studies. 10. Viability and sterilization studies. 11. Biopsies on patients.
Conclusion: We present the first 3D manual biopsy system guided by dedicated breast PET, its design, and its clinical utility. The development of this technique will allow the diagnosis of breast pathology to be much more precise and provide image services with an additional tool.

B-1397 11:34

Does breast MRI have a high negative predictive value for identifying residual axillary metastases in patients treated with neoadjuvant chemotherapy

N. Sharma, S. Rajan, B. Dall; *Leeds/UK (Nisha.sharma2@nhs.net)*

Purpose: It has been well documented that Breast MRI has a high negative predictive value (95%) for axillary metastases in women being staged for breast cancer. The question being asked is how good is breast MRI in determining complete pathological response in the malignant axilla in those women treated with neoadjuvant chemotherapy (NACT) and monitored with breast MRI. The end of treatment MRI T1 and T2 weighted sequences were reviewed to assess the axilla.
Methods and Materials: From October 2013-July 2015 49 patients who had breast cancer and biopsy proven malignant axillary lymph nodes treated with NACT were identified. All patients had an end of treatment MRI scan prior to axillary surgery. The lymph nodes were classified as normal or abnormal based on the T1 and T2 W sequences.
Results: 49 patients had axillary surgery. 57%(28/49) had malignant nodes at axillary clearance and 86% were correctly identified by MRI. 43%(21/49) had pathological complete response in the axilla and MRI correctly identified 71% of the cases. MRI overcalled 6 cases as being positive that were negative at surgery - all these lymph nodes showed evidence of tumour regression at histology.
Conclusion: MRI has a lower negative predictive value in assessing the axilla in women treated with NACT. This maybe related to the fact that these lymph nodes show evidence of tumour regression in the nodes which would account for signal and morphological changes seen on MRI which categorises the lymph nodes as being equivocal rather than normal.

B-1398 11:42

Comparison between standard specimen mammography and intraoperative specimen mammography (Faxitron®) located in the surgical block: has anything changed?

L.J. Pavan, M. Durando, G. Mariscotti, S. Martinello, G. Cappello, A. Ala, I. Castellano, P. Fonio, G. Gandini; *Turin/IT*

Purpose: To compare standard specimen mammography (SSM) with remote intraoperative specimen mammography (ISM)(Faxitron®), carried out by surgeons and remotely interpreted by radiologists, assessing operative times, intraoperative additional excision (IAE) and re-intervention rates for breast conserving surgery (BCS).
Methods and Materials: We retrospectively collected 129 consecutive patients (mean age 62±11 years, 136 lesions) who had BCS with SSM at our centre between 11/2011 and 02/2013 and 138 consecutive patients (mean age 60±11 years, 144 lesions) who underwent BCS with ISM between 08/2014 and 02/2015. We excluded patients treated in the first 6 months since ISM introduction, to avoid low-experience bias. Mammographic lesions were: 88 masses, 26 microcalcifications and 22 architectural distortions in SSM group, and 95, 23 and 26 in ISM group, respectively. Diagnostic reliability of SMM and ISM was evaluated considering pathology as gold standard, using Chi-square or Fisher's tests for categorical variables, and Mann-Whitney test for continuous variables.
Results: The two groups did not statistically differ for age (p=0.2), lesion sizes (p=0.29) and tumour histotypes (p=0.75). Intraoperative time was significantly (p<0.00001) higher for SSM (132±43min) than for ISM (90±42min). In SSM group, 39/136 (29%) lesions required IAE and 53/144 (37%) in ISM group, with no significant differences (p=0.16), even at a stratified analysis by each mammographic sign. Re-intervention rates were not statistically different between the two groups [SSM: 19/136 (14%), ISM: 11/144 (8%); p=0.08]. At pathology, 9/39 (23%) IAE specimens were positive for cancer in SSM group and 18/53 (34%) in ISM group, not statistically different (p=0.25).
Conclusion: The introduction of ISM significantly reduced surgical time without significant changes in IAE rates and surgical accuracy, corroborating the comprehension between surgeons and radiologists.

Volumetric interpolated breath-hold MRI sequence: value and reliability in diagnosis of mesial temporal sclerosis

N.F. El Ameen, M.F. Amin; *El Minia/EG (nadia.elameen@yahoo.com)*

Purpose: To evaluate the role of 3D volumetric interpolated breath-hold sequence (VIBE) MRI of the brain in diagnosis of mesial temporal lobe sclerosis (MTS).
Methods and Materials: A prospective study included 45 patients with intractable epilepsy and suspected to have MTS. The patients were recruited between June 2015 and April 2016. All patients were referred from neurology department to radiology department in our institution. They underwent VIBE MRI in addition to the routine MRI protocol of the brain. Inter-observer reliability was done to the results to evaluate the reliability of VIBE sequence in diagnosis of MTS.
Results: Conventional T2WI was positive and diagnosed MTS in 34/45 (75.6%) and negative in 11/45 (24.4%) with sensitivity 90%, specificity 70% and accuracy 78%, while VIBE sequence was positive and diagnosed MTS in 39/45 (86.7%) and negative in 6/45 (13.3%) patients with sensitivity 92%, specificity 77% and accuracy 82%.
Conclusion: VIBE is a novel 3D gradient-echo sequence that offers several promising advantages if the object moves during the scan. Patients with intractable epilepsy could get much benefit from application of this sequence in routine imaging practice. It gives more clear images than T2WI and reduces the need for anaesthesia especially in children population.

Description of white matter damage in patients with mesial temporal sclerosis evaluated by diffusion tensor imaging (DTI)

L.L. Resende, K. Lyra, C. Lôbo, L. Castro, V. Passarelli, R. Valerio, C. Jorge, C.D. Leite, M. Otaduy; *São Paulo/BR (carlosfelipetl2@gmail.com)*

Purpose: Mesial temporal sclerosis (MTS) is a common cause of focal epilepsy. Although epilepsy is considered a grey-matter disease, white matter abnormalities have also been described. Describing white matter abnormality extension might help to understand differents surgical outcomes. Our purpose is to describe the tracts affected and to evaluate differences in patients with right or left MTS.
Methods and Materials: 51 patients and 30 healthy controls were submitted to brain MRI and Diffusion tensor imaging (DTI) sequences with 32 gradient encoding direction. DTI images were post-processed with the FSL software and mean and median values of fractional anisotropy (FA) were obtained from 20 tracts. We grouped patients in left and right-sided MTS and compared FA between patients and controls for commissural, association and projection tracts, grouping tracts in ipsilateral and contralateral, regarding the laterality of MTS. We considered a p value <0.05 as statistically significant.
Results: In the comparison of commissural tracts, MTS patients showed a significant lower FA for forceps minor tract. In the comparison of association and projection tracts, we observed that right-sided MTS patients had a significantly lower FA in 7 of 9 right tracts (ipsilateral) and a lower FA in 6 of 9 left tracts (contralateral). Left-sided MTS patients had a significant lower FA in 3 of 9 left tracts (ipsilateral) and 6 of 9 right tracts (contralateral).
Conclusion: This study revealed diffusional abnormalities in 14 of the 20 tracts analysed. Curiously, MTS patients presented more damage on right-sided tracts, regardless the laterality of the hippocampal sclerosis.

B-1401 10:55

Incomplete hippocampal inversion does not affect the hippocampal volume in neurologically healthy subjects

D. Bajic[1], E. Kumlien[1], M. Milivojevic[2], R. Raininko[1]; [1]*Uppsala/SE*, [2]*Uzice/RS (drabaj02@yahoo.se)*

Purpose: In cases with incomplete hippocampal inversion (IHI), also called hippocampal malrotation, the hippocampus always looks narrow in axial images. In coronal images, it is difficult to compare the volumes of the hippocampi, which can be important in epilepsy, if there is IHI in one side. The aim of the study was to evaluate if IHI affects the hippocampal volume.
Methods and Materials: Hippocampal volumes were measured semiautomatically on MRIs of 99 neurologically healthy subjects aged 1-67 years. Asymmetry indices (AI) were calculated. AI was considered positive if the right hippocampus was larger and negative if the left was larger.
Results: 25/99 (25%) of the neurologically healthy subjects had IHI: 19 left-sided, 6 bilateral. The right hippocampus was larger in 63/74 (85%) subjects without IHI and in 86 (86%) of all subjects. The volumes of the left hippocampus in subjects without and with IHI did not differ statistically significantly. AI was 0.042±0.049 (mean±SD) in the 74 subjects without IHI and it was not age-dependent. AI was 0.029±0.036 in the 19 subjects with left-sided IHI, and 0.061±0.048 in the six subjects with bilateral IHI. Differences were not statistically significant. The ±2SD limits for AI were 0.14 and -0.05 in all subjects.
Conclusion: IHI does not seem to affect the hippocampal volume in neurologically healthy subjects. Consequently, AI is not affected by IHI. AI is not age-dependent and the same criteria for normal asymmetry can be used in the evaluation of the patients at all ages.

B-1402 11:03

Utility of volumetric assessment of the hippocampal substructures in hippocampal sclerosis

A.M. Granados, J.F. Orejuela; *Cali/CO (anamaria.granados@gmail.com)*

Purpose: Pathological classification of hippocampal sclerosis (HS) is based on neuronal loss of hippocampal substructures, which has been correlated with disease duration, memory function performance, and postoperative prognosis. The purpose of this work is to evaluate the usefulness of an automated method for the assessment of hippocampal substructures on MRI studies.
Methods and Materials: Twenty-five patients with unilateral-HS and twenty-five healthy subjects were included. Volumes of the whole hippocampus and hippocampal subfields were obtained using FreeSurfer. A p value less than 0.05 was considered statistically significant.
Results: A statistically significant decrease in the ipsilateral hippocampus was found in 22 cases (88.0%). With the exception of the fissure, there was a decrease in all ipsilateral hippocampal substructures in right-HS (CA1, p=0.0223; CA2-CA3, p=0.0066; CA4-DG, p=0.0066; fimbria, p=0.0046; presubiculum, p=0.0087; subiculum, p=0.0017), and left-HS (CA1, p<0.0001; CA2-CA3, p<0. 0001; CA4-DG, p<0. 0001; fimbria, p=0.0183; presubiculum, p<0. 0001; subiculum, p<0. 0001). No decrease in overall volume was observed in three patients; however, one case showed a decrease in the volume of CA1, CA2-CA3, and CA4-DG, the second case of CA1, CA2-CA3, and subiculum; and in the other case, CA4-DG, fimbria, and presubiculum volumes were decreased.
Conclusion: The automated method used in this work could improve the predictive values of quantitative MRI analysis in the diagnosis of HS as it allows to identify focal alterations before global structural changes occur. Moreover, the good correlation found with the last ILAE classification suggests that this method could also play an important role as a prognosis tool.

B-1403 11:11

Prefrontal lobe cortex-thalamus pathway impairment in intractable temporal lobe epilepsy with executive control function abnormal: evidence from structural and functional MRI study

C. Zhang, N. Chen, K. Li, H. Yang; *Beijing/CN (chaozhang0328@hotmail.com)*

Purpose: The aim of this study was to investigate structure and functional connectivity of prefrontal lobe cortex (PFC)-thalamus pathway in unilateral intractable temporal lobe epilepsy (TLE) patients with impaired executive control function (ECF).
Methods and Materials: Thirty-seven intractable left TLE patients and twenty-three volunteers were recruited for diffusion tensor imaging and resting-state fMRI scanning. The patients were divided into two subgroups according to ECF performance which judged by Wisconsin card sorting test (WCST): ECF decreased group (18 subjects) as G1 and ECF normal group (21 subjects) as G2. The healthy control group (HC) included all 23 volunteers. The region of interest (ROI) was set in bilateral prefrontal cortex and bilateral thalamus. A general linear model (GLM) was employed to analyse fibres and functional connectivity (FC) between each pair of ROI among G1, G2 and HC (p<0.05). Pearson correlation between FC, fibre number and WCST score was also observed through partial correlation analysis (p<0.05).
Results: Fibre number and FC between left dorsolateral frontal gyrus and left thalamus of G1 were increased significantly when compared with G2 and HC (p=0.017). Both fibre number and FC had significantly negative correlation with WCST score (p<0.05).
Conclusion: This study demonstrated that decreased ECF was related to PFC-thalamus pathway. Furthermore, such alternation may potentially act as an important imaging feature for differentiating TLE patients with ECF impairment.

B-1404 11:19

Comparison between different post-processing techniques in the identification of focal cortical dysplasias in children with pharmacoresistant epilepsy

M. Rossi Espagnet, E. Bassanelli, A. Napolitano, N. Pietrafusa, L. De Palma, N. Specchio, D. Longo; *Rome/IT (camilla.rossiespagnet@gmail.com)*

Purpose: Different techniques have been developed to improve identification of malformations of cortical development such as focal cortical dysplasias (FCD) in MRI-negative patients affected by pharmacoresistant epilepsy (PRE). However, no studies investigated the reliability of these methods for the paediatric population so far. The purpose of this prospective on-going study is to compare the MAP and the SUPR-FLAIR techniques for the pre-surgical evaluation of the paediatric brain in children with PRE.
Methods and Materials: A group of 90 healthy subjects (age range 8-16 years) was used as a control group, while 10 patients (4 RMN positive and 6 RMN negative) with drug-resistant epilepsy, and histological proof of FCD, were analysed to compare the two methods. All subjects were scanned with a 3T Siemens Skyra (Erlangen, Germany). The original Map method has been optimised (Opti-MAP) by creating a specific template for paediatric subjects (90 healthy subjects), and inserting two tools into the algorithm: BET and N4ITK. For the SUPR-FLAIR Analysis the original algorithm was followed.
Results: The Opti-Map approach was successful in the 90% of cases despite the fact that most of the FCDs were type I. Conversely, the SUPR-FLAIR approach succeeded only in 20% of cases . In no cases, there was any overlap between the 2 methods.
Conclusion: From these preliminary results optimised MAP post-processing seems to be a more reliable tool compared to the SUPR-FLAIR technique in the pre-surgical evaluation of pharmacoresistant epilepsy in children. Further data are necessary to further optimise the template and validate these results.

B-1405 11:27

Mesial temporal sclerosis: is standard MRI protocol enough?

J. Ponnatapura Satyanarayana; *Bangalore/IN (psjanardhan@yahoo.com)*

Purpose: Evaluation of the different protocols of MR imaging in MTS and correlation with EEG findings. Pearls and pitfalls of MRI.
Methods and Materials: A prospective study was conducted of 52 mesial temporal sclerosis patients who underwent dedicated epilepsy protocol MRI and volumetric MRI on 1.5T within 7 days from the onset of seizures. A routine EEG from the scalp electrodes was obtained 3 days before or after the MRI.

Results: Thirty-six patients (69%) presented with partial seizure, and 31% presented with generalized clonic tonic seizure. 26% had childhood history of febrile illness. 62% diagnosed with MTS on MRI showed abnormal EEG findings and 10 showed normal EEG findings. The lateralisation of EEG in MTS patients was 70-76% (p>0.5). 98% of patients with MTS showed positive MR volumetric study (p<0.5), of which 36% showed normal EEG study (p<0.5). 100% of patients with hippocampal sclerosis were detected using "epilepsy protocol" MRI, which would have been missed if only "standard protocol" MRI was done.
Conclusion: Mesial temporal findings on MRI did not always result in abnormal EEG findings and hence newer imaging modalities like MR volumetric study, functional MRI, MR spectroscopy, SPECT and PET should be done in medically refractory seizures, especially before planning surgery.

B-1406 11:35

Comparison between BOLD-fMRI and Stereo-EEG in the pre-surgical evaluation of language dominance in children affected by pharmacoresistant epilepsy

M. Rossi Espagnet, E. Bassanelli, N. Pietrafusa, L. Figà-Talamanca, L. De Palma, D. Longo, A. Napolitano; *Rome/IT (camilla.rossiespagnet@gmail.com)*

Purpose: The optimal pre-surgical management of patients with pharmacoresistant epilepsy (PRE) has the aim to correctly identify the seizure onset zone and to verify the localisation of "critical" regions to avoid post-surgery deficits. Both task-based fMRI and Stereo-EEG demonstrated good correlation in the identification of language dominance compared to WADA test. The purpose of this preliminary study is to verify the correlation between Stereo-EEG and fMRI results in the identification of language dominance in children with PRE.
Methods and Materials: Language Task-based fMRI obtained from a 3T scanner (Siemens Skyra, Erlangen, Germany) in 5 patients with PRE were retrospectively analysed to calculate lateralisation index (LI) for all the tasks applied (semantic task, verb generation and story listening). Stereo-EEG data obtained from all patients after electrode stimulation during language-related tasks were also reviewed to verify language dominance.
Results: Language dominance obtained from SEEG and fMRI was concordant in all patients. 4/5 patients demonstrated a left language lateralisation whilst 1/5 patient with a left fronto-temporo-parietal perinatal stroke demonstrated right language lateralisation. The location of language-related areas obtained from fMRI tasks demonstrated a good correlation with those that determined a block in language tests during electrode stimulation.
Conclusion: task-based fMRI and stereo-EEG provided good correlation in the evaluation of language dominance and can be considered reliable tools in the pre-surgical evaluation of children affected by PRE.

B-1407 11:43

The role of conventional MRI-based scale in distinguishing chronic disorders of consciousness

S. Morozova, E.I. Kremneva, L. Legostaeva, E. Mochalova, D. Sinitsyn, D. Sergeev, M. Krotenkova, N. Suponeva, M. Piradov; *Moscow/RU (kulikovasn@gmail.com)*

Purpose: To evaluate predictive role of new suggested conventional MRI-based scale in distinguishing chronic disorders of consciousness (DOCDS-disorders of consciousness distinguishing scale).
Methods and Materials: Data were acquired from 24 patients with clinically assessed chronic disorders of consciousness (12 with minimal consciousness state (MCS) and 12 with unresponsive wakefulness syndrome (UWS)) due to anoxia or trauma age ranged 21-56. All patients underwent conventional MRI on Siemens Verio 3.0 T scanner, scanning protocol included conventional T2 sequence, T1 multiplanar sequence, which were used for scaling. The following parameters were suggested for DOCDS: general cortical atrophy, inner and external hydrocephalus, leukoareosis, brainstem degeneration, corpus callosum degeneration and lesions. T2WI and T1WI of all patients were assessed according to the scale resulting in a total score. Images were analysed by two experts blinded to diagnosis and it's cause. Statistical analysis was performed using SPSS 20.0.0.
Results: Total DOCDS score ranged 2-9. ROC-analysis showed threshold score 5,5, which means that patients with total DOCDS score 6 and more refer to UWS, 5 and less refer to MCS with sensitivity 76,9%, specificity 90,9% (area under the curve (AUC) = 82,9%, p=0,006).
Conclusion: Taking into consideration relatively high sensitivity and specificity, DOCDS could be used as an additional instrument in distinguishing chronic disorders of consciousness. The study was supported by Russian Science Foundation under grant 16-15-00274.

B-1408 11:51

Utility of MRI brain epilepsy protocol in new onset seizures: how is it different in developing countries?

J. Ponnatapura Satyanarayana; *Bangalore/IN (psjanardhan@yahoo.com)*

Purpose: To evaluate the diagnostic efficacy of standard MRI brain in patients with first-onset seizures and to identify whether there is an increase in the diagnostic yield with addition of a dedicated seizure protocol.
Methods and Materials: 129 cases were studied for a period of 18 months. Chi-square test was used to test for the difference in proportion. The correlation between MRI brain and EEG was studied using McNemar test. Patients underwent both standard protocol and dedicated epilepsy protocol MRI brain scanning on 1.5T within 7 days from the onset of seizures. A routine EEG from the scalp electrodes obtained 3 days before or after the MRI and after presentation with the index seizure, preferably within 48 hours.
Results: The diagnostic yield of MRI was 47%. Infection and inflammation was most common (28%). Of the 59 patients with potential epileptogenic lesions, 63% were detected using "standard protocol" MRI and remaining 37% lesions were detected using "dedicated epilepsy protocol" MRI. Of the epileptogenic lesions, all 11 patients (100%) with hippocampal sclerosis were detected using "epilepsy protocol" MRI which would have been missed if only "standard protocol" MRI was done. Patients with focal-onset seizures had a higher proportion of potentially epileptogenic lesions (81%) compared with the patients with generalized clonic tonic seizures.
Conclusion: A dedicated epilepsy protocol MRI should be done in all patients who present with first-onset seizures, which allows identification of a lesion and earlier consideration of epilepsy surgery especially in patients with focal-onset seizures.

Is there a difference in the degree of enhancement in contrast-enhanced spectral mammography between invasive lobular carcinomas and invasive ductal carcinomas?

T. van Nijnatten[1], M.B. Lobbes[1], K. Pinker[2], D.M. Keating[2], J.S. Sung[2], M. Morrow[2], J.E. Wildberger[1], M. Smidt[1], M.S. Jochelson[2]; [1]*Maastricht/NL*, [2]*New York, NY/US (t.vannijnatten@maastrichtuniversity.nl)*

Purpose: To investigate the differences in the degree of lesion enhancement of invasive lobular carcinomas (ILC) and invasive ductal carcinomas in contrast-enhanced spectral mammography (CESM).
Methods and Materials: This two-centre HPAA-compliant retrospective study included consecutive patients with ILC or IDC who underwent preoperative CESM between 2010 and 2017. Three independent readers (one expert CESM reader, one reader with greater than 4 years of experience in CESM and one inexperienced reader) assessed the degree of lesion enhancement of the cancers, blinded to histology. Enhancement was scored as: possible, weak, moderate or strong. Interobserver agreement was calculated by using quadratic-weighted kappa (including 95% confidence intervals) to compare the results of the expert CESM reader with the other readers.
Results: A total of 44 patients were included: 22 patients with ILC and 22 patients with IDC. The degree of lesion enhancement was classified significantly more often as possible or weak in patients with ILC compared to IDC (reader 1: 31.8% versus 4.5%, p=0.045; reader 2: 36.4% versus 18.2%, p=0.310; reader 3: 22.7% versus 4.5%, p=0.185). All other lesions were considered moderate or strong enhancement. Inter-observer agreement was good for the two experienced CESM readers (κ=0.723 (0.584 - 0.862) as well as for the expert CESM reader compared to the non-experienced CESM reader (κ=0.728 (0.598 - 0.858)).
Conclusion: There is a difference in the degree of enhancement between ILC and IDC, with ILC significantly more often presenting with weak enhancement. In case of weak lesion enhancement, radiologists should consider ILC for the final diagnosis.

Quantification of enhancement in contrast-enhanced spectral mammography using a custom-made quantifier tool: a proof-of-concept study

H.K.P. Mulder, C.R. Jeukens, M. Rousch, J.E. Wildberger, M.B. Lobbes; *Maastricht/NL (harmen.mulder@mumc.nl)*

Purpose: Contrast-enhanced spectral mammography (CESM) is superior to conventional mammography and is able to show contrast agent uptake (enhancement) in breast lesions, increasing its diagnostic accuracy. A major step forward would be the ability to quantify enhancement, perhaps allowing discrimination between malign and benign tumours. In this proof-of-concept study, we present a novel quantification method for rating CESM enhancement.
Methods and Materials: We developed a novel, custom-made quantifier tool (*I*-STRIP) filled with different concentrations of contrast agent, which is positioned near the breast during acquisition. The measured CESM signal in the *I*-STRIP is used to quantify iodine mass thickness (IMT) in the breast. We evaluated the accuracy and precision using a dedicated phantom containing lesions with known IMT. Furthermore, we tested its effect on image quality and clinical use in five breast cancer patients.
Results: Phantom experiments showed that measured enhancement scales linearly with IMT. Furthermore, enhancement in a medium-thick (4.6 cm) breast phantom corresponded within 11.8%, 9.0% and 13.2% to enhancement in the *I*-STRIP for IMT's of 1.5, 3.0 and 7.5 mg/cm^2, respectively. Only for lesions near the periphery of the phantom the so-called breast-within-breast artefact resulted in overestimation of enhancement. In five clinical experiments, the workflow and the image quality were not influenced by the *I*-STRIP. The mean IMT of five invasive breast cancers was 2.1 mg/cm^2 (range 1.3-3.4 mg/cm^2).
Conclusion: We showed in both phantom and clinical experiments that we could accurately quantify the CESM enhancement on recombined CESM images without affecting image quality.

Contrast-enhanced spectral mammography and diffusion-weighted image with backward signal suppression: which is more effective in breast cancer detection?

N.A.E. ElDeib, F.M.E.S. Singer, S.M.M.T. Talaat, M. Anas, M. Rezk; *Cairo/EG (nohasaid.rad@hotmail.com)*

Purpose: The purpose of this study is to assess diagnostic accuracy of diffusion weighted imaging with background signal suppression (DWIBS) compared with contrast-enhanced mammography in the diagnosis of breast lesions and correlate the findings with the histopathological results.
Methods and Materials: 52 female patients have enrolled in this prospective study their age ranged between 23-77 years old, mean age is about (47.83,+/-SD=11.55)years. The patients presented with breast lesions by mammography were assessed by both contrast-enhanced mammography and DWIBS MR. Written consent was taken from the patients. The maximum dimension of the lesion or lesions was measured in both studies. Findings assessed by two radiologists, one for each modality without knowing pathologic results.
Results: The primary unit of analysis was the lesion ,54 lesions were detected in 52 cases .39/54 of the lesions were histopathologically proven as malignant and 15/54 were benign. The calculated sensitivity ,specificity,total accuracy ,PPV and NPV for CEDM were (100.00%, 73.30%, 92.60%, 90.70% and 100.00%)respectively The calculated sensitivity, specificity, total accuracy PPV and NPV for DWIBS MRI were (94.90%, 93.30%, 94.40%,97.40% and 87.50%)respectively DWIBS MRI showed the highest diagnostic performance and accuracy due to improved specificity by reducing number of false positive results, compared to CEDM.
Conclusion: The DWIBS is a new non-contrast imaging technique with an improved specificity when compared to CEDM. DWIBS is superior to CEDM in the detection of both malignant and benign lesions. CEDM is less expensive , easier and quicker examination compared to MRI.

B-1412 10:54

Feasibility of contrast-enhanced spectrum mammography in breast cancer diagnosis

L. Zheng, C. Zhang, K. LI; *Shanghai/CN (zhenglinfeng04@aliyun.com)*

Purpose: To study feasibility of contrast-enhanced spectral mammography (CESM) in the diagnosis of breast cancer.
Methods and Materials: Institutional review board approved this study. Ninety-one cases clinically diagnosed with breast cancer were underwent CESM, mammography (MG) and contrast-enhanced magnetic resonance imaging (CE-MRI). Detectable rate of CESM, MG and CE-MRI were compared, respectively. Then average maximum dimension of suspicious lesions on CESM image was measured and compared with pathological specimen. Finally, morphologic features of CESM images were analysed for four different molecular subtypes of breast cancer cases.
Results: CESM has high detectable rate than MG and CE-MRI for breast cancer (97.0% vs 83.3% vs 91.0%; P<0.05). For the measurement of mass average maximum dimension, no difference was found between CESM and pathology (P>0.05). However, CESM image features of the four different molecular subtype cases, including average maximum dimension of mass, shape, margin, enhancement and enlargement of lymph node, were of statistical difference (P<0.05).
Conclusion: CESM may play an important role in the breast cancer clinical practice.

B-1413 11:02

Features from computerised texture analysis of breast cancer on contrast-enhanced spectral mammography to predict tumour aggressiveness

C. Bassi, L.S. Fournier, M. Bouaboula, C. Rousseau, A.-S. Jannot, C. Ngo, H. Roussel, F. Chamming's; *Paris/FR (clotilde.bassi@gmail.com)*

Purpose: To evaluate whether heterogeneity as evaluated by texture analysis on contrast enhanced spectral mammography (CESM) was associated with breast cancer features on pathology.
Methods and Materials: Institutional review board was obtained. 79 patients with 79 breast cancers who underwent CESM between january 2015 and may 2017 were included in this retrospective monocentric study. 2D texture analysis was performed using TexRAD software. Quantitative texture parameters were compared with pathological features. Eigen value analysis was used to determine the number of independent parameters. Univariate analysis was performed to determine texture parameters significantly associated with tumour pathology. After Bonferroni correction, P less than 0,0014 was considered statistically significant.
Results: On univariate analysis, Kurtosis for Spatial scale filter (SSF) 0,5 (P = 0,0015) and 4 (P = 0,0006), skewness for SSF2 (P = 0,003) and mean proportion of positive pixels (MPP) for SSF2 (P = 0,004) showed significant association with mitotic index. There was also a trend for association between MPP SSF2 (P = 0,003) and SSF4 (P = 0,004) and tumour grade.
Conclusion: On CESM, heterogeneity of breast cancers as measured by texture analysis is associated with mitotic index and could be a promising biomarker of tumour aggressiveness.

B-1414 11:10

Impact of mammogrphic features and level of tumour-infiltrating lymphocytes on prognosis of tripple-negative breast cancer

C. Casella, G. Mariscotti, M. Durando, I. Castellano, E. Vissio, F. Esposito, S. Osella Abate, P. Fonio, G. Gandini; *Turin/IT (loricri@inwind.it)*

Purpose: Triple-negative breast cancer (TNBC) is known to be associated with aggressive clinical behaviour and poor clinical outcomes. Elevated levels of tumor-infiltrating lymphocytes (TILs) positively correlate with the pathologic complete response and increased survival in patients with TNBC. The purpose of this study was to investigate associations between mammographic features, TIL levels and prognosis in patients with TNBC.
Methods and Materials: We conducted a retrospective observer study that includes 81 patients (mean age 56,6 years; range:36,6-88,1) with pathologically confirmed TNBC, who consecutively underwent preoperative digital mammography between January 2010 and March 2017. All mammographic lesions were evaluated by radiologists and classified in accordance with the BI-RADS lexicon. Tumors were divided into two groups: those with a TIL level of less than 10% and those ≥10%. Univariate and multivariate analysis were performed on the data.
Results: TNBCs were predominantly mass lesions (73/81, 90,1%), subgrouped in 16(21,9%) masses associated with microcalcifications, 3(4,1%) with architectural distortions and 1 with microcalcifications and architectural distortion. Out of 73 masses, 22(30%) had circumscribed margins, statistically associated with favourable clinical behaviour (IC 0.02-1.00, p=0.05); considering the 20/81(24.7%) cases with recurrence, only in 1 case the TNBC was a mass with circumscribed margins. In 36/81(44.5%) TNBC TILs level was ≥10% and in 45(55.5%) <10%. TILs ≥ 10% proved to be a positive prognostic biomarker for disease free-survival (HR 0.30; p=0.05).
Conclusion: In the TNBCs, circumscribed margins at mammography, as well TILs≥10% could provide added diagnostic benefit for the identification and treatment planning of TNBC with a good prognosis.

B-1415 11:18

Low-dose perfusion CT for quantification of tumour vascularity in breast cancer: correlation with prognostic biomarkers

B.K. Seo[1], E.K. Park[1], M. Kwon[1], C.S. Ko[1], J. Cha[1], K.R. Cho[2], O.H. Woo[2]; [1]*Ansan/KR*, [2]*Seoul/KR (seoboky@korea.ac.kr)*

Purpose: To investigate the feasibility of low-dose perfusion computed tomography (CT) in breast cancers for quantification of tumor vascularity and to correlate perfusion indexes with prognostic biomarkers.
Methods and Materials: Low-dose perfusion CT was performed in 70 patients with invasive breast cancers. CT was performed in the prone position with a spectral CT (iQon, Philips Healthcare) after contrast media (Xenetix350, Guerbet) injection. On CT perfusion maps, perfusion (mL/100g/min), blood volume (mL/100g), time to peak (sec) and peak enhancement (HU) were measured in the tumor, normal breast glandular tissues and fat. Pathologically, tumor grade, estrogen receptor (ER), progesterone receptor (PR), human epidermal growth factor receptor 2 (HER2), and Ki67 level were evaluated. Statistically, CT perfusion indexes of the tumor and normal glandular tissues or fat was compared using the Wilcoxon signed rank test and CT indexes were correlated with histological characteristics with the Mann-Whitney or Kruskal-Wallis test.
Results: In breast cancers, perfusion, blood volume and peak enhancement values were significantly higher and time to peak was shorter than these values in normal glandular tissues and fat ($P < .05$). Perfusion significantly increased in breast cancers with high grade, ER- or HER2+ ($P < .05$). Time to peak decreased in cancers with high grade, ER-, HER2+ or high Ki67 level ($P < .05$). Peak enhancement significantly increased in high grade cancers ($P < .05$).
Conclusion: Low-dose perfusion CT in the prone position is feasible to quantify tumor vascularity in breast cancers and CT perfusion indexes may predict prognostic biomarkers.

B-1416 11:26

A visual grading analysis of propagation-based phase-contrast CT mammography

S. Tavakoli Taba[1], P. Baran[2], S. Lewis[1], R. Heard[1], S. Pacile[3], Y.I. Nesterets[2], S.C. Mayo[2], C. Dullin[4], D. Dreossi[3], F. Arfelli[3], D. Thompson[2], M. McCormack[2], M. Alakhra[1], F. Brun[3], M. Pinamonti[3], C. Nickson[2], C. Hall[2], F. Zanconati[3], D.J. Lockie[2], H. Quiney[2], G. Tromba[3], T.E. Gureyev[2], P.C. Brennan[1]; [1]*Sydney/AU*, [2]*Melbourne/AU*, [3]*Trieste/IT*, [4]*Göttingen/DE*

Purpose: While all current X-ray based breast imaging modalities rely on differences in soft tissue X-ray attenuation (absorption contrast), phase-contrast imaging (PCI) has capacity to also visualise variations in X-ray refraction (phase contrast). To successfully translate the preclinical results of PCI technology into clinical implementation, the imaging variables of the technology must first be optimised through radiological assessments by breast radiologists and medical imaging experts. We conducted a series of assessments to establish the optimum imaging conditions of X-ray propagation-based imaging (PBI), which is experimentally the simplest PCI technique for clinical purposes.
Methods and Materials: We investigated 161 synchrotron-based CT reconstructions of one full-size section of a breast specimen produced by adjusting the following five imaging parameters: sample-to-detector distance, X-ray energy, CT reconstruction method, phase retrieval algorithm applied to the CT projection images and maximum intensity projection in image reconstruction. A visual grading analysis was conducted in two stages (13 assessors in stage I and 15 assessors in stage II) by comparing various radiological image quality attributes of PBI CT scans with reference images approximating conventional CT images.
Results: The results showed that the application of the longest sample-to-detector distance (9.31 m in our experiments), the lowest employed X-ray energy (32 keV), full application of the phase retrieval algorithm and the use of maximum intensity projection could substantially improve the image quality compared with conventional imaging.
Conclusion: The results from this study should provide a strong basis for future radiological assessments and clinical testing of this advanced X-ray imaging technology.

Exploring contrast agents in phase-contrast x-ray mammography: an ex vivo pilot study

K. Lang[1], C. Arboleda[2], S. Forte[3], Z. Wang[2], R. Kubik-Huch[3], M. Stampanoni[4]; [1]*Zurich/CH*, [2]*Villigen/CH*, [3]*Baden/CH*, [4]*Zürich/CH (kristina.lang@med.lu.se)*

Purpose: Phase contrast x-ray mammography (PCM) is an experimental breast imaging method, at the edge of clinical implementation, that besides absorption can measure the refraction and scattering of x-rays resulting in differential-phase-contrast (DPC) and dark-field (DF) images. We assessed the feasibility of using microbubbles and iodine contrast agents in PCM.
Methods and Materials: An ex vivo phantom of a fresh chicken breast (5x5x3cm) with fragments of eggshells simulating calcification clusters was used. Native and post-contrast images were acquired with a clinically compatible grating-interferometry-based mammography setup, based on a modified Philips MicroDose mammography system, operated at 38 kvP, 14 sec acquisition time, with an estimated dose of 1.3 mGy. 2 mL of sulphur hexafluoride microbubbles (SonoVue 8 µL/mL, Bracco) used for contrast-enhanced ultrasound, and iodine (Iopamiro 370 mg/mL, Bayer) were, respectively, injected into the phantom. The visibility of the contrast agents in the absorption, DPC and DF images were analysed in a side-by-side comparison and the contrast-to-noise-ratio (CNR) between the contrast agent and surrounding tissue was calculated.
Results: The microbubbles were clearly visible in the DF image (CNR=2.5), but not in the absorption or DPC images. The iodine was visible in the absorption image (CNR=15.8) and as noise in both the DF and DPC images.
Conclusion: This is a first proof-of-principle that microbubbles can be used as a contrast agent in clinically compatible PCM, due to their scattering properties, which implies a potential use of a contrast agent with a high safety profile in x-ray-based breast imaging.

Effectiveness of superb microvascular imaging (SMI) in differentiating intraductal breast lesions

S. Bakdik, S. Arslan, F. Öncü, M.S. Durmaz, A. Altunkeser, M.A. Eryilmaz, Y. Unlu; *Konya/TR (oncufatih@gmail.com)*

Purpose: The aim of this study is to compare the diagnostic performance of Superb Microvascular Imaging (SMI) and power Doppler imaging (PDI) for differentiation of intraductal breast lesions.
Methods and Materials: A total of 54 intraductal breast lesions (13 solidified debris, 26 benign, 10 atypical and 5 malignant) in 53 patients were examined with B-mode ultrasonography, PDI and SMI. Vascularity grading, distribution of microvessels and penetrating vessels were evaluated with each doppler technique. Diagnostic performances of both methods were compared.
Results: SMI is more efficient in detecting flow signals than PDI. The highest diagnostic accuracy rates were achieved with SMI by using vascular grading. When hypervascularity was used as a cut-off value to differentiate malign and atypical lesions from benign lesions, sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were 66.6%, 80.7%, 66.6%, 80.7%, and 75.6% for PDI, 86.6%, 76.9%, 68.4%, 90.9% and 80.4% for SMI respectively.
Conclusion: SMI is more sensitive than PDI in detecting subtle blood flow of intraductal breast lesions. The novel and promising vascular imaging technique can be helpful to B-mode ultrasonography to distinguish intraductal breast lesions.

Usefulness of automated breast volume scanner to evaluate the early response to neoadjuvant therapy in breast cancer patients: a prospective study

A. D'angelo[1], P. Rinaldi[1], R. Rella[1], M. Giuliani[1], P. Belli[1], G. Carlino[1], C. Grippo[1], M. Romani[1], R. Manfredi[2]; [1]*Rome/IT*, [2]*Verona/IT (anna.dangelo05@gmail.com)*

Purpose: To investigate the accuracy of ABVS compared with conventional ultrasound (US) to evaluate the early assessment of response to neoadjuvant therapy (NADT, chemotherapy/hormone therapy).
Methods and Materials: IRB-approved prospective single-center study. 35 consecutive patients (range 25-65 years), eligible for NADT, were enrolled. They underwent ABVS, US, MRI and mammography at the beginning of NADT, at the mid-therapy and before the surgery. MRI has been considered the gold standard. Two breast radiologists independently assigned a BI-RADS score to ABVS, MRI, US and MG, and they evaluated tumour response using RECIST criteria. Cohen's kappa coefficient was used to assess the agreement between ABVS and US.

Results: The comparison of ABVS and US showed that ABVS had a sensitivity of 86.7% [26 positive cases at ABVS/30 positive cases at US; 95% confidence interval (CI) 70.3%-94.7%], and a specificity of 80.0% (4 negative cases at ABVS/5 negative cases at US; 95% CI 37.6%-96.4%). Positive and negative predictive values (PPV and NPV) were, respectively, 96.3% (26 positive cases at ABVS and US/27 total positive cases at ABVS; 95% CI 81.7%-99.3%) and 50% (4 negative cases at ABVS and US/8 total negative cases at ABVS; 95% CI 21.5%-78.5%). The agreement between ABVS and US was 53.3% (Cohen's kappa p value=0.001).
Conclusion: Diagnostic performance of ABVS is high, indicating a potential use of it, in addition to MRI, as a useful tool for early prediction of response to NADT.

3D printed model based on knee MRI as a new tool in surgical planning of anterior cruciate ligament reconstruction
L.J. Pavan, R. Faletti, L. Nicolet, A. Cosentino, A. Di Chio, M. Gatti, S. Fiore, F. Bonino, P. Fonio; *Turin/IT (lucajpavan@gmail.com)*

Purpose: The aim of the study was to compare measurement of transepicondylar femoral axis (TFA) and planned length of the surgical graft, both calculated on 3D printing models and on multiplanar reconstruction (MPR) of knee MRI, in view of anterior cruciate ligament (ACL) surgical reconstruction.
Methods and Materials: Sixteen healthy volunteers with no ACL lesions (6 females, 10 males, mean age 27 years, range 22-34y) underwent standard knee MRI examination on a 1.5T scanner (Philips Achieva 2.6®) with a complimentary T1-weighted volumetric gradient echo sequence. Knee bones were isolated and elaborated with open source softwares (Osirix®, Meshmixer®, Cura®, Slic3r®) to obtain a STL file for a Ultimaker2+® 3D extrusion printer. TFA measurement and ACL graft length were blindly calculated by an orthopaedic on 3D-printed models and by a radiologist on MPR images and compared using Wilcoxon signed-rank test.
Results: Mean values of TFA were 82,2±7 mm on 3D model and 83,1±7 mm on MPR images, with no significant difference (p=0.056). Mean values of graft lengths were significantly lower (p<0.001) on 3D printed models (136.6±13 mm) than on MPR images (146.1±13 mm), with a mean difference of 9.5±4 mm. Mean printing time was 11±1.8 hours and mean material cost 4.33±0.5 €.
Conclusion: 3D printing is a reliable, non-expensive technique with good anatomical correlation that needs further studies for a better assessment. A 9.5 mm difference in the planned length of ACL graft may still be acceptable from an orthopaedic point of view, on an average 140-160-mm graft.

B-1421 10:38

Anterior inferior iliac spine morphology: quantitative and qualitative assessment in an asymptomatic population
F.F. Ergen[1], O. Topcuoglu[1,2], S. Ardali[1], T. Cankurtaran[1], A. Dolgun Barak[1], U. Aydingoz[1]; [1]*Ankara/TR*, [2]*Istanbul/TR (omtopcuoglu@gmail.com)*

Purpose: To assess the prevalence of anterior inferior iliac spine (AIIS) types, and to investigate the quantitative measurements that characterise AIIS morphology in an asymptomatic adult population.
Methods and Materials: In this prospective study, 358 hips from 179 consecutive subjects (age range, 19-82 years; 91 males, 88 females), who underwent CT examination for reasons other than hip problems and were negative for hip impingement test, were analysed. AIIS types were determined (1, flat wall of the ilium between distal end of AIIS and acetebular rim; 2, bony eminence between distal end of AIIS and acetebular rim; and 3, extension of AIIS to the anterior superior acetabular rim) and AIIS tip angle (TA), direct distance (DD) of the anterior acetabular rim to AIIS as well as projectional distances in vertical (VD) and horizontal (HD) planes were measured. Age- and gender-related factors were searched using two-way ANOVA test under three age groups (18-39, 40-59, and ≥60 years).
Results: There were 238 (66.5%) type 1, 118 (33.0%) type 2, and 2 (0.5%) type 3 AIISs, with significant difference between AIIS types among age groups and genders (P<0.001). VD and DD showed age- and gender-related (P<0.001, P=0.001), and TA demonstrated gender-related differences (P=0.001). Inter-observer variability was good for TA and moderate to poor for other measurements.
Conclusion: Type 1 AIIS is the most common shape across all age groups in adult females and in young and middle-aged adult males. TA, DD, and VD might be reliably used for the evaluation of AIIS morphology.

B-1422 10:46

Association between cam type femoroacetabular impingement and osteitis pubis on MR images
A.S. Akgun, M. Agirman; *Istanbul/TR (drayserap80@gmail.com)*

Purpose: Retrospectively to search whether there is an increase prevalance of osteitis pubis by MR imaging in patients with cam femoroacetabular impingement (FAI).
Methods and Materials: The study included 178 subjects; 90 patients with cam-type FAI diagnosed by magnetic resonance imaging and 88 subjects used as a control group. Additionally their MR data were analyzed for the characteristics of osteitis pubis, with severity graded from minimal to severe (4-point scale).
Results: A statistically significant increase in the prevalence of osteitis pubis was found in patients with femoroacetabular impingement compared with age-matched control subjects, with a prevalence of 45.6 % in the femoroacetabular impingement group compared with 5.7 % in the control group (*p*= 0,000).
Conclusion: Femoroacetabular impingement results in restriction of internal rotation of the hip joint. This abnormal biomechanical stress lead to increased stresses at the pubis symphysis.
Keywords: Femoroacetabular impingement, Alpha angle, Osteitis pubis.

B-1423 10:54

Gouty knee arthritis: ultrasound findings compared to dual-energy CT
M.M.H. Abd Ellah[1,2], S. Strobl[1], S. Rauch[1], E.J. Halpern[3], C. Kremser[1], W. Jaschke[1], A. Klauser[1]; [1]*Innsbruck/AT*, [2]*Assiut/EG*, [3]*Philadelphia, PA/US (dr_m_hamdy2006@hotmail.com)*

Purpose: To describe and compare findings of ultrasound (US) and dual-energy computed tomography (DECT) in patients with gouty knee arthritis.
Methods and Materials: Sixty-five patients (52 males and 13 females, mean age 61.7 years) with gouty knee arthritis underwent DECT examination using 128-multidetector CT scanner (Somatom Definition Flash, Siemens Healthcare, Forchheim, Germany) followed by US examination using a 5-18 MHz linear array transducer (Hitachi Aloka Medical, HI Vision Preirus, LTD, Tokyo). Both intra- and extra-articular findings of each modality were tabulated and the accuracy of imaging was compared to clinical diagnosis.
Results: The overall diagnosis of gout was positive in 52/65 patients (80%) by DECT versus 33/65 patients (50.8%) by US (P=0.0016). Among positive exams, DECT demonstrated intra-articular gouty deposits in 43/52 patients (cartilage 51.9%, lateral meniscus 65.4% and medial meniscus 42.3%), while US demonstrated intra-articular deposits in 31/33 patients (double contour 69.7%, tophi 51.5%, aggregates 27.3%), P=0.059. DECT demonstrated extra-articular deposits in 44/52 patients (quadriceps tendon 48.1%, patellar tendon 42.3%, lateral collateral ligament 15.4% and medial collateral ligament 23.1%), while US demonstrated extra-articular deposits in 11/33 patients (P<0.0001).
Conclusion: Although DECT and US both can detect gouty deposits in the knee, DECT is more sensitive than US for detection of gouty deposits. However, US still has a role as a cost-effective and widely available imaging modality in gout diagnosis especially upon detection of certain findings as double contour.

B-1424 11:02

Influence of meniscus tears on cartilage T2 relaxation time in subjects with and without knee osteoarthritis
R. Kijowski, K. Woo, F. Liu; *Madison, WI/US (rkijowski@uwhealth.org)*

Purpose: To investigate the influence of meniscus tears on cartilage T2 relaxation time in subjects with and without knee osteoarthritis.
Methods and Materials: Cartilage T2 was measured in the medial and lateral compartments of the knee in 93 subjects with 87 medial and 27 lateral meniscus tears and in a control group of 30 subjects without meniscus tears. Radiographs were reviewed to determine the Kellgren-Lawrence (KL) grade of knee osteoarthritis. Linear regression models adjusted for age and gender were used to compare cartilage T2 between groups of subjects and between meniscus tear types (vertical, horizontal, complex, and root).
Results: KL-0 (n=46), KL-1 (n=27), and KL-2 (n=20) subjects with meniscus tears had significantly higher (p<0.001) cartilage T2 within the medial compartment than KL-0 control subjects without meniscus tears (n=30). KL-1 and KL-2 subjects with meniscus tears had significantly higher (p<0.01) cartilage T2 within the lateral compartment than KL-0 control subjects. KL-0 subjects with medial meniscus tears (n=44) had significantly higher (p<0.001) cartilage T2 in the medial compartment than KL-0 control subjects. There was no significant difference (p=0.09-0.84) in cartilage T2 within the medial and lateral compartments between KL-0, KL-1, and KL-2 subjects with meniscus tears. Cartilage T2 in the same compartment as the meniscus tear was not significantly different (p=0.06-0.81) between tear types.

Conclusion: Subjects with meniscus tears had significantly higher cartilage T2 within the knee than subjects without meniscus tears controlling for age, gender, and KL grade which indicates that meniscus tears are an independent risk factor for cartilage degeneration.

B-1425 11:10

Subchondral bone/cartilage: a functional unit? Bone density and cartilage thickness are correlated

P. Omoumi, H. Babel, B. Jolles, J. Favre; *Lausanne/CH (patrick.omoumi@chuv.ch)*

Purpose: To test whether subchondral bone mineral density (sBMD) and cartilage thickness (CTh) of femoral condyles are correlated in knees without and with severe medial femorotibial osteoarthritis (OA), using a subregional analysis with CT arthrography.
Methods and Materials: Knee CT arthrograms of 80 patients, divided into groups of non-OA (n=40,13males,61.4±6.2years) and severe medial OA (n=40,19males,64.2±10.8years) knees, were retrospectively analyzed. Cartilage and subchondral bone contours were segmented on a custom-designed software, leading to 3D models on which each point of the articular surface is given a CTh and sBMD (average signal intensity over the most superficial 3mm of subchondral bone) value. 3D property maps were produced by calculating average values for the entire weight-bearing regions as well as standard subregions of interest. Multiple regression analyses were performed to test for relationships between sBMD and CTh (regional and subregional values, as well as medial-to-lateral ratios), with covariates of age, gender and femoral bone size in any of the groups and regions/subregions (alpha<5%)
Results: For non-OA knees, sBMD medial-to-lateral ratios were significantly positively correlated with CTh medial-to-lateral ratios for the total regions (R^2=0.23,p<0.01), the external (R^2=0.35,p<0.01), and internal (R^2=0.12,p<0.03) subregions. For OA knees, sBMD medial-to-lateral ratios were significantly negatively correlated with CTh ratios for all regions/subregions (all R^2≥0.33,p<0.01), except for the internal subregion (R^2=0.08,p=0.08).
Conclusion: The positive correlation between sBMD and CTh in non-OA knees, and the negative one in OA knees brings support to the theory of a subchondral bone/cartilage functional unit, which could help to better understand the pathophysiology of OA.

B-1426 11:18

Increased perfusion in subchondral bone marrow lesions in knee osteoarthritis measured with quantitative DCE-MRI

B. De Vries, J. Verschueren, D. Poot, E. Oei, G.P. Krestin; *Rotterdam/NL (b.devries@erasmusmc.nl)*

Purpose: Knee osteoarthritis (OA) on MRI is characterized by articular cartilage degeneration, synovial inflammation, and subchondral bone marrow lesions (BMLs). Altered blood perfusion in subchondral bone is also considered an important OA process which may be associated with altered fluid dynamics, inflammation, bone remodeling, and cartilage degeneration. Since it is unknown whether BMLs directly represent altered blood perfusion, our aim was to quantitatively analyze perfusion in subchondral BMLs with dynamic contrast-enhanced MRI (DCE-MRI).
Methods and Materials: 16 patients with unicompartmental knee OA were prospectively included. Multisequence MRI including DCE-MRI was performed at 3T (GE Discovery MR750) using an 8-channel knee coil. DCE-MRI was acquired using a sagittal fat-suppressed 3D SPGR sequence (35 phases of 10 seconds) after intravenous contrast administration (0.2 mmol/kg gadopentetate dimeglumine, 2 ml/s). On fat-saturated T2-weighted images, regions-of-interest (ROIs) were defined in tibial or femoral subchondral bone containing BMLs and in surrounding subchondral bone without BMLs. Ktrans, a measure of capillary permeability, was calculated in each ROI. Mean Ktrans was mapped and compared between subchondral bone with and without BMLs using the Wilcoxon signed rank test.
Results: Subchondral BMLs were present in all patients. Perfusion maps and analysis of Ktrans consistently showed significantly (p<0.001) higher Ktrans values within subchondral BML ROIs compared to surrounding subchondral bone without BMLs.
Conclusion: Subchondral BMLs are associated with increased blood perfusion compared to subchondral bone regions without BMLs. This finding may aid in the understanding of OA pathogenesis and further research is needed to elucidate temporal relationships and correlation with symptoms.

B-1427 11:26

Who runs further? Intra-articular Platelet Rich Plasma (PRP) vs Viscosupplementation (HA) and PRP in the treatment of knee osteoartrithis: six-months follow-up study using T2 mapping

E. Cannizzaro, F. Bruno, S. Quarchioni, I. Capretti, S. Mariani, F. Arrigoni, L. Zugaro, A. Barile, C. Masciocchi; *L'Aquila/IT (estercannizzaro@hotmail.it)*

Purpose: To evaluate clinical outcomes and the degree of knee cartilage repair using T2 mapping sequences in patients with knee condropathy treated with intrarticular injection of Platelet Rich Plasma (PRP) or combined Viscosupplementation (HA) and PRP.
Methods and Materials: We analyzed 58 patients (33 males and 25 females; mean age 32,6±11,5 years) who underwent to intrarticular injection procedures in our center, with diagnosis of knee condropathy. All patients underwent to MRI (3T) and were evaluated before and after treatment (6 months) using images findings (WORMS score and T2 mapping values) and clinical outcomes (WOMAC index). All patients were randomly divided into two groups: Group A (29 patients) treated with PRP and Group B (29 patients) treated with PRP and HA.
Results: Group A showed an improvement of WOMAC index of 40%; the WORMS score showed improvement with decrease of the mean values (from 8,6 pre-treatment to 6,9 post-treatment). T2 mapping evaluation showed mean values of 46,7ms post-treatment (51,86 ms pre-treatment). Group B showed a clinical improvement of WOMAC index of 65%, with a decrease of WORMS score from 8,4 to 6,7. Mean T2 mapping values were 51,39 pre-treatment vs 45,19 post-treatment . All results showed statistical significance (p< 0.005).
Conclusion: Both treatments showed similar results in terms of morphological improvement as showed by T2 mapping evaluation. Combined therapy PRP and HA showed higher efficacy in terms of clinical improvement compared to PRP therapy.

B-1428 11:34

The patella-shape: is it relevant to the analysis of patella malalignment?

A. Kolb, C. Chiari, R. Windhager; *Vienna/AT (alexander.kolb@meduniwien.ac.at)*

Purpose: The tibial-tubercle-trochlear-groove-distance (TT-TG) is an established risk factor for patellar instability. However, it was criticised that TT-TG-measurements might be increased due to trochlear dysplasia despite a normal tibial tubercle position. To avoid this problem, the tibial-tubercle-posterior-cruciate-ligament-distance (TT-PCL) was suggested. Our study aimed to analyse, whether the patella shape represented as patellar-ridge-offset (PRO), is suitable to correct the TT-TG-distance in cases of trochlear dysplasia.
Methods and Materials: A retrospective analysis of 20 routine MRIs of patients with mixed patellar shapes and history of patellar instability was performed (mean age 24yrs). The PRO was defined as distance between the patellar-ridge and the patella-midpoint parallel to the inclined patella, measured on axial MRI slices. In contrast to the TT-TG-distance the combined PRO-TT-TG-distance gives information on the position of the knee extensor complex relative to the tibial tubercle.
Results: Mean RPO was 4.0mm (STD=2.00; range -1.5 to 7.6mm). TT-TG showed a very strong correlation to TT-PCL and PRO-TT-TG (p=<0.001; r= 0.847 and r=0.915); TT-PCL and PRO-TT-TG showed a strong correlation (p=<0.001; r=0.777). PRO showed no significant correlation to the difference between TT-TG and TT-PCL (p= 0.801; r=-0.062. In cases with PRO above 6mm, trochlear angle tends to be decreased (not significant, p=0.174).
Conclusion: The PRO is a promising parameter to adjust the TT-TG-distance to different trochlear and patellar shapes. Interestingly the effect of PRO is not correlated to the difference between TT-TG and TT-PCL, suggesting that TT-PCL is not only independent from trochlear dysplasia, but moreover influenced by other factors.

B-1429 11:42

The association of patellar maltracking with infrapatellar fat pad oedema and chondromalacia patella: a quantitative morphologic MRI analysis

M. Gursoy[1], B. Dirim Mete[1], Y.K. Cetinoglu[1], O. Oyar[1], N. Erdogan[1], M. Uluc[1], T. Bulut[1], G. Safa[2]; [1]*Izmir/TR*, [2]*Ankara/TR (kenancetinoglu@hotmail.com)*

Purpose: Oedema in the superolateral portion of infrapatellar fat pad and chondromalacia patella (CP) could be related to impingement of fat between the patellar tendon or lateral patellar facet and the lateral femoral condyle. Due to the lack of extensive literature on the association of patellar maltracking with infrapatellar fat pad oedema, the evidence supporting this view remains suspicious. The aim of this study is to investigate the relationship of patellofemoral joint morphology with infrapatellar fat pad oedema and CP using patellar maltracking parameters on MRI.
Methods and Materials: Fifty patients with oedema in the superolateral portion of the infrapatellar fat pad (the study group) and control group (50 patients) with a normal infrapatellar fat pad were identified on MRI to compare with regard to five patellar maltracking parameters retrospectively. These

parameters were trochlear depth, the trochlear sulcus angle (TSA), patellar translation, the lateral patellofemoral angle (PFA) and the Insall-Salvati ratio. The relationship between patellar maltracking and the CP was also evaluated using the same parameters.
Results: In the study group the Insall-Salvati index and TSA were significantly high (p=0.001), the trochlear depth and PFA were low (p=0.001, p=0.01), while patellar translation showed no difference (p=0.957). In the CP group the Insall-Salvati index and TSA were significantly high (p=0.001), the trochlear depth was low (p=0.001). No statistically significant difference was found in PFA and patellar translation (p=0.292, p=0.446).
Conclusion: Oedema in the superolateral portion of infrapatellar fat pad and CP are associated with patellar maltracking.

3D-printed models of the knee for evaluation of trochlear dysplasia in comparison to standard radiographs and computed tomography
B. Fritz[1], S. Fucentese[1], S. Zimmermann[1], P.M. Tscholl[2], R. Sutter[1], C.W. Pfirrmann[1]; [1]*Zurich/CH*, [2]*Geneva/CH (benjamin.fritz@gmx.net)*

Purpose: To test the hypothesis that 3D-printed specimens improve diagnosis of trochlear dysplasia and Dejour´s classification in comparison to radiographs and computed tomography (Rx/CT).
Methods and Materials: This retrospective study was approved by the local ethics committee. 50 patients were included. 3D-models of the distal femur were printed after segmentation of CT-datasets. An expert panel consisting of a senior musculoskeletal radiologist and a senior knee surgeon classified the knees into normal or Dejour grade A-D, which served as the standard of reference. Therefore, the experts reviewed radiographs, CT, the 3D-specimens and patients' clinical history. The 3D-specimens and Rx/CT were evaluated by two readers independently and separately at the interval of 3 weeks for trochlear dysplasia and Dejour A-D. Statistics included general descriptive statistics, ROC-analysis and inter-reader reliability.
Results: The expert panel diagnosed a trochlear dysplasia in 28/50 patients. In comparison to the panel's diagnoses, the diagnostic accuracy for the presence/absence of trochlear dysplasia after evaluation of 3D-specimens and Rx/CT was for reader1 0.937 and 0.823 (p=0.029) and for reader2 0.982 and 0.946 (p=0.147). Inter-reader reliability was excellent for 3D-specimens and substantial for Rx/CT (Kappa: 0.920 and 0.788). For Dejour-classification, the proportion of exact matches for 3D- and Rx/CT-analysis were for reader1 36% and 59% and for reader2 48% and 52%. Inter-reader reliability was poor for 3D-specimens and fair for Rx/CT (Kappa: 0.148 and 0.368).
Conclusion: 3D-models can improve detection of trochlear dysplasia in comparison to radiographs and CT, whereas no additional value for grading into Dejour A-D could be demonstrated.

Task-based radiation dose assessment for paediatric dental CBCT imaging
A. Stratis, G. Zhang, R. Jacobs, R. Bogaerts, H. Bosmans; *Leuven/BE (andreas.stratis@uzleuven.be)*

Purpose: to calculate organ doses, effective dose-ED and LAR-incidence (cases/100,000 persons) for paediatric patients undergoing the most frequently applied dental-cone-beam-CT (CBCT) protocols in 5 scanners via Monte Carlo (MC) simulations.
Methods and Materials: An EGSnrc-MC framework and an in-house-built voxel-model-database (8 male and 10 female paediatric heads, 3 to 14 y.o) were employed. The MC-framework was customized and validated for Promax-3D-Max (Planmeca, FI), NewTom VGi-evo and NewTom 5G (QR srl, IT), CS9300 (Carestream, USA) and Accuitomo 170 (Morita, JP) scanners. Organ doses were assessed for single-tooth, upper/lower-jaw, cleft, maxillofacial complex, sinus, face and skull imaging by simulating the respective scanner-specific and age-dependent FOVs-protocols.
Results: Females were slightly more radiosensitive in all cases (3% to 5% depending on the protocol), with organ-dose and radiation-risk increasing with decreasing age-at-exposure. The lowest risk protocol was for central-incisor-tooth imaging (14 y.o male, ED=13µSv, LAR=0.29) whereas the highest one was for skull imaging (5 y.o female, ED=323µSv, LAR=13.8). Salivary glands and oral mucosa were the highest irradiated organs in all cases, followed by the Extra-thoracic-tissue (ET) in protocols where the entire nasal cavity was inside the primary field. The dose to thyroid was considerably high for young patients (max=1.1 mGy-5y.o-female-skull-protocol). The lowest doses were observed in scanners with tube-current-modulation and added-Cu-filtration.
Conclusion: Thyroid-lead-aprons are recommended for young patients. Small FOV-scans reach the dose levels of conventional panoramic acquisitions. The unavailability of manual collimation results in dose increase, especially for young patients, as the preset FOVs can extend the radiation field beyond the clinical volume of interest.

Sliding organ motion regularisation for motion-compensated cone-beam CT (CBCT) in image-guided radiation therapy (IGRT)
S. Sauppe[1], J. Kuhm[1], M. Brehm[2], P. Paysan[2], D. Seghers[2], M. Kachelrieß[1]; [1]*Heidelberg/DE*, [2]*Baden-Dättwil/CH (marc.kachelriess@dkfz.de)*

Purpose: To improve the accuracy of motion estimation and motion compensation in CBCT of the thorax.
Methods and Materials: Respiratory-gated images minimize the motion artefacts, but yield severe sparseness artefacts. We propose a 4D motion-compensation (MoCo) algorithm with an enhanced underlying motion model that handles sliding organ motion. Our MoCo removes both motion artefacts and sparse view artefacts and ensures 100% data usage [MedPhys 40(10):101913,2013]. Image quality depends on the underlying motion model. Due to strong streak artefacts, regularization of the motion vector fields (MVFs) during motion estimation for continuity is necessary. Our guided regularization filter inputs a bone and lung segmentation. The algorithm handles sliding organ motion such as it occurs between the diaphragm and the lung wall. The filter passes motion perpendicular to the sliding organ boundary. We thus prevent non-physiological motion of the rib cage. For validation, we use an artificially deformed clinical CT scan and patient data acquired with a TrueBeam™ 4D CBCT system (Varian Medical Systems).
Results: Our guided regularization filter yields realistic high-fidelity thorax MVFs. Hereby, we can reconstruct 4D respiratory motion-compensated images, almost free of motion artefacts. Moreover, our proposed sliding organ motion model prevents unphysiological bone motion in motion-compensated images. We significantly improve spatial resolution and noise level by our 4D MoCo approach, preserving high temporal resolution for respiratory motion.
Conclusion: Our patient data demonstrate that good image quality is achievable at identical x-ray dose levels and at acquisition times as for today's 3D CBCT. Lung tumour treatments may benefit from our motion-compensated images.

Material-guided scatter correction in cone-beam-computed tomography using spectroscopic information
C. Egan, P. Scott, N. Loxley; *Sedgefield/UK (c.egan@ibexinnovations.co.uk)*

Purpose: Scatter is a major problem in cone-beam-computed tomography (CBCT), causing reconstruction artefacts and reduced contrast. A material-guided scatter correction algorithm is introduced using spectral information generated from pixel-wise attenuation modulation of the x-ray beam.
Methods and Materials: A metal plate which is designed to cause a pixel-wise attenuation modulation of the x-ray beam is placed directly in front of a flat panel detector in a CBCT system. This modulation yields spectroscopic information, which is decomposed to give thickness and composition information about the sample. These data used to predict scatter using a Monte Carlo model, which is subtracted from the x-ray image. The material information is updated based upon this new scatter-corrected image. An iterative procedure then operates to converge to a solution where the scatter estimate and materials estimate no longer changes, leaving the final scatter-corrected image. This procedure is applied to every projection in a CBCT dataset which can be reconstructed using conventional algorithms.
Results: Applying the material-guided scatter correction algorithm to a water phantom removes the cupping artefact leaving a flat cross-sectional profile and at the same time improves mean contrast by 18%. Other phantom and cadaver samples have been processed, again showing reduced artefacts and enhanced contrast.
Conclusion: The material-guided scatter correction algorithm can accurately predict and correct scatter yielding superior quality images without the use of anti-scatter grids and no impact on dose.

Moving metal artifact reduction (MMAR) for cone-beam CT (CBCT) scans of the thorax region

A. Hahn, S. Sauppe, M. Knaup, M. Kachelrieß; *Heidelberg/DE (andreas.hahn@dkfz.de)*

Purpose: Established metal artifact reduction (MAR) methods are insufficient in cone-beam CT (CBCT) scans with moving metal implants such as fiducial gold markers. A method for moving metal artifact reduction (MMAR) is introduced.
Methods and Materials: Standard inpainting-based MAR methods do not account for respiratory patient motion and fail in cases with strong metal motion. MMAR resolves this issue by applying a motion compensation (MoCo) algorithm [MedPhys 40(10):101913, 2013]. This results in a 4D volume without motion blurring but with metal artifacts. They are corrected using a normalized MAR (NMAR) [Med Phys. 2010 Oct;37(10):5482-93]. A simulation was created by adding 5 analytical cylindrical gold markers of different sizes to a thorax scan that was acquired using a TrueBeam™ 4D CBCT system (Varian Medical Systems). Realistic deformation vector fields of different magnitudes were applied to simulate cases of different motion. The proposed algorithm was compared to standard linear interpolation MAR and was applied to CBCT data of a patient with metal markers.
Results: Using the MMAR algorithm, a 4D volume with a high temporal resolution is reconstructed. Remaining metal artifacts are almost completely removed in the 4D volume for all motion magnitudes. Simple MAR was able to reduce artifacts in cases of small motion but failed for large motion.
Conclusion: MMAR is able to properly account for motion of moving metal markers and is able to remove metal artifacts where classical linear interpolation MAR fails. The advantage of MMAR compared to MAR increases for larger motion.

B-1435 11:02

Focal spot blur correction for cone-beam CT (CBCT)

N.K. Waltrich, S. Sawall, M. Kachelrieß; *Heidelberg/DE (nadine.waltrich@dkfz.de)*

Purpose: To correct for the spatial resolution mismatch caused by anode angulation in CBCT.
Methods and Materials: The combination of anode angulation and large fan and cone angles causes a position-dependent focal spot blur in CBCT data. This results in a variation of spatial resolution along the u- and v-direction of the flat detector and a resolution mismatch within the reconstructed volume. To assess the spatial resolution, a metal edge was measured at different u-v-positions close to the focal spot. The full width at half maximum of the line spread function is measured for each u-v-position and inter- and extrapolated to be available for each detector position. A projection-domain deconvolution iteratively achieves a user-prescribed (e.g. uniform) spatial resolution across the whole detector. Noise is reduced using a bilateral filter in the image domain with a position-dependent domain filter shape. The proposed method is validated using data from a line pattern phantom, an anthropomorphic head phantom, and patient measurements acquired with a CBCT system in short scan mode. This scan mode results in images with higher spatial resolution on the right side compared to the left side.
Results: On the right side, five iterations of the deconvolution algorithm increase the line pattern contrast from 198 HU to 442 HU. On the left side, 460 HU is measured before and after blur correction. This indicates a nearly complete spatial resolution restoration. The findings were confirmed in patient measurements.
Conclusion: The proposed method results in a homogeneous resolution throughout the complete volume.

B-1436 11:10

Spectroscopic cone-beam-computed tomography using pixel-wise attenuation modulation

C. Egan, P. Scott, N. Loxley; *Sedgefield/UK (c.egan@ibexinnovations.co.uk)*

Purpose: Quantitative information can be extracted from dual-energy-computed tomography (DECT) such as precise electron densities and effective atomic numbers, which can be used for accurate dose planning in radiotherapy, for example. DECT is normally implemented either using dual-source scanners or via rapid kV switching. Here we introduce a technique for obtaining spectroscopic information from a CBCT system using pixel-wise attenuation modulation of the x-ray beam, without the need for kV switching or dual sources.
Methods and Materials: A metal plate which is designed to cause a pixel-wise attenuation modulation of the x-ray beam is placed directly in front of a flat panel detector in a CBCT system. The differential attenuation of the x-ray beam over a group of pixels yields spectroscopic information, which can be decomposed to give quantitative composition information about the sample. This data is then run through a standard iterative reconstruction algorithm. The reconstructed materials information is examined in 2D scatter plots, similar to standard DECT systems.
Results: A quantitative phantom containing tissue equivalent material inserts was scanned to yield 2D scatter plots in a materials space. Data in this space are classified using a Mahalanobis distance measure. The accuracy of this approach is quantified, and, compared to the literature values from standard DECT systems, yields analogous results.
Conclusion: Spectroscopic information can be extracted from a CBCT system without the need for kV switching or multiple sources, yielding comparable results to standard DECT systems.

Stack transition motion compensation in sequential and in cardiac CT

S. Lebedev[1,2], K. Stierstorfer[2], M. Kachelrieß[1]; [1]*Heidelberg/DE*, [2]*Forchheim/DE (marc.kachelriess@dkfz.de)*

Purpose: Sequential CT scans and cardiac CT scans result in image stacks whose overlapping regions may be inconsistent due to patient motion. We thus propose a motion compensation method for stack transition artefact removal (STAR).
Methods and Materials: To estimate stack-to-stack patient motion, STAR uses a novel symmetric deformable image registration algorithm to register stack overlap regions of adjacent stacks. The registration algorithm scans the surroundings of control points situated within stack overlaps for matching sub-volume pairs and finds the pair that maximizes a similarity metric. The optimal displacement for a control point yields the deformation vector at the respective position. To get a densely sampled motion vector field (MVF), a trilinear interpolation between the control points is performed within the transition areas. The MVFs are then extrapolated across the whole stack to minimise distortions. Cardiac CT patient data from a Somatom Definition Flash and a Somatom Definition Edge CT system (Siemens Healthineers, Forchheim, Germany) were used to validate the STAR algorithm.
Results: STAR is able to reduce the stacks transition artefacts and displace/deform structures in a size range of multiple millimetres and make small adjustments in the millimetre range. In all cases, the images become sharper and the information in the stack transition regions becomes consistent between adjacent stacks. The coronary arteries are much better defined even in cases with strong stack-to-stack patient motion.
Conclusion: Artefacts at stack transitions due to irregular motion can be addressed using symmetric registration. STAR was able to considerably improve image quality.

First evaluation of new photon counting CT technology

J. Da Silva, M. Yveborg, F. Grönberg, M. Sjölin, S. Holmin, J. Lundberg, M. Danielsson; *Stockholm/SE (jds@kth.se)*

Purpose: We are developing a new photon-counting edge-on silicon detector with 0.2x0.3 mm^2 detector elements at the isocenter and 8 energy bins for clinical CT applications. The purpose of this work is to present the first images using our detector technology, and show significantly improved spectral and spatial resolution compared to current state-of-the-art. In addition, we demonstrate the feasibility of projection based three-material basis decomposition based on the novel technology.
Methods and Materials: For this work, several objects were imaged using a spectrally resolved silicon detector. The reconstructed CT images were compared to images using current state-of-the art CT scanners at the Karolinska University hospital. Specifically, we compared spatial resolution, artefact visibility and identification of iodine. In addition, we performed projection based three-material basis decomposition using recent developments in forward model calibration.
Results: The results demonstrate improved spatial and spectral resolution, compared to current state-of-the-art. Specifically, we demonstrate improved visibility of small details, decreased visibility of artefacts and improved identification of iodine. In addition, reconstructed un-biased iodine basis images are presented.
Conclusion: Several objects have successfully been imaged using a novel spectrally resolved photon counting silicon detector with sub-millimetre resolution. Compared to current state-of-the-art, reconstructed CT images demonstrate a potential improvement for clinical CT applications by improved spectral and spatial resolution.

Phase-contrast monochromatic breast-CT: a feasibility study

R. Longo[1], M.A. Cova[1], P. Delogu[2], B. Golosio[3], G. Mettivier[4], A. Taibi[5], M. Tonutti[1], G. Tromba[1], F. Zanconati[1]; [1]*Trieste/IT*, [2]*Siena/IT*, [3]*Cagliari/IT*, [4]*Naples/IT*, [5]*Ferrara/IT (renata.longo@ts.infn.it)*

Purpose: To develop methods and the facility to perform the first study in phase-contrast (PhC) breast computed tomography (breast-CT) exploiting the monochromatic beam available at the Elettra synchrotron radiation (SR) laboratory.
Methods and Materials: Images of test objects and large breast specimens were acquired at the SR facility used for the first clinical study of PhC mammography and up-dated for breast-CT. The CdTe detector was a state-of-the-art dead-time-free single-photon-counting with a 60 µm pixel size. The monochromatic x-ray beam was set in the energy range 32-38 keV and the delivered mean glandular dose (MGD) was in the range 5-20 mGy. Since the SR provides high energy resolution and spatial coherence, the free-propagation PhC imaging technique was used and the phase-retrieval algorithm was applied on the projections before the image reconstruction. Contrast-to-noise ratio (CNR) and resolution performances were evaluated for both absorption and phase-retrieved images by considering fat and glandular tissue.
Results: The phase-retrieval approach resulted in a remarkable CNR increase with respect to the absorption image (from 0.5 to 3.5), while the resolution loss is significantly lower than the one obtained by applying common de-noising filters. Furthermore, the full volume reconstructions of a breast lumpectomy (about 9 cm diameter and 3 cm thickness) are presented (MGD about 5 mGy).
Conclusion: This investigation indicates that PhC monochromatic breast-CT, evaluated so far in terms of CNR, spatial resolution and scan volume, is feasible.

B-1440 11:42

Digital breast tomosynthesis: flat panel and photon counting detectors comparison

A. Loria[1], P. Signorotto[1], M. Campoleoni[1], N. Paruccini[2], R. Villa[2], E. Venturini[1], P. Panizza[1], A. del Vecchio[1]; [1]*Milan/IT*, [2]*Monza/IT (loria.alessandro@hsr.it)*

Purpose: In this study three digital breast tomosynthesis (DBT) devices equipped with different flat panel detectors (FPD) and a prototype equipped with a scan-spectral photon counting detector (PCD) are compared. The aim is to evaluate if a PCD device can guarantee comparable or even better image quality (IQ) delivering lower radiation doses than FPD devices.
Methods and Materials: Image quality performances were evaluated exposing two IQ DBT phantoms, Tomophan and Agatha, the CDMAM phantom and a homemade phantom for low-contrast detectability (LCD). Exposures were performed in automatic exposure control mode. Images with the lowest achievable post-processing were analysed. Geometric distortion, signal-difference-to-noise ratio (SDNR), LCD, in-plane resolution as modulation transfer function (MTF) in scan and sub-scan directions, slice-sensitivity profile (SSP), noise power spectrum (NPS) and artefact spread function (ASF) were evaluated.
Results: Geometric distortion, SDNR and NPS resulted comparable. PCD device showed the best LCD. In-plane resolution was higher for PCD device: FPD devices exhibit a reduction in $MTF_{0.1}$ between 38% and 62%, both in scan and sub-scan direction. SSP showed comparable results for PCD and one of the FPD devices, while it was up to 60% worse for the others. PCD device had the worst ASF. Delivered dose with PCD device was 50% lower than doses delivered with FPD devices.
Conclusion: PCD device ensures a comparable or even better IQ than FPD devices, especially for spatial resolution and detectability of low-contrast objects, delivering much lower radiation dose. Photon counting seems to be really an impressive approach to DBT.

B-1441 11:50

Digital breast tomosynthesis index (DBTI): a score to evaluate digital breast tomosynthesis (DBT) device performance

A. Loria, P. Signorotto, E. Venturini, P. Panizza, A. del Vecchio; *Milan/IT (loria.alessandro@hsr.it)*

Purpose: The aim of this study is to combine image quality (IQ) and dosimetric parameters into a score to evaluate the goodness of a digital breast tomosynthesis (DBT) device.
Methods and Materials: Digital Breast Tomosynthesis Index (DBTI) is derived from two figure of merit (FoM) introduced to evaluate CT devices (Rose and ImPACT). These FoMs include parameters as contrast-to-noise ratio (CNR), spatial resolution in terms of modulation transfer function (MTF), slice thickness and a dosimetric quantity (CTDI). In the same way, DBTI is designed to be dependent on signal-difference-to-noise ratio (SDNR), MTF, slice-sensitivity profile (SSP) and average glandular dose (AGD). IQ parameters were measured using the Tomophan phantom. SDNR was evaluated with the 0.2-mm-thick aluminum insert. MTF was calculated for scan and sub-scan directions from the point spread function of the 0.18mm tungsten bead. SSP evaluation was performed with the two reversing angled bead ramps method. These parameters were evaluated for two different DBT devices at seven different values of AGD, obtained manually setting the tube current time product.
Results: Each DBT device showed a characteristic value of DBTI. These values were constant as the tube current time product changes, with a standard deviation of 2% and 6% for the two devices.
Conclusion: Independence of DBTI from exposure parameters could make it a good FoM to benchmark DBT devices. Compared to CT, DBT have less clinical questions, so a single score could provide a reliable estimation of the goodness of the DBT device.

Does the post-processing annotation of images become a standard practice in digital radiography today?

E. Saukko[1], M. Wirtanen[2], K. Kortelainen[2]; [1]*Turku/FI*, [2]*Helsinki/FI (ekaterina.saukko@tyks.fi)*

Purpose: Digital radiography allows post-processing annotation of mages, which enables radiographers to apply markers electronically onto images post-exposure. This advancement has led to a decrease in use of lead anatomical side markers (ASMs), although the best practice has always been to place markers within primary beam. The aim of this study was to assess the radiographers' perception on the use of lead ASMs in Finland.
Methods and Materials: A self-designed questionnaire was sent in April 2017 to all members of the Society of Radiographers in Finland using the society's e-mail list (n=1696). In total, 278 responses were received.
Results: Among all respondents, only 32% reports that there were guidelines for lead ASMs use in their radiological department. About 88% of radiographers stated that lead ASMs were sufficiently available in the x-ray rooms and 18% had personal markers. The preference of ASMs use within primary beam over the post-processing annotation varied depending on the type of anatomy examined. Radiographers prefer using ASMs pre-exposure in radiographs demonstrating both sides of unilateral anatomy (72%, n=199), while in examinations performed outside the imaging departments the lead ASMs use was very scarce (21%, n=57). Longer work experience was associated with increased lead ASMs use in radiography of the skull and face (*p=0.004*), chest (*p=0.006*), bones and joints (*p=0.021*), spine (*p=0.002*) and in radiographs showing both sides of unilateral anatomy (*p=0.019*).
Conclusion: Overall, the use of ASMs post-exposure is predominated among radiographers. Written protocols, regular audits of practice and continuous staff education are recommended.

Implementation of DR detectors for paediatric chest x-ray in NICU

D. Pekarovic, U. Zdesar, P.A. Jesih, M. Pungrčar; *Ljubljana/SI (dean.pekarovic@kclj.si)*

Purpose: Development of exposure charts when changing image detectors from imagining plates (CR) to digital detectors (DR).
Methods and Materials: After commissioning of a new mobile DR system in NICU, a group of radiographers, radiologist and medical physicist were established to optimise exposure technique. Patients were divided into seven age groups from neonates to the age of 18. Anode voltage (kV) and exposure (mAs) were changed in small steps from the factory settings and radiologist was consulted about image quality. Exposure index (EI) was used as a measure of detector exposure and dose area product (DAP) as a measure of patient exposure. As the last step, the DAP values for each group was compared to proposed EU diagnostic reference levels (PiDRL-paediatric dose reference levels). During the process, the gaps in knowledge regarding DR systems were identified and training curriculum for radiographers was prepared.

Results: A target exposure index (TEI) of 300 was set and radiographers were instructed to follow deviation index (DI). Data from 1816 patients were analysed in the period of 11 months. Average DI was 0.35 being largest (0.8) at the youngest age group (0-7 days). 5.8% of patients had DI larger than ±3 (1.6% underexposed and 4.2% overexposed). Measured DAP were compared to diagnostic reference levels PiDRL. Third quartile DAP values for all groups were far below PiDRLs.
Conclusion: Introduction of new imaging equipment in radiology department often requires adoption of new exposure techniques required for optimised imaging. Technique changes should be followed by additional training of radiographers operating the equipment.

B-1444 10:46

Practitioner variability in collimation and centring for AP shoulder projections

D. Browne[1], K. Szczepura[2], A. England[1]; [1]*Manchester/UK*, [2]*M6 6PU/UK (A.England@salford.ac.uk)*

Purpose: Radiographic positioning textbooks recommend AP shoulder projections using either a square- or diamond-shaped radiation field. Recommendations reflect the likely differences in radiation dose to breast tissue but this is unproven. Within these texts there are also variations in the centring points proposed. The aim of this study was to assess differences in collimation field and centring point, and their effect on breast dose and image quality (IQ).
Methods and Materials: Six volunteers were invited to position and expose a PIXY phantom for an AP shoulder projection using both square- and diamond-shaped field. Entrance surface doses (ESD) were measured at four locations around a simulated breast to determine which scenario delivered the lowest overall ESD.
Results: Study findings demonstrated that switching from a square to a diamond X-ray field shape increased (24.5%) the total ESD to the breast (55.1 mGy vs 72.9 mGy; P<0.0001). Positional accuracy results (IQ) indicated that practitioners can use either field shape accurately (P>0.05). Evaluation of centring points suggests that practitioners showed a tendency to centre more medially and inferiorly when compared to textbooks.
Conclusion: Evidence from this study suggests that the absorbed dose to the breast could increase by moving from a square field to a diamond shape. Both techniques can be performed with similar accuracy and centring points used by participants did differ slightly from positioning texts. Findings from this pilot study warrant further investigation.

B-1445 10:54

Study of scattered radiation during fluoroscopy in hip surgery

O. Lesyuk[1], L.P. Ribeiro[2], A.F. Abrantes[2], P. Sousa[2], S. Rodrigues[2], R.P. Almeida[2], K.B. Azevedo[2], J.P. Pinheiro[2]; [1]*São Brás de Alportel/PT*, [2]*Faro/PT (oksanalesyuk@gmail.com)*

Purpose: To measure the scattered radiation dose at different positions simulating hip surgery.
Methods and Materials: We simulated fluoroscopy-assisted hip surgery in order to study the distribution of scattered radiation in the operating room. To simulate the patient, we used an anthropomorphic whole-body phantom and a X-ray-specific detector to quantify the scattered radiation. Radiographs were obtained with a mobile C-arm X-ray system in continuous scan mode, with the tube at 0° (configuration 1) or 90° (configuration 2). The operating parameters employed (voltage, current, and exposure time) were determined by a statistical analysis based on the observation of orthopedic surgical procedures involving the hip.
Results: For all measurements, higher exposures were observed in configuration 2. In the measurements obtained as a function of height, the maximum dose rates observed were 1.167 (± 0.023) μ Sv/s and 2.278 (± 0.023) μ Sv/s in configurations 1 and 2, respectively, corresponding to the chest level of health care professionals within the operating room. Near to the patient, the maximum values were recorded in the position occupied by the surgeon.
Conclusion: We can conclude that, in the scenario under study, health care professionals workers are exposed to low levels of radiation, and that those levels can be reduced through the use of personal protective equipment.

B-1446 11:02

An investigation of the impact of image viewing parameter settings on the performance of 2.4 MP colour monitor in visualising low contrast detail using the CDRAD phantom

S.H. Al-Murshedi, P.H. Hogg, M.M. Benhalim, M. Alrowily, A. England; *Manchester/UK (p.hogg@salford.ac.uk)*

Purpose: To investigate the relation between the observer performance for low contrast details detection and the image viewing settings (magnification, window setting) for a wide range of image quality on 2.4 MP colour monitor
Methods and Materials: Six images of CDRAD phantom were generated, using adults chest radiography protocols with different image quality. Five observers evaluated the images on 2.4 MP colour monitor. The images were assessed in four different ways: firstly, the observers were not free in adjusting the contrast, intensity, and magnification of the image; secondly, only the magnification was allowed to be adjusted; thirdly, only the contrast and intensity were allowed to be adjusted; finally, the observers were free to adjust the contrast, intensity and magnification of the image
Results: Data analysis was conducted via repeated measures of variance (ANOVA). For the images with high quality, using magnification only has no significant difference on improvement of image scoring p=0.10, whereas significant difference was noted between employing windowing solely and using both windowing and magnification with p=0.03 and p=0.00 respectively. Furthermore, it was found image viewing manipulation has negative influence on image scoring for the ones characterised by low quality
Conclusion: The study demonstrates that adopting both magnification and windowing is of a significant impact on improving image scoring; employing windowing solely has the second highest impact. Hence, this study recommends the utilisation of image viewing manipulation only with the images that are of high image quality, while it should be avoided with the images that are of low quality

B-1447 11:10

The optimised location to assist patient during imaging of scoliosis with EOS system device

H.M.S. Laitinen, H. Niiniviita, E. Saukko, E. Svedström; *Turku/FI (helena.laitinen@edu.turkuamk.fi)*

Purpose: With challenging scoliosis patients, it is occasionally necessary to assist patient in the examination room during exposure for patient safety and preventing movement. EOS system is a slot-scanning technique specialised to orthopaedic imaging, especially scoliosis. Finland's first EOS system installation was made at Turku University Hospital in 2017. The aim of this study was to measure scattered radiation during imaging of scoliosis with this new technique and thereby find the optimized place for the assistance.
Methods and Materials: An anthropomorphic phantom was set at the isocenter and scanned using standard scoliosis protocol, with both AP and LAT views. The scattered dose rates were measured at seven points from one meter above the floor level with ion chamber survey meter. At three points measurements were made also with lead shields. For reliability and repeatability measurements were repeated three times and average dose rates were calculated.
Results: The dose rate at the closest point (45 cm from isocentre) was 10.5 mSv/h, but lead apron reduced the dose significantly to 263 μSv/h. At the most distant point (175 cm from isocentre) the dose was 0.73 mSv/h and with lead shield 8.0 μSv/h. There was more scattered radiation on the lateral side than the AP/PA side.
Conclusion: Assistant should wear lead apron if holding the patient is necessary. If only presence in the same room is sufficient, assistant should be on the AP/PA side, behind lead shield, wear lead apron, and take distance, but keep the eye-contact to patient.

B-1448 11:18

A tool for automated assessment of imaging system resolution

R. Us, A. Matja ič, R. Bizjak, T. Hribar, Z. Malinova, N. Mekis; *Ljubljana/SI*

Purpose: To develop and deploy a software solution for automatic, consistent and quantitative characterisation of an imaging system's spatial resolution.
Methods and Materials: We used an ETR-1 test plate, a Siemens Multix/Vertix system, AGFA CR MD 4.0 general cassettes and an AGFA 25.0 scanner. The study was conducted in two parts. The first series of exposures was done using the small focal spot while the second series utilised the large focal spot. All exposures were conducted in line with QC guidelines. Parameters including SID, tube voltage as well as the product of exposure time and tube current were held constant throughout. 20 exposures were done at different z axis positions to record system performance under each set of conditions, for a total of 40 images. We moved the test plate by 20 mm toward the cathode end of the FOV between successive exposures. An ImageJ macro was developed to carry out consistent characterisation of ETR-1's line pair segments. This data was used to chart an approximate MTF curve for each position along the z axis.
Results: Our results take the form of 2 spreadsheets containing MTF values for 20 different frequencies in the vertical direction and 19 different z axis positions in the horizontal direction. The sampling resolution limit was clearly visible in the first series at between 3,1 and 3,4 lp/mm which is consistent with our scanner specifications.
Conclusion: Our macro consistently produced a comprehensive quantitative characterisation of system performance using images from test plate exposures.

B-1449 11:26

Scattering in dental cone-beam computed tomography

J. Heikkinen, P. Sepponen, A. Henner; *Oulu/FI (anja.henner@oamk.fi)*

Purpose: The aim of this study was to produce information of scattered radiation that can be utilized in aforesaid situations and possibly in future CBCT applications and radiation protection. The measurement system and the presentation of the results can also be commonly utilized for scattering measurements. Therefore it's important to figure out doses, dose rates and directions of scattered radiation around the CBCT machine during the examination.
Methods and Materials: The scattering was measured using a RaySafe X2 X-ray measurement system and its survey-sensor. The studied CBCT machine was Scanora 3D (Soredex). CIRS ATOM 711-HN was used as an anthropomorphic patient-phantom. Measurements were performed on three different heights with normal dental imaging parameters (dental infection) and on one height with the largest FOV and highest resolution.
Results: Four scattering maps that represent the X-ray scattering in the X-ray simulation room were obtained. The highest doses were naturally measured in the vicinity of the CBCT machine on the height of the isocenter of the x-ray beam. Increasing the FOV and resolution led to increased scattered radiation. In addition to dose and dose rate measurements the dose rate as a function of time during the rotation of the gantry was examined.
Conclusion: The dose rates in the examination room were significant and regarding radiation protection. The scattering maps show the safest areas in the examination room

B-1450 11:34

Overview of CT throughput in a radiology department: drawbacks and solutions

B. Kara[1], A. Toker[1], S. Horoz[1], M. Onur[1], S. Sanje[2], D. Akata[1]; [1]*Ankara/TR*, [2]*Istanbul/TR (tomografi@hotmail.com)*

Purpose: The aim of this study to investigate the productivity of computed tomography (CT) units in a radiology department and to draw conclusions on how to achieve efficient outcomes.
Methods and Materials: A total number of 69.865 CT scans performed in four different multislice CT scanners (Scanner A, B,C,D) between May 2016 and April 2017 were analysed in terms of equipment utilization rate against institutional entitlement and industry benchmarks, staff utilization, adoption to protocol standardization, patient flow and end to end radiology value stream leveraging Lean Six Sigma methodology.
Results: Utilization rate of overall CT units was found as 61% against industry benchmarks (85%, 80%, 120%, 35% for scanners A, B, C and D, respectively). Based on data; 57% of CT requests were scanned at the same day whereas for 25% of patients it takes more than 5 days. Although CT examinations are mostly scheduled in office hours (between 8 am to 6 pm), utilization rates decreased significantly during lunch and staff shift change times. Patient preparation time was increased when there is single radiographer per scanner. Unnecessary activities in scanner room including manual entrance of patient information, patient questions, and opening route for intravenous contrast agent administration constituted 13% of total observed time in CT rooms.
Conclusion: Overview of radiology departments in guidance with professional partners using bench-markings is helpful for management and improvement of CT throughput. Changed behaviours of staff in accordance with innovative perspective of radiology departments will be helpful for overcoming drawbacks in CT throughput.

Eye-lens dose in head CT examinations: evaluation of different methods through the use of gantry angulation and barium shields

M.V.C. Reis, S. Rodrigues, A.F. Abrantes, L.P. Ribeiro, R.P.P. Almeida, O. Lesyuk; *Faro/PT (monica14@live.com.pt)*

Purpose: To evaluate the effect of gantry angulation, scanning techniques (spiral vs sequential) and barium eye shielding on radiation dose to the eye lens during head CT examinations.
Methods and Materials: An anthropomorphic phantom was scanned with a routine head CT protocol using a 16-slices CT equipment. Three exposures were performed for each of the following settings with different combinations: (1) spiral and sequential scanning techniques, (2) with and without barium shields and (3) gantry angulation at 12º, 0º, -12º and -22º using the orbitomeatal line as reference. Thermoluminescent dosimeters (TLD) were used to measure the entrance skin dose (ESD) in eye lens.
Results: An ESD reduction range from 15% to 21% was verified in all configurations with barium shields. The lower ESD value was observed in configuration with barium shields and gantry angulation at -12º (28,86mGy). In terms of effective dose, it was found that the sequential scanning technique at 0º with no barium shield presents the higher value (0.43mSv), although below the dose threshold. The lower effective dose (0.29mSv) was verified with the use of barium shield in combination with -12º of gantry angulation.
Conclusion: These results may be used to provide more adequate procedures and to ensure that protocols are operated safely below thresholds. Tilting the gantry to avoid the orbits and using the barium eye shielding are effective measures for reducing radiation dose to the eye lens in clinical practice. These actions should be considered when they are consistent with the clinical task and patient anatomy.

Patients' experiences in coronary angiography

A. Henner, A. Lahdenperä, H. Suutari, K. Koivunen, K. Paalimäki-Paakki; *Oulu/FI (anja.henner@oamk.fi)*

Purpose: The purpose of this study was to find out patient's experiences after coronary angiography.
Methods and Materials: Patients' experiences were studied with group and individual theme interviews. 12 persons (aged 59-84 years) were interviewed in Autumn 2016. The data were analysed with inductive content analysis. Purpose of this study was to describe the patients' experiences in coronary angiography.
Results: According to the data, the patients felt that they are not encountered as individuals, but they still trust on the professionalism of the care team. Invasive nature of the coronary angiography affects strongly to the experience. Patients felt they have got very good care. On the other hand, the patients felt they are on conveyor belt and they are medicated too heavily. The invasive examination rises anxiety and fear. Patient's background and personality affects to what kind of and how much counselling they require before, during and after examination. According to patients, nobody told them about the use of radiation. The possibility to discuss and share the experiences with other patients is highly valued.
Conclusion: This study gives additional information about the patient's experience in coronary angiography. This study gave to interviewees a possibility to participate in the development of the future care pathway and also gives them a possibility to share their experiences. Results of our study can be used in the development of the coronary angiography procedure, more personalized patient counseling and patient profiles.

Computed tomography CT: derived fractional flow reserve improves reader confidence for coronary CT angiography

C. Schabel[1], K. Nikolaou[1], L. Hurwitz[2]; [1]*Tübingen/DE*, [2]*Durham, NC/US (christoph.schabel@med.uni-tuebingen.de)*

Purpose: To assess the impact of fractional flow reserve computed tomography (FFR_{CT}) on reader confidence and time efficiency for interpretation of coronary computed tomography angiography (CCTA).
Methods and Materials: This IRB-approved, HIPAA-compliant, consent waivered, retrospective quality-assessment study included 50 patients (23 women, age 67±12years, body mass index 28.7±5.3kg/m^2). CCTA was acquired on 2nd&3rd generation dual-source MDCT with use of beta-blockers and nitroglycerin, and FFR_{CT} was calculated (HeartFlow,Redwood City,CA). Two readers with experience level COCATS2 (Core-Cardiology-Training-Symposium) and two with COCATS3 assessed CCTA alone and CCTA plus FFR_{CT}. Readers' confidence to diagnose or exclude coronary artery disease (CAD) and hemodynamically significant stenosis (HS) was rated on a 4-point Likert-scale (1=high, 2=good, 3=limited, 4=none) for the four major epicardial coronary artery vessels (CAV). Time to interpret was recorded.
Results: The severity of CAD in the cohort population was CAD-RADS1 (Coronary-Artery-Disease Reporting-and-Data-System) n=15, CAD-RADS2 n=8, CAD-RADS3 n=11, and CAD-RADS4A n=16. Sixty-four CAV in 33 patients had FFR_{CT} values <0.8. Readers' confidence when FFR_{CT} was available increased for CAD and HS (p=0.0001) with a reduction of "non-confident" patient reads (rank 3&4) by 27% and 75%, respectively. The change in confidence was not associated with CAD-RADS (p>0.1) but correlated with readers' experience (p=0.0001). The median time-to-read a CCTA study decreased by 5 minutes when FFR_{CT} was available (p<0.0001).

Conclusion: Interpretation of CCTA in conjunction with FFR_{CT} improved readers' confidence to identify or exclude CAD and HS with reduction of "non-confident" reads by 27% and 75%, respectively, and decreased the median time-to-interpret a CCTA by 5 minutes.

Effect of coronary calcium on the diagnostic performance of machine learning-based coronary CT angiography-derived fractional flow reserve: results from the machine registry

C. Tesche[1], K. Otani[2], M. Albrecht[3], C.N. De Cecco[3], T. duguay[3], S. Baumann[4], M. Renker[5], A. Varga-Szemes[3], U.J. Schoepf[3]; [1]*Munich/DE*, [2]*Tokyo/JP*, [3]*Charleston, SC/US*, [4]*Mannheim/DE*, [5]*Bad Nauheim/DE*
(tesche.christian@googlemail.com)

Purpose: To investigate the effect of coronary artery calcium (CAC) on the diagnostic performance of machine learning-based coronary CT angiography (cCTA)-derived fractional flow reserve (CT-FFR).
Methods and Materials: 481 vessels from 314 patients (62.3±9.3 years, 77% male) who had undergone cCTA followed by invasive fractional flow reserve (FFR) were investigated in this retrospective analysis of the MACHINE registry (Machine leArning-based CT angiograpHy-derIved FFR: a Multi-ceNtEr Registry) data. CAC was quantified using the Agatston convention. The diagnostic performance of CT-FFR to detect lesion-specific ischaemia was assessed across all Agatston score quartiles with invasive FFR as the reference standard.
Results: The diagnostic accuracy of CT-FFR vs invasive FFR was superior to that of cCTA alone on a per-vessel (78% vs 58%) and per-patient (83% vs 73%) basis across all Agatston score quartiles. CT-FFR demonstrated high discriminatory power in vessels with high Agatston scores (250-2066) and a low to intermediate Agatston scores (0-249) without a statistically significant difference in the area under the receiver-operating characteristic curve (AUC) (AUC: 0.77 [95%CI 0.68-0.86] vs 0.86 [95%CI 0.82-0.90], p=0.76). CT-FFR showed incremental diagnostic value over cCTA in vessels with high Agatston scores (AUC 0.77 vs 0.55, p<0.001) and low to intermediate Agatston scores (AUC 0.86 vs 0.66, p<0.001).
Conclusion: Machine learning-based CT-FFR demonstrated superior diagnostic performance over cCTA alone in calcified coronary arteries on a per-lesion and per-patient level with no difference in the performance of CT-FFR between patients with low to intermediate and patients with high Agatston scores.

Artificial intelligence deep-learning-based coronary CT fractional flow reserve: the impact of iterative and filtered back projection reconstruction techniques

D. Mastrodicasa[1], C.N. De Cecco[1], A. Moritz[2], A. Varga-Szemes[1], G. Muscogiuri[3], M. van Assen[4], M. Eid[1], F. Lavra[5], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Horb/DE*, [3]*Milan/IT*, [4]*Groningen/NL*, [5]*Cagliari/IT*
(domenico.mastrodicasa@gmail.com)

Purpose: To evaluate the influence of CT reconstruction algorithms on machine-learning-based computed tomography-derived fractional flow reserve ($CT\text{-}FFR_{ML}$) results and processing time.
Methods and Materials: Iterative reconstruction in image space (IRIS) and filtered back-projection (FBP) datasets were retrospectively included from 40 patients who underwent coronary CT angiography (CCTA) on a 3rd-generation dual-source scanner. Using a machine-learning software prototype, CT-FFR was computed on a per-vessel and per-segment basis, as well as proximal and distal to lesions with ≥50% luminal stenosis according to CCTA. Invasive FFR comparison was performed when available. Significant ischaemia was defined as invasive FFR and CT-FFR values ≤0.80. Computational times were recorded. Pearson correlation, Wilcoxon, and McNemar testing were used for data analysis.
Results: A total of 320 vessels were analysed to calculate CT-FFR. Per-vessel analysis of IRIS and FBP reconstructions showed significantly different CT-FFR values (p≤0.05). Correlations between the two algorithms for the left main (r=0.74), left anterior descending (r=0.76) and right coronary artery (r=0.70) were high. A per-segment analysis revealed significantly different CT-FFR values (p≤0.05) and high correlation for all proximal and middle segments (r=0.73 and r=0.70, p≤0.001, respectively). No difference in diagnostic accuracy was observed between algorithms (81.8%, p=1.000). Per-lesion correlation with invasive FFR values was moderate for both IRIS (r=0.53, p=0.117) and FBP (r=0.49, p=0.142). CT-FFR computational time was significantly shorter using IRIS reconstruction (15.9 vs 19.8 minutes, p≤0.05).
Conclusion: IRIS improves $CT\text{-}FFR_{ML}$ post-processing speed, likely owing to reduced image noise. However, the reconstruction algorithm influences CT-FFR results with potential implications on patient management.

Gender differences in machine learning-based coronary CT angiography-derived fractional flow reserve: results from the machine registry

B.E. Jacobs[1], S. Baumann[1,2], M. Renker[1,3], C. Tesche[1,4], T. Duguay[1], M.H. Albrecht[1,5], A. Coenen[6], K. Nieman[6], U.J. Schoepf[1]; [1]*Charleston, SC/US*, [2]*Mannheim/DE*, [3]*Bad Nauheim/DE*, [4]*München/DE*, [5]*Frankfurt/DE*, [6]*Rotterdam/NL (jacobsbr@musc.edu)*

Purpose: Coronary computed tomography angiography (cCTA)-derived fractional flow reserve (cFFR) is a non-invasive FFR approach that improves diagnostic accuracy in detecting haemodynamically relevant lesions over cCTA alone. An artificial intelligence deep machine-learning method of calculating cFFR (ML-cFFR) has recently been introduced. Currently, no data exist regarding the influence of patient sex on the accuracy of artificial intelligence ML-cFFR.
Methods and Materials: Five centres enrolled 351 patients (73.5% male) with 525 vessels in the retrospective MACHINE (Machine leArning Based CT angiograpHy derIved FFR: a Multi-ceNtEr) registry (NCT02805621). ML-cFFR and invasive FFR ≤0.80 were considered haemodynamically significant, whereas cCTA luminal stenosis ≥50% was considered obstructive.
Results: Compared with invasive FFR on a per-lesion basis, ML-cFFR reached a pooled sensitivity, specificity, positive predictive value, and negative predictive value of 83.0% (95%CI: 76.6-88.2), 73.4% (95%CI: 67.1-79.1), 71.2% (95%CI: 66.3-75.7), and 84.5% (95%CI: 79.5-88.4) in men vs 69.4% (95%CI: 51.9-83.7, p=0.0009), 83.5% (95%CI: 74.3-90.5, p=0.0207), 62.5% (95%CI: 50.0-73.5, p=0.0650) and 87.4% (95%CI: 80.7-91.9, p=0.4234) in women, respectively. The AUC of ML-cFFR was not significantly superior to cCTA alone on a per-vessel basis [0.83 (95%CI: 0.75-0.90) vs 0.79 (95%CI: 0.70-0.87), p=0.4752] in women, but showed a statistically significant improvement in men [0.83 (95%CI: 0.79-0.87) vs 0.74 (95%CI: 0.69-0.79), p<0.0001].
Conclusion: ML-cFFR significantly improves the diagnostic performance over cCTA alone for the detection of haemodynamically relevant lesions, using invasive FFR values as the reference standard. The incremental value is greater in men than in women.

B-1457 11:02

Noninvasive CT-derived FFR based on structural and fluid analysis with low radiation dose using a full iterative reconstruction

H. Takagi, K. Kikuchi, R. Tanaka, K. Yoshioka; *Morioka/JP*
(hdnb69tkg@gmail.com)

Purpose: The purpose of this study was to evaluate the diagnostic performance for functional significance of coronary artery stenosis (i.e. ischaemia) of CT-derived fractional flow reserve (CT-FFR) at low radiation dose using a full iterative reconstruction (IR) technique.
Methods and Materials: This retrospective study included 19 vessels in 16 patients with suspected coronary artery disease (CAD) who underwent coronary CT angiography (CCTA), followed by invasive fractional flow reserve (FFR). All CCTA examinations were performed with a 320-row MDCT scanner, and all CT data were reconstructed with a full IR technique. CT-FFR was derived using a reduced order model performed with dedicated software on a standard desktop computer. Ischaemia was defined as a CT-FFR and FFR ≤0.80. The diagnostic performance with 95% confidence interval (95%CI) of CT-FFR was assessed with invasive FFR as the reference standard. The effective radiation dose of CCTA was calculated by a dose-length product (mGy·cm) and a standard conversion factor of 0.014 (mSv/mGy·cm).
Results: Ischaemia was observed in 58% (11/19) vessels during invasive FFR. On a per-vessel basis, sensitivity, specificity, accuracy, and area under the curve were 82% (95%CI, 63-89), 88% (95%CI, 62-98), 84% (95%CI, 63-93) and 0.85 (95%CI, 0.60-0.95) for CT-FFR. The CT-FFR and FFR were well correlated (r=0.79, p<0.01), and there was no significant difference between CT-FFR and FFR (-0.01±0.07, p=0.68). The mean effective radiation dose for CCTA was 1.9±1.0 mSv.

Conclusion: Noninvasive CT-FFR with low radiation dose using a full IR demonstrated a high diagnostic performance for the detection of ischaemia.

Intermodel agreement of myocardial blood flow quantification in dynamic myocardial perfusion CT

M. van Assen[1], G. Pelgrim[2], M. Stijnen[3], S. Van Tuijl[3], U.J. Schoepf[1], R. Vliegenthart[2], M. Oudkerk[2]; [1]*Charleston, SC/US*, [2]*Groningen/NL*, [3]*Eindhoven/NL (m.van.assen@umcg.nl)*

Purpose: To assess intermodel agreement of tracer kinetic models to determine myocardial blood flow (MBF) and ischemia in dynamic CT myocardial perfusion imaging (CTMPI).
Methods and Materials: Three porcine hearts perfused in Langendorff mode (Physioheart©, LifeTec Group, Eindhoven,The Netherlands) and 8 patients with suspected CAD and rest-stress perfusion single photon emission CT (SPECT) were included. Dynamic CTMPI was performed in shuttle-mode (70kVp, 350mAs/rot, z-range 10.2cm) on 3rd-generation dual-source CT. In porcine hearts and patients, myocardial segments were drawn according to the AHA-16-segment model. Tissue attenuation curves were calculated per segment. The arterial input function was derived from the aorta. True MBF was calculated in the porcine model based on input flow and weight of the heart. In patients, ischemic segments were defined based on previous SPECT results. MBF (ml/g/min) quantification was performed using the upslope, Extended Toft (ET), Two-compartment (TC) and Fermi models.
Results: For the non-ischemic segments in the porcine hearts, the upslope method resulted in lower MBF (median 1.23, interquartile range[IQR]:1.07-1.46) compared to the Fermi, ET and TC model, which had median values of 1.93 (1.37-2.63), 2.78 (1.56-3.81) and 2.26 (1.64-3.29). True global MBF was calculated at median 1.88 (IQR:1.80-2.80). In patients all models showed a significant difference between ischemic and non-ischemic segments (p-value<0.001). Again the upslope model showed the lowest MBF values.
Conclusion: The most commonly used upslope method yielded lower absolute MBF values compared to other models and true MBF in porcine hearts. In patients all models were able to discriminate between ischemic and non-ischemic segments.

Additional diagnostic value of CT perfusion over coronary CT angiography in stented patients with suspected in stent restenosis or coronary artery disease progression: Advantage study

D. Andreini[1], S. Mushtaq[1], J. Sonck[2], G. Pontone[1], E. Conte[1], M. Mancini[1], A. Baggiano[1], A.L. Bartorelli[1], M. Pepi[1]; [1]*Milan/IT*, [2]*Brussels/BE (daniele.andreini@ccfm.it)*

Purpose: Aim of the study is to assess the diagnostic performance of CCTA alone, CTP alone and CCTA plus CTP when compared to invasive coronary angiography (ICA) in patients with coronary stents.
Methods and Materials: A cohort of consecutive patients referred to ICA were enrolled. The feasibility of CCTA, CTP and the combined evaluation CCTA plus CTP were calculated. Sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy of CCTA, CTP, combined evaluation CCTA-CTP (considered as positive when CCTA indicated a >50% stenosis or ISR and/or CTP indicated a perfusion defect) and concordant evaluation CCTA-CTP vs. ICA were calculated. Radiation exposure was recorded.
Results: Sixty nine patients were enrolled. CTP feasibility was significantly higher than CCTA feasibility in a stent-, territory- and patient-based analysis. The feasibility of the combined evaluation CCTA-CTP was significantly higher than CCTA feasibility. The diagnostic accuracy of CCTA was 78%, 81%, and 78%, respectively; the diagnostic accuracy of CTP was 90%, 92% and 84%, respectively; the diagnostic accuracy of combined CCTA-CTP was 84%, 88%, and 83%, respectively; the diagnostic accuracy of concordant CCTA-CTP was 95%, 97% and 96%, respectively. The diagnostic accuracy of concordant CCTA-CTP was higher than that of CCTA and CTP in a patient-based analysis. The mean effective dose of CCTA-CTP was 3.89±1.35 mSv.
Conclusion: The CTP assessment appears more feasible accurate than the anatomical evaluation alone by CCTA in patients with coronary stents. When results of CCTA and CTP are concordant the diagnostic accuracy of the combined evaluation is very high.

B-1460 11:26

Accuracy of CCTA to detect obstructive CAD using stress vs rest dataset in patients referred to stress CTP

M. Guglielmo[1], A. Guaricci[2], A. Baggiano[1], F. Fazzari[3], D. Andreini[1], F. Fabiocchi[1], A. Lualdi[1], A. Bartorelli[1], G. Pontone[1]; [1]*Milan/IT*, [2]*Bari/IT*, [3]*Palermo/IT (marco.guglielmo@ccfm.it)*

Purpose: We sought to compare diagnostic accuracy of CCTA (coronary computed tomographic angiography) to detect obstructive CAD (coronary artery disease) between stress versus rest dataset as compared to invasive coronary angiography (ICA).
Methods and Materials: 66 symptomatic patients with intermediate to high pre-test probability of CAD and scheduled for clinically indicated ICA were prospectively enrolled. All patients underwent rest-CCTA followed by stress-CTP protocol with adenosine (revolution CT scanner, GE Healthcare, Milwaukee, WI) with injection of 70 ml of iodixanol 320 (Visipaque 320 mg/ml, GE Healthcare, Oslo, Norway). For both datasets, the image quality was evaluated with Likert score.The severity of coronary lesions was quantified by identifying the minimum diameter and reference diameter for all stenoses, and the percentage of stenosis will be derived according to the following formula: (Dref–Dmin)/Dref·100, where Dref is the reference diameter and Dmin is the minimum diameter. For CCTA and ICA, the obstructive CAD was defined as the presence of coronary artery stenosis ≥50%.
Results: Obstructive CAD was found in 61% of patients at ICA. In vessel-based model, the stress dataset showed a higher heart rate as compared to the rest dataset (p<0.001) with similar image quality. Stress dataset showed similar sensitivity (95% [CI95%: 89-100)] vs 93% [CI95%: 89-100)] but slightly lower specificity (75% [CI95%: 69-82)] vs 80% [CI95%: 74-86), p: 0.05] as compared to rest dataset. In both vessel and patient-based model, stress and rest dataset showed similar area under the curve (AUC) (0.84 vs 0.82 and 0.84 vs 0.84).
Conclusion: In static stress CTP, the new-generation scanner allows to perform the coronary artery imaging in the stress dataset with the same accuracy of rest dataset.

B-1461 11:34

The impact of a tiered cardiac CT protocol compared to functional testing on cardiovascular risk management in patients with suspected coronary artery disease

F. Nous[1], M.M. Lubbers[1], J. Akkerhuis[1], T. Bruning[1], B. Krenning[1], M. Kofflard[2], B.L. Kietselaer[3], R.P. Budde[1], K. Nieman[1]; [1]*Rotterdam/NL*, [2]*Dordrecht/NL*, [3]*Maastricht/NL (f.nous@erasmusmc.nl)*

Purpose: To assess the impact of a tiered cardiac CT protocol, compared to functional testing, on cardiovascular risk factors and life style changes in patients evaluated for coronary artery disease (CAD).
Methods and Materials: Patients with suspected CAD, who participated in the CRESENT I or CRESENT II trials, who were randomly assigned to cardiac CT or functional testing, were assessed. The protocol included a calcium scan and when indicated a coronary CT angiography (CCTA) (calcium score >0/high pre-test probability) and a CT myocardial perfusion (CRESENT II, CCTA: stenosis >50%), or functional-testing according to European guidelines. The use of preventive medication was registered at baseline and at 6 months (CRESENT I) or 1 year (CRESENT II) and patients were asked to fill out a questionnaire about their health status (smoking, diet, exercise, weight change, blood pressure and cholesterol level) at follow-up.
Results: Patients who underwent a cardiac CT (n=372) were more likely to improve at least one of the risk factors or life style changes compared to patients who underwent functional-testing (n=246) (78% vs. 67%, p<0.01). They were more likely to increase their exercise (p<0.05), to gain less weight (p<0.001) and to normalise their cholesterol levels (p<0.01). Fewer patients used antiplatelet agents and/or statins after diagnostic testing, from 31% to 24% (p<0.01) after CT, and from 45% to 39% (p<0.05). No differences were found between both groups.
Conclusion: A tiered cardiac CT protocol is associated with more change in life style in patients evaluated for CAD compare to functional testing.

Deep learning-based analysis of the left ventricular myocardium in coronary CTA images improves specificity for detection of functionally significant coronary artery stenosis

R.W. van Hamersvelt, M. Zreik, M. Voskuil, I. Isgum, T. Leiner; *Utrecht/NL (R.w.vanhamersvelt-3@umcutrecht.nl)*

Purpose: To evaluate the added value of fully automatic deep learning-based analysis of left ventricular myocardium (LVM) in addition to routine stenosis

degree assessment for the detection of functionally significant coronary artery stenosis in resting coronary computed tomography angiography (CCTA).
Methods and Materials: We retrospectively studied 126 consecutive patients (76.9% male) who received a CCTA within one year prior to an invasive fractional flow reserve (FFR) measurement. An FFR≤0.80 and/or PCI performed was used as a reference to indicate a functionally significant stenosis. Resting CCTA scans were performed on a 256-slice CT. Stenosis degree was categorised as 0%, 1-30%, 31-49%, 50-69% and ≥70% by visual assessment. Patients with stenosis ≥70% were considered significant and ≤30% non-significant. Patients with intermediate stenosis (31-69%) were referred for deep learning analysis of the LVM evaluating presence of functionally significant stenosis. LVM was automatically segmented using a multiscale convolutional neural network and subsequently characterised using a convolutional auto-encoder. Using these encodings, patients with functionally significant stenosis were identified using a support vector machine classifier. Diagnostic performance of the combined method was compared with stenosis degree evaluation on CCTA alone (≥50% stenosis indicating functional significance).
Results: In 84 patients (66.7%) a functionally significant stenosis was present. Sensitivity and specificity of stenosis degree evaluation alone (cut-off≥50%) were 91.7% and 31.0%. The combined method resulted in an increase in specificity to 50% with only minor decrease in sensitivity (82.1%).
Conclusion: Adding deep learning-based analysis of the LVM to stenosis grading improves specificity with only minor decrease in sensitivity.

A meta-analysis on functional CT for diagnosing haemodynamically significant coronary artery disease: ready for prime time?
C. Celeng[1], T. Leiner[1], P. Maurovich-Horvat[2], B. Merkely[2], P. de Jong[1], J.W. Dankbaar[1], B. Ghoshhajra[3], U. Hoffmann[3], R.A. Takx[1]; [1]*Utrecht/NL*, [2]*Budapest/HU*, [3]*Boston, MA/US*

Purpose: Coronary CT angiography (CCTA) provides excellent anatomical albeit limited functional information about coronary artery disease (CAD). Various CT techniques have emerged for the assessment of myocardial ischemia. We performed a meta-analysis to determine the diagnostic accuracy of myocardial perfusion (CTP), CT derived fractional flow reserve (FFR_{CT}) and coronary transluminal attenuation gradient (TAG) for the detection of hemodynamically significant CAD.
Methods and Materials: This meta-analysis was performed according to the PRISMA guidelines. We systematically searched PubMed, EMBASE and Web of Science for studies using invasive FFR as a reference standard for the assessment of CAD. Results were pooled to compute summary sensitivity, specificity and the diagnostic odds ratio on vessel level. Since stenosis degree on CCTA as a standalone technique has an excellent sensitivity, specificity was considered most relevant.
Results: Thirty-four studies reported on CCTA, 12 on CTP, 17 on FFR_{CT} and 6 on TAG. With CCTA 6225, with CTP 2170, with FFR_{CT} 2372 and with TAG 726 vessels were analyzed. For the assessment of hemodynamically significant stenosis at vessel level the specificity of CCTA was 65% [95% CI: 63-66%], of CTP was 79% [95% CI: 77-81%], of FFR_{CT} was 76% [95% CI: 74-79%] and of TAG was 64% [95% CI: 60-69%]. Combining CTP with CTA resulted in a slight improvement in specificity of 84% [95% CI: 81-86%] compared to CTP alone.
Conclusion: Functional CT (CTP and FFR_{CT}) yielded a substantial improvement in the identification of hemodynamically significant CAD, therefore it is ready to be integrated into the clinical routine.

Updated evidence-based European Society of Urogenital Radiology (ESUR) Contrast Media Safety Committee (CMSC) Guidelines for prevention of post-contrast acute kidney injury (PC-AKI)
A.J. Van Der Molen[1], P. Reimer[2], I. Dekkers[1], G. Bongartz[3], H.S. Thomsen[4]; [1]*Leiden/NL*, [2]*Karlsruhe/DE*, [3]*Basle/CH*, [4]*Herlev/DK*
(A.J.van_der_Molen@lumc.nl)

Purpose: To update current ESUR CMSC guidelines for prevention of PC-AKI after administration of iodine-based contrast media (CM).
Methods and Materials: Ten answerable clinical questions were phrased by the writing group. A systematic literature search was performed for each of the questions using PubMed, Medline, Embase and Web of Science databases. Literature was selected with help of published quality metrics (PRISMA, CONSORT, STROBE), and scientific evidence was graded using Oxford CEBM levels of evidence. Scientific evidence was combined with logistic and economic aspects into practical clinical recommendations.
Results: CM are much less nephrotoxic than previously defined. PC-AKI is the preferred terminology as in most instances the causative relation with CM can't be established. The CKD-EPI and updated Schwarz equations are recommended for estimation of glomerular filtration rate (eGFR). Patients are at increased risk for PC-AKI if eGFR <30ml/min/1.73m^2 if CM is administered intravenously or intra-arterially with second pass renal exposure. For maximum safety, eGFR <45ml/min/1.73m^2 is employed if CM is administered intra-arterially with first pass renal exposure and in ICU patients. Hydration with normal saline or bicarbonate remains the primary preventive measure, using shortened protocols. Other measures in addition to hydration have not been found sufficiently effective. Metformin should be stopped temporarily if eGFR <30ml/min/1.73m^2 and prescribing physician should be informed. It is not needed to align contrast-enhanced procedures with schedules of chronic renal dialysis.
Conclusion: Updated CMSC guidelines for prevention of PC-AKI lowered the cut-off for preventive measures to eGFR <30ml/min/1.73cm2 and shortened hydration protocols, resulting in reduced costs.

Intravenous contrast media administration: is there a risk of acute kidney injury?
M.D. Ferrer Puchol, E. Sanz-Rodrigo, P. Montesinos Garcia, E. Taberner Lopez, E. Blanco Pérez, M. Forment Navarro; *Alzira/ES*
(lolesferrer@ono.com)

Purpose: To assess whether intravenous contrast media administration (IVCMA) is associated with an increase in creatinine levels and risk for acute kidney injury.
Methods and Materials: This is a retrospective cohort analysis that included all patients who attended the Emergency Department (ED) during 6-year period (2010-2015) with a baseline creatinine (C1) and other creatinine (C2) 24-72 hours later.The Ethics Committee approved this study. An experienced systems analyst extracted all clinical information from the available data-base stored in the institution.Exclusion criteria: patients less 18 years, serum creatinine less 0.04 mg/dL or more 4.0 mg/dL and IVCMA in the 6 months before the study.Our mean annual census in ED was 105,435 visits.There were 3 groups: 1. Patients undergoing contrast-enhanced CT (n=6,662), 2. Patients undergoing non-contrast-enhanced CT (n=6,193), 3. Not CT received patients (n=33,802).We used both criteria for "Contrast-induced Nephropathy" (CIN) and for "Acute Kidney Injury Network/Kidney Disease" (AKI).Results were presented as odds ratios using Stata 15.
Results: We analysed 52,411 patients and, after applying exclusion criteria 46,637.Mean-age 67.95 years. C1 values:1.16 mg/dL (SD:0.61), C2 values: 1.14 mg/dL (SD:0.66). Multivariable logistic regression revealed:Using AKI and CNI criteria: CT with IVCM was not associated with increased incidence of acute injury (OR:0.9, 95% CI 0.83-0.99 and OR:0.89, 95% CI 0.81-0.98, respectively).The value of baseline creatinine conditioned nephropathy (OR:1.41) independently of CT being performed or not.

Conclusion: These findings demonstrate that in our context, contrast media administration is not associated with an increase in incidence of acute kidney injury.

B-1466 10:46

Survey of contrast-induced nephropathy after CT scan in patients who stayed in Sari Imam Khomeini Hospital from 2016 to 2017

H. Majidi, F. Godazandeh, R. Abdi, F. Espahbodi, R. Alimohammadpur, M. Tayebi; *Sari/IR (farnaz_godazandeh@yahoo.com)*

Purpose: With the growing use of contrast agents in diagnostic imaging techniques, the contrast-induced nephropathy (CIN) has become a major source of hospital morbidity. The aim of this study was to determine the incidence of CIN after a CT scan with contrast and identifying its risk factors.
Methods and Materials: This cross-sectional study was induced on 100 patients who had CT scan with contrast. Predictors of CIN were evaluated in four general categories: demographic variables, underlying disease, concomitant medications, and laboratory findings (level of Cr, BUN and eGFR). Cr measurement was performed 24 and 48 hours after receiving contrast agent and increment of its baseline level to more than 25% or 0.5mg/dl after 48 hours was considered as an indicator of the CIN.
Results: The incidence of CIN was 7% and it was significantly associated with hypertension (P=0.028) and use of ARBs (P=0.019). BUN and eGFR parallel to each other were observed as more accurate markers than Cr in prediction of CIN incidence. However, BUN showed higher sensitivity (71.4% vs 57.1%), eGFR indicated higher specificity (75.3% vs 65.6%).
Conclusion: Hypertension and use of ARBs are the most important risk factors for CIN. BUN has been found to be a better marker compared to eGFR and Cr in CIN prediction. Thus, attention to marker BUN in initial assessments of the CIN incidence in patients undergoing CT with contrast is highly recommended.

B-1467 10:54

Multiphase urinary tract imaging with dual contrast using spectral photon-counting CT

S.A. Si-Mohamed[1], M. Sigovan[2], G. Normand[2], P. Coulon[3], D. Bar-Ness[2], L. Boussel[1], P. Douek[1]; [1]*Bron/FR*, [2]*Lyon/FR*, [3]*Suresne/FR (salimaymeric@gmail.com)*

Purpose: To demonstrate the feasibility of dual contrast multiphase imaging of urinary tract using a spectral photon-counting computed tomography (SPCCT).
Methods and Materials: SPCCT with 5 energy bins (Philips Healthcare, Haifa, Israel) was used at 120 kVp, 100 mA to acquire the urinary tract in 3 rabbits, following approval by an ethics committee. The protocol was to inject at 6 minutes apart first an iodine contrast agent (Xenetix, 350 mg/ml, 1 mg/kg, Guerbet) followed by a macrocyclic gadolinium contrast agent (Dotarem, 0.5 M, 3 ml/kg, Guerbet) in order to beneficiate from two different phases imaging, i.e. urinary for iodine and renal for gadolinium. Acquisitions were made at 10 and 30 seconds after second injection. SPCCT provided conventional HU and quantitative material decomposition iodine and specific K-edge gadolinium maps.
Results: The conventional CT images could not allow to discriminate the specific contrast agent pharmacokinetics opposite to the gadolinium and iodine maps. We observed a dual-phase imaging with urinary cavity enhancement by the first contrast media injected and a cortical and medullar enhancement resulting from the second contrast media injected, matching the expected pharmacokinetics of the contrast media. Moreover, the water images allowed visualisation of a non-enhanced-like image.
Conclusion: SPCCT allows in vivo dual contrast quantitative multi-phase imaging in a single acquisition. This finding pinpoints major clinical applications in multiphase imaging with no registration issues and with the additional value of reducing radiation dose to patients by reducing the number of acquisitions.

Split-bolus vs single-bolus MDCT urography: comparison of urinary tract opacification, radiation dose exposure and diagnostic capability

C. Valle[1], P. Bonaffini[2], F. Invernizzi[3], A. Barletta[1], A. Casiraghi[2], A. Pappini[3], S. Sironi[1]; [1]*Bergamo/IT*, [2]*Monza/IT*, [3]*Desio/IT (clarissa.valle1987@icloud.com)*

Purpose: To compare urinary tract opacification, radiation dose exposure and diagnostic capability of split-bolus MDCT urography (CTU) as compared to single-bolus protocol.
Methods and Materials: Forty-eight patients (18-83 years), undergone CTU on a 64-row scanner (Aquilion, Toshiba) after IV administration of 90-110 mL of iodinated CM (350 mg/mL), were retrospectively analyzed: 24 (study group) performed a split-bolus CTU (combined nephrographic-excretory phase) and 24 (control group) a single-bolus protocol. Quantitative analysis of intraluminal opacification (HU) was achieved by placing ROIs in renal pelvis, ureters and bladder. Qualitative analysis was performed by two radiologists (1-consultant;2-resident) using a 4-point scale (0:none;3:excellent); inter-observer agreement was calculated. The radiation dose exposure was calculated as DLP (mGy*cm) and CTDIvol (mGy). The diagnostic capability was evaluated using a 2-point scale (0:no answer;1: question satisfied) and considering histology, further imaging and endoscopy.
Results: The split-bolus protocol demonstrated significantly lower mean urinary attenuation (HU) as compared to the control group (L pelvis 909 vs 1326, R pelvis 877 vs 1253, L ureter 810 vs 1114, R ureter 655 vs 1127, bladder 605 vs 939); no differences were observed in quality of intraluminal opacification. The mean DLP was significantly lower (1869 vs 3002 mGy*cm;p=0.045) in the study group (dose exposure reduction of 37%). Split-bolus protocol answered to the clinical question in almost all the cases (2 diagnoses missed).
Conclusion: With a qualitatively comparable urinary tract opacification as compared to single-bolus protocols, split-bolus CTU results in a proper ability to answer the clinical question with a significant dose reduction of 37%.

B-1469 11:10

Evaluation of parenchymal and vascular enhancement in split-bolus MDCT urography compared to standard single-bolus protocol: a feasibility study

M. Balbi[1], F. Invernizzi[2], P.A. Bonaffini[3], G.C. Preziosa[1], D. Nicoletta[2], C. Valle[1], A. Pappini[2], S. Sironi[1]; [1]*Bergamo/IT*, [2]*Desio/IT*, [3]*Monza/IT (balbi.m@libero.it)*

Purpose: To evaluate parenchymal and vascular enhancement in split-bolus MDCT urography (CTU) studies compared to standard single-bolus protocol.
Methods and Materials: A total of 20 split-bolus (study group, a) and 20 single-bolus (control group, b) CTU studies were retrospectively reviewed. All examinations were performed in adult patients (19-84 years) following i.v. injection of 90-110 mL of iodinated contrast medium (CM; 350 mg/mL), on a 64-row scanner (Aquilion, Toshiba). Two radiologists (1-consultant, 2-resident) independently analyzed parenchymal and vascular enhancement in both groups on combined nephro-urographic (a) and portal venous phase (b) respectively. ROIs (regions of interest) were placed on: kidneys, liver, spleen, abdominal aorta and inferior vena cava (IVC). The corresponding mean HU and radiation dose exposure values (CTDIvol and DLP) were compared between the groups and statistically analyzed.
Results: In terms of HU values there were no statistically significant differences ($p > 0.05$) between the study and the control group. The mean attenuation values for split-bolus and single-bolus CTU were respectively: 187 vs 176 HU (R kidney), 188 vs 180 HU (L kidney), 109 vs 105 HU (liver), 114 vs 106 HU (spleen), 162 vs 152 HU (aorta) and 132 vs 121 HU (IVC). CTDIvol and DLP values in the study group were significantly lower ($p < 0.05$; mean values, 54 *vs* 104 mGy and 1663 *vs* 3065 mGy*cm, respectively).
Conclusion: Split-bolus CTU may provide studies potentially useful for the evaluation of extra-renal findings due to proper vascular and parenchymal enhancement, coupled to an overall dose reduction of about 47%.

B-1470 11:18

Diagnostic value of virtual monoenergetic urographic phase images in the assessment of urothelial carcinoma

D. Zopfs, S. Lennartz, D. Maintz, T. Persigehl; *Cologne/DE (david.zopfs@uk-koeln.de)*

Purpose: To compare virtual monoenergetic images of the urographic phase (U-VMI) with polyenergetic images of the venous (V-PI) and the urographic phase (U-PI) regarding image quality, organ and vessel contrast as well as diagnostic assessment of urothelial carcinoma using a spectral-detector CT (SDCT).
Methods and Materials: Contrast-enhanced SDCT of 13 patients with histologically confirmed urothelial carcinoma were included at this retrospective study. Attenuation (HU), image noise (SD) as well as signal- and contrast-to-noise-ratio (SNR, CNR) in V-PI, U-PI and U-VMI (40-200keV) were obtained from ROI-based measurements in following regions: liver, pancreas, renal cortex and medulla, psoas muscle, subcutaneous fat, renal vein and artery, portal vein, wall of urinary bladder, lymph node, prostate and uterus. Moreover, subjective assessment of vessel contrast, parenchymal organs, urothelial carcinoma and corticomedullar differentiation of the kidneys was rated using a 5-point Likert scale.
Results: Attenuation and SNR in U-VMI at 40keV were equivalent or higher compared to V-PI (p-range: 0.69 - 0.01). Regarding image noise, no significant difference was found between V-PI and U-VMI at 40keV ($p \geq 0.05$ each). CNR of urothelial carcinoma was significantly higher in U-VMI at 40keV than in V-PI (8.24 vs. 3.80, $p \leq 0.01$). Subjective vessel contrast, assessment of parenchymal organs, carcinoma and corticomedullar differentiation received equivalent or higher Likert scores in U-VMI at 40keV compared to V-PI (p-range: 0.06 - 0.6).
Conclusion: U-VMI at 40keV yield equivalent SNR of parenchymal organs and an even increased CNR of malignant lesions in comparison to V-PI, allowing for a better delineation of urothelial carcinoma.

B-1471 11:26

CT urography: dependence of distal ureter opacification on excretory-phase timing and urinary-bladder volume

U.L. Mueller-Lisse, R. Ebner, S. Seifert, C. Stief, J. Ricke, M.F. Reiser, U.G. Mueller-Lisse; *Munich/DE*

Purpose: CT urography (CTU) is challenged by distal ureter opacification in the excretory phase (DUO). Potential dependence of DUO on excretory-phase timing after venous-phase scanning (EPT) and urinary-bladder volume (UBV) were retrospectively analysed.
Methods and Materials: Ethics committee approval was obtained for an institutional picture-archiving-and-communication-system (PACS) search of CTU-examinations from 2007 to 2016 (three sites, nine different CT-scanners) in patients with extra-urinary abdominal or pelvic tumour or trauma or suspicion of tumour and reports of unremarkable native urinary tracts bilaterally. A random sample of 147 adult patients (age+/-standard-deviation, 63+/-14 years, 66 females) was reviewed by two researchers who consented on DUO of each pelvic ureter (>80% opacified). EPT-intervals (3-34 minutes) were retrieved from PACS. Venous-phase and excretory-phase UBV were estimated in multi-planar image-reconstructions (ellipsoid formula). Two-tailed statistical tests were significant for p<0.05.
Results: DUO was positive bilaterally in more than 75% and failed bilaterally in less than 10% of patients for EPT 8-11 minutes (1/50 failed, versus 19/59 <8 minutes, and 12/28 12-18 minutes, 3x2-chi-square, 9.51, 0.005<p<0.010). DUO frequently failed (5/7) in venous-phase UBV <120 ml and associated excretory-phase UBV increase <50 ml after 12-18 minutes (versus 9/32, Fisher's exact test, p=0.0442). Technical parameters (tube-charge, CTDI, DLP, slice thickness) did not differ significantly (all T tests, p>>0.05).
Conclusion: DUO appears to be most successful for EPT 8-11 minutes. EPT 12-18 minutes is likely to fail DUO when venous-phase UBV is <120 ml and excretory-phase UBV-increase <50 ml.

Kinking of the upper ureter in CT urography: anatomic and clinical significance

M. Kamo, T. Nozaki, K. Yoshida, U. Tateishi, K. Akita; *Tokyo/JP (kamomino@luke.ac.jp)*

Purpose: Although the course of the ureter is described as a straight descent in the retroperitoneum, kinking of the upper ureter is often seen at imaging. The aim of this study was to investigate kinking of the ureter and its underlying anatomico-clinical significance.
Methods and Materials: We evaluated 176 computed tomography (CT) images and classified kinking into three grades: no/mild kinking as Grade 1, moderate as Grade 2, and severe as Grade 3. We defined the ''crossing point'' (CP) as where the ureter crosses over the gonadal vein and assessed its relation to the kinking. Fourteen halves from seven cadavers were used for examination. Approaching anteriorly, we macroscopically observed the ureter and surrounding structures.
Results: On CT, the rate of the radiologically "significant" kinking classified into either Grade 2 or 3 was 18.4% on the right and 21.8% on the left. All kinking was either at or above the level of the CP. In cadavers, the ureter was relatively mobile in the perirenal fat and then beginning at approximately the level of the CP became firmly fixed to the anteromedial aspect of the psoas major muscle.
Conclusion: Kinking of the upper ureter is not a clinically significant finding and arises from the ureter having a relatively mobile portion in the perirenal space compared to its caudal portion. The fixation boundary can be identified by observing the CP.

B-1473 11:42

Characterisation of renal stones using spectral detector computed tomography using normal and low-dose protocols

N. Grosse Hokamp[1,2], J. Salem[1], J. Holz[1], G. Dervishi[1], M. Ritter[3], A. Heidenreich[1], D. Maintz[1], S. Haneder[1]; [1]*Cologne/DE*, [2]*Cleveland, OH/US*, [3]*Mannheim/DE (nils.grosse-hokamp@uk-koeln.de)*

Purpose: To investigate the feasibility of renal stone composition analysis using a spectral detector computed tomography scanner with normal and low-dose imaging protocols (SDCT).
Methods and Materials: 180 stones harvested from nephrolithotripsy or nephrolithotomy with a known composition as determined by infrared spectroscopy were examined in a non-anthropomorphic phantom on a SDCT (IQon, Philips Healthcare, The Netherlands), imaging was performed with 120kVp and a) 40mAs and b) 200mAs, resulting in an CTDIvol of 2mGy and 10mGy, respectively. Besides conventional CT images (CI), SDCT enables reconstruction virtual monoenergetic images (40-200keV). Spectral coefficient images (SC) were calculated performing a voxel-by-voxel subtraction of 40keV and 200keV images (Matlab R2017b, Mathworks Inc, USA). All stones were semi-automatically 3D-segmented on CI using a threshold-based algorithm implemented in an offline Dicom-viewer. Statistic assessment was performed applying ANOVA with Tukey-HSD post hoc for multiple comparisons.
Results: Whewellite (n=73), weddellite (n=13), brushite (n=32), cysteine (n=19) struvite (n=15) and uric acid stones (n=28) were included in the analysis. Stone volume ranged from 10.0 to 599.2mm^3. While on CI attenuation differed significantly between calcified and non-calcified stones only (whewellit/weddellit/brushite vs others: 393HU vs 173HU, p≤0.05), the spectral coefficient differed significantly between (//): whewellite, weddellite//brushite//struvite, cysteine//uric acid in 10mGy protocol (all p≤0.05; 95% confidence intervals 3.4-4.3//2.6-3.6//1.4-2.2//0.5-0.9). The same results were found for the 2mGy protocol, except differentiation of brushite from whewellite and weddellite concrements was not possible (p=0.6).
Conclusion: SDCT allows for differentiation of renal stones using semi-automatic segmentation and spectral coefficient images, even in low-dose imaging protocols.

B-1474 11:50

Diagnostic performance of advanced modelled iterative reconstruction-applied images for detecting urinary stones on submillisievert low-dose computed tomography

J. Ahn, S. Kim, S. Kim, I. Nam, S.-J. Lee; *Busan/KR (radiresi@gmail.com)*

Purpose: To compare the sensitivities among the variable advanced modelled iterative reconstruction (ADMIRE) strengths applied to submillisievert (sub-mSv) low-dose CT (LDCT) and standard-dose CT (SDCT) for the detection of urinary stones.
Methods and Materials: A total of 92 consecutive patients (62 men and 30 women, mean age 50.8 years, range 17-79 years) with urinary stones underwent non-enhanced abdomino-pelvic CT that consisted of SDCT (120 kVp, 200 mAs) and LDCT (80 kVp, 60 mAs). The LDCT images were reconstructed separately with 5 different strengths of ADMIRE (hereafter, S1-S5) and filtered back projection (FBP). Two blinded radiologists independently recorded a number of urinary stones in the 6 LDCT data sets and SDCT. The sensitivity of each set for detecting urinary stones was compared using the McNemar test.
Results: A total of 309 urinary stones were analysed. The sensitivities of the 6 LDCT data sets showed no significant difference (FBP, S1-S5, for reader 1: 61%, 61%, 61%, 62%, 63%, and 62%; for reader 2: 47%, 49%, 50%, 50%, 51%, and 51%, $P > 0.05$, respectively), which were lower than those of SDCT for both readers (reader 1: 88%; reader 2:f 81%, $P < 0.05$, respectively).
Conclusion: The sensitivities for detecting urinary stones showed no significant differences among sub-mSv LDCT with variable ADMIRE strengths and were lower than those of SDCT.

The value of whole tumour volume-based T2 histogram analysis of differential diagnosis in paediatric posterior fossa tumours

K. Xu, Y. Zhang; *Zhengzhou/CN (15188367223@163.com)*

Purpose: To study the value of whole tumour T2 histogram analysis of differential diagnosis in three common paediatric posterior fossa tumours (ependymoma, astrocytoma, medulloblastoma).
Methods and Materials: A retrospective analysis was conducted by brain MRI examination and pathology diagnosis of 133 cases of posterior fossa tumours in children patients in our hospital. Among them, there are 49 cases of ependymoma (there are 25 males and 24 females), 36 cases of astrocytoma (there were 19 males and 17 females), 48 cases of medulloblastoma (there were 36 males and 12 females), respectively, to draw the region of interest (ROI) in the T_2 MR transaxial images of three groups on each layer of tumour level using Mazda software and analyse the whole tumour gray histogram, performing a statistical analysis on the three sets of parameters obtained from histograms to find out statistical significance of each parameter.
Results: Through histogram analysis of 9 parameters, these 9 parameters were statistically significant (all P <0.05), including mean, variance, kurtosis, skewness, Perc.01%, Perc.10%, Perc.50%, Perc.90% and Perc.99%.
Conclusion: The whole tumours T2 grey histogram analysis of three kinds of paediatric posterior fossa tumours in the differential diagnosis has certain value. It can be used as a new auxiliary method of diagnosis in three paediatric posterior fossa tumours.

B-1476 10:38

Predicting medulloblastoma genomic subtypes by exploiting MRI morphologic phenotypes

M.S. Alahmadi, M. Alharbi, N. Mobark, A.N. Alsaad, A. Daghriri, A.B. Anver, M.S.J. Althagafi, S. Raja; *Riyadh/SA (mo.alahmadi@gmail.com)*

Purpose: Standard of care mandates classification of medulloblastomas into 4 genomic subtypes (SHH, WNT, grade III and grade IV) at presentation. However, the subtyping is done invasively. Recent work suggests that MRI features may classify the subtypes non-invasively. We postulate that a combination of morphologic MRI features may be more accurate, for subtype prediction.
Methods and Materials: A retrospective review of baseline MRI of all patients already having Medullaobastoma genomic subtyping (no=22) were reviewed blindly and the MRI features were categorized by 3 radiologists (expert, intermediate, novice), based on modified Vasari criteria for example contrast enhancement, morphologic features such as location, hemorrhage, cystic component etc. using Access data-sheet, and subsequently exported to SPSS modeler for subsequent analysis.
Results: Out of 22 cases with genomic subtypes of SHH, WNT, Group III and Group IV (6,3,3 and 10). We performed a binary classification by combining into two separate groups, more aggressive Group III+IV (morAg), and less aggressive SHH+WNT (lesAg). The best discriminator was peritumoral oedema, and the 2nd best was length of lesion. The classification accuracy of the model was 90%, the model classified all lesAg correctly.
Conclusion: Our results strongly suggest that peritumoral oedema and length of lesion on MRI can accurately discriminate medulloblastoma genomic subtypes non-invasively. The unique ability of peritumoral oedema to separate between the two groups, has not yet been described in the literature. Our results show significant peritumoral oedema around lesAG lesions contrary to what is expected, we observed that the aggressive medulloblastomas show minimal peritumoral oedema.

B-1477 10:46

Application of MRI whole-tumour histogram analysis in assessment risk of medulloblastoma recurrence

Q. Lv; *Zhengzhou/CN (478071645@qq.com)*

Purpose: To explore the value of MRI whole-tumour histogram in the risk assessment of medulloblastoma recurrence.
Methods and Materials: Retrospective analysis of 26 patients which were pathologically confirmed medulloblastoma. These patients were divided into two groups, which were defined as the recurrent group and the non-recurrent group, each of the groups has 13 cases. Drawing the region of interest (ROI) on each slice of enhanced MR sagittal image including and doing the histogram analysis, the two steps were both conducted by the software Mazda. The histogram parameters were analysed statistically to find out the characteristics of the significant differences between the two groups. Next, we drew the ROC curve to assess diagnostic efficiency in medulloblastoma recurrence.
Results: As for the 9 parameters extracted from histogram, the differences of the variance, the 90th and 99th percentiles between the two groups have statistical significance ($P<0.05$). Areas under the ROC curve were 0.799, 0.728 and 0.746, respectively. The variance showed the sensitivity and the specificity of the risk of medulloblastoma recurrence which were 84.6% and 61.5%, respectively; the 90th percentile suggested both the sensitivity and the specificity were 69.2%, and by the 99th percentile, they were 69.2% and 61.5%, respectively. The cutoff of variance, the 90th percentile and 99th percentile were 414.66, 128.4, 159.235, respectively.
Conclusion: MRI whole-tumour histogram analysis can be used as an important supplementary method to assess the risk of medulloblastoma recurrence.

B-1478 10:54

Paediatric astrocytic tumour grading: comparison between ASL and DSC MRI perfusion

S. Stagliano[1], D. Tortora[2], M. Severino[2], C. Martinetti[2], M. Garrè[2], A. Rossi[2], G. Morana[2]; [1]*Rome/IT*, [2]*Genova/IT (sere.stagliano@gmail.com)*

Purpose: The aim of this study was to compare arterial spin labelling (ASL) and dynamic susceptibility contrast (DSC) MRI perfusion with respect to diagnostic performance in tumour grading in paediatric patients with low- and high-grade astrocytic tumours (AT).
Methods and Materials: We retrospectively analysed 37 children with histologically proven treatment-naïve low- and high-grade AT who underwent pre-operative ASL and DSC MRI perfusion. Studies were performed on a 1.5 T scanner and a pulsed technique was used for ASL. DSC data were post-processed with a leakage correction software. Normalisation of tumour perfusion parameters was performed with contralateral normal-appearing gray matter. Normalised ASL-derived cerebral blood flow (nASL-CBF) values in the most perfused area of each neoplasm were compared with normalised DSC-derived cerebral blood flow (nDSC-CBF) and cerebral blood volume (nCBV) data and correlated with WHO tumour grade. Statistics included Pearson's chi-square and Mann-Whitney U tests, Spearman's rank correlation and receiver operating characteristic (ROC) analysis.
Results: A significant correlation was demonstrated between ASL and DSC data ($p<0.001$). Significant differences in terms of ASL and DSC data were found between low- and high-grade AT ($p<0.001$). ROC analysis demonstrated similar performances between all parameters in predicting tumour grade (nASL-CBF: AUC 0.98, $p<0.001$; nDSC-CBF: AUC 0.97, $p<0.001$; nCBV: AUC 0.97, $p<0.001$).
Conclusion: Normalised pulsed ASL performed with a 1.5 T scanner provides comparable results to DSC MRI perfusion in paediatric AT and allows distinction between high- and low-grade AT.

B-1479 11:02

Differentiation of medulloblastoma and astrocytoma in children using histogram analysis of enhancement MRI

W. Wang[1], Y. Zhang[1], J. Cheng[1], Z. Zhang[2]; [1]*Zhengzhou/CN*, [2]*Henan/CN (252936888@qq.com)*

Purpose: To investigate the diagnostic value of the histogram analysis derived from enhancement MR imaging in differentiating medulloblastomas from astrocytomas.
Methods and Materials: Retrospective analysis of 47 patients which were pathologically confirmed posterior fossa tumours, including 29 cases of medulloblastoma and 18 cases of astrocytoma. Drawing the region of interest (ROI) on the maximum level of enhanced MR sagittal image and going on histogram analysis, these two steps are all performed on the software named Mazda. A statistical analysis was performed on the histogram parameters to find out the characteristics of the significant differences between the two groups.
Results: In the 9 parameters which are extracted from histogram, C99 has the statistical significance. The maximum area under the ROC curve was 0.85. The optimum C99 to distinguish medulloblastomas from astrocytomas was 176.5 (76% specificity and 61% sensitivity).
Conclusion: Histogram analysis of enhancement MR imaging can provide reliably objective basis for differentiating medulloblastomas from astrocytomas.

B-1480 11:10

3D fast spin-echo T1 black-blood imaging for the preoperative detection of venous sinus invasion of meningioma: comparison with contrast-enhanced MRV

D. Wang; *Shanghai/CN (wangddfsk@126.com)*

Purpose: A comprehensive understanding of venous situation is helpful for optimised treatment decisions and for managing the severe complications of meningiomas adjacent to venous sinuses. To prospectively evaluate the diagnostic value of 3D FSE T1 CUBE MR imaging in comparison with contrast-enhanced MRV in the detection of sinus invasion by meningiomas.
Methods and Materials: Forty consecutive patients with suspected meningiomas adjacent to venous sinus underwent conventional MR imaging, CE-MRV and 3D CUBE T1WI scanning. Two neuroradiologists independently assessed images for (1) wall invasion and (2) lumen invasion of target venous sinus.
Results: 3D CUBE T1WI imaging was found to afford an easy way to detect the venous wall invasion by para-venous lesions. The inter-observer agreement was excellent (κ=0.851; 95% CI, 0.769-0.933) and the result was basically aligned with the surgical findings (sensitivity of 90.91%, specificity of 94.44%, PPV of 95.23%, NPV of 89.47% and Youden Index of 0.85). In the analysis of the lumen invasion, the inter-observer agreement obtained by 3D CUBE T1WI sequence was excellent (κ=0.958; 95% CI, 0.917-0.999) with a diagnostic accuracy of 92.5% based on surgical findings, which surpassed CE-MRV not only in inter-observer agreement (κ=0.717; 95% CI, 0.622-0.812) but also in diagnostic value (accuracy=65%). Among all 40 patients, no correlation was found between the extent of peritumoural oedema and venous invasion.
Conclusion: 3D CUBE T1WI sequence is a reliable technique to provide accurate assessment about the venous sinus invasion by meningioma. Meanwhile, CE-MRV is more suitable in the evaluation of the bypass draining veins around the tumour.

B-1482 11:18

Quantitative T1rho-weighted magnetic resonance imaging in gliomas: a preliminary study of its biochemical mechanism

Y. Yu, Y. Ren, H. Pang, Z. Yao; *Shanghai/CN (yy_0324@126.com)*

Purpose: To evaluate the utility of quantitative T1rho value for differentiating between low-grade and high-grade gliomas, and make a preliminary exploration of its possible molecular basis.
Methods and Materials: Thirty-six patients (28 males and 8 females; 43.9 ± 13.7 years) with pathologically verified gliomas were included in this study. MRI was performed for each patient on a 3.0T MRI system. An echo-planar

imaging-based T1rho-weighted MR pulse sequence (spin-lock times 20, 40, 60, and 80 ms) was employed to obtain single-slice images of maximum lesion. T1rho value maps were created using MATLAB software. The T1rho value of glioma parenchyma was measured on a manually drawn region of interest and correlated with the pathological grade of the gliomas. Furthermore, we calculated the hyaluronan intensity of each pathologic sections and analysed the correlation between intensity of hyaluronan and T1rho value.
Results: There were a total of 37 lesions (0, 22, 3 and 12 tumours of grades I, II, III, and IV, respectively) in the study. Low-grade (grades I and II) gliomas had significantly higher T1rho value than high-grade (grades III and IV) gliomas (179.22 ± 44.93 ms vs. 126.24 ± 22.91 ms; $P < 0.001$). With a cutoff T1rho value of 147.68 ms, the sensitivity for glioma grading was 81.8% and the specificity was 93.3%. Pathologically, T1rho value has a poor correlation with hyaluronan intensity in glioma.
Conclusion: Quantitative T1rho value can be a reliable imaging biomarker of the malignancy of brain gliomas. The cellular and molecular basis of T1rho is still unknown.

B-1483 11:26

DCE-MRI in human gliomas: a surrogate for assessment of invasive hypoxia marker HIF-1α based on MRI-neuronavigation stereotactic biopsies

Q. Xie[1], J. Wu[2], Y. Ren[1], H. Pang[1], H. Zhang[1], T. Jin[1], Y. Wu[1], Z. Yao[1], X. Feng[1]; [1]*Shanghai/CN*, [2]*Nantong/CN (xieqianjames@foxmail.com)*

Purpose: The purpose of this study was to correlate dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) parameters with data from a specific marker of hypoxia, hypoxia-inducible factor 1α(HIF-1α), in human gliomas on a point-to-point basis using coregistered MRI and frameless stereotactic biopsies.
Methods and Materials: Thirty-four patients with treatment-naive gliomas underwent DCE,axial T1-weighted(T1W),T2-weighted (T2W),T2-weighted fluid acquisition of inversion recovery (T2FLAIR),and three-dimensional T1-weighted brain volume with gadolinium contrast enhancement(3D T1BRAVO+C)sequences on a 3.0-T MR scanner before stereotactic surgery. Quantitative perfusion indices such as endothelial transfer constant (K^{trans}), fractional extravascular extracellular space volume (V_e),fractional plasma volume (fpV), and reflux rate (k_{ep}) were measured at corresponding stereotactic biopsy sites.Each sample was considered an independent measurement, and its histology grade was diagnosed.HIF-1α expression was quantified from the point-to-point biopsy tissues. Analyses of receiver operating characteristic (ROC) curves were done for HIF-1α to discriminate different grades of glioma.To look for correlations between immunohistochemical (IHC) parameters and DCE indices, Spearman's correlation coefficient was used.
Results: Seventy biopsy samples from 34 subjects were included in the analysis. Mean immunoreactivity scores of HIF-1α were 2.75±1.11 for grade II (n=24), 6.20±2.33 for grade III (n=20) and 10.46±2.42 for grade IV(n=26). HIF-1α showed very good-to-excellent accuracy in discriminating grade II from III,III from IV,and II from IV (area under the curve=0.838, 0.862 and 0.994, respectively). K^{trans} and V_e showed a significantly positive correlation with HIF-1α expression($r = 0.686$, $P < 0.001$; $r = 0.549$, $P<0.001$, respectively).
Conclusion: Our study demonstrated HIF-1α to be a significant predictor of different grades of gliomas with high sensitivity and specificity. DCE-MRI is a useful, non-invasive imaging tool for quantitative evaluation of HIF-1α, and its parameters may be used as a surrogate for HIF-1α expression.

B-1484 11:34

3D MRSI biomarkers of glial tumour

T. Anastasia, I. Pronin, L. Fadeeva, V. Kornienko; *Moscow/RU (alfa.net@list.ru)*

Purpose: To evaluate metabolite ratio in the whole tumour volume on the base of 3D 1H-MP spectroscopy in patients with glial brain tumours.
Methods and Materials: 20 healthy volunteers (age 26-65 years), 20 patients (age 28-65 years) with low-grade gliomas and 20 patients (age 25-60 years) with high-grade gliomas were examined in our study. We assessed the following metabolites: choline, creatine and N-acetylaspartate.
Results: In control group of healthy volunteers, we measured the metabolite ratio in white and grey brain matter. There were following ratios in white matter: Cho/NAA - 1.45±0.30, Cho/Cr - 1.15±0.11, NAA/Cr - 2.70±0.20 and grey matter: Cho/NAA - 0.52 ± 0.09, Cho/Cr - 1.14 ± 0.11, NAA/Cr - 2.53 ± 0.19. In glial brain tumours the good correlation between an elevation of Cho/Cr ratio, decreases of NAA/Cr ratio and degree of malignancy were found. High-grade gliomas demonstrated an elevation of Cho/Cr (3.41±0.79) and Cho/NAA (2.27±1.3), compared with low-grade tumours Cho/Cr (2.54±1.44) and Cho/NAA (2.76±1.2). NAA/Cr ratio was higher in low-grade gliomas (1.44±0.57) in comparison with grade III-IV lesions (0.95±0.41).
Conclusion: 3D MRSI provides the clinicians qualitative and quantitative markers of brain biochemistry in normal brain and in gliomas. Precisely to evaluate the tumour malignancy.

B-1485 11:42

Brain tumour-induced alterations in haemodynamic responses of BOLD fMRI

L. Wang[1,2], Y. Zhang[3], Z. Liu[4], D. Chen[5], L. Liu[1], H. Mao[2]; [1]*Shenzhen/CN*, [2]*Atlanta, GA/US*, [3]*ShenZhen/CN*, [4]*Nanchang/CN*, [5]*Suzhou/CN (2718377613@qq.com)*

Purpose: To investigate the effect of brain tumours on the haemodynamic responses and its impact on BOLD MRI signal time course to better understand tumour-induced alterations in haemodynamic responses and for accurate mapping in brain tumour patients.
Methods and Materials: fMRI data from 42 glioma patients who underwent presurgical mapping of primary motor cortex (PMC) with a block-designed fingertapping paradigm were analysed, retrospectively. Cases were divided into high- (n=24) and low- (n=18) grade groups based on pathology. Tumour volume and distance to the activated PMCs were measured. BOLD signal time courses from selected regions of interest (ROIs) in the PMCs of tumouraffected and contralateral unaffected hemispheres were obtained from each patient. Tumour-induced changes of BOLD signal intensity and time to peak (TTP) were analysed statistically.
Results: BOLD signal intensity and TTP in the tumour-affected PMCs are altered when compared with that in the unaffected hemisphere. The average BOLD signal level is statistically significantly lower in the affected PMCs. The average TTP in the affected PMCs is shorter in the high-grade group, but longer in the low-grade group compared to the contralateral unaffected hemisphere. The degrees of alterations in BOLD signal time courses are related to both the distance to activated foci and tumour volume, with a stronger effect in tumour distance to activated PMC.
Conclusion: Alterations in BOLD signal time courses are strongly related to tumour grade, tumour volume, and distance to the activated foci. Such alterations may impair accurate mapping of tumour-affected functional areas when using conventional fixed models.

Volumetric histogram-based analysis of SUV and ADC values for the assessment of paediatric sarcomas at staging: preliminary results of a PET/MR study

A. Varotto[1], G. Orsatti[1], F. Crimì[1], D. Cecchin[1], P. Zucchetta[1], M. Weber[2], R. Stramare[1], C. Giraudo[1]; [1]*Padua/IT*, [2]*Vienna/AT (ale.varotto86@gmail.com)*

Purpose: Previous studies showed heterogeneous results about the correlation between metabolic activity and cell density in sarcomas. Thus, our aim was to assess the relationship between ADCs and SUVs in paediatric sarcomas at staging, using histograms obtained by volumetric analyses.
Methods and Materials: Paediatric patients with histologically proven sarcoma, referring to our tertiary centre for a whole-body [18F]-FDG-PET/MR for staging and including DWI in the MR protocol were investigated. First, TIRM and PET images were re-sliced and resampled according to the ADC maps (i.e. Osirix Software). Regions of interest were drawn along tumour margins on TIRM images and then copied on PET and ADC datasets. Pixel-based SUVs and ADCs were collected from the entire volume of each lesion. Mean, median, skewness, kurtosis of SUVs and ADCs values were computed and Pearson correlation coefficient was applied (i.e. for the entire population and separately, for histological subgroups including more than five patients).
Results: Ten patients met the inclusion criteria (five males; mean age 8.9±5.7years). Histology revealed six rhabdomyosarcoma (i.e. three alveolar and three embryonal), two Ewing-sarcoma, one diffuse myofibromatosis and one chondroblastic osteosarcoma. The mean volume of the lesions was 135.46±172.16cm^3. A significant negative correlation between ADCs' and SUVs' mean (r_{mean}=-0.326, p<0.001), median (r_{median}=-0.393, p<0,001) and skewness ($r_{skewness}$=-0.623, p<0.001) emerged for the entire population and for rhabdomyosarcomas (r_{mean}=-0.365, p=0.002, r_{median}=-0.467, p<0.001, $r_{skewness}$=-0.691, p<0.001) whereas a significant positive correlation was found for kurtosis ($r_{kurtosis}$=0.412, p<0.001 and $r_{kurtosis}$=0.395, p<0.001, respectively, for the entire population and for rhabdomyosarcomas).
Conclusion: Our preliminary results demonstrate that, using volumetric histograms, SUVs and ADCs are dependent biomarkers in paediatric sarcomas. Further studies, on a larger population, are necessary to confirm this evidence and assess its clinical implications after therapeutic treatment.

B-1487 10:34

Computer-assisted detection of acute pulmonary embolism in children and young adults: inter-observer effect

C. Tang[1], C. Zhou[1], U.J. Schoepf[2], D. Mastrodicasa[3], Y. Zhao[1], L. Lu[1], X. Li[1], M. Lu[1], L. Zhang[1]; [1]*Nanjing/CN*, [2]*Charleston, SC/US*, [3]*Chieti/IT (522956587@qq.com)*

Purpose: To evaluate the effect of a CAD algorithm on the identification of acute PE on CTPA studies in children and young adults by readers with varying experience levels.
Methods and Materials: In this retrospective study, six readers with differing levels of experience evaluated 303 patients' CTPA studies (range, 6-25 years) on per-emboli basis. Observers were asked to independently determine the presence of PE and rank their diagnostic confidence on a five-point scale with and without CAD. Reading time was recorded and sensitivities, specificities, accuracies, PPVs and NPVs were calculated.
Results: For all readers, there was no diagnostic performance difference in detecting central PE in the first to the third levels of the pulmonary arteries with or without the CAD (all *P* values >0.05). However, significant differences were found in the detection of peripheral PE with CAD versus without CAD. Except the most experienced reader, the sensitivities and NPVs differed significantly between with CAD and non-CAD readings. Additionally, the accuracies of all readers differed significantly between readings done with or without CAD. For each reader, the time with CAD was longer than those without CAD. Significant differences were found for confidence scores in inter-group measurements with CAD (P=0.045) and without CAD (P<0.001), but no difference in the confidence scores of any individual readers between CAD and non-CAD readings (P>0.05).
Conclusion: At the expense of longer reading time, the use of CAD improves sensitivities and NPVs for most readers and the accuracies of all readers in peripheral PE detection.

Clinical equivalence assessment of T2 synthetic paediatric brain MRI

B. Kerleroux[1], T. Kober[2], T. Hilbert[3], D. Sirinelli[1], B. Morel[1]; [1]*Tours/FR*, [2]*Zurich/CH*, [3]*Lausanne/CH (basile.kerleroux@gmail.com)*

Purpose: Automated synthetic MR imaging (SyntMRI) provides different image contrasts as well as quantitative information from one scan. It would well suit paediatric neuroradiology for various applications such as analysis of white matter disorders. However, SyntMRI has been poorly evaluated in this population. The purpose of this study was to compare the image quality of synthetic T2 with conventional TSE T2 in paediatric brain MRI.
Methods and Materials: This was a mono-centre prospective study. Synthetic and conventional MRI acquisitions at 1.5 Tesla were performed for each patient during the same session using a prototype accelerated T2 mapping sequence package ($TA_{synthetic}$=3:07 min, $TA_{conventional}$=2:33 min). Image sets were blindly and randomly analysed by senior and fellow paediatric neuroradiologists. Global image quality, morphologic legibility of standard structures and artefacts were assessed using a 4-point Likert scale. Inter-observer kappa agreements were calculated. The capability of SyntMRI and conventional T2 to discern normal and pathological cases was evaluated.
Results: Sixty patients were enrolled. The diagnostic quality of SyntMRI was non-inferior to conventional imaging scale (p=0.06). There was no significant difference in the legibility of normal and pathological anatomic structures of synthetic and conventional T2 (all p > 0.05) as well as for artefacts except for phase encoding (p=0.008). Interobserver agreement was good to almost perfect (kappa between 0.66 and 1).
Conclusion: T2 SyntMRI, which provides quantitative T2 information that could be used to build normative databases of healthy subjects, could be suggested as an equivalent technique in paediatric neuro-imaging, compared to conventional TSE T2.

Effect of a child-adjusted method for brain volume quantification on group comparisons in dyslexia

T. Phan, D. Smeets, M. Vandermosten; *Leuven/BE (van.phan@icometrix.com)*

Purpose: A child-adjusted method for the quantification of grey matter (GM) and white matter (WM) volumes in young children is introduced, and its impact on group comparisons between healthy controls and dyslexia is assessed.
Methods and Materials: T1-weighted images were acquired from children of 5-6 years old (21 controls, 15 children with dyslexia) and checked for motion artefacts. For brain volume quantification, the brain segmentation was adjusted to children by the use of an age-specific atlas and probabilistic model-based algorithm (referred to as childmetrix). Group comparisons based on GM and WM volumes estimated by this method are compared to results obtained with a method using the same segmentation algorithm, but based on an adult atlas (icobrain) and a method using a surface model-based segmentation based on an adult atlas (Freesurfer).
Results: Subtle differences between healthy controls and children with dyslexia were better captured by childmetrix that showed a higher effect size (Cohen's d of 0.40 for GM and 0.45 for WM) compared with icobrain (GM: 0.27, WM: 0.40) and Freesurfer (GM: 0.31, WM: 0.38). Compared to the literature, the results obtained with childmetrix on children of 5-6 years old were similar to differences measured in older populations (GM: 0.40, WM: 0.40).
Conclusion: The choice of segmentation method has an impact on group comparisons. Brain segmentation is adapted to young children (under 6 years old) by the use of an age-specific atlas, which enables measuring the subtle differences that might not be observed using standard methods based on adult atlas.

Enhancement of MRI histogram in the identification of children with medulloblastoma and ependymoma

W. Wang, J. Cheng, Y. Zhang; *Zhengzhou/CN (weijianwang520@163.com)*

Purpose: To investigate the diagnostic value of the histogram analysis derived from enhancement MR imaging in differentiating medulloblastomas from ependymoma.
Methods and Materials: Retrospective analysis of pathologically confirmed 36 cases of posterior fossa tumors, including 20 cases of medulloblastoma, 16 cases of ependymoma. The collection of the two kinds of tumor T1, T2 and enhanced T1 weighted magnetic resonance images, extraction of tumor region of interest using the software of MaZda (region of interest, ROI), histogram analysis for the maximum level of tumor region of interest, using the average value, variance, skewness, kurtosis, the 1,10,50,90,99 percentile characteristics, find out the significant differences between the two kinds of tumors.
Results: Histogram analysis of ADC including the mean, variance, skewness, kurtosis, the 1,10,50,90,99 percentile characteristics.The mean, variance, skewness,90th and 99th percentile were detected statistical significance.ROC curve analysis of the variance yielded the best area under the ROC curve (AUC; 0.90), sensitivity of 92%, and specificity of 90%, with a cutoff value of 820.
Conclusion: Histogram analysis can provide more quantitative information characteristics, which provides a new method for the differential diagnosis of children with medulloblastoma and ependymoma.

B-1491 10:50

Prenatal imaging of anorectal malformations

L. Rohrer, Y. Vial, R. Meuli, L. Alamo-Maestre; *Lausanne/CH (lysiane.rohrer@gmail.com)*

Purpose: Anorectal malformations (ARM) are usually classified as low, intermediate and high type. Most of them are first discovered after birth. The purpose of this study is to describe the imaging signs suggesting ARMs at prenatal US and MRI exams in order to improve early diagnosis and optimize perinatal care.
Methods and Materials: All available prenatal imaging studies performed on children treated for ARM at the University Hospital of Lausanne between 2001-2016 were retrospectively reviewed and compared with the final diagnosis (low or intermediate-high ARM), obtained from postnatal imaging studies, surgery and/or autopsy records.
Results: We identified 54 children treated for ARM. Only 5 cases (9.2%) were diagnosed *in utero*. Prenatal exams were available in 17 cases (15 US, 7 MRI) corresponding to 5 low- and 12 intermediate-high type ARM, including 5 cloaca. Diagnosis was prenatally suspected in 5/17 (29.4%) and associated anomalies, mainly vertebral and renal, present in 15/17 cases (88%). Retrospectively evaluation identified imaging findings suggesting ARMs in 11/17 cases (64.7%, 1/5 low and 10/12 intermediate-high type ARMs). Findings include small or no anus identification and distal digestive dilatation in ARMs without fistula; rectal echogenic fluid and rectal hyperintense signal in T2-WI MRI images in ARMs with fistula and genital duplication and pelvic cystic masses in cloaca.
Conclusion: Prenatal diagnosis of ARMs requires a routine and systematic examination of the fetal pelvis and perineal area, especially in presence of vertebral, renal or genital anomalies. However, low type malformations remain extremely difficult to recognize.

B-1492 10:54

Prognostic value of radiological response assessment after induction therapy in paediatric soft tissue sarcomas

G. Orsatti[1], A. Varotto[1], F. Crimì[2], G. Bisogno[1], I. Zanetti[1], C. Giraudo[1], R. Stramare[1]; [1]*Padua/IT*, [2]*Vicenza/IT (giovanna_orsatti@hotmail.it)*

Purpose: Previous studies showed controversial results about the correlation between the dimensional modification, due to induction therapy, of paediatric soft tissue sarcomas (pSTS) and patients' outcome. Thus, our aims were to compare three methods of pSTSs dimensional assessment and evaluate their prognostic value.
Methods and Materials: Forty-five paediatric patients with non-metastatic STS (26 rhabdomyosarcomas and 19 non-rhabdomyosarcomas) who underwent MR or CT imaging at staging and after three cycles of chemotherapy were included.Three observers measured the tumour size using three different methods:maximal diameter, estimated volumetric assessment(the product of the three-maximal diameters and Π/6) and software-assisted volumetric assessment.To investigate the interobserver agreement, the Overall Concordance Correlation Coefficient(OCCC) was calculated.Regarding tumour response, each patient was classified as "Good responder"(i.e.,including Very good and Partial Response) or "Poor responder"(i.e.,including Stable and Progressive Disease)according to each radiological method.To assess the inter-method agreement,Cohen's kappa coefficient was calculated.The Kaplan-Meier method was used to estimate the event-free survival(EFS) distribution.Differences between survival curves were analysed by the log-rank test.
Results: Interobserver agreement was very high for each method (OCCC>0.9).The three methods showed a poor agreement regarding the classification of tumour response (i.e.,highest value, k=0.56 between the two volumetric techniques).In rhabdomyosarcomas, the three-years EFS resulted to be significantly higher in "Good Responders" than in "Poor responders" using the estimated (76.2% vs 40%,p=0.02) and the software-assisted volumetric assessment (80% vs 33.3%,p=0.002) whereas no significant differences emerged for the "non-rhabdomyosarcomas"(p>0.05,for each method).
Conclusion: The volumetric assessment, especially when software-assisted, demonstrated to be a significant prognostic factor for paediatric STSs. Larger future studies are necessary to confirm these preliminary results.

B-1493 10:58

Central nervous system (CNS) involvement in congenital heart diseases (CHD): value of foetal MRI

R. Petrillo, A. Antonelli, S. Bernardo, S. Satta, V. Vinci, L. Manganaro, C. Catalano; *Rome/IT (roberta.petrillo@hotmail.it)*

Purpose: To demonstrate the diagnostic value of foetal MRI in the detection of CNS impairment in prenatally echocardiographic diagnosed CHD.
Methods and Materials: We retrospectively examined 24 fetuses (mean gestational age: 19-33), between February 2012 and April 2017, who underwent MRI in our institution at 1.5 T (Siemens Magnetom Avanto), without maternal sedation, after a foetal echocardiography. Prenatal findings were compared to fetopsy results, foetal MRI after 30 GW or postnatal MRI.
Results: On 24 cases, 7/24 had interatrial septal defect (IASD), interventricular septal defect (IVSD), and atrioventricular canal defect (CAVC), 6/24 had cardiac rhabdomyomas, 3/24 had hypoplastic left heart syndrome and hypoplastic aorta, 2/24 had transposition of the great vessels, 2/24 had Fallot tetralogy, 2/24 had aorta coartation and 2/24 had intracardiac masses of uncertain significance. Magnetic resonance imaging was able to detect CNS impairment: we recognise 11/24 corpus callosum (CC) dysgenesis (4/13 CC hypoplasia, 4/13 complete CC agenesis, 3/13 partial CC agenesis), 7/24 ventriculomegalies or hydrocephalus, 3/24 subtentorial anomalies (Dandy-Walker, vermian hypoplasia and vermian malrotation), and 3/24 gyration anomalies.
Conclusion: Due to the high risk of CNS involvement in prenatal congenital heart diseases, it is essential to suggest an MRI study of the evolving foetal brain, especially in complexes forms that suggest a syndromic background. Foetal MRI of the CNS is mandatory in the study of congenital heart disease due to the high rate of encephalic anomalies associated, particularly in IASD, IVSD and CAVC.

B-1494 11:02

Vermis-to-Pons ratio in the differential diagnosis of Vermian malformations: a foetal MRI study

A. Antonelli, S. Bernardo, R. Petrillo, S. Satta, S. Ciulla, V. Vinci, L. Manganaro, C. Catalano; *Rome/IT (amanda.antonelli@hotmail.it)*

Purpose: To assess the feasibility of Vermis-to-Pons Ratio in helping the prenatal MR diagnosis of isolated Dandy-Walker Malformation (DWM), in fetuses with a Ultrasonographic (US) suspicion of Posterior Cranial Fossa (PCF) abnormalities.
Methods and Materials: A total of 38 fetal MRI, performed in our department between April 2013 and June 2017 after a US examination, were retrospectively reviewed. All MRI examinations were performed using a 1.5 Tesla Magnetom Avanto (Siemens, Erlangen, Germany) without maternal sedation. Gestational Age (GA) range was 20-31 weeks. The study sample included fetuses with a US suspicion of PCF malformations such as DWM, vermian hypoplasia/agenesis, vermian malrotation and Walker Warbourg Syndrome (WWS); fetuses with Chiari Malformation type II, cerebellar hemorrhage and rhomboencephalosynapsis were excluded. Vermis-to-Pons Ratio was manually measured in all cases.
Results: Fetal Magnetic Resonance Imaging found 16/38 cases of DWM, 6/38 of vermian malrotation, 2/38 of WWS and 4/38 isolated vermian hypoplasia; 10/38 fetuses had normal PCF anatomy and sub-tentorial morphology. In DWM the Vermis-to-Pons ratio was <1, while in normal fetuses was ≥1. Depending on the maternal decision to continue the pregnancy, prenatal MRI findings matched with both fetopsy results and postnatal MRI.
Conclusion: The Vermis-to-Pons Ratio could be an additional parameter and a helpful tool in the assessment of PCF malformations, with a special focus on the differential diagnosis between DWM and vermian malrotation.

B-1495 11:06

Radiation use in paediatric age: are paediatricians updates of the state of the art legislation?

S. Salerno[1], C. Tudisca[1], C. Granata[2], D. Origgi[3], L. Moro[4], M. Barbagallo[5], G. Corsello[1], A. Villani[6]; [1]*Palermo/IT*, [2]*Genoa/IT*, [3]*Milan/IT*, [4]*Pavia/IT*, [5]*Catania/IT*, [6]*Rome/IT (ssalerno@sirm.org)*

Purpose: To assess the opinion on use of radiation in paediatric age and radiation protection knowledge by paediatricians members of the Italian Paediatric Society (SIP) via an online survey.
Methods and Materials: All members received an email invitation to join the survey as an initiative by the "Radiation in Paediatrics" project involving SIP, Italian Society of Medical Radiology (SIRM) and Italian Association of Medical Physics (AIFM) Scientific Societies. The survey included 11 questions about general knowledge on radiation protection and new legislation on the theme/issue of the respondents and eventual criticisms found in radiation protection field in the everyday practice.
Results: 877 SIP members participated in the survey and have entirely fulfilled the questionnaire. The most significant results of the survey were: 57.6% of the participants ignore the existence of guidelines that can help them in choosing the most appropriate diagnostic examination according to patient's symptoms, and the 47,1% has difficulties to evaluate the risk related to the use of examination using ionizing radiation. 43% do not know the European Directive 2013/59 Euratom. 98% of the participants believe it is necessary to grow their knowledge on the topic of radiation protection, considering useful a specific training on practical issues.
Conclusion: Most paediatricians were interested in radiation protection theme and considered their knowledge inadequate for their daily practice. Aim of the radiological society should be to organize a large-scale information campaign to spread the theme of radiation protection in a paediatric environment.

B-1496 11:10

Histogram analysis of apparent diffusion coefficients may predict molecular subgroups of medulloblastoma in children

W. Wang, J. Cheng, Y. Zhang; *Zhengzhou/CN (weijianwang520@163.com)*

Purpose: The aim is to verify if ADC histogram is able to predict new subgroups of MB.
Methods and Materials: sixty-five patients with diagnosis of MB(30 classic, 8 desmoplastic/nodular, 7 extensive nodularity, 20 large cell/anaplastic), with pretreatment MR imaging, histologic, genomic characterisation after surgery, were retrospectively selected. ADC maps were coregistered with T1w post-contrast and T2 images. Drawing the region of interest(ROI) on the maximum level of ADC maps and going on histogram analysis,these two steps are all performed on the software named Mazda.We used the Mann-Whitney test to evaluate the capacity of histogram parameters to discriminate among paired MB subgroups.
Results: Desmoplastic/nodular and extensive nodularity were detected no statistical significance. A trend in differences was found between classic and large cell/anaplastic. 9 texture parameters using histogram extracted, with statistical significance (mean,variance,1 percent,10 percent). ROC curve analysis of the 10th percentile yielded the best area under the ROC curve (AUC; 0.96), sensitivity of 98%, and specificity of 96%, with a cutoff value of 90.
Conclusion: The study shows histograms analysis of apparent diffusion coefficient can provide reliably objective basis for molecular subgroups of medulloblastoma in children.

B-1497 11:14

The role of prenatal diffusion weighted MRI in the evaluation of the fetal CNS condition in patients who received intrauterine blood hemotransfusion as the hemolytic disease threatment

A.A. Berman[1], A. Ageev[1], O. Chernova[2], A. Vazhenin[2]; [1]*Ekaterinburg/RU*, [2]*Chelyabinsk/RU (ageev.artem@gmail.com)*

Purpose: The purpose of the study is to evaluate the apropriateness of prenatal MRI using diffusion weighted sequences in the evaluation of fetal brain focal lesions in cases of mother`s hemolytic anemia before and after treatment of fetuses by intrauterine hemotransfusion.
Methods and Materials: The focus group included 30 pregnant women with presence of haemolytic fetal disease by Rh- factor, which required treatment who underwent intrauterine blood hemotransfusion, and further their 30 newborns with hemolytic disease and perinatal hypoxic-ischemic brain injury.
The control group included 15 pregnant women without hemolytic disease with concomitant pathology of pregnancy comparable in gestational age, and further their 15 newborns. Prenatal MRI were performed at 1,5 T scanner. MRI protocol included DWI sequences with b0 and b700 s/mm2. The local lesions in the fetal brain detected on MRI were defined as focal zones of hyperintensive signal at the T2 and DWI sequences accompanied by the signal restriction on the ADC maps.
Results: 45 focal lesions in 30 patients in focus group were revealed before therapy and only 12 focal lesions were revealed after therapy before birth.
Average size of lesions was 1,8x1,9x2,1 mm and 0,4x0,4x0,5 mm respectively. No lesions were revealed in control group.
Conclusion: A statistically significant difference in the MRI data in focus and control group and before and after intrauterine blood transfusion was obtained thus prenatal MRI with DWI sequences was considered to be apropriate for pathomorphological evaluation of fetal focal brain lesions and evaluation of effectiveness of intrauterine hemotransfusion.

B-1498 11:18

Hepatobiliary ultrasonographic abnormalities and clinical severity score of paediatric sickle cell anaemia patients in a resource-poor setting

D. Ibe; *Kaduna/NG (church.donaldo@yahoo.com)*

Purpose: To determine the relationship between hepatobiliary ultrasonographic abnormalities and clinical severity score of paediatric sickle cell anaemia patients.
Methods and Materials: A cross-sectional descriptive study of hepatobiliary ultrasonographic findings of 420 steady-state paediatric sickle cell anaemia patients aged 1-18 years was conducted using Mindray (DC8) ultrasound machine. Clinical severity score was assessed based on 3 parameters: (a) the present state of the child: splenic (0-2) and hepatic (0-2) enlargement, current haematocrit (0-2) and total white blood count (0-2); (b) frequency of significant painful episodes (0-3), blood transfusion (0-3), and hospitalization (0-3) in the previous 12 months and (c) lifetime cumulative incidence of complications for each patient: cerebrovascular accident (5), acute chest syndrome (3), pneumococcal meningitis (3), avascular necrosis (2), gallstone (1), chronic leg ulcer (1), osteomyelitis (1), or priapism (1). A total score calculated ranged from 0 to 34 and the disease categorized as: mild (<8), moderate (8-17) and severe (>17). Chi-square test and Fisher's exact test were used to test for statistical relationship between variables.
Results: One hundred and forty-seven (35%) patients had hepatobiliary abnormalities with hepatomegaly (66.7%), biliary sludge (28.6%) and gallstones (17%) as the common findings. Mild and moderate forms of clinical severity of sickle cell anaemia were seen in 45.6% and 54.5%, respectively. None of the patients had a severe form of clinical severity. There was a statistically significant association between hepatobiliary abnormalities and the clinical severity of steady-state paediatric sickle cell anaemia patients (p value <0.001).
Conclusion: Hepatobiliary abnormalities have a statistically significant association with clinical severity score of paediatric sickle cell anaemia patients.

B-1499 11:22

Ultrasound diagnostics of the respiratory distress syndrome in premature infants

O. Sorochan; *Kharkiv/UA (Sorochanop@gmail.com)*

Purpose: To identify capabilities of lung ultrasound (LUS) in the diagnostics of respiratory distress syndrome (RDS) in premature infants.
Methods and Materials: We studied 54 preterm infants (32 boys, 22 girls) gestation age 25-34 weeks with diagnosis of RDS with varying severity grades. Ultrasound was performed at the bedside of a patient using the device Logiq E, GE Medical Systems, linear transducer with a frequency of 5-12 MHz. Chest x-ray (CXR) was performed for all patients the same day.
Results: The basic patterns of the lung tissue changes we found was B-line and consolidation ("white lung"). Evaluation was carried out according to the number of B-lines in the intercostal spaces. The most serious degree manifested pattern of "white lung". On the base of this pattern premature infants with RDS were divided into four groups by degree of severity: 1st - 20.0%, 2nd - 40%, 3rd - 36.1%, and 4th - 13.9%. There was high correlation in CXR and LUS severity data that indicates possibility of its using in medical practice.
Conclusion: Ultrasound could not replace CXR to estimate all changes of the lungs, but can complement it. Also it can be useful for monitoring already established RDS to reduce radiation exposure.

B-1500 11:26

Role of MR enterography in evaluation of disease activity and treatment response in paediatric Crohn's disease correlation between MRE and PCDAI scores

A. Chellathurai, A. Narasingam, S. Radhakrishnan, S. Sankaranarayanan, D. Arun; *Chennai/IN (amarrd02@yahoo.co.in)*

Purpose: The aim of the study was to assess the role of MR enterography in the diagnosis and follow-up of children with Crohn's disease and to correlate disease activity indices with known MR enterography features of active disease.
Methods and Materials: This was a retrospective study including 24 patients (median age 11yrs, male 17) with clinically and histologically proven CD who underwent MRE. Two previously validated MRE scores - MR enterography global score (MEGS) and CD MRI index(CDMI) were calculated. A correlative analysis was made between the PCDAI score and MRE scores as well as individually with each MR variable. Comparison of both the MR scores was made between patients with different disease activity.
Results: MEGS and PCDAI scores showed strong positive correlation (r equals 0.724, p equal to or less than 0.001) CDMI and PCDAI scores showed moderate positive correlation (r equal to 0.661, p equal to 0.0004). There was a statistically significant difference in the MR scores between patients grouped by clinical activity. Among individual MR variables, mural thickness and enhancement best predicted the disease activity.
Conclusion: MR enterography-based scores and findings correlate with clinical activity in paediatric Crohn's. Thereby, MRE can be considered a valuable tool in the management of CD, predicting disease activity and offering a potential alternative to endoscopy in monitoring patients during follow-up.

B-1501 11:30

Transverse comparisons between ultrasound and radionuclide parameters in children with pelviureteric junction obstruction

N.O. Shwaky; *Cairo/EG (norhanmedecine@yahoo.com)*

Purpose: Correlation between ultrasound parameters and dynamic scintigraphic parameters in pelviureteric junction obstruction, the importance of each factor, and which of the ultrasound parameters most reflect the renal function, and if we can predict, on the basis of ultrasound parameters, the patient in whom radionuclide renography can be avoided. The role of ultrasound and radionuclide parameters in deciding on surgery was studied .
Methods and Materials: Ultrasound and renographic studies were compared. Anteroposterior pelvic diameter (APD) and calyceal size were divided into three levels of dilatation. Parenchymal thickness was considered either normal or significantly decreased. Acquisition of renograms with quantification of DRF, quality of renal drainage and cortical transit was carried out.
Results: The low DRF and poor drainage were higher among those with major hydronephrosis, severe calyceal dilatation or parenchymal thinning. Impaired cortical transit, which is a major risk factor for functional decline, was seen more frequently among those with very severe calyceal dilatation. However, none of the structural ultrasound parameters was able to predict whether the level of renal function or the quality of drainage was normal or abnormal. Alternatively, an APD <30 mm, a calyceal dilatation of <10 mm and a normal parenchymal thickness were associated with a low probability of decreased renal function.
Conclusion: Nuclear medicine examinations may be postponed in those with an APD <30 mm, a calyceal dilatation of <10 mm and a normal parenchymal thickness. On the contrary, precise estimation of DRF and renal cortical transit should be performed in APD >30 mm, major calyceal dilatation and/or parenchymal thinning.

B-1502 11:34

Spectrum of malformations of cortical development with clinicoradiological correlation and analysis of associated abnormalities: experience from a tertiary care centre in Egypt

D.M. El-Mossly, S.A. Mohammad, E.M. Abelhafez, N. Osman, K.A. Ahmad; *Cairo/EG (dollyelmossly@yahoo.com)*

Purpose: Malformations of cortical development (MCD) usually cause developmental disability, focal neurological deficits and seizures in children which are frequently resistant to anticonvulsant treatment. The structural neuroimaging technique especially MRI is the most important non-invasive method in their diagnosis and other associated brain abnormalities, thus

smaller lesions can be identified. So, it is important to exclude MCD in every case of developmental delay, congenital neurological signs and intractable epilepsy.
Methods and Materials: All paediatric cases with MCD diagnosed on MRI at Ain Shams University Hospital during the period from January 2015 till January 2017 were retrospectively reviewed with correlation to their presenting symptoms.
Results: Among 4300 paediatric patients referred for MRI brain, 72 cases with MCD were identified with prevalence of 1.67%. Epilepsy was the main presenting symptom (72%) and focal epilepsy was seen in 19.5% of the cases. There was an association between focal cortical dysplasia and focal epilepsy (P=0.005), polymicrogyria and global developmental delay (P=0.008) and also between tuberous sclerosis and epilepsy (P=0.007). The most common type of MCD was polymicrogyria (25%), followed by tuberous sclerosis (21%). MCD was seen in association with other neuroimaging findings, or as a part of syndromes as congenital muscular dystrophy spectrum especially Walker-Warburg syndrome and also it was seen in Sturge Weber and chronic infantile neurological cutaneous articular (CINCA) syndromes.
Conclusion: MCD showed relatively high prevalence among Egyptian children being associated with epilepsy and developmental delay. MCD was infrequently isolated, also occurred in association, or as a part of syndromes.

B-1503 11:38

Role of MRI vs CT in staging and decision making in paediatric renal masses

E. Nasr, A. Youssef, W. Zekry, T. Raafat, A. Younis, H.A. Elkiki; *Cairo/EG (emannasr84@yahoo.com)*

Purpose: To determine whether MRI can replace CT in local staging of newly diagnosed renal tumours in paediatric age group renal masses to avoid radiation exposure and contrast material administration.
Methods and Materials: 50 children with newly diagnosed renal masses were included. Contrast-enhanced CT and non-contrast MRI were done in all patients. Local staging was done in both studies separately. The surgical and pathological findings were the reference standard.
Results: The sensitivity of CT and MRI for detecting capsular penetration was 68.6% and 62.9%, respectively, while specificity was 86.5% and 83.8%. The sensitivity of CT and MRI for detecting lymph node metastasis was 76.5% and 52.9%, and specificity was 90.4% and 92.3%. Synchronous contra-lateral lesions were identified by CT in 4/9 cases and by MRI in 7/9 cases.
Conclusion: CT and MRI have similar diagnostic performance for detection of lymph node metastasis and capsular penetration. MR detected more contra-lateral synchronous lesions; however, these were present in a very small number of cases. Either modality can be used for initial loco-regional staging of paediatric renal tumours.

B-1504 11:42

Closed spinal dysraphisms: how to improve prenatal diagnosis

T. Nguyen, V. Houfflin-Debarge, M. Vinchon, N. Boutry, F.E. Avni; *Lille/FR (nguyentoan5989@gmail.com)*

Purpose: Prenatal diagnosis of closed spinal dysraphisms (CSDs) is difficult and not well studied. The purpose was to study the contribution of prenatal imaging in the diagnosis of CSD to improve their screening.
Methods and Materials: Patients with postnatally diagnosed CSD by spinal MRI or surgery in Lille University Hospital were included. Ultrasound signs, proportion of positive and negative prenatal diagnosis and the contribution of prenatal imaging techniques were analysed.
Results: 38 patients with CSD were included, 17 of whom were diagnosed prenatally. Utrasound signs were a posterior soft tissue mass in 9 cases, low position of the conus medullaris in 8 cases, vertebral anomalies in 7 cases and spinal cord anomalies in 4 cases. Ultrasound was excellent in screening and characterizing cystic masses (8 diagnosed on 8 included), unlike fatty masses (1 only on 11). It was less successful in screening (7 on 14) and characterizing vertebral anomalies. In these cases, foetal CT scan permitted a full diagnosis. Foetal MRI was performed in 12 cases, allowing to characterize posterior soft tissues mass (100% of concordance between ultrasound and MRI). It was less accurate than ultrasound in studying the wall of the mass, the conus medullaris level and the spinal cord morphology.
Conclusion: Ultrasound must remain the first-line imaging technique and its study has to contain three parts: vertebral, spinal cord and posterior soft tissue study. Foetal MRI seems to be useful in characterizing a posterior soft tissue mass when ultrasound is difficult. Foetal CT scan is useful to characterize vertebral anomalies.

B-1505 11:46

Radiological appearance and follow up results of diaphragmatic mesothelial cysts during childhood

I. Akdulum[1], M. Öztürk[2], S. Karatoprak[3], A. Sığırcı[3]; [1]*Ankara/TR*, [2]*Konya/TR*, [3]*Malatya/TR (iakdulum@yahoo.com)*

Purpose: Diaphragmatic mesothelial cysts (DMC) are rare congenital benign lesions. DMC often cannot be distinguished from liver cystic lesions and cause management failure. The aim of this study is to describe radiologic findings of DMC and to evaluate our follow-up results.
Methods and Materials: Ultrasound (US), computed tomography (CT) or magnetic resonance imaging (MRI) of DMCs were acquired from 20 children. Patients' age, gender, indication for imaging, size of cyst and follow-up times were evaluated prospectively.
Results: The patients were aged between 4 months to 13 years. Eight of 20 patients were female and 12 were male. The most common indication for imaging was abdominal pain. All patients had US exam. The long diameter of the DMC was between 14 and 39 mm. All DMC were located near to liver segment 6-7, extraparenchymal and bilobular. In addition, a triangular echogenic area of fatty tissue extending between the supra-lateral segment of the DMC and the liver parenchyma, which we have described as the "lateral fat sign", was detected. We confirmed the lateral fat sign in 6 patients with CT and in 2 patients with MRI. Patients were monitored for 12-36 months and the size of the lesions was stable in 13 patients. The lesion dimensions in 7 patients were reduced, but this was not statistically significant.
Conclusion: Cysts were treated with ablation techniques in the literature. We followed asymptomatic patients. With typical localization, bilobular form and lateral fat sign, diagnosis is clear. US is useful for diagnosis and follow-up of DMC.

Meta-analysis of spectral CT image analysis tools and multi-phase CT enhancement in diagnostic accuracy of hepatic cell carcinoma

Y. Zhou; *Zhengzhou/CN*

Purpose: To assess and compare the overall diagnostic value of spectral CT image analysis tools and multi-phase CT enhancement with hepatic cell carcinoma using meta-analysis.
Methods and Materials: Relevant English articles published on PubMed, EMBASE, Cochrane library database and Chinese articles published on CNKI and Wanfang database were searched. Characteristics of included articles were summarised and extracted. Statistical analyses were performed using Meta Disc version 1.4 and Review Manager 5.3. Heterogeneities of included articles were tested and selected using proper effect model. Pooled sensitivity, specificity, 95% CI, summary receiver operating characteristics (SROC) curve and area under curve (AUC) were calculated. The heterogeneity and sub-group analyses were explored.
Results: 12 of 101 retrieved articles were included, in which 3 articles used two methods of imaging modalities at the same time. Spectral CT image analysis tools consist of four articles of monochromatic image, three articles of spectral curve and four of spectral quantitative parameters, respectively. The pooled sensitivity, specificity (95% CI) and AUC of SROC for spectral CT image analysis tools and DECT were 0.91 (0.88-0.94), 0.78 (0.73-0.83), 0.9022 and 0.85 (0.78-0.90), 0.71 (0.60-0.80), 0.874. Sub-group analysis showed that category of spectral CT image analysis tools was the essential factor for diagnosis of HCC. The pooled sensitivity, specificity (95% CI) and AUC of SROC for monochromatic image, spectral curve and spectral quantitative parameters were 0.83 (0.74-0.91), 0.75(0.65-0.84), 0.8935; 0.87 (0.81-0.92), 0.73 (0.65-0.80), 0.9412 and 0.99 (0.96-1.00), 0.94 (0.85-0.98), 0.9877.
Conclusion: Spectral CT image analysis tools showed higher sensitivity, specificity and better diagnostic performance compared to conventional DECT, especially for spectral quantitative parameters.

B-1507 14:08

Perfusion CT vs triphasic CT in evaluation of hepatic masses

V. Laxmi, V. Chowdhury, R. Dixit, A. Agarwal; *New Delhi/IN (drvijaylaxmi25@gmail.com)*

Purpose: Compare the diagnostic accuracy of triphasic and perfusion CT in characterisation of focal liver lesions as benign and malignant lesions. Correlation of radiological findings with histopathology.
Methods and Materials: Total of 50 patients with a clinical suspicion of focal liver lesions were included. Clinical and lab findings were recorded followed by CT examination on 128 slice scanner. Hepatic perfusion CT of entire liver volume was performed followed by routine scan of whole abdomen. Perfusion maps of the liver were generated using dedicated hepatic CT perfusion software. Various perfusion parameters like blood flow, blood volume, time to peak, permeability, arterial liver perfusion, portal venous perfusion and hepatic perfusion index were evaluated. The data set of perfusion CT was used to generate arterial phase images. The whole abdomen scan was taken as portal venous phase. Delayed phase scans were obtained wherever indicated. These images were analysed for presence of focal lesions and their enhancement pattern/perfusion parameters to characterise them. Findings were compared with histopathological/operative diagnosis/clinical follow up.
Results: Sensitivity of both Triple phase CT and perfusion CT for characterisation of lesion as malignant was equal at 97 %. Specificity and positive predictive value of triple phase was 88.89% and 97% respectively. Both specificity and positive predictive value of perfusion CT was 100%.
Conclusion: Perfusion CT with a high sensitivity, specificity and positive predictive value is a useful tool for characterisation of liver lesions

B-1508 14:16

Iterative reconstruction in "virtual non-contrast" with dual-energy CT: is it an alternative to conventional unenhanced phase?

S. Jamali, C. Dragean, N. Michoux; *Brussels/BE (sanaa.jamali@uclouvain.be)*

Purpose: To compare attenuation values and image quality of virtual non-contrast (VNC) with conventional true non-enhanced phase (TNC), on dual-energy double-detector computed tomography (CT) and to assess potential radiation dose reduction.
Methods and Materials: 286 patients with the pre- and post-contrast imaging in dual-layer spectral detector CT were retrospectively analysed. Quantitative analysis was performed for 247 patients by the measurements of the mean attenuation value in different regions of the abdomen for VNC and TNC. Qualitative analysis was performed for 48 patients using a graded scale for image quality. The radiation dose delivered to patients was compared with dose of protocols without TNC.
Results: Difference of mean attenuation values between TNC and VNC is less than 15 UH in 98.3% and less than 10 UH in 92.3%. The higher difference was found for perineal fat. VNC overestimated attenuation in fat and underestimated it in aorta comparatively to TNC. Image quality was evaluated as good or excellent in 77% of TNC and 54% of VNC. VNC was in most cases an alternative acceptable for the replacement of TNC. Using VNC, the radiation dose can be diminished by 32%.
Conclusion: VNC reconstructions demonstrate good correlation with TNC images in different abdominals tissues. VNC image quality is satisfying and acceptable in most cases; technical improvement is needed to correct imperfect iodine removal. VNC seems one interesting alternative to TNC with reduction in irradiation dose. However, further studies are needed to evaluate VNC in the pathological cases.

B-1509 14:24

Segmental variation of CT liver attenuation index in living-related liver donors: correlation with histopathological findings

A. Rana[1], A. Jang[1], M. Jehangir[1], M. Asghar[1], R. Nazir[1], S. Burki[2], K. Shakeel[1]; [1]*Islamabad/PK*, [2]*Rawalpindi/PK (aisha_jang@yahoo.com)*

Purpose: To find out the variation in CT liver attenuation index between anterior and posterior liver segments on non-enhanced CT scan and correlate it with histological degree of steatosis.
Methods and Materials: A radiologist blinded to histological grading calculated mean anterior and posterior segments CT hepatic attenuation in 74 potential living-related liver donors.
Results: Significant association (with p value of 0.00) is found between anterior segment liver attenuation index and histopathological findings, whereas no significant association is seen between posterior and combined CT liver attenuation index with histopathological findings.
Conclusion: The results of our study suggest that mean liver attenuation index of posterior liver segments does not correctly predict the degree of steatosis and rather results in significant over estimation of steatosis due to beam hardening. Hence, while calculating CT liver attenuation index, only the anterior segments of liver should be sampled to quantify steatosis.

B-1512 14:32

Evaluation of tumour response in patients with neuroendocrine hepatic metastasis treated using transarterial chemoembolisation (TACE) on MRI

M. Lapteva, M. Shorikov, D. Frantsev, O.N. Sergeeva, E. Virshke, B. Dolgushin; *Moscow/RU (mglapteva@inbox.ru)*

Purpose: The purpose of the paper is to develop suitable TACE evaluation criteria in liver metastatic neuroendocrine tumour (mNET) patients on MRI.
Methods and Materials: 23 liver mNET patients (G1-9, G2-10, G3-2, unknown grade-2) who underwent 36 TACE procedures were enrolled in the study. 68 MRI studies performed 3-86 days before (median 28 days) and 23-147 days (median 61 days) after TACE were analysed retrospectively. Using 1.5T MRI scanner, we acquired: 1) 3DT1WIFS in the axial plane before i.v. contrast injection and after in the portal and delayed phases; 2) diffusion weighted images with ADC maps. We measured before/after TACE: (1) maximum necrotic/fibrotic zone diameter and solid component thickness on its periphery in the largest targeted lesion; (2) ADC and MR contrast agent accumulation dynamics (dSI) in regions of interest in tumour solid component.
Results: TACE effect according to RECIST (1.1) was evaluated as progressive disease in 8.3% cases, stabilised in 83.3% cases and partial response in 8.3% cases. The diameter of the fibrosis/necrosis areas before/after TACE demonstrated no changes (p=0.614), but solid component thickness on its periphery decreased significantly (p=0.003, median 16%). ADC values increased significantly in solid portions of mNETs after TACE (p=0.003). MR contrast agent accumulation of the lesions in portal phase decreased significantly after TACE (p=0.003, median 8.5%). Decrease of MR contrast agent accumulation in the solid part of the target lesions by more than 10% after TACE is associated with a longer time to progression of the disease (p=0.025). There is an increase in MR contrast agent washout time in the solid part of the target lesions after TACE (p=0.032).
Conclusion: Parameters changed in liver mNET after TACE: (1) solid component thickness in cases of central necrosis/fibrosis (decrease); (2) ADC (increase); (3) SI T1WI in portal phase (decrease) and this is the positive prognostic factor; 4) MR contrast agent washout time (increase).

B-1513 14:40

Perfusion CT imaging: diagnostic biomarker tool for survival predictor of tumour in response to antiangiogenic treatment in patients with advanced HCC lesions

D. Ippolito[1], G. Querques[1], C.R. Talei Franzesi[2], S. Lombardi[1], A. Pecorelli[3], S. Sironi[1]; [1]*Monza/IT*, [2]*Milan/IT*, [3]*Bergamo/IT (davide.atena@tiscalinet.it)*

Purpose: To investigate whether perfusion-CT (p-CT) imaging could depict the inhibition of tumour neoangiogenesis induced by sorafenib in advanced hepatocellular carcinoma (HCC), and whether it could be useful in determining the efficacy of anti-angiogenic therapy and predicting survival during treatment.
Methods and Materials: Ninety-eight p-CT examinations were performed among 29 cirrhotic patients, with advanced HCC, before and every 2 months after Sorafenib administration. Perfusion-CT protocol was performed on a 256-slice MDCT scanner, during injection of 50 ml of contrast medium. Perfusion parameters were considered (hepatic perfusion; arterial perfusion; hepatic perfusion index and time to peak) and statistically compared, at baseline and follow-up, between responders (complete response, stable disease or partial response) and non-responders (progressive disease). Kaplan-Meier analyses estimated the time to survival in overall population, after stratifying patients according to mRECIST.
Results: Percentage variation of perfusion parameters (ΔHP and ΔAP), from baseline to follow-up study was assessed and correlated with response classified according to mRECIST criteria. The group that responded to sorafenib showed a significant reduction of values in HCC target lesions after anti-angiogenic therapy (HP 29.4±23.7 vs 51.9±16.8; AP 29.8±25.5 vs 52.2±17.9; $p<0.01$), in comparison with progressor group that demonstrated an increase or no significant variation after treatment. When patients were stratified into mRECIST, higher survival rate was observed in the non-progressor group compared to the progressor (48.6% vs 28.6%), and statistically significant correlation was found between mRECIST-ΔHP (p=0.04) and mRECIST-ΔAP (p=0.01) and overall survival rate.
Conclusion: Quantitative analysis of perfusion parameters represents prognostic indicators useful in assessment of response to anti-angiogenic therapy, allowing for optimization of individualized treatment.

B-1514 14:48

Diagnostic value and radiation dose reduction of model-based iterative reconstruction compared with hybrid iterative reconstruction in abdominal CT study

A. de Vito[1], D. Ippolito[1], C.R. Talei Franzesi[2], L. Riva[2], S. Drago[1], S. Sironi[1]; [1]*Monza/IT*, [2]*Milan/IT (a.devito@campus.unimib.it)*

Purpose: To evaluate dose reduction and image quality of routinely abdominal CT images reconstructed with model-based iterative reconstruction (IMR) and low-kV setting compared with hybrid iterative reconstruction (iDose4) and standard kV protocol.
Methods and Materials: We prospectively enrolled 72 patients who underwent entire abdominal CT scan; 36 patients were examined using a low-kV setting(100kV) while the other 36 patients were investigated using standard kV setting(120 kV), on the same 256-row CT scanner (iCT Elite). In the study group images were reconstructed using IMR algorithm while in the control group we used iDose4 technique. CTDIvol and DLP were evaluated. Region of interests were drawn in three different levels in the liver and in spleen to evaluate absolute enhancement values (HU), SNR and CNR.
Results: Compared to standard dose iDose4-CT study the low kV IMR-CT presented lower CTDIvol (9.2 ± 1.2 vs 17.7 ± 2.5 mGy) and DLP (570.5 ± 8.3 vs 911 ± 10.2 mGy x cm) with ED of 6.3 ±1.8 vs 9.44 ± 1.8 mSv. Low kV IMR images yielded higher attenuation values (HU) and higher SNR and CNR in liver and spleen, compared with standard dose iDose4 images. The subjective image quality of low-kV IMR CT was also higher compared with iDose4-CT.
Conclusion: Low dose CT scan (100kV and automated mAs modulation) reconstructed with IMR algorithm represents a feasible protocol for routinely daily examination of the abdomen, achieving excellent image quality with extremely low noise, and a significant dose reduction within acceptable reconstruction times (mean time of 3 minutes).

B-1515 14:56

Dual-energy CT in patients with abdominal malignant lymphoma: impact of noise-optimised virtual monoenergetic imaging on objective and subjective image quality

L. Lenga, D. Leithner, M.H. Albrecht, C. Booz, J.L. Wichmann, T.J. Vogl, S.S. Martin; *Frankfurt a. Main/DE (lukas.lenga@gmail.com)*

Purpose: To evaluate the impact of the noise-optimised virtual monoenergetic imaging (VMI+) technique on objective and subjective image quality in patients with malignant lymphoma undergoing abdominal dual-energy computed tomography (DECT).
Methods and Materials: 35 consecutive patients (mean age, 53.8±18.6 years; range, 21-82 years) with histologically proven malignant lymphoma of the abdomen were enrolled in this IRB-approved retrospective study. DECT image series were reconstructed using standard linearly blended (M_0.6), as well as traditional VMI, and VMI+ reconstructions at 40 to 100 keV in 10-keV intervals. Attenuation measurements were performed in lymphoma lesions to calculate signal-to-noise (SNR) and contrast-to-noise ratios (CNR). Three independent radiologists assessed the overall image quality, lesion delineation, and image noise using five-point Likert scales.
Results: Assessment of objective image parameters showed the highest SNR and CNR values for 40-keV VMI+ (SNR, 15.77±7.74; CNR, 18.27±8.04) compared to standard linearly blended (SNR, 7.96±3.26; CNR, 13.55±3.47) and all traditional VMI series (P<0.001). Regarding the subjective image evaluation, overall image quality peaked in the 60-keV VMI+ series (median, 5) with significant differences to all other series (P<0.001). Evaluation of lesion delineation was superior in 40-keV VMI+ series (median, 5), whereas image noise showed best rating scores for 100-keV VMI+ (median, 5).
Conclusion: Low-keV VMI+ series significantly increase objective image quality of malignant lymphoma lesions in abdominal DECT examinations compared to standard DECT and VMI series. In addition, the highest lesion delineation can be achieved using 40-keV VMI+ reconstructions.

B-1516 15:04

Sarcopenic index as a predictor of post-transplant morbidity and mortality

S. Singhal[1], B.K. Saranga[2], D. Balakrishnan[2]; [1]*Bangalore/IN*, [2]*Kochi/IN (drsoumilsinghal75@gmail.com)*

Purpose: Nutrition assessment in chronic liver disease is a challenge as the common indices such as anthropometric measurements and body mass index are inaccurate and overexpressed; hence, the use of sarcopenia index has shown to solve this problem. The primary aim of my study is to assess morbidity and mortality in post-transplant patient using sarcopenia index.
Methods and Materials: A cross-sectional prospective study was performed between October 2014 and November 2016, at Amrita Institute of Medical Sciences. The study was approved by the ethical committee. 60 patients (59 male, 1 female) were included in the study. Sarcopenia was assessed by calculating psoas volume and psoas index using volumetric software Aquarius Intuition Terrarecon version 4.4.11 . All statistical analyses were done using IBM SPSS version 20.0.
Results: Among the 60 patients included in the study 6 belonged to class 0, 16 to class 1 and 38 to class 2, patients who had normal psoas index (class 0 - as per European working group on sarcopenia in older people guideline of 2010) had nil mortality. Mean comparison analysis showed high risk of mortality in patients with sarcopenia. Correlation analysis of psoas index with ICU stay showed a negative correlation which was statistically significant. On associational analysis, the reintubation was found to have a significant correlation with mortality 72% (p value <0.001).
Conclusion: Sarcopenia index acts as an important prognostic tool in post-transplant patients.

Carcinoma pancreas: how good is multi-detector-computed tomography: a single-centre experience

S. Singhal[1], N.K. Prabhu[2]; [1]*Karnataka/IN*, [2]*Kochi/IN (drsoumilsinghal75@gmail.com)*

Purpose: To compare the staging of pancreatic carcinoma assessed by MDCT with surgery in a tertiary referral centre in Kerala.
Methods and Materials: A cross-sectional observational study was performed between November 2014 and October 2016, 25 patients (12 male and 13 female patients) were evaluated with a mean age of 54.2 years. CT was performed on all patients. The gold standard for diagnosis was operative and histopathology data. All statistical analyses were done using IBM SPSS version 20.0. Validity parameters like sensitivity, specificity, accuracy, positive and negative predictive value were computed for CT with respect to surgery.
Results: Of the 25 patients who were evaluated for surgery, 15 cases (60%) were classified as resectable tumours, 3 (12%) as borderline resectable and 7 (28%) as unresectable tumours. CT showed a sensitivity of 82.3% with a specificity of 87.5%. On assessing vascular invasion CT showed a sensitivity and specificity of 100% and 93.3%, respectively. Three patients who were classified as having borderline resectable tumour underwent vascular reconstruction during the surgery.
Conclusion: Contrast-enhanced multiphase pancreatic imaging using CT plays a pivotal role in diagnosing and assessing the resectability and vascular invasion of pancreatic tumours. It is very useful for determining borderline resectable tumours pre-operatively, which aids for better treatment planning.

B-1518 14:08

The diagnostic role of 256 multidetector-row CT in the detection and characterisation of incidental pancreatic cystic lesions: comparison with MR colangiopancreatography

S. Drago, D. Ippolito, C. Talei Franzesi, A. Nasatti, A. Parlati, A. Casiraghi, S. Sironi; *Monza/IT (silvia.drago@hotmail.it)*

Purpose: To compare the diagnostic accuracy of contrast-enhanced MDCT scan with MRI with MRCP sequences, in the detection of pancreatic cystic lesions and those features useful for their characterisation.
Methods and Materials: Fifty patients with no history of pancreatitis, neoplasm and prior surgical procedures in pancreas, who underwent both MDCT and MRI with MRCP (time interval lower than 90 days) for pancreatic cysts characterisation, were evaluated. All CT and MRI examinations were performed, respectively, on a 256 slice CT (Brilliance iCT; Philips) and on a 1,5 T magnet (Achieva, Philips). The reviewer recorded the number of lesions in each patient and the main morphologic features of the defined target lesions: location (head, uncinate process, neck, body, tail), number, size, communication with main pancreatic duct (MPD), maximum MPD diameter, presence of septa, mural enhancing nodules and calcifications. Data were analysed to compare the diagnostic performance of MDCT and MRI.
Results: A greater number of pancreatic cysts were identified on MRI than CT examinations (227 vs 128); however, the ICC value was 0.76, suggesting a good agreement. Very good agreement (ICC 0.98) was found regarding the diameter of target lesions (21.4mm on CT vs 21.8mm on MRI), location of target lesion (κ=0.90), detection of MPD dilatation (κ=1.00) and septa (κ=0.86). Fair agreement on the evaluation of MPD communication (κ=0.33) and calcifications (κ=0.22) was found.

Conclusion: MDCT can be considered almost equivalent to MRI with MRCP in the evaluation of pancreatic cystic lesion, offering detailed morphologic features helpful for their characterisation and correlation with a high risk of malignancy.

B-1519 14:16

CT features of primary pancreatic lymphoma: experience from three referral centres for pancreatic diseases

E. Boninsegna[1], G. Zamboni[1], D. Facchinelli[1], C. Triantopoulou[2], S. Gourtsoyianni[3], M.C. Ambrosetti[1], R. Pozzi Mucelli[1]; [1]*Verona/IT*, [2]*Athens/GR*, [3]*London/UK (boninsegnae@gmail.com)*

Purpose: To describe CT characteristics of primary pancreatic lymphoma (PPL), a rare disease with features in common with adenocarcinoma.
Methods and Materials: Fourteen patients were enrolled. CT: unenhanced scan, contrast-enhanced pancreatic and venous phases. Image analysis: tumour location; peri-pancreatic vessels encasement; necrosis; enlarged lymph nodes; fat stranding; enlarged bile duct and pancreatic duct; neoplasm longest dimension, volume and density.
Results: Histopathological diagnoses: follicular non-Hodgkin lymphoma (5/14), diffuse large B-cell lymphoma (6/14), high-grade B-cell lymphoma not otherwise specified (3/14). 6/14 PPLs were located in the pancreatic head, 7/14 in the body-tail and 1/14 involved the whole gland. In 5/14 cases superior mesenteric artery and vein were encased; splenic vein and artery encasement was depicted in 2 PPLs. Necrosis was present in 2/14. Enlarged retroperitoneal lymph nodes were found in 11 cases; fat stranding in all patients. Bile duct was dilated in 6 cases, pancreatic duct in 5. Mean neoplasm longest diameter and volume were 8.05 cm and 210.8 cm^3. Mean tumour attenuation values were 39.1 HU at baseline, 60.6 HU in the pancreatic phase and 71.4 HU in the venous phase.
Conclusion: PPL presents as a large lesion with delayed homogeneous enhancement; peri-pancreatic fat stranding and vessel encasement are present, without vascular infiltration; pancreatic duct dilatation is rare.

B-1520 14:24

CT and pathologic correlation in pancreatic cancer after neoadjuvant chemoradiotherapy

J.R. Ayuso, M. Cuatrecasas, J. Maurel, O. Reig, C. Conill, A. Darnell, M. Pages, S. Rodríguez, S. Sanchez; *Barcelona/ES (JRAYUSO@clinic.cat)*

Purpose: To correlate morphologic changes observed in CT after neoadjuvant chemoradiotherapy (CRT) with the pathologic piece in patients with pancreatic cancer (PC).
Methods and Materials: Eleven patients with resectable pancreatic cancer (RPC) (Group1) who underwent surgery after CRT and nine with borderline pancreatic cancer (BPC) (Group2), selected form those included in the GEMCAD1003 trial, who completed the CRT treatment and underwent tumour resection were evaluated by CT before and after treatment. CT changes in tumour volume were determined by three orthogonal measurements and a semiautomatic tool. Tumour density measured in the portal venous phase and changes in vascular infiltration (only in group 2) were compared to pathologic tumour volume and tumour regression grade (TRG). Spearman coefficient and Wilcoxon test were used to compare results.
Results: The Spearman's correlation coefficients were 0.92 and 0.95, respectively, for manual and semiautomatic tumour volumes measured before and after CRT, but only 0.231 for post-CRT CT and pathologic tumour volume measurements. It was 0.39 for the correlation between CT volume reduction and tumour/fibrosis ratio. No correlation was observed between the CT volume reduction and pathologic TRG (p=0.96), or between variations in tumour density in the portal venous phase and the percentage of tumoural fibrosis (p=0.15). In group 2 patients, the percentage of radial and longitudinal tumour/vessel contact remained unchanged in 10/11 patients.
Conclusion: CT changes in size, density and extension in vascular infiltration in PC after CRT do not correlate with pathological tumour response.

B-1521 14:32

Lobar distribution of liver metastases based on the site of pancreatic neuroendocrine tumours

C. Fabris, G. Zamboni, M.C. Ambrosetti, R. Negrelli, R. Pozzi Mucelli; *Verona/IT (cristina.fabris@yahoo.it)*

Purpose: The presence of liver metastases from neuroendocrine tumours does not preclude surgery; the distribution of the metastases is important for treatment planning. Our purpose was to assess whether the location of the primary neuroendocrine tumour (pNET) in the pancreas influences the lobar distribution of metastases within the liver.
Methods and Materials: This is a retrospective review of the CTs performed on 49 patients with pNETs (27 males, 22 females) and liver metastases. Of these patients, 11 had a primary tumour in the head (group A: mean age 50,3 years) and 38 in the body-tail (group B: mean age 59,3 years). We evaluated tumour site, diameter, vascular invasion and number of metastases within each lobe. We used an unpaired t-test to compare the total number of metastases between the two groups and Fisher's test to evaluate the number of metastases in the two lobes.
Results: Group B primary tumours were larger than group A (59,55 vs 39,82 mm; p 0.043). The number of liver metastases was higher in the right lobe in both groups (p=ns). The ratio of metastases in the right-to-left hemi-liver was 2,5:1 for group A compared with 1,79:1 for group B (p=0,0423). The splenic vein was more commonly involved in patients in group B.
Conclusion: Tumours from all locations in the pancreas will give a higher number of metastases in the right lobe. The right-to-left ratio is however significantly different based on the site of the primary tumour.

B-1522 14:40

MRI and MRCP features of chronic pancreatitis in patients with or without pancreas divisum abnormality and their ralationship to patients age

M. Monti, G. Zamboni, L. Bertuzzo, R. Pozzi Mucelli; *Verona/IT (marialaura.monti@hotmail.it)*

Purpose: To compare the MRI and MRCP features of chronic pancreatitis (CP) in patients with or without pancreas divisum (PD) and to determine their relationship to patient age.
Methods and Materials: We retrospectively reviewed the MRI/MRCPs of 175 patients (mean age 53years) with symptomatic CP. 86 had CP associated with PD, and 89 had CP without PD. Both patients with PD and without PD were stratified by age: <40 years (26 PD; 33 non-PD), 41-60 years (27 PD; 28 non-PD), >60 years (33 PD; 32 non-PD). Two readers reviewed the scans for: morphological changes, signal intensity abnormalities, pancreatic ducts changes, filling defects. All MRI features were compared between age groups by using Chi-square test.
Results: No difference was observed in mean patient age between PD and non-PD patients(p=ns). Parenchymal intensity was significantly more often reduced in non-PD than in PD patients(p<0,001). The degree of parenchymal thinning, and irregularity of margins were significantly higher in non-PD patients in the groups aged <40 and 41-60 (p<0,001). No difference was observed between PD and non-PD patients aged >60 for irregularity of parenchymal margins (p=0,3). In non-PD patients, main pancreatic duct (MPD) and branch-ducts were significantly more often dilated(p=0,0031), and filling defects were more common (p<0,0007). A significant association was found between parenchymal T1-hypointensity, MPD dilation and filling defects and increasing age in non-PD patients compared to PD patients in all the age groups(p<0,001).
Conclusion: Patients with PD show less severe morphological alterations as compared with patients affected by other forms of CP.

B-1523 14:48

MRI evaluation of pathologically confirmed IPMNs of the pancreas using Fukuoka Guidelines: can we differentiate between invasive/high-grade IPMNs and low/moderate-grade IPMNs?

C. Fabris, G. Zamboni, R. Negrelli, E. Boninsegna, R. Pozzi Mucelli; *Verona/IT (cristina.fabris@yahoo.it)*

Purpose: IPMNs of the pancreas are intraductal mucin-producing cystic neoplasms with malignant potential. The Fukuoka criteria are commonly used to assess the risk of malignancy. Our purpose was to assess if these criteria can differentiate between invasive/high grade IPMNs and low/moderate grade IPMNs.
Methods and Materials: We reviewed the preoperative MRIs from 42 patients (25 males, 17 females; mean age 63,62 years) with a confirmed pathologic diagnosis of IPMN (invasive= 7; non invasive= 35). Two readers analyzed in consensus the MRIs for tumor size (>/< 3 cm), diameter of the main pancreatic duct (MPD) (>10 mm, <10 mm), presence of enhancing solid components, radiologic signs of pancreatitis, enhancing or nonenhancing nodules, thickened/enhancing walls, abrupt change in MPD caliber with distal atrophy, lymphadenopathy. MRI and pathology findings were compared using Fisher's test dividing the patients in two groups: invasive/high grade IPMNs vs low/moderate dysplasia IPMNs.
Results: A MPD >10 mm was significantly more common in patients with invasive/ high grade dysplasia IPMN than in patients with low/moderate dysplasia (p=0,0026). No significant difference was observed between the two groups for the tumor diameter, presence of solid nonenhancing or enhancing nodules, thickened enhancing walls, pancreatitis, abrupt change in MPD and presence of lymphadenopathy.
Conclusion: Fukuoka criteria are being commonly used to assess the risk of malignancy in patients with IPMN. The only criterion that appears to be helpful in differentiating between invasive/high grade IPMNs and low/moderate grade IPMNs is a MPD >10 mm.

B-1524 14:56

Preoperative classification of resectability of pancreatic cancer using multi-detector row CT: a study of interobserver reliability

I. Joo[1], J. Lee[1], E. Lee[1], D. Lee[1], J.-Y. Son[1], W. Chang[2], S. Lee[3], H. Yang[1]; [1]*Seoul/KR*, [2]*Seongnam/KR*, [3]*Anyang/KR (hijijin@gmail.com)*

Purpose: To investigate the interobserver reliability in the preoperative classification of resectability of pancreatic cancer using multi-detector row CT (MDCT).
Methods and Materials: In this retrospective study, we included 110 patients with pathologically confirmed pancreatic cancer who underwent baseline multiphasic contrast-enhanced MDCT. Eight board-certified radiologists with different levels of experience (more experienced, n=4; less experienced, n=4) reviewed MDCT images to score the likelihood of local resectability using a 5-point Likert scale based on each reviewer's impression and to determine categories of resectable, borderline resectable, or unresectable based on given MDCT criteria. Diagnostic performance and interobserver agreement were determined by receiver operating characteristic (ROC) curve analysis and Fleiss kappa statistics, respectively.
Results: Overall interobserver agreements were fair in Likert scale (kappa = 0.360 [95% confidence interval (CI): 0.344-0.375]) and moderate in categories (kappa = 0.477 [95% CI: 0.452-0.502]). More experienced reviewers showed higher agreement in the determination of categories than those with less experience (kappa = 0.548 [95% CI: 0.495-0.600] vs 0.432 [95% CI: 0.377-0.487]) while there was no significant difference in Likert scale according to experience level (kappa = 0.395 [95% CI: 0.361-0.428] vs 0.347 [95% CI: 0.312-0.382]). In patients with reference standard for local resectability (n=82), area under the ROC curves were 0.845-0.978 on 5-point Likert scale and 0.833-0.960 on 3 categories.
Conclusion: In the resectability assessment of pancreatic cancer, MDCT shows only fair to moderate interobserver agreement. Radiologists with higher experience level would be more likely to make consistent classifications of resectability.

Application of CT texture analysis in quantification of pancreatic cystadenoma phenotype images

Z. Feng, Z. Hu; *Hangzhou/CN (gerxyuan@126.com)*

Purpose: Pancreatic serous cystadenoma and pancreatic mucinous cystadenoma differ greatly in biological characteristics, as well as their treatment and prognosis. We quantified the special imaging features of pancreatic cystadenomas and to provide new parameters for identifying of pancreatic cystic tumours using computed tomography texture analysis (CTTA).
Methods and Materials: We retrospectively analysed contrast-enhanced CT data from patients who were admitted and had pathologically confirmed pancreatic serous cystadenomas (N = 48) and mucinous cystadenomas (n = 34) in our hospital from January 2009 to December 2016. Regions of interest were drawn manually on the parenchymal phase CT images according to the border of the tumours. A Laplacian of Gaussian band-pass filter was chosen to highlight the characteristics of the image. Mean grey-level intensity (M), variance (V), entropy (E), skewness (Ske) and kurtosis (Kur) were derived with different spatial scales from fine texture (σ =1.0) to coarse texture (σ =2.5).
Results: There were no statistically significant differences ($p > 0.05$) in value M, but statistically significant difference ($p < 0.05$) in value $V_{2.5}$, $E_{2.5}$, $Kur_{2.5}$ and $Ske_{0\text{-}2.5}$ between the two sets of serous cystadenomas and mucinous cystic tumours. Areas under the ROC curve for the two sets based on the texture parameters above ranged between 0.56 and 0.84.
Conclusion: CTTA can quantify and extract the specific and abstract texture features of medical images, and reveal the inherent heterogeneity between tumours, which facilitates objective evaluation of pancreatic cystadenoma image, and greatly improve clinical diagnosis and prognostic analysis.

Microcystic serous pancreatic cystic neoplasms: the added diagnostic value of contrast-enhanced ultrasound

Y. Dong, F. Mao, J. Cao, P. Fan, W. Wang; *Shanghai/CN (drdaisydong@hotmail.com)*

Purpose: Preoperative diagnosis of microcystic serous pancreatic cystic neoplasms (MPN) is clinical challenges. The purpose of current study is to analyse contrast-enhanced ultrasound (CEUS) features of histologically proven MPN, in comparison to pancreatic ductal adenocarcinomas (PDA).
Methods and Materials: The present study was approved by the institutional ethics committee and informed consent was waived. Twenty-five patients with histologically proved MPN lesions and 30 patients with histologically proved PDA lesions were retrospectively analyzed. The CEUS features of pancreatic lesions were compared to the surrounding normal pancreatic parenchyma. Two radiologists assessed the CEUS enhancement pattern in consensus.
Results: All MPN and PDA lesions were hypoechoic on B-mode ultrasound. Twenty (80 %) MPN present as solitary multilocular microcystic lesion. With colour Doppler imaging (CDI), typical 'spoke wheel' macrovessels were identified in 64 % of lesions. On CEUS, most MPN lesions displayed hyper- (96 %) or isoenhancement (4 %) in the arterial phase with 'honeycomb' architectures. In contrast, all PDA lesions showed hypoenhancment in the arterial phase ($P < 0.01$).
Conclusion: CEUS of the pancreas has the potential to aid differentiation of MPN from other neoplastic lesions. The differential diagnosis to the typically hypovascularised pancreatic adenocarcinoma was always possible.

B-1527 15:20

Assessment of local vascular invasion in pancreatic carcinoma by MDCT using the angle measuring tool

D. Šaponjski, A. Djuric Stefanovic; *Belgrade/RS (saponjski.d@gmail.com)*

Purpose: According to the NCCN criteria, resectability of pancreatic carcinoma (PC) is commonly assessed by MDCT and depends on tumour's relation to neighbouring blood vessels, such as celiac trunk (CT), hepatic artery (HA), superior mesenteric artery (SMA), portal vein (PV) and superior mesenteric vein (SMV). The aim of study was to investigate methodology of the assessment of local vascular invasion of pancreatic carcinoma by MDCT using the angle measuring tool.
Methods and Materials: Fifty consecutive 64-MDCT scans of patients with the PC were retrospectively analysed. Maximal angle of blood vessel's circumference that was in direct contact with the tumour was measured using the angle measuring tool on axial section, and length of direct contact on MPR-reconstructed section. Accordingly, resectability was estimated using the NCCN criteria. Frequencies and correlations were statistically analysed using Spearman's (r_S) and Pearson's correlation coefficient (r).
Results: Average size of tumour was 36 ± 13 mm (10-68 mm). Majority of PCs were in advanced stage (60% T3 and 36% T4), located in the head of the pancreas (62%). 22% tumours were estimated as resectable, 48% borderline resectable, and 30% unresectable. SMV and PV were invaded most frequently (50% and 46%), and surrounding arteries in lower percent (SMA in 26%, HA in 22% and CT in 16%). Location, size and T-stage correlated with the frequency of local vascular invasion (r_S>0.450). Maximal angle correlated with the length of the vascular infiltration (r>0.450).
Conclusion: Precise estimation of vascular invasion in PC by MDCT is possible using the angle measuring tool.

7 T MR imaging for fibrosis evaluation in a radiation-induced murine model of colitis

M. Zappa[1], S. Doblas[2], D. Cazals-Hatem[1], F. Milliat[3], P. Garteiser[2], M. David[1], V. Vilgrain[1], B. Van Beers[1], E. Ogier-Denis[2]; [1]*Clichy/FR*, [2]*Paris/FR*, [3]*Fontenay-aux-Roses/FR (magaly.zappa@netc.fr)*

Purpose: Crohn's disease transmural bowel wall inflammation can lead to fibrosis causing luminal narrowing and fistula which are the main indications to surgery. The aim of our study was to evaluate MR imaging to distinguish submucosal from transmural fibrosis using an original murine model of radiation-induced colitis.
Methods and Materials: Colitis was induced with localised single-dose radiation (27 Gy). We included an inflammation group of 24 rats with pathologic features of severe acute inflammation associated with minimal submucosal fibrosis and a mixed group of 39 rats with pathological features of severe inflammation associated with transmural fibrosis, obtained two and twelve weeks after irradiation, respectively. Fat suppressed T2- and T1-weighted, diffusion-weighted, magnetisation transfer and perfusion using ASL technique 7 T MR imaging was performed.
Results: MR imaging showed significant differences between inflammation and mixed groups in normalised to muscle signal intensity on T2-weighted images (4.2 vs 3.1, $P < 0.0001$) and T1-weighted images (1.4 vs 1.3, $P = 0.0003$), ADC (2.17×10^{-3} vs 1.69×10^{-3} mm^2/s, $P < 0.0001$), magnetisation transfer ratio (35 vs 42%, $P < 0.0001$) and perfusion (60 vs 38 mL/min/100g, $P = 0.0009$). Monoparametric analysis with the best AUC to differentiate the two groups included T2-weighted signal intensity, ADC and magnetisation transfer

ratio. The combination with the best global predictive value (94%) included all parameters but T1-weighted parameter (AUC 0.94).
Conclusion: MR multiparametric analysis was able to distinguish transmural from submucosal fibrosis in our radiation-induced model. This model could be used to evaluate antifibrotic treatments currently under development.

B-1529 14:08

Accuracy of multi-parametric magnetic resonance imaging in the diagnosis and grading of intestinal acute Graft-versus-Host disease after allogenic bone marrow transplantation

D. Vitale, F. Maccioni, V. Buonocore, D. Bencardino, M. Lopez, A. Iori, C. Catalano; *Rome/IT (davide.vitale@uniroma1.it)*

Purpose: The diagnosis of the intestinal acute Graft-versus-Host disease (a-GVHD) after allogenic bone marrow transplantation is based on clinical symptoms, CT findings and biopsies. We assessed Magnetic Resonance Imaging (MRI) diagnostic accuracy.
Methods and Materials: We performed a prospective study on 35 patients (range 9-69 years) with clinical suspicion of intestinal a-GvHD, who underwent clinical-endoscopic, histological and multi-parametric MRI evaluation. Inclusion criteria: intestinal symptoms within 100 days from transplantation, <2 weeks between MRI and clinical-endoscopic evaluation. The following MRI features were evaluated: small and large bowel wall thickening, T2 signal and Gadolinium-enhancement of the intestinal wall, mesenteric lymph nodes, peritoneal effusion, comb-sign and restricted diffusion. Histology, clinical-endoscopic data and follow-up were considered as gold standard for diagnosis and staging. Sensibility, specificity, accuracy and Cohen's kappa were calculated.
Results: In 21/35 (60%) a-GvHD was confirmed at histology and follow-up. In true positive patients, MRI showed significant continuous wall thickening in 76.2%, stratified wall contrast-enhancement in 90%, comb-sign in 76%, increased number of mesenteric lymph nodes in 19%, and free intra-peritoneal fluid in 57.2%. A significant correlation was found between number of pathological intestinal segments and clinical grade of a-GvHD (r=0.54, p=0.009). The distal ileum was the segment most frequently involved (85.7%). MRI sensitivity was 90.5%, specificity 78%, the PPV 86%, NPV 84%, accuracy 85%. Furthermore, MRI detected early disease in 82% of patients without intestinal symptoms.
Conclusion: In patients with intestinal a-GvHD, MRI can diagnose and grade the disease with high accuracy, in both early and more advanced or severe stages.

B-1530 14:16

DWI ADC values are influenced not only by bowel distention degree but also the presence of osmotically active agent: results from research in healthy subjects

I. Apine, M.P.M. Angerer, M. Baduna, G. Krumina; *Riga/LV (dr.ilze.apine@gmail.com)*

Purpose: To assess dependence of bowel distention and presence of mannitol in MRE examinations on ADC values.
Methods and Materials: ADC values of small and large bowel walls with high SI in DWI images at b=600 and b=800 grading bowel filling as "distended" and "collapsed" were measured before and after oral ingeston of 2.5% mannitol (1-1.5 l) in 54 patients with no evidence of IBD. ADC differences between bowel filling grades and presence of mannitol were assessed with t-test and Wilcoxon signed-rank test.
Results: Statistically significant differences (p<0.05) were gained in jejunum after preparation where ADC values were lower in wall of collapsed bowel than of distended one (the mean ADC in collapsed bowel at b=600 and b=800 was 1.76×10-3 mm2/s (SD=0.48) and 1.10 (SD 0.32), respectively, whereas in distended bowel at b=600 and b=800 being 2.56×10-3 mm2/s (SD=0.63) and 1.95 (SD 0.41), respectively). Regarding presence of mannitol, higher ADC was achieved in collapsed jejunum for b 600 and 800, respectively, being 1.35 (SD 0.51) and 1.10 (SD 0.32) before preparation, 1.76 (SD 0.51) and 1.47 (SD 0.36) after preparation as well as in distended colon ascendens for ADC 600 and 800, being 1.56 (SD 0.26) and 1.36 (SD 0.27) before preparation and 2.48 (SD 0.59) and 2.10 (SD 0.44) after preparation.
Conclusion: ADC is influenced by both bowel distention degree and presence of mannitol which has to be considered in diagnosis of IBD.

B-1531 14:24

Magnetisation transfer MRI can characterise the degree of intestinal fibrosis in patients with Crohn's disease: comparing with contrast-enhanced and diffusion-weighted MRI

X. Li, S. Huang, Z. Fang, Z. Li; *Guangzhou/CN (lixuehua803@163.com)*

Purpose: To evaluate the role of magnetisation transfer imaging (MTI) for characterisation of intestinal fibrosis compared with contrast-enhanced (CE) imaging and DWI and its capability for differentiating fibrotic from inflammatory strictures in humans with Crohn's disease (CD).
Methods and Materials: Abdominal MTI, CE and DWI of 31 consecutive CD patients were analysed before elective surgery. Bowel wall MT ratio (MTR) normalised to skeletal muscle, ADC and the percentage of enhancement gain were calculated and region-by-region correlation with surgical specimen was performed for histologic degree of fibrosis and inflammation. The performance of MTI was validated on 5 new patients.
Results: Normalised MTRs correlated with fibrosis scores (r=0.769, P<0.001) but did not correlate with inflammation scores (r=-0.034, P=0.740). Significant differences in normalised MTRs were found among non-fibrotic, mildly, moderately and severely fibrotic walls (all P<0.05). Normalised MTRs of mixed fibrotic and inflammatory bowel walls were significantly higher than that of purely inflammatory bowel walls (P<0.001). High accuracy of normalised MTRs was shown with an AUC of 0.919 (P<0.001) for differentiating moderately-severely fibrotic from non-fibrotic and mildly fibrotic bowel walls, followed by ADC (AUC=0.747, P=0.001) and the percentage of enhancement gain (AUC=0.592, P<0.001). Sensitivity, specificity and AUC of MTI for diagnosing moderate-severe fibrosis in the validation dataset were 80%, 100% and 0.9 (P=0.033), respectively.
Conclusion: MTI outperforms ADC and CE imaging in detecting and distinguishing varying degrees of bowel fibrosis with or without coexisting inflammation. It could potentially be used as a method to differentiate fibrotic from inflammatory intestinal strictures in CD.

B-1532 14:32

Biomarkers derived from time-intensity curves in patients with Crohn's disease

E. Quaia[1], A. Gennari[2], M.A. Cova[2], E.J. Van Beek[1]; [1]*Edinburgh/UK*, [2]*Trieste/IT (equaia@exseed.ed.ac.uk)*

Purpose: To assess the best predictors of response to therapy in patients with Crohn's disease calculated from time - intensity curves after microbubble injection.
Methods and Materials: One-hundred-and-fifteen consecutive patients (66 male and 49 female; 45.76 years ± 11) with a proven diagnosis of Crohn's disease involving the terminal ileal loop and scheduled to begin or under therapy with corticosteroids or biologics (infliximab or adalimumab) and with stricture of the terminal ileal loop were scanned after sulphur hexafluoride-filled microbubble injection. In each patient the terminal ileal loop was scanned with CEUS before the beginning and at the end of week 6 of pharmacologic treatment. In each patient the percent change (Post - Pre x 100/Pre) of each kinetic parameter - peak enhancement, wash-in and washout rate, mean transit time, area under the whole time-intensity curve (AUC), AUC during wash-in (AUCWI), and AUC during wash-out (AUCWO) were automatically calculated from time intensity curves. Percent changes of responders and non-responders were compared by Mann Whitney test. Separate univariate logistic regressions were conducted to determine the relationship between the percent change of each kinetic parameter (independent variables), and the therapeutic outcome as responder (dependent outcome variable).
Results: Responders (n=72 patients) and non-responders (n=43) differed (P <0.05) in the percent change of peak enhancement, and area under the curve. Percent change of AUC, AUCWI, AUCWO were found predictors of therapeutic outcome.
Conclusion: Area under time-intensity curve obtained after microbubble contrast agent injection is predictor of response to therapy in patients with Crohn's disease.

Performance of PET/MR enterography vs MR enterography alone vs PET alone in evaluating active inflammation in Crohn's disease

O.A. Catalano[1,1], V. Wu[1], U. Mahmood[1], A. Soricelli[2], A. Signore[3], M. Salvatore[2], D. Gervais[1], B.R. Rosen[4]; [1]*Boston, MA/US*, [2]*Naples/IT*, [3]*Rome/IT*, [4]*Charlestown, MA/US (alberto.signore@uniroma1.it)*

Purpose: To explore the performance of PET/MR enterography (PET-MR-E) versus MR enterography (MR-E) alone and PET alone in evaluating active inflammation in Crohn's disease patients.
Methods and Materials: 21 Crohn's disease patients underwent PET/MR-E followed by surgery within 8 weeks, and constitute our study population. The gastrointestinal tract was divided into 5 segments in each patient. Two readers evaluated MR-E alone, PET alone, and PET/MR-E for active inflammation in each segment.
Results: 59/105 bowel segments were positive for active inflammation at surgery. Sensitivity of PET (91.5%) and of PET/MR-E (88%) were statistically significantly higher than MR-E alone (80%) (p = 0.02 and p=0.08, respectively). No statistically significant differences were found between sensitivity of PET and PET/MR-E (p = 0.48). Specificity of MR-E (87%) and PET/MR-E (93%) were statistically significantly higher than PET (74%) (p=0.01 and 0.04, respectively) but no statistically significant difference was found between MR-E and PET/MR-E (p=0.37). Accuracy of PET/MR-E (91%) was statistically

significantly higher than PET (84%) and MR-E (83%) (p=0.02 and 0.01, respectively). No statistically significant difference was found between PET and MR-E (p=1.00).
Conclusion: PET/MR-E is significantly more accurate than sub-modality alone and more specific than PET alone in the detection of active inflammation in patients with Crohn's disease.

B-1534 14:48

Detection of inflammatory bowel segments with [18F]-FDG PET/MR enterography by Crohn's disease: which surrogate marker is better? MaRIA, Clermont score or PET?

Y. Li, K.J. Beiderwellen, F. Nensa, K. Herrmann, L. Jost, L. Umutlu; *Essen/DE (yan.li@uk-essen.de)*

Purpose: To compare the diagnostic accuracy of magnetic resonance index of activity (MaRIA), Clermont score and PET parameter in detecting ileocolonic inflammation in Crohn's disease (CD) with an integrated whole-body PET/MR scanner.
Methods and Materials: 50 patients with known CD and recurrent symptoms underwent ileocolonoscopy with biopsy (reference standard) as well as PET/MR enterography. The average time interval between endoscopy and PET/MR scan was 3 days. The endoscopic activity of inflammation was determined by simplified endoscopic activity score for Crohn's disease (SES-CD) and categorized in absent, mild to moderate and severe (ulcerative inflammation).
Results: A total of 309 ileocolonic segments could be analysed. To detect active inflammatory segments, area under the curve (AUC) of receiver operating characteristic (ROC) for MaRIA was 0.93, sensitivity 0.86 and specificity 0.92 (cutoff ≥ 11.5); for Clermont score 0.89, 0.82 and 0.91 (cutoff ≥ 13); for SUVmax_ratio (SUVmax of the segment divided by SUVmax of liver) 0.87, 0.77 and 0.89 (cutoff ≥ 1.2), respectively. In detecting severe ulcerative inflammatory segments, AUC of ROC for MaRIA was 0.97, sensitivity 1.0 and specificity 0.89 (cutoff ≥ 14); for Clermont score 0.98, 1.0 and 0.93 (cutoff ≥ 17); for SUVmax_ratio 0.95, 0.86 and 0.91 (cutoff ≥ 1.5). MaRIA, Clermont score and SUVmax_ratio all correlated significantly with global SES-CD (rho = 0.76, 0.56 and 0.52, p<0.001).
Conclusion: Both MR parameters were superior to PET in detecting active inflammatory segments. All of the three surrogate markers facilitate high diagnostic accuracy in detecting severe ulcerative inflammation.

B-1535 14:56

Magnetisation transfer and conventional MRI for characterisation of intestinal fibrosis and inflammation in patients with Crohn's disease

Z. Fang[1], X. Li[1], S. Huang[1], Z. Zhang[2], C.C. Sun[1], S.-T. Feng[1], Z. Li[1]; [1]*Guangzhou/CN*, [2]*Winston-Salam, NC/US (fangzn05@126.com)*

Purpose: An accurate and non-invasive technique to identify inflammation or fibrosis predominant strictures in Crohn's disease (CD) patients is crucial for treatment strategy. The aim of this study is to evaluate the value of magnetic transfer imaging as well as conventional MRI in characterizing types of CD strictures, using surgical histopathology as a reference standard.
Methods and Materials: Seventeen CD patients with 56 specimens who had MRI studies within 15 days before surgery were enrolled in this study. MRI findings and variables included MTR, normalized MTR, T2WI high signal intensity, wall thickness, changes of enhancement pattern over time, enhancement pattern and enhancement gain ratio in each phase of the dynamic contrast-enhanced study. Correlation analysis, group difference analysis and logistic regression analysis were performed to find specific MRI variables as predictors for moderate-severe inflammation and fibrosis.
Results: The severity of inflammation was significantly associated with the following MRI variables: T2WI high signal intensity and wall thickness (both P<0.05). The degree of fibrosis was significantly associated with the following MRI variables: MTR, normalized MTR and wall thickness (all P<0.05). Using T2WI high signal intensity as a predictor, MRI is able to differentiate mild and moderate-severe inflammation with a sensitivity of 0.913 and a specificity of 0.800. Using normalized MTR to discriminate mild and moderate-severe fibrosis, the sensitivity and specificity were 0.875 and 0.875, respectively.
Conclusion: T2WI high signal intensity and normalized MTR may serve as MRI markers for predicting moderate-severe inflammation and fibrosis, respectively, which can provide information for clinical treatment options.

B-1536 15:04

A simulated fast magnetic resonance enterography protocol in patients with Crohn's disease: a retrospective, randomised, double-blind study

G. Cicero, S. Mondello, A. Blandino, G. Ascenti, T. D'Angelo, S. Mazziotti; *Messina/IT (gcicero87@gmail.com)*

Purpose: Magnetic resonance enterography (MRE) is a radiation-free and accurate technique in the assessment of Crohn's disease, mainly impaired by high costs and prolonged scanning times. Our purpose is to compare the diagnostic performance of standard MRE vs a "fast" protocol consisting of only three sequences.
Methods and Materials: 73 standard MRE examinations of patients with Crohn's disease performed over a 7-month period were retrospectively evaluated. The images of the two protocols were separated and evaluated by two radiologists with 12 and 2 years of experience in MRE. Statistical analysis was performed using the Cohen kappa value, the Lin's concordance correlation, Bland-Altman plot, and the nonparametric Mann-Whitney U test.
Results: Inter-protocol agreement was excellent for the presence and number of lesions, assessment of intestinal complications, and excellent in recognising inflammation pattern and extra-intestinal complications (kappa value 0.94-0.096). The assessment of fibrosis had lower agreement with a kappa value of 0.84, while an almost perfect concordance (ρc=0.999) was found in the assessment of lesion extension. Inter-observer agreement was excellent for the presence and number of lesions, inflammation and intestinal and extra-intestinal complications; the assessment of fibrosis showed a lower agreement (93%; κ=0.84; 95% CI, 0.69 to 0.96). A concordance coefficient of 0.997 (95% CI 0.995-0.999) between the readers was obtained for the lesion extensions. Moreover, time spent in the evaluation of the fast protocol was significantly lower.
Conclusion: The fast protocol achieves comparable performance with standard MRE. Furthermore, it has potentially enormous benefits in terms of patient's comfort, time and health-care cost savings.

Established bowel damage detected on MR enterography in patients with Crohn's disease in complete endoscopic remission

J. Rimola, I. Alfaro, D. Vas, I. Ordás, E. Ricart, J. Panes; *Barcelona/ES (jrimola@clinic.cat)*

Purpose: To identify the MRE lesions that persist in patients with Crohn's disease (CD) in endoscopic remission as indicators of established damage and to determine its relationship with pre-treatment MRE lesions.
Methods and Materials: Patients with CD who had been included in prospective studies on autologous haematopoietic stem cell transplant and/or anti-TNF drugs were evaluated for this study. Inclusion criteria were: presence of at least one segment with severe inflammatory lesions on endoscopy (CDEIS>8.5) or MRE (MaRIA>11) before treatment and achievement of endoscopic remission after 1 year of treatment. Baseline and 1-year MRE were reviewed.
Results: 73 intestinal segments with severe inflammatory lesions from 28 patients achieved endoscopic remission. The prevalence of creeping fat and bowel mural fat did not change in association with achievement of endoscopic remission (p=0.34 and p=0.35, respectively). Furthermore, luminal stenosis persisted in 50% of initial stenosis and mural thickness>3mm remained in 29% of segments. At least one of the aforementioned residual lesions was present in 30/73 segments with endoscopic remission. Regression analysis showed that the predictive factors on MRE for established residual mural lesions after achieving endoscopic remission were the presence of bowel fat deposition (OR=48.3, p=0.001) and stenosis (OR=15.96, p=0.004), whereas creeping fat was the predictive factor for persistent extramural lesions (OR=35.8, p<0.001) and for either mural or extramural lesions (OR=16.25, p<0.001).
Conclusion: Up to 41% of bowel segments in endoscopic long-standing remission after treatment had residual lesions at MRE. The presence of bowel fat deposition, stenosis and creeping fat may predict the development of established damage.

B-1538 15:20

Dual-energy CT enterography in evaluation of Crohn's disease: the role of virtual monochromatic images

E. Güler, N.G. Ünal, I. Hekimsoy, T. Köse, M. Harman, Z.N. Elmas; *Izmir/TR (gulerezgi@yahoo.com)*

Purpose: The purpose of this study is to evaluate the performance of virtual monochromatic images (VMI) in differentiating diseased and non-diseased bowel segments in Crohn's disease (CD). The second aim is to compare mural enhancement between patients with and without CD by using VMI.
Methods and Materials: Dual-energy CT enterography (CTE) of 61 patients(47 with CD and 14 without CD) were retrospectively reviewed. Images were reconstructed at VMI energy levels from 40 to 110keV in 10 keV increments. Attenuation, signal-to-noise ratio(SNR), and contrast-to-noise ratio(CNR) were obtained from diseased and non-diseased bowel segments. Subjective analysis of image quality of VMI and polychromatic images(PCI) was performed by two radiologists in consensus. Repeated measures ANOVA and Wilcoxon tests were used in the assessment of quantitative and subjective analyses, respectively.
Results: Attenuation, SNR, and CNR were found to be higher with a statistical significant difference in diseased segments than non-diseased segments in patients with CD at each energy level of VMI. In the evaluation of patients with and without CD, optimal attenuation, SNR, and CNR values were observed at 40keV (area under ROC curve (AUC):0.913;95% confidence interval(CI):0.843-

0.984), 40keV (AUC:0.807;95%CI:0.679-0.935), and 70keV (AUC:0.906;95%CI:0.82-0.987), respectively. For subjective analysis, there was a statistically significant difference between the comparison of VMI and PCI ($p<0.05$).
Conclusion: VMI of dual-energy CTE provide information in differentiating diseased bowel segments in CD by assessing mural enhancement quantitatively. In the evaluation of CD and controls, VMI at 40keV and 70keV allow for the optimal attenuation and CNR of bowel segments, respectively.

Interventional radiology approach in the treatment of symptomatic uterine fibroids: from diagnosis to treatment: our experience
P. Palumbo, S. Quarchioni, F. Bruno, M.V. Micelli, A. Giordano, M. Varrassi, S. Carducci, M. Di Luzio, C. Masciocchi; *L'Aquila/IT*
(palumbopierpaolo89@gmail.com)

Purpose: Uterine fibroids (UF) are the most common benign uterine neoplasm. Uterine artery embolization (UAE) and Magnetic Resonance guided Focused UltraSound (MRgFUS) have been demonstrated to be safe and effective as uterus-sparing therapeutic option. Our purpose is to demonstrate the efficacy of both procedures in the treatment of symptomatic UF.
Methods and Materials: We retrospectively analysed 105 women. 58/105 were treated with MRgFUS and 47/105 were treated with UAE. They were screened by magnetic resonance imaging (MRI) to evaluate Non-Perfused-Volume (NPV) and Perfused Volume (PV) of remains fibroids. The UFs questionnaire (UFS-QOL) is used in order to assesses clinical symptoms severity before and after one year post procedure.
Results: After one year, the NPV mean value was of 95% using UAE and of 91% using MRgFUS. The post-treatment UFS-QOL has shown a significant reduction of score when compared to pre-treatment score. High efficay of MRgFUS depends on the correct selection criteria (better efficacy for type 0 and 1 UFs when compared to other). The UFS-QOL too, show high value in case of inappropriate MRgFUS treatment (post-treatment score near to pre-treatment values, with mean value between 40 to 60), with necessity of retreatment or other treatment as UAE or myomectomy.
Conclusion: UAE is more radical compared to MRgFUS, but it is necessary to consider the age of patients and their wishing to conceive; considering controversial aspect about pregnancy after UAE, we consider always MRgFUS as first treatment option especially in young patients.

B-1540 14:17
A comparative study of quantitative T1 perfusion parameters in magnetic resonance-guided high-intensity focused ultrasound ablation of uterine fibroids
N.M. Duc[1], B. Keserci[1], H.Q. Huy[1], P.N. Hoa[1], P.M. Thong[2]; [1]*Ho Chi Minh/VN*, [2]*Ha Noi/VN (bsnguyenminhduc@pnt.edu.vn)*

Purpose: To investigate the predictive role of quantitative perfusion parameters in magnetic resonance-guided high-intensity focused ultrasound (MR-HIFU) ablation of uterine fibroids.
Methods and Materials: 100 uterine fibroid patients (39.4 ± 5.9 years with a range of 22-52 years) underwent MR-HIFU were accessed in this study. The population was divided into 2 groups based on dynamic contrast-enhanced MR images at screening: group A (n = 75) if the time-intensity curves of uterine fibroids is lower than that of myometrium and group B (n = 25) if the time-intensity curves of uterine fibroids is equal or higher than that of myometrium. K_{trans}, area under the curve (AUC) of both fibroids and myometrium and the ratio K_{trans} and AUC of uterine fibroids relative to myometrium were investigated.
Results: K_{trans}, AUC, K_{trans} ratio and AUC ratio were 83.1 ± 59.0 (30.1-315.2); 20.7 ± 16.1 (3.2-69.8); 0.56 ± 0.18 (0.2-1.0); 0.6 ± 0.2 (0.3-1.0); for group A and 189.1 ± 87.9 (55.2-372.4); 38.4 ± 27.1 (9.2-99.1); 1.8 ± 0.7 (0.7-3.8); 1.8 ± 0.5 (1.3-2.9) for group B ($p < 0.05$), respectively. Immediate post-treatment non-perfused volume (NPV) ratio of uterine fibroids was 95.71% ± 5.9 (80-100%) for group A and 54.26% ± 25.77 (4.26-80.17%) for group B ($p<0.05$). Multiple linear regression manifested that there were K_{trans} ratio and AUC ratio parameters had significant effect on NPV ratio ($p < 0.05$).
Conclusion: The K_{trans} ratio and AUC ratio parameters could be served as a potential criteria in patient selection for an improved NPV ratio.

B-1541 14:25
MR-guided focused ultrasound (MRgFUS) compared to the main current therapeutic approaches for the treatment of uterine fibroids
S. Dababou, F. Andrani, A. Napoli, R. Scipione, C. Marrocchio, H.-P. Erasmus, C. Catalano; *Rome/IT (susy150791@gmail.com)*

Purpose: To prospectively evaluate the clinical outcome of magnetic resonance focused ultrasound (MRgFUS), uterine artery embolization (UAE) and surgery for symptomatic uterine fibroids.
Methods and Materials: 585 symptomatic uterine fibroids underwent pre-treatment MR evaluation to assess myoma characteristics and MRgFUS eligibility. 187(32%) were considered eligible for MRgFUS and treated with ExAblate-InSightec 2100 system, while 398 were ineligible and directed toward other therapeutic strategies. Of these, 137 patients underwent UAE, 143 myomectomy and 61 hysterectomy. The clinical outcome was evaluated by comparing the pre-treatment Symptoms Severity Score (SSS) with post-treatment SSS at the 3-month and 12-month follow-up. Data concerning the number and type of complications, days of hospitalization and days of convalescence were also collected and compared.
Results: The mean SSS reduction at 3 and 12 months was respectively 27,4% and 56,3% for the MRgFUS group; 48,7% and 56,9% for the UAE group; 69,8% and 67,1% for the myomectomy group; 96,6% and 94,5% for the hysterectomy group. The MRgFUS group demonstrated fewer complications (4 patients, 2,3%), while the major adverse events rate was reported in the UAE group (33 patients, 25,4%). All MRgFUS patients were treated in an outpatient setting, while the mean days for hospitalization and convalescence were, respectively, 3,4+/-2 and 11,7+/-9 days for the UAE group; 4,1+/-2 and 16,9+/-12 days for the myomectomy group; 4,5+/-1 and 24,6+/-14 days for the hysterectomy group.
Conclusion: The clinical efficacy of MRgFUS for uterine fibroids treatment is comparable to UAE, but slightly lower than that for myomectomy. However, MRgFUS is feasible in an outpatient setting and adverse events rate is significantly lower than that of other therapeutic strategies.

B-1542 14:33
Follow-up studies of uterine fibroids (UFs) treated with MRgFUS: who are the best candidates for treatment?
I. Capretti, S. Iafrate, E. Cannizzaro, F. Arrigoni, M. Di Luzio, A. Giordano, S. Mascaretti, G. Mascaretti, C. Masciocchi; *L'Aquila/IT*
(ilaria_capretti@hotmail.it)

Purpose: To investigate the individual variables that can influence a good clinical result in patients affected by symptomatic UFs and treated with MRgFUS.
Methods and Materials: A population of 110 women with symptomatic UFs (aged between 27 and 49) and treated with MRgFUS was retrospectively analyzed. These women were submitted to c.e.MRI immediately after treatment and after twelve months in order to evaluate the Non-Perfused Volume (NPV). Clinical outcome was investigated by means of a questionnaire about symptoms and health-related quality of life (UFS-QOL). Acoustic window, patients' BMI and distance from skin tissue to fibroid in the anterior or posterior uterine wall were considered as individual characteristics.
Results: All patients presented a mean value of NPV extension ranging between 68% and 81% after treatment and a reduction of 50% at twelve months. In 94 patients an improvement of symptomatology was observed: mean UFS-QOL value of 51.6 before treatment and 16.7 at the follow-up. Some women (70) became asymptomatic during the follow-up. Women with higher NPV ratio, appropriate and wide acoustic window, lower BMI and less distance between skin tissue and fibroid, in particular UFs of anterior uterine wall, achieved good clinical success.
Conclusion: MRgFUS may be considered a valid alternative therapy in patients affected by UFs. Some favorable conditions such as appropriate acoustic window and lower BMI and distance from the skin may be related to a better clinical success.

B-1543 14:41
Tips and tricks to treat difficult cases of uterine fibroids (UFs): how to increase elegibility in MRgFUS (magnetic resonance-guided focused ultrasound surgery)
S. Iafrate, I. Capretti, E. Cannizzaro, F. Arrigoni, M. Di Luzio, A. Giordano, S. Mascaretti, G. Mascaretti, C. Masciocchi; *L'Aquila/IT*
(sonia.iafrate87@gmail.com)

Purpose: To increase eligibility of uterine fibroids(UFs) treatment by MRgFUS,via some practical strategies,in order to obtain an adequate acoustic window for the ultrasound beam in difficult cases.

Methods and Materials: Fourteen patients affected by UFs,displaying an inadequate acoustic window to MRgFUS, were assessed from May 2014 to September 2016.Additionally to the common techniques used to obtain an adequate acoustic window,we tried to evaluate some strategies to increase the eligibility to the procedure.Inversion table together with abdominal massages were used to move up the bowel loops with the patients in antigravity position. To minimise intestinal bloating and peristalsis a low-fibre diet for a week before the MRgFUS was advised.Filling bladder to move-up bowel loops and filling rectum to outdistance the UFs from the sacrum were also used.The volume of treated UFs and Non perfuse volume(NPV) were calculated,while symptom outcome was assessed with a symptom severity score questionnaire (UFS-QOL).
Results: Fourteen patients, affected by UFS and with inadequate acoustic window, were evaluated.After using inversion table(20%),filling bladder and rectum(50%),low-fibre diet(30%) inadequate acoustic window was obtained and 10 patients underwent MRgFUS. A mean extension of NPV of 50-65% with a good effectiveness of the treatment was observed in all treated UFs. Furthermore, patients experienced a reduction of UFS-QOL around 70%,when compared with the pre-treatment score.No severe side effects were observed.Despite these practical strategies,4 patients were not treated due to inadequate acoustic window.
Conclusion: Some practical strategies may increase eligibility to MRgFUS obtaining an adequate acoustic window for the ultrasound beam; in these patients, MRgFUS may improve clinical outcome.

B-1544 14:49

Combined uterine artery embolisation with intra-arterial chemoinfusion as a sole management for scar and cervical ectopic pregnancy

A. Elmokadem, R. Abdel-Wahab, A.A. El-Zayadi, M. ElRakhawy; *Mansoura/EG (mokadem83@yahoo.com)*

Purpose: To evaluate the technical and clinical outcomes of uterine artery embolization (UAE) along with the chemoinfusion of methotrexate (MTX) for cesarean scar (CSP) and cervical pregnancy (CP) as an alternative nonsurgical treatment to control bleeding and uterine preservation.
Methods and Materials: This study included eleven patients (age range between 25-40 year, mean; 31.8) with 7 CSP & 4 CP. They presented with vaginal bleeding and elevated β-HCG levels (mean 31.245 mIU/mL). The diagnosis of ectopic pregnancy was confirmed by sonography and magnetic resonance imaging. They were treated with UAE using embolic particles (500-700 microns) and gelatin sponge particles. In all patients, the infusion of MTX (50mg/m2) was performed before UAE. Angiographic features as contrast extravasation and utero-ovarian anastomosis were reported. Follow-up periods after UAE ranged between 6 to 24 months included weekly sonography and β-HCG level assessment with MRI scan after 2 months.
Results: All patients had prior history of cesarean section. The gestational sac age range between 6-11 week. In ten patients, UAE controlled active vaginal bleeding and postprocedural HCG levels were reduced significantly by the second week . One patient presented with persistent elevated HCG level and vaginal rebleeding was encountered. The rebleeding was successfully controlled by second UAE procedure. The ectopic pregnancies were dramatically resolved & uterus was preserved in all patients. No major complications were detected. Normal menses resumed within 2 months after UAE.
Conclusion: UAE along with chemoinfusion of MTX is effective non surgical alternative for treating SCP and CP with uterine preservation.

Transperineal ultrasound-guided laser ablation for the treatment of benign prostatic hyperplasia in interventional radiology: preliminary results

G. Patelli[1], A. Ranieri[1], G.A. Paganelli[1], A. D'Alessio[2], F. Besana[1], G. Mauri[3], C.M. Pacella[4]; [1]*Seriate/IT*, [2]*Osio Sotto-Zingonia/IT*, [3]*Milan/IT*, [4]*Albano Laziale/IT (gianluigi.patelli@asst-bergamoest.it)*

Purpose: To assess the safety and efficacy of ultrasound-guided (US-g) transperineal laser ablation (TPLA) in treating benign prostatic hyperplasia (BPH).
Methods and Materials: fifty-five patients (age 72.6±10.4 years, range 58-93) suffering from obstructive syndrome secondary to BPH underwent TPLA using continuous wave (CW) diode laser source operating at 1064 nm (Echolaser SoracteLite, Elesta s.r.l., Calenzano (FI), Italy). Under US-g, depending on basal volume, up to two 21 G introducer needles for each lobe were inserted via transperineal approach. Each treatment was performed with a fixed power protocol (3W) changing the illumination time case by case according to the prostate volume. The efficacy of the treatment was evaluated considering the changes of International Prostate Symptoms Score (IPSS), Quality of Life(QoL), post-void residual (PVR), peak urinary flow rate (Qmax) and prostate volume. the mean hospital stay and mean catheterization time were measured.
Results: In all patients, the treatment was successful without intraoperative and perioperative complications. The mean operation time was 43.3±8.7 min, mean ablation time 15.9±3.9 min, mean energy deployed 11,470.0±3,570.6J, mean hospital stay 1.5±0.4 days and mean catheterization time after the procedure 14.4±7.7 days. The mean follow-up was 11.5 months (range 4-36). IPSS improved from 22.2 to 7.7 (P<0.001), QoL from 4.5 to 1 (P<0.001), Qmax from 7.6 to 13.3 ml/s (P=0.001), PVR from 148.0 to 58.2 ml (P<0.001) and mean prostate volume from 80.6 to 52.6 ml (P<0.001). No major complications occurred.
Conclusion: TPLA is a novel option to treat patients affected by BPH. The study demonstrated that this approach was efficacious and safe with significant and durable results.

B-1546 15:05

MRI-guided percutaneous transgluteal ablation of unilateral prostate carcinoma: initial experiences and results

J. Figiel, A. Koenig, A. Hegele, A. Mahnken; *Marburg/DE (figiel@med.uni-marburg.de)*

Purpose: To evaluate safety, periprocedural imaging features and short-term-outcome of MRI-guided percutaneous transgluteal cryo-ablation of focal prostate carcinoma in a 1.5T MR-scanner.
Methods and Materials: The analysis includes 10 consecutive Patients (age 46-75, average 60) with 11 interventions performed between 06/2016 and 07/2017. All patients had histologically proven unilateral prostate carcinoma (5 low risk, 6 intermediate risk). Pre- and postinterventional PSA-levels were measured. MRI-guided semigland-ablation was performed under general anesthesia via a transgluteal access. Realtime-imaging was used for positioning of the cryo-needle. Periprocedural imaging was used to monitor ice-ball formation. Rectum, urethral sphincter and bladder-tissue were spared. Postprocedural multiparametric MRI was performed to assess results after 1 day, 6 months and 12 months.
Results: Average procedure time was 2:41 h (2:07 h - 3:49 h). There were no major complications. One patient suffered hematuria for 4 weeks requiring no further treatment, one patient had a clinically irrelevant mucosal defect in the rectum and one patient had postinterventional urinary retention requiring prolonged transurethral catheterization. Peri- and postinterventional MRI showed full coverage of 9 lesions. In 1 lesions postinterventional biopsy revealed residual tumor and the intervention was repeated 10 months after initial procedure. PSA-levels declined by an average of 71,5% (18,2-99,5%). During follow-up no death or distant metastasis occurred.
Conclusion: Initial results show, that percutaneous MRI-guided cryoablation of focal prostate carcinoma is a safe and effective minimal-invasive therapy for a selected group of patients with prostate carcinoma. It may provide a viable alternative in patients under active surveillance.

B-1547 15:13

MR-guided focused ultrasound treatment for management of organ-confined intermediate-risk prostate cancer: evaluation of safety and effectiveness

S. Bednarova, A. Napoli, R. Scipione, S. Dababou, C. Marrocchio, H.-P. Erasmus, V. Panebianco, C. Catalano; *Rome/IT (sandra.bednarova@gmail.com)*

Purpose: To evaluate the safety and effectiveness of MR-guided focused ultrasound (MRgFUS) ablation of organ-confined intermediate-risk prostate cancer (PCa) in patients seeking urogenital functional preservation while controlling tumour growth, postponing or avoiding the need of definitive treatment.
Methods and Materials: This prospective single-arm study was approved by the institutional review board, and informed consent was obtained from all subjects. Sixteen treatment-naïve patients (age range 50-74 years) with histologically proven organ-confined intermediate-risk PCa (Gleason score ≤7=3+4/4+3, T1-T2b, N0, M0 stage, PSA≤20ng/ml) underwent pre-treatment 3T multiparametric MR imaging (mpMRI) and for MR visible lesions MRgFUS treatment with ExAblate (InSightec) was performed. Safety of treatment was determined by evaluation of the incidence and severity of device-related complications while clinical efficacy was evaluated in terms of prostate MRI changes and serum PSA (sPSa) levels at 3, 6 and 12 months follow-up.
Results: MRgFUS shows low operative morbidity and no systemic side effects: one patient reported urinary incontinence and two patients referred erectile dysfunction after treatment. Contrast-enhanced MRI (DCE-MRI) at 3, 6 and 12 months follow-up showed no recurrence/residual disease in treated patients. Progressive decrease of sPSA levels was encountered; an average value of 17.1 ng/ml before treatment dropped to 2.2 ng/ml at 12 months follow-up. Yet all patients included in this study are considered free of clinically significant PCa with no present need of definitive treatment.
Conclusion: MRgFUS can reduce the need of surgery or radiation therapy in patients with intermediate-risk prostate cancer representing a safe and effective treatment.

B-1548 15:21

MR-guided in-bore prostate biopsy for clinically significant cancer detection in patients with negative TRUS biopsies and rising PSA level

N. Matinyan[1], V. Kuplevatsky[2], I. Minasyan[1], M. Cherkashin[2], N. Berezina[2], D. Sahakyan[1]; [1]*Yerevan/AM*, [2]*St. Petersburg/RU (matinyan@doctor.com)*

Purpose: To evaluate the potential of MRI-guided prostate biopsy in individuals with negative TRUS biopsy and rising PSA level.
Methods and Materials: This study covered 91 patients (aged 40-70), with negative TRUS biopsy and rising PSA level, who underwent multiparametric MRI, with high-field 3T scanner (MAGNETOM Verio) or 1.5T scanners (MAGNETOM Aera and Symphony). Quantitative and qualitative assessment of changes were carried out in accordance with the recommendations of PI-RADSv2. MRI-guided in-bore biopsy was performed using a MRI-compatible "In vivo" biopsy set, with a 150mm/16g needle gun. To navigate and control the location of the needle, T2 WI was used in the sagittal and coronal projection.
Results: Based on the results of multiparametric MRI, 40 patients were graded as PI-RADS 3, 32 patients as PI-RADS 4 and 19 patients as PI-RADS 5. Based on the histological data after the MRI-guided biopsy, in the group of patients with PI-RADS 3 score, 32 were diagnosed with adenocarcinoma (in one case clinically insignificant cancer was diagnosed, in the rest Gleason score did not exceed 3+4=7). In the group of patients with PI-RADS 4 score, 28 were diagnosed with adenocarcinoma (with average Gleason score 4+3=7). In the group of patients with PI-RADS 5 score, 19 were diagnosed with adenocarcinoma (with average Gleason score 4+3=7).
Conclusion: The MRI-guided biopsy is an efficient procedure for detecting clinically significant prostate cancer in patients with previous negative TRUS biopsies results and rising PSA level.

Automated volumetry of peripheral pulmonary vessels based on CT angiography in suspected pulmonary hypertension

C. Melzig[1], O. Weinheimer[1], B. Egenlauf[1], M. Messerli[2], E. Grünig[1], H.-U. Kauczor[1], C. Heussel[1], F. Rengier[1]; [1]*Heidelberg/DE*, [2]*Zurich/CH (claudius1.melzig@med.uni-heidelberg.de)*

Purpose: To assess automated volumetry of the peripheral lung vasculature based on pulmonary CT angiography (CTPA) for the detection of pulmonary hypertension (PH).
Methods and Materials: 74 consecutive patients (mean 66.2 years, 50 female) who underwent right heart catheterization (RHC) and CTPA for suspected PH at our institution were included. Patients with chronic thromboembolic PH were excluded. In-house developed software was used for automated vessel segmentation. Vascular volumes within 10 mm, 15 mm and 20 mm of the lung borders were calculated.
Results: 42 out of 74 patients had PH (mean pulmonary arterial pressure (mPAP) 37±11 mmHg, 57%), while 32 had normal mPAP (17±4 mmHg). Peripheral vessel volumes were significantly enlarged in patients with PH compared to patients without PH: 86±29 vs. 66±23 cm^3 within 20 mm, 59±24 vs. 42±19 cm^3 within 15 mm and 31±17 vs. 19±14 cm^3 within 10 mm of the lung borders (all $p < 0.003$). ROC analysis showed AUC for the detection of PH of 0.73 for 20 mm, 0.74 for 15 mm and 0.75 for 10 mm of the peripheral vascular volume. A cutoff value of 19.4 cm^3 for the 10 mm peripheral vascular volume identified PH with 74% sensitivity, 72% specificity, 78% positive and 67% negative predictive value.
Conclusion: Automated volumetry of peripheral pulmonary vasculature is feasible and demonstrated significantly enlarged vessel volumes in patients with confirmed PH with the highest diagnostic accuracy within 10 mm of the lung periphery. The technique may facilitate non-invasive detection of PH.

B-1550 14:08

CT evaluation of small pulmonary vessel area in patients with bronchiolitis obliterans syndrome after lung transplantation

Y. Sato, J. Tominaga, N. Mori, Y. Matsuda, Y. Okada, K. Takase; *Sendai/JP (maroty0507@gmail.com)*

Purpose: To evaluate the cross-sectional area (CSA) of small pulmonary vessels measured on CT for detection of bronchiolitis obliterans syndrome (BOS) in patients who have undergone bilateral lung transplantation.
Methods and Materials: The institutional review board approved this study and waived informed consent. The study comprised consecutive 26 patients who underwent bilateral lung transplantation. The patients were divided into two groups: non-BOS and BOS on the basis of spirometry test. We measured CSA less than 5 mm^2 and calculated the percentage of total CSA for the lung area (%CSA<5) using plain chest CT. Three CT slices were selected for the measurement of CSA. The upper slice was taken 1 cm above the upper margin of the aortic arch, the middle slice was taken 1 cm below the carina, and the lower slice was taken 1 cm below the right inferior pulmonary vein. These three CT slices were analysed using ImageJ. The values of %CSA<5 were compared between the non-BOS and the BOS groups using the Mann-Whitney U test. $P<0.05$ indicated statistical significance.
Results: Six patients had BOS grade 0-p, two patients had BOS grade 2, and two patient had BOS grade 3. The remaining 16 patients had no BOS. Median %CSA<5 of the BOS group was significantly lower than that of the non-BOS group (0.49 versus 0.66, P=0.047). The ROC curve revealed that the area under the curve was 0.74.
Conclusion: CSA of small pulmonary vessels measured by CT may be useful for diagnosis of BOS after lung transplantation.

B-1551 14:16

High-resolution computerised tomography (HRCT) features of Group 1 pulmonary arterial hypertension (PAH): a case series of 21 lung transplant patients

M.S. Juárez-García, E. Pallisa, M. López-Meseguer, D. Varona Porres, A.L. Sanchez Martinez, E. Maciag, L. Cabanzo Campos, J. Andreu, O. Persiva Morenza; *Barcelona/ES (anchante.juarez@gmail.com)*

Purpose: Characterise HRCT features of PAH in a case series of patients who posteriorly received a uni-/bilung graft between the years 2010 and 2017.
Methods and Materials: We retrospectively evaluated a case series of 21 PAH patients and described the last pre-transplant thoracic/HRCT features. These features were analysed by two independent thoracic-radiologists at five levels: origin of great vessels; main carina; pulmonary venous confluence; halfway between the third and fifth section; above the right hemidiaphragm. We defined the disease extension and the extent of the primary and secondary radiological features at each level. Primary features were centrilobular nodules, ground-glass opacities, and interlobular septal smooth thickening. Secondary features were enlargement of mediastinal lymph nodes, pleural/pericardial effusion, and egg-banana sign.
Results: Eight patients had idiopathic/heritable PAH, five had scleroderma, four had pulmonary veno-occlusive disease/Group 1´(PVOD), and four had left heart disease. Almost all idiopathic/heritable PAH patients had all the primary and secondary HRCT features, except interlobular septal thickening, which was only described in one patient (12.5%). All scleroderma patients had more than 50% of disease extension and positive egg-banana sign; however, no patient had interlobular septal thickening. All PVOD patients had centrilobular nodules, interlobular septal thickening and mediastinal lymph node enlargement, but none had positive egg-banana sign. All left heart disease patients had centrilobular nodules and interlobular septal thickening, but none had lymph node enlargement or pleural/pericardial effusion.
Conclusion: In our case series, the scleroderma patients had the greatest lung disease extension and the highest positivity of egg-banana sign. All POVD patients showed the classical radiological features as described in the literature.

B-1552 14:24

Dual-energy CT (DECT) lung perfusion in chronic thromboembolic pulmonary hypertension (CTEPH): diagnostic accuracy and concordance with radionuclide scintigraphy

M. Masy, J. Giordano, C. Hossein-Foucher, G. Petyt, J. Remy, M. Remy-Jardin; *Lille/FR (martine.remy@chru-lille.fr)*

Purpose: To evaluate the concordance rate of DECT lung perfusion and ventilation/perfusion (V/Q) scintigraphy in diagnosing chronic thromboembolic pulmonary hypertension (CTEPH) amongst patients with proven pulmonary hypertension (PH).
Methods and Materials: 80 patients with proven PH underwent V/Q scintigraphy and DECT lung perfusion. Diagnosis of CTEPH was established by the presence of at least one segmental triangular perfusion defect on DECT perfusion images and by characteristic V/Q mismatch on scintigraphic examinations.
Results: The study population comprised 36 patients with CTEPH ("CTEPH group") and 44 patients with other aetiologies of PH (i.e. "non CTEPH group"). On DECT perfusion images alone, 35 were true positive, 6 false positive and 1 false negative (sensitivity: 0.97; specificity: 0.86; positive predictive value: 0.85; negative predictive value: 0.97). On V/Q scans, there were 36 true positives and 1 false positive (sensitivity: 1; specificity: 0.97; positive predictive value: 0.97; negative predictive value: 1). There was excellent agreement between DECT perfusion and scintigraphy in diagnosing CTEPH (kappa: 0.80). Combined information from DECT lung perfusion and CT angiographic images

enabled reclassification of (a) the 6 false-positive cases into the "non CTEPH group", triangular defects being related to small airway disease; (b) the false-negative case into the "CTEPH group", based on the finding of mild central and extensive peripheral chronic PE.
Conclusion: There is excellent agreement between DECT perfusion and V/Q scintigraphy. The diagnostic accuracy of DECT is reinforced by the morpho-functional analysis of datasets.

Overdiagnosis of PE in pregnancy? Interpretative discrepancy in the diagnosis of pulmonary embolism in pregnant patients undergoing CTPA
D.P. Mitchell, C.D. Gillespie, H. Moriarty, C.A. Ridge, P.J. MacMahon;
Dublin/IE (dpmmitchell@gmail.com)

Purpose: To evaluate the rate of discrepancy in the diagnosis of PE in pregnant patients undergoing CTPA.
Methods and Materials: Retrospective review of all CTPA studies performed on pregnant patients referred to a tertiary referral centre over a two-year period. CTPA studies reported as positive for PE were matched with negative CTPA studies. This mixed subset was blindly reviewed by two subspecialist radiologists. CTPA study quality and thrombus volume was recorded.
Results: 98 CTPA studies were performed on pregnant patients over the two-year period. 14% (14/98) of studies were initially read as positive for PE. A subset of 30 studies (14 PE-positive and 16 PE-negative studies) were blindly assessed by two sub-specialist reviewers. There was 97% agreement between reviewers (29/30 studies). 1 study was considered nondiagnostic and 3 studies were determined to be suboptimal but sufficient for the diagnosis of a large- or medium-sized PE. The diagnostic agreement between the reviewers and the initial reporting radiologist in 83% (25/30). 36% (5/14) of "PE positive" studies were reclassified as false positives.
Conclusion: There was a higher than expected rate of discrepancy in the interpretation of positive CTPA studies. By raising awareness of this issue of PE over-diagnosis, the percentage of CTPAs reported as positive for PE dropped from 14% to 2% in our institution. We strongly recommend the addition of "MDT review" to the diagnostic treatment algorithm for all positive PE cases in pregnancy to ensure a subspeciality double read of all positive CTPA studies.

B-1555 14:40

Indeterminate CT pulmonary angiograms (CTPA) with dual-source CT (DSCT): prospective evaluation in 449 patients suspected of acute pulmonary embolism (PE)
J. Hennicaux, A. Hutt, J.-B. Faivre, S. Khung, J. Remy, M. Remy-Jardin;
Lille/FR (martine.remy@chru-lille.fr)

Purpose: To evaluate (a) the rate of indeterminate CTPA acquired with a 3rd-generation DSCT system; and (b) the impact of correcting factors immediately applicable.
Methods and Materials: 449 patients underwent a DSCT angiogram with single- (SE) (n=276; 61.5%) or dual-energy (DE) CT (n=173; 38.5%). An indeterminate study was defined by (a) a totally nondiagnostic examination; or (b) an examination limiting the level of analyzability of pulmonary arteries to central vessels.
Results: Twelve CTPAs (12/449; 2.7%) were deemed indeterminate with a proportion that did not differ between examinations acquired with SE (9/276; 3.2%) and DE (3/173; 1.73%) (p=0.38). The contributing factors comprised (a) motion artifacts due to the lack of patient cooperation (1/12) ; (b) a poor level of enhancement (6/12); or (c) patient-related limitations (5/12). In the case of indeterminate SE examination (n=9): (a) a second acquisition was immediately obtained after correction of the presumed contributing factor: (i) repeated instructions to maintain apnea (1/9); (ii) selection of a lower kVp, higher iodine concentration or both (7/9); (iii) no change in the repeat CTPA (1/9); (b) the second acquisition was subsequently diagnostic in all but one patient. In the case of DE indeterminate acquisitions (n=3), the reading of low-kVp images restored a diagnostic image quality. After correction, the final rate of indeterminate CTPA was 0.2% (1/449).
Conclusion: The rate of indeterminate CTPA decreased from 2.7% to 0.2% after a second acquisition (SE) or the reading of low-kVp images of the initial acquisition (DE).

Significant reduction of contrast agent dose for venous phase chest CT scans: first experiences using monoenergetic reconstructions from a novel spectral detector scanner
T. Hickethier, J. Kröger, B. Baessler, D. Maintz, D.-H. Chang; *Cologne/DE (tilman.hickethier@uk-koeln.de)*

Purpose: Monoenergetic reconstructions (MonoE) from Dual-Energy-CT systems can elevate iodine attenuation and therefore might permit a significant reduction of contrast agent dose. In this study, we investigated the influence of MonoE from a novel Spectral-Detector-CT (SDCT) on delineation of mediastinal structures and overall image quality in chest CT examinations with significantly reduced contrast agent dose (>50%).
Methods and Materials: 41 patients underwent venous phase CT scans of the chest on a SDCT (IQon, Philips) and 35 instead of 75ml contrast agent followed by a NaCl flush of 60 ml. Images were calculated conventionally (Conv) and with MonoE at 40 keV. Contrast-to-noise-ratio (CNR) was measured for a hilar lymph-node (LN) as well as its attenuation difference to the adjacent pulmonary artery (LNPA). Image quality (IQ) was evaluated by 2 readers with respect to overall diagnostic certainty (ODC) and LN delineation (LND) using a 5-point-Likert-scale: 1=non-diagnostic; 2=barely diagnostic; 3=fair; 4=adequate; 5=excellent.
Results: Both subjective IQ parameters were significantly improved using MonoE compared to Conv (ODC 4.2 vs. 2.7; p<.01 / LND: 3.8 vs. 2.3; p<.01). The IQ of all MonoE reconstructions was rated at least as adequate without any non-diagnostic results. Objectively measured CNR and LNPA were superior using MonoE compared to Conv (CNR 14.18 vs. 5.96; p<.01 / LNPA 111.99 vs. 38.02 HU; p<.01).
Conclusion: In venous phase chest CT scans with markedly reduced contrast agent dose subjective image impression and objective IQ parameters can be significantly improved by using monoenergetic reconstructions from a novel SDCT.

Investigation of a roll pump contrast media injector for individually adapted iodine concentrations
I. Rychina[1], T. Rienmüller[2], V. Makarenko[1], V. Bereznitskiy[1], A. Tikhonov[1], J.A. Oreshkova[1], P. Frank[3], L. Bockeria[1], R. Rienmüller[2]; [1]*Moscow/RU*, [2]*Graz/AT*, [3]*Ulm/DE (rainer@rienmueller.net)*

Purpose: To investigate the precision of different iodine concentrations obtained using an automatic contrast media (CM) injector and commercially available CM with higher iodine concentration.
Methods and Materials: Starting from an initial concentration of 320 (Iodixanol, blood iso-osmolarity) and 350 mgI/ml (Iohexol, low osmolarity) the CM were sequentially mixed with physiological NaCl-solution using the CT motion XD 8000 ulrich medical automatic CM injector with an injection speed of 2, 5, and 8 ml/s. The Iodine concentration was reduced in steps of 10% down to 50% of the starting concentrations. Calibration standards were prepared diluting the initial solutions with distilled water. High-performance liquid chromatography (HPLC) measurements of the probes were performed on Agile 1290 Infinity instrument equipped with ZORBAX Eclipse Plus C18 column maintained at 30°C and UV/Vis detector. The relative deviation of probes from the desired concentration was computed.
Results: For Iodixanol 320 an average relative deviation of 6.91% (min 1.5, max 12.63%) at an injection speed of 2 ml/s, 6.03% (min: 0.88, max: 16.89%) at 5 ml/s and 3.38% (min: 0.07, max: 9.37%) at 8 ml/s was obtained. Iohexol 350 showed an average relative error of 4.26% (min 0.3, max 7.8%) at 2 ml/s, 5.13% (min 1.2, max 9.6%) at 5 ml/s and 2.9% (min 1.1, max 5.1%) at 8 ml/s.
Conclusion: Our data confirm the feasibility of obtaining the desired iodine concentration using the automatic roll pump CM injector under investigation.

Lesion detection on the "all-in-one" window: is it as good as on conventional window settings? A feasibility study
A. Snoeckx[1], B. Broeckx[2], K. Carpentier[1], R. Corthouts[1], E. Luyckx[1], S. Nicolay[1], M.J. Spinhoven[1], A. Van Hoyweghen[1], J. Cant[3]; [1]*Edegem/BE*, [2]*Merelbeke/BE*, [3]*Mortsel/BE (annemie.snoeckx@uza.be)*

Purpose: Historically, CT studies are always viewed in several window settings, optimized to evaluate specific anatomic structures and regions (mediastinal, lung, bone and vascular window). A newly developed image processing technique fuses these conventional windows into a single "all-in-one" window. Our purpose was to compare lesion detection on this "all-in-one" window versus conventional window settings.
Methods and Materials: In this study, 50 consecutive thoracic oncology chest CT examinations, containing 417 documented lesions and features, were reviewed by 6 radiologists, subdivided into 2 groups of 3 radiologists each, with

similar levels of expertise in each group (experienced, junior and radiology resident). All scans were reviewed in conventional window settings (as in routine daily practice), by one group, and in the "all-in-one" window by the other group. Lesions were listed as 'missed' when they were not seen by at least two out of three observers and as 'well diagnosed' when seen by at least two out of three observers.
Results: Out of the 417 lesions, 68 lesions were missed: 21 on the "all-in-one" window, 30 on conventional views and 17 on both views. Statistical analysis with linear mixed model showed that use of the "all-in-one" window did not result in an increase of missed lesions (p=1). Conversely, we found a tendency towards better lesion detection on the "all-in-one" window, though not strongly significant (p=0.07). Inter-observer agreement in both groups was similar (p=0.462).
Conclusion: In chest CT examinations, lesion detection on the "all-in-one" window is at least as good as on conventional window settings.

The influence of intelligent optimum tube voltage-combined low dose of contrast medium injection based on BMI on radiation dose and image quality of chest CT enhancement
Y. Zhou; *Zhengzhou/CN (zhouyue779@163.com)*

Purpose: To investigate influence of intelligent optimum tube voltage-combined low dose of contrast medium based on BMI on radiation dose and image quality of chest CT enhancement.
Methods and Materials: 104 patients who received spectral chest CT enhancement were randomly divided into groups A and B: group A with conventional 120 kVp, 450mgI/Kg contrast medium injection; group B with intelligent optimum tube voltage, 300mgI/Kg contrast medium injection. Patients were divided into three sub-groups based on BMI. Subjective image quality score, SNR, CNR of descending aorta at different layers and radiation dose were compared.
Results: Image quality scores of A1, A2 were higher than that of B1, B2 during arterial phase, while no significant difference during venous phase. A3 and B3 showed no statistical difference during arterial and venous phase. CNR of descending aorta at tracheal bifurcation, right pulmonary artery layer in A1 and B1, left/right atrium layer in A2 and B2, left/right atrium layer in A3 and B3 during venous phase have no statistical difference, other layers in group B were higher than that of group A. SNR in group B was superior to that of group A. Radiation dose in A1, A2 were lower vs B1, B2, dropped by 16.39% and 14.50%, respectively; however, there was no significant difference between A3 and B3.
Conclusion: Optimal tube voltage can be selected according to BMI using intelligent optimum tube voltage technique, which can reduce radiation dose and improve CNR. Combined low-contrast medium infection can reduce contrast agent injection and maintain image quality.

A prospective study to compare the outcomes of MRF-TB and 12-core SB in different PSA groups
J.-M. Xu, Y.Q. Chen; *Shanghai/CN (junmei_510@126.com)*

Purpose: To assess and compare the rate of detection of clinically significant prostate cancer (csPCa) between magnetic resonance imaging (MRI)-ultrasound fusion-targeted prostate biopsy (MRF-TB) and 12-core systematic biopsy (SB) in the different prostate-specific antigen (PSA) groups.
Methods and Materials: This prospective study included 156 patients who underwent pre-biopsy MRI and 12-core SB between September 2014 and August 2016. In the patients with MRI-suspicious lesions (n=123), MRF-TB was performed before SB. In the clinically suspicious patients with normal MRI (n=33), SB was performed without MRF-TB. The detection rates for any cancer and csPCa were compared between MRF-TB and SB.
Results: Detection rate for any cancer was not significantly different between MRF-TB (64/123, 52.0%) and SB (66/156, 42.3%; p=0.106). For csPCa, the detection rate of MRF-TB (61/123, 49.6%) was significantly higher than that of SB (46/156, 29.5%; p=0.001). In a subset analysis of patients with PSA<10ng/ml, csPCa detection rate of MRF-TB (26/67, 38.8%) was significantly higher than that of SB (16/83, 19.3%; p=0.008). In 10≤PSA<20ng/ml group, csPCa detection rate of MRF-TB (20/38, 52.6%) was also significantly higher than that of SB (15/52, 28.8%; p=0.022). In PSA≥20ng/ml group, csPCa detection rate of MRF-TB (15/18, 83.3%) was higher than that of SB (15/21, 71.4%), but no significant difference was found (p=0.379).
Conclusion: Our prospective study revealed a similar rate of prostate cancer detection between MRF-TB and SB, and MRF-TB could improve the overall detection of csPCa compared to SB. We also found that MRF-TB was superior to SB for csPCa detection in subset patients with PSA<10ng/ml and 10≤PSA<20ng/ml, but was similar in patients with PSA≥20ng/ml. Therefore, the traditional SB may be replaced by MRF-TB for detection of csPCa.

B-1561 14:08

The accuracy of MRI/TRUS fusion biopsy in detection of high-risk prostate cancer vs random biopsies: advertisement or necessary innovation?
F. Kossov[1], I.I. Abdullin[1], B. Kamolov[1], B. Olimov[1], O. Orlov[1], V. Panov[1], I. Tyurin[1], E. Fedorenko[1], V. Kapustin[2]; [1]*Moscow/RU*, [2]*Moscow Oblast/RU (fil-doc@yandex.ru)*

Purpose: Systematic biopsies (SB) are an integral part of prostate cancer (PCa) diagnostics. SB PCa detection varies from 31% to 42%; however, the number of false-negative results is high. MRI/TRUS fusion target biopsy (MRI/TRUS FTB) probably would improve the detection of high-risk cancer (HRC) both in initial biopsy and in patients with preliminary negative SB results.
Methods and Materials: 82 patients with suspected PCa were examined. The criteria of patients inclusion was the presence of: 1) PSA>4 ng/ml and positive results of the digital rectal examination; 2) mpMRI data. The examination includes: 1) prostate mpMRI; 2) MRI/TRUS FTB; 3) SB.
Results: PCa was detected in 66 cases (including 12 cases with previously negative SB). MRI/TRUS FTB PCa detection rate includes: 1) 13.3% cases with Gleason=6; 2) 33.5% with Gleason=7; 3) 53.2% with Gleason=8-10. SB evaluates PCa in: 1) 27.8% patients with Gleason=6; 2) 38.9% with Gleason=7; 3) 27.8% with Gleason=8-10. MRI/TRUS FTB data is significantly highly competitive in high malignancy potential nodes detection with SB (p<0.0001). The HRC detection accuracy using MRI/TRUS FTB appears higher in comparison with SB data (p<0.0001). MRI data (estimated by PI-RADS v.2) showed significant correlation with the MRI/TRUS FTB results (p<0.02, correlation coefficient 0.7).
Conclusion: The MRI/TRUS FTB provides an opportunity to decrease the necessary number of punctures in PCa patients for detection of the histological material with the highest malignancy rate. MRI/TRUS FTB exposes low sensibility to insignificant PCa. It increases the detection of clinically relevant forms of PCa.

B-1562 14:16

MRI/US fusion prostate biopsy a single-centre experience
C. Cicero, E. Lievore, A. Casarin, B. De concilio, A. Celia, L. Genesio, A. Guarise; *Bassano del Grappa/IT (aircalo@yahoo.it)*

Purpose: MRI-US fusion biopsy system is a diagnostic procedure which permits the withdrawal of prostate specimens directly from a suspected lesion seen at MRI, bypassing random prostate biopsies. We studied the efficacy of the method among the patients evaluated in our facility.
Methods and Materials: 150 patients with findings suspicious for PCa (mean age 65,5 years, median PSA 5,533ng/mL and median prostate volume 59cc) underwent mpMRI. All the mpMRI were evaluated by a specialised uroradiologist. The suspected lesions were classified according to the PI-RADS and marked. Data were transferred in the Biopsee® system and, with superimposition of MRI on real-time transrectal US, three-dimensional biopsy planning was conducted and transperineal biopsies were performed according to the planning. We conducted statistical evaluation of cancer detection in these patients.
Results: 58 out of 150 patients (39%) were found positive for PCa. The correlation between mpMRI findings and histologic evaluation was satisfactory for lesion marked as PI-RADS 5 or highly suspicious for PCa (34 over 52 or 65%) but mild for lesions classified as PI-RADS 4 or moderately suspicious for PCa (28 over 106 or 26,5%). Regarding complications, three patients were affected by acute urinary retention and one experienced haematuria.
Conclusion: Transperineal stereotactic prostate biopsy combining US/MR enables targeted evaluation of suspected lesions. The method is safe with few complications. The correlation between PI-RADS and histologic lesion approximates the results of similarly-conducted studies. The procedure is overall promising, and opens to other utilisations beyond the detection of PCa, such as focal therapy and active surveillance.

B-1563 14:24

Transrectal ultrasound-guided targeted biopsy of transition zone prostate cancer: usefulness of across midline sign

S. Park, S. Won; *Seoul/KR (WSY0622@yuhs.ac)*

Purpose: To retrospectively evaluate diagnostic performance of transrectal ultrasound (TRUS)-guided targeted biopsy (TB) of transition zone (TZ) prostate cancer (PCa) in patients with prebiopsy magnetic resonance imaging (MRI).
Methods and Materials: Consecutive series of 38 patients who underwent TRUS-guided TB of TZ lesions were evaluated. TB (mean core number, 2.4±0.6; range, 2-4) was performed by a single experienced radiologist under cognitive registration between prebiopsy MRI and TRUS. Across midline sign was defined by a focal lesion traversing the midline of prostatic TZ on MRI and TRUS, leading to discontinuity of the midline. Prostate Imaging-Reporting and Data System version 2 (PI-RADSv2) scoring for targeted TZ lesions was also conducted with T2-weighted and diffusion-weighted MRI by the same radiologist.
Results: PI-RADSv2 categories from 2 to 5 for TZ lesions consisted of 4, 14, 7, and 13. Cancer detection rate of TRUS-guided TB for TZ lesions was 78.9% (30/38). Across midline sign was identified in 50.0% (19/38). Cancer detection rate of TRUS-guided TB for TZ lesions showing across midline sign on both MRI and TRUS was 94.7% (18/19).
Conclusion: Under cognitive registration, TRUS-guided TB for TZ lesions showing across midline sign on both MRI and TRUS may be highly predictive of TZ PCa.

B-1564 14:32

In-bore biopsies of the prostate assisted by a remote-controlled manipulator at 1.5 T

N.P. Linder, A. Schaudinn, T.-O. Petersen, R. Stange, M. Moche, P. Stumpp, T. Kahn, H. Busse; *Leipzig/DE (linder@uniklinik-leipzig.de)*

Purpose: To evaluate technical and clinical performance of a fully MRI-compatible, pneumatically driven remote-controlled manipulator (RCM, "robot") for 1.5-T in-bore biopsies of the prostate.
Methods and Materials: This preliminary prospective study included the first 15 patients that underwent robotic (Soteria Medical, Arnhem, Netherlands), in-bore biopsies of the prostate in a wide-bore 1.5 T MRI (Magnetom Aera, Siemens Healthcare, Erlangen, Germany). Targeting and control of the transrectal needle guide were realized by rapid MR imaging (balanced SSFP sequence with acquisition times around 10 s). Biopsies were performed by two radiologists, each with 4 years of experience with prostate interventions. Analysis involved pre-biopsy MRI reports (PIRADS version 2), procedure times (between planning and final control MRI), periprocedural complications and histopathologic results of the samples.
Results: Mean age (range) was 67 (54 - 80) years and mean PSA level was 11.1 (0.7 - 21.5) ng/dl. Twelve patients (80%) had received prior biopsies under transrectal ultrasound guidance. Prebiopsy MRI reports involved 12 cases with a single suspicious finding (2x PIRADS 3, 5x "P4" and 5x "P5") and 3 cases with two ones (2x "P3" and 1x "P5"). Histopathologic examination revealed prostate cancer in 7 of 15 cases. One patient developed urosepsis which was successfully treated with antibiotics. Procedure times ranged between 26 and 85 min.
Conclusion: In-bore, transrectal prostate biopsies could be successfully performed with a robotic manipulator at a field strength of 1.5 T. Unlike with passive interventional devices, the patient may remain inside the bore for needle-guide adjustments.

B-1565 14:40

Experience with MRI guided prostate biopsies using the 3D Navigo system in an oncologic referral centre

S. Heijmink, R. van den Bergh, E. Wit, H. van der Poel; *Amsterdam/NL (swheijmink@live.com)*

Purpose: Multiparametric (mp) MRI has the potential to increase biopsy yield of prostate cancer detection. This study presents experiences with the Navigo system for MRI-TRUS fusion.
Methods and Materials: Navigo MRI-TRUS fusion biopsies was performed from 2015-2017. All patients received prebiopsy 3TmpMRI. Dependent on biopsy indication, random non-guided biopsies were taken in the same session. We recorded any encountered problems, compared Navigo and NG biopsy cancer detection rates, and explored predictors for positive biopsy outcome.
Results: Navigo biopsies were planned in 228 patients for diverse indications, of whom 26 (11%) could not be performed. In 18 (9%) of the remaining patients a problem was reported during the procedure. Any of the guided biopsies was positive in 24-85%, dependent on indication. Of the 202 Navigo procedures, additional non-guided cores were taken in 99 patients. Similar results between Navigo and non-guided biopsies were found for any positive biopsy rate, %positive cores, and mean Gleason score (all $p>0.05$), but the absolute number of cores taken was almost half for the Navigo biopsies. Lowest lesion mean ADC was a persistent predictor in multivariable analysis for positive biopsy outcomes.
Conclusion: The benefit of 3TmpMRI targeted Navigo fusion biopsies was seen in the lower number of biopsy cores needed, but not in cancer detection rate or mean Gleason score. In patients without primary diagnosis, guided biopsies did not obviate the need for additional random biopsies. ADC was the main biopsy outcome predictor for guided and non-guided biopsies.

B-1566 14:48

Typical MR imaging findings after HIFU-hemiablation of the prostate

N.P. Linder[1], J. Michaelis[1], J. Gawlitza[1], H. Busse[1], P. Ho-Thi[1], T. Kahn[1], P. Stumpp[†], R. Ganzer[2], A. Schaudinn[1]; [1]*Leipzig/DE*, [2]*Bad Tölz/DE (linder@uniklinik-leipzig.de)*

Purpose: To evaluate MR imaging features of the prostate after high-intensity focused ultrasound (HIFU) treatment of the hemigland.
Methods and Materials: Eighteen patients with a mean age of 67.1 (48.9-78.5) years, mean Prostate-specific-Antigen level of 6.35 (4.0-9.8) ng/dl and biopsy-proven unilateral Prostate Cancer (PCa) received MRI before and 12 months after HIFU (Hemiablation, Focal One). MR/ultrasound fusion-guided Biopsy was performed after 12 months to exclude recurrent/contralateral cancer. MRI (3T) followed PIRADS version 2 guidelines with T2 TSE, diffusion-weighted imaging (DWI) and dynamic-contrast enhanced-T1 imaging (DCE). MR-analysis included quantitative and qualitative imaging characteristics, such as T2-volumetry, DCE and DWI signal-intensity measurements.
Results: Treatment resulted in a mean volume reduction of the target lobe by 49.1% (27.9-69.5%) and of the whole gland by 28.1% (1.0-45.6%), respectively. The typical image patterns of the ablated lobe consisted of a centrally positioned, T2-hyperintens, well circumscribed area, defined as seroma and/or a T2-hypointens area with heterogeneous DWI signal intensity, interpreted as scar, mainly adjacent laterally to the seroma. The combination seroma/scar was observed in 16 of 18 patients, whereas only scar was observed in 2 cases. In 50% of the cases a rim-like contrast media uptake around the ablation area was observed. MRI detected one of four cases of biopsy-proven low grade contralateral PCa and none of two cases of ipsilateral recurrent PCa (Ø Gleason: 6.5).
Conclusion: MRI analysis revealed distinct image patterns at 12 months after hemiablation, such as seroma, scar and volume reduction. However detection rate of recurrent or contralateral prostate cancer was low.

B-1567 14:56

Six months follow-up of periprostatic nerve plexus changes after robot-assisted radical prostatectomy using MRI tractography.

A. Cybulski, S. Brancato, V. Di Paola, R. Negrelli, E. Boninsegna, M. Catania, A. Tafuri, S. Siracusano, R. Pozzi Mucelli; *Verona/IT (sarix_89@hotmail.it)*

Purpose: To evaluate early and late modifications of periprostatic nerve plexus (PNP) after robot-assisted radical prostatectomy (RARP) with MRI tractography and their clinical correlations.
Methods and Materials: 34 patients (mean age:64,8) candidate to RARP performed 3 MRI examinations completed with 32-directions DTI sequences respectively before, 1 (mean:39,4 days) and 6 months (mean:201,7 days) after RARP. Tractography reconstructions were performed by positioning 6 ROIs of PNP, evaluating the following parameters: number of fibers(N), number of voxels(V), fractional anisotropy(FA), apparent diffusion coefficient(ADC), fiber length(L). Before each MRI, 2 questionnaires were administered to investigate urinary continence(ICIQ-SF) and erectile function(IIEF-5). Each tractography parameter of the 3 examinations was compared using Student's T-test and was correlated with urinary incontinence and erectile dysfunction using Kendall's-tau test.
Results: Reduction of N and V was observed 1 month after RARP, without any increment at 6 months. 1 month-MRI demonstrates reduction of FA, which returns to pre-surgery values at 6 months-control. Reduction of ADC was observed at 6 months-MRI compared with the previous examinations ($p<0,001$). No modification of L emerged. Positive correlation has been established between N($\tau=0,297$), V($\tau=0,282$), FA($\tau=-0,249$) and potency and between N($\tau=-0,257$), V($\tau=-0,231$) and urinary continence($p\leq0,001$).
Conclusion: MRI tractography is able to identify complex changes regarding the number of fibers(N and V reduction post-RARP) and fiber patterns of PNP(FA reduction at 1 month, growing up back to pre-surgery values at 6 months). These changes correlate both with potency and urinary continence.

B-1568 15:04

Predicting and improving postprostatectomy urinary continence by pelvic floor measures on MR

S. Heijmink, N. Grivas, C. Tillier, R. van der Roest, E. van Muilekom, H. van der Poel; *Amsterdam/NL (swheijmink@live.com)*

Purpose: Urinary incontinence is a frequent complication of prostatectomy. MRI imaging of pelvic floor musculature has learned that several anatomical characteristics predict postprostatectomy continence function. We used this

information to attempt reconstruction of the pelvic floor after prostatectomy to improve continence outcome.
Methods and Materials: In 439 patients preprostatectomy MRI images were correlated to functional outcome continence scores (ICIQ-SF) for 10 pelvic measurements. Based on the obtained measures we changed the pelvic floor reconstruction from median fibrous raphe reconstruction only and added medialisation of the anterior muscle fibers of the levator ani muscle behind the urethra. In a prospective comparative analysis we studied the 6 months postoperative ICIQ-SF score in men with median fibrous raphe reconstruction with or without levator suspension and standard urethral-bladder anastomosis.
Results: A longer membranous urethral length (MUL), smaller interlevator distance (ILD) and more extpensive fascia preservation score were predictive of earlier continence recovery. We developed an algorithm to predict continence outcome after prostatectomy based on these predictors. Since we hypothesized that narrowing of the pelvic floor exit by medializing anterior fibers of the levator ani muscle would artificially decrease ILD and elongate MUL and therefore improve postprostatectomy continence we performed this procedure in 211 men undergoing RARP. In comparison to standard (n=1375) or median fibrous raphe reconstruction (n=271) bladder-urethral anastomosis, MALF addition improved early (3w) (p=0.01) but not late (6m) continence recovery.
Conclusion: MRI-based pelvic floor prostatometry individualizes prediction of postprostatectomy continence. Increasing pelvic floor support of the urethra improves early, but not overall continence.

B-1569 15:12

Correlation of short- and long-term urinary continence after radical prostatectomy with findings of preoperative multiparametric prostate MRI
M. Sauer, R. Pompe, P. Tennstedt, L. Budaeus, G. Salomon, G. Adam, D. Beyersdorff; *Hamburg/DE (m.sauer@uke.de)*

Purpose: To evaluate whether preoperative multiparametric prostate MRI (mpMRI) can help to stratify the risk of urinary continence (UC) after radical prostatectomy (RP) based on specified image findings.
Methods and Materials: Our institutional review board approved this retrospective study. 233 patients (median age 66.1 years) underwent standardized mpMRI at 3T prior to prostatectomy, including high-resolution T2w-TSE-imaging in 3 planes, T1w-TSE, DWI with ADC map, PD-TSE and Gd-DCE. Membranous urethra length, urethra angle and apex shape were measured systematically in T2w sequences in the sagittal plane. Prostate volume was determined during transrectal sonography. Image findings and clinical data (age, type of surgery) were correlated to UC as evaluated by a standardized questionnaire determining the amount of necessary hygiene pads one week (response rate 100%) and one year after surgery (response rate 61.4%; n=143 patients).
Results: Of all clinical parameters, there was a small yet significant positive correlation of age with UC one week (Spearman r=0.27, p=0.0001) and one year after surgery (r=0.20, p=0.02). Urethra angle and apex shape as measured in mpMRI did not correlate significantly with UC at neither time point. Correlation of the membranous urethra length with UC was small negative after one week (r=-0.22, p=0.001) and close to medium negative after one year (r=-0.29, p=0.001). Sonographic prostate volume did not correlate with UC and will be complemented by outstanding MRI volumetries.
Conclusion: Measurements of the membranous urethra length in mpMRI correlate with short- and long-term UC after radical prostatectomy and should be acknowledged during preoperative risk stratification.

B-1570 15:20

Additional value of early imaging of ^{68}Ga-PSMA-11 PET/CT in the assessment of local recurrence in prostate cancer patients with biochemical relapse
C. Uprimny, A. Kroiss, C. Decristoforo, J. Fritz, B. Nilica, W. Horninger, I. Virgolini; *Innsbruck/AT (Christian.UPRIMNY@tirol-kliniken.at)*

Purpose: Evaluation of local recurrence (LR) in prostate cancer patients with biochemical recurrence is hampered by high physiologic urinary bladder activity present on ^{68}Ga-PSMA-11 PET/CT exams, usually conducted 60 min after tracer injection (p.i.). This study aims to investigate whether additional early static PET scans could enhance diagnostic performance of ^{68}Ga-PSMA-11 PET/CT in the evaluation of LR.
Methods and Materials: 213 prostate cancer patients with biochemical recurrence referred to ^{68}Ga-PSMA-11 PET/CT were analysed retrospectively (median PSA: 1.47 ng/ml). In all patients an early static scan of the pelvis was performed with a median starting time of 281 sec p.i., followed by a whole-body PET/CT 60 min p.i. Image interpretation was based on visual analysis. Furthermore, calculation of maximum standardized uptake value (SUV_{max}) of pathologic lesions was performed.
Results: On standard PET images 60 min p.i. a LR-suggestive lesion (median SUV_{max}: 11.0) could be detected in 28 patients (13.1%), whereas an equivocal finding was present in 36 patients (16.9%). In contrast, on early PET scans a pathologic lesion compatible with LR was revealed in 52 patients (median SUV_{max}: 5.9) and an unclear finding in only nine patients (4.2%). Early PET images led to a significant rise in the detection rate (p<0.001) as well as a significant reduction of equivocal findings (p<0.001) compared to PET-imaging 60 min p.i.
Conclusion: Assessment of local recurrence in prostate cancer patients with biochemical relapse referred to ^{68}Ga-PSMA-11 PET/CT is improved by additional early PET imaging.

Lung cancer screening with MRI: application of Lung-RADS in the first two screening rounds
M. Meier-Schroers, R. Homsi, H. Schild, D. Thomas; *Bonn/DE (michael.meier@ukbonn.de)*

Purpose: To evaluate if Lung-RADS can be applied for MRI based on the results of the first two rounds of a lung cancer screening.
Methods and Materials: 224 participants of a lung cancer screening were examined with MRI and low-dose CT (LDCT). Acquired sequences were T2-MVXD, balanced-FFE, 3D-T1, and DWI. MRI was prospectively analysed regarding nodules blinded to LDCT (minimum nodule size 4mm). Nodules were assigned a Lung-RADS score based on their appearance and size at baseline and in follow-up examinations after 3, 6, and 12 months. MRI findings were correlated with LDCT.
Results: The early recall rate dropped from 13.8% at baseline to 1.9% in the second round with biopsy rates of 3.6% in the first round and 0.5% in the second round. All eight lung cancers were accurately depicted by MRI. The following categories were assigned on MRI with results of LDCT in parentheses: 4B/4X in 10 (10) cases, 4A in 16 (15) cases, 3 in 13 (12) cases, 2 in 77 (92) cases, 1 in 140 (126) cases. Lung-RADS scoring significantly correlated between MRI and CT (p<0.001). The score was overestimated by MRI in one case for category 4A, in two cases for category 3, and in five cases for category 2. The MRI-based Lung-RADS score was only underestimated for category 1 in 20 cases.
Conclusion: Lung-RADS might be applied for lung cancer screening with MRI, since findings significantly correlated with LDCT. Relevant findings with a Lung-RADS score of ≥3 were never missed or underestimated by MRI.

B-1572 14:08

The value of diffusion-weighted imaging based on monoexponential and biexponential model in the diagnosis of benign and malignant lung nodules and masses
J. Jiang[1], L. Cui[2], X. Gu[3], Q. Hong[1], Y. Fu[1], G. Xu[1]; [1]*Yancheng/CN*, [2]*Nantong/CN*, [3]*Suzhou/CN (1021809719@qq.com)*

Purpose: To compare the value of lesion-to-spinal cord signal-intensity ratio (LSR), apparent diffusion coefficient (ADC) and intravoxel incoherent motion (IVIM) parameters in the differention of pulmonary nodules and masses, and to explore the preferred region-of-interest (ROI) method.
Methods and Materials: 63 lesions (18 benign cases and 45 malignant cases) in forms of pulmonary nodules (n=26) or masses (n=37) were erolled. DWI and IVIM scans were performed on a 3T MRI machine. LSR_{800} was drawn and ADC_{mean}, ADC_{min}, D, D*, f were measured using single-slice ROI_s and volumetric ROI_v. ICCs were assessed. Parameters obtained by these two ROIs were compared using paired t-test and indepnedent t-test was adopted to compare parameters between benign and malignant lesions. ROC curves were generated to identify the best parameters and thresholds to distinguish the benign and malignant lung nodules and masses.
Results: The inter-observer reproducibility of D* was relatively poor. There were no significant differences in ADC_{mean}, ADC_{min}, D and f values obtained by different ROI methods (P=0.029). Between benign and malignant lung nodules, only ADCmean(ROI_s) showed difference while for lung masses, ADC_{mean}, ADC_{min}(ROI_v), D and f(ROI_s) all had diagnostic value, the highest belonging to D(ROI_v).
Conclusion: DWI can better diagnose pulmonary masses than pulmonary nodules. For the latter only ADC_{mean} obtained by single-slice ROI has the diagnostic value. For the former, ADC_{mean}, ADC_{min}, D and f all could do, but D obtained by volumetric analysis was perferred.

B-1573 14:16

Computed diffusion-weighted image: utility for differentiation of malignant from benign pulmonary nodules as compared with actually obtained diffusion-weighted image

Y. Kishida[1], S. Shinichiro[1], T. Yoshikawa[1], M. Yui[2], Y. Kassai[2], K. Kyotani[1], Y. Ohno[1]; [1]*Kobe/JP*, [2]*Ōtawara/JP (yjk121@med.kobe-u.ac.jp)*

Purpose: To determine the utility of computed diffusion-weighted image (DWI) for differentiation of malignant from benign pulmonary nodules as compared with actually obtained DWI (aDWI).
Methods and Materials: 61 consecutive patients with 82 pulmonary nodules (41 malignant and 41 benign nodules) underwent 3T MRI. All DWI were obtained using fast advanced spin-echo (FASE) sequence with b-values at 0 and 1000s/mm2 ($aDWI_{0,\ 1000}$). Computed DWIs (cDWIs) were generated as 400, 600, 800, 1000, 1500 and 2000 ($cDWI_{400\text{-}2000}$) s/mm2 by commercially available software. Then, signal-to-noise ratio (SNR) and contrast ratio (CR) between nodule and thoracic muscles were determined by ROI measurement at each nodule. To compare image quality between $aDWI_{1000}$ and each cDWI, SNR and CR were compared among all DWIs by Dunnett multiple comparison test. To compare diagnostic performance of pulmonary nodule and determine the threshold values of each DWIs, receiver operating characteristic (ROC) analyses were performed. Sensitivity, specificity and accuracy were compared among all DWIs and $aDWI_{1000}$ combined with each cDWI by McNemar's test.
Results: SNRs of $cDWI_{400}$ and $cDWI_{600}$ were significantly higher than that of $aDWI_{1000}$ ($p<0.05$). AUCs of $cDWI_{800}$ and $cDWI_{1000}$ were significantly larger than that of $cDWI_{2000}$ ($p<0.05$). There were no significant differences of diagnostic performance among all DWIs and $aDWI_{1000}$ with each cDWI ($p>0.05$). However, specificity and accuracy of $aDWI_{1000}$ were improved, when combined with $cDWI_{600}$.
Conclusion: Computed DWI is suggested as useful for differentiating malignant from benign pulmonary nodules, when added with actual DWI in routine clinical practice.

Functional MRI evaluation of b-2000 images improve mediastinal lesion characterisation

J. Coolen, F. De Keyzer, E. Verbeken, A. Dubbeldam, C. Dooms, P. De Leyn, W. De Wever, D. Van Raemdonck, J.A. Verschakelen; *Leuven/BE (johan.coolen@uzleuven.be)*

Purpose: Invasive surgical procedures are at the moment the cornerstone of mediastinal staging. We attempted to use a noninvasive MRI approach to differentiate benign from malignant mediastinal lesions and at the same time attempt to provide an imaging-based preoperative evaluation of lesion resectability.
Methods and Materials: 100 consecutive patients (58 male, 42 female), with a suspicious mediastinal lesion on clinical or on imaging-based (CT, PET or EBUS) examinations, were inluded. Additional to the anatomical MRI sequences on a 3 Tesla scanner DWI-acquisition was performed. All MR images were evaluated by visual inspection and by calculating the ADC values (mean) of the whole lesion (WL) (based on b-1000) and of the hyperintens b-1000 zones (based on b-2000). Histological examinations of operative specimens served as reference.
Results: A total of 43 benign and 57 malignant lesions were included. Diagnosis based on the mean ADC calculated from the WL (b-1000) was rather disappointing (sens.75.4%, spec.60.5% and acc.69.0%) and showed an optimal threshold of $1.97x10^{-3}$ mm/s^2 between benign and malignant lesions. The ADC calculation on b-1000 images (b-2000) was much better (sens.94.7%, spec.88.4% and acc.92.0%) with an optimal cutt-off value of $1.79x10^{-3}$ mm/s^2. Over all patients, a very good correlation was found between MR-signs of local invasion and surgical resectability (kappa 0.87, $p<0.0001$).
Conclusion: This MR imaging technique with DWI might provide additional information for preoperative lesion characterization and assessment of lesion resectability. Volume and especially heterogeneity of the WL seem to preclude a b-1000 evaluation for diagnosis, but b-2000 rating allow better accuracies.

B-1575 14:32

Characterisation of mediastinal anterior masses with magnetic resonance imaging (MRI) using diffusion-weighted imaging

M. Gavrel, E. Auclin, C.S. Balleyguier, C. Caramella; *Villejuif/FR (gavrelmarie@gmail.com)*

Purpose: To characterise mediastinal anterior masses (MAM) in a qualitative and quantitative MRI evaluation using diffusion-weighted imaging (DWI). To correlate imaging features of epithelial thymic malignancies with the World Health Organization (WHO) and Masaoka-Koga classifications.
Methods and Materials: A retrospective analysis of patients referred for an MAM between 2000 and 2017 was made. Correlation with histopathological examinations was performed except for patients with typical thymic hyperplasia or rebound. Chi-square, Fisher and Student's tests were used for data description. Logistic regression models and areas under the ROC curves were estimated.
Results: Out of 94 patients, 66 were included. 21 patients had a benign MAM and 45 had a malignant MAM including 25 thymomas and 10 thymic carcinomas. Qualitative assessment demonstrated significant differences for contours, shape, septas, capsule, calcifications, cystic or necrotic areas, invasiveness, homogeneity and pattern of enhancement ($p<0,05$). Mean chemical shift radio (CSR) differed significantly between benign and malignant MAM ($0,66 \pm 0,26$ and $1,45 \pm 1,36$, respectively, $p=0,003$). Cutoff point for CSR was 0,880 (sensitivity 94%, specificity 84%). Mean apparent diffusion coefficient (ADC) differed significantly between benign and malignant MAM ($2,31\ 10^{-3}$ sec/mm² $\pm$ 1,1 and $1,17\ 10^{-3}$ sec/mm² $\pm$ 0,64, respectively, $p=0,001$). Cutoff point for ADC was $1,39\ 10^{-3}$ sec/mm² (sensitivity 87%, specificity 68%). High-risk thymomas showed stronger enhancement than low-risk thymomas ($p=0,04$). Qualitative assessment demonstrated significant differences between thymomas according to the Masaoka-Koga classification for shape, contours, capsule, septas, invasiveness, homogeneity and pattern of enhancement ($p<0,05$).
Conclusion: DWI-MRI is a useful non-invasive technique for the characterisation of MAM.

B-1576 14:40

Quantitative analysis of diffusion weighted magnetic resonance imaging for characterization of mediastinal lymphadenopathy

A. Sudarkina, A. Dergilev, N. Gorbunov; *Novosibirsk/RU (a.sudarkina@mail.ru)*

Purpose: To evaluate the possibilities of diffusion-weighted imaging (DWI) with different scan parameters for the characterisation of mediastinal lymphadenopathy.
Methods and Materials: 30 patients with metastases (n=12), lymphoma (n=3), sarcoidosis (n=8) and reactive hyperplasia (n=7) of mediastinal lymph nodes were underwent DWI of the chest on 1.5T machine. Two series of DWI with different types of data acquisition (during free breathing and synchronised with breathing) and scan parameters (repetition time, slice thickness, values of acquired b-factors et al.) were obtained for all patients. The apparent diffusion coefficient (ADC) maps were calculated automatically. Altogether, 371 measurements of ADC were performed in the solid area of the lymph nodes in consecutive slices.
Results: The mean ADC values in metastases, lymphoma, sarcoidosis and reactive hyperplasia of mediastinal lymph nodes were $0.97\pm0.31\times10^{-3}$ mm^2/s, $0.89\pm0.07\times10^{-3}$ mm^2/s, $1.54\pm0.24\times10^{-3}$ mm^2/s, $1.66\pm0.32\times10^{-3}$ mm^2/s, respectively. The mean ADC value in benign lymphadenopathy ($1.62\pm0.28\times10^{-3}$ mm^2/s) was significantly higher ($p<0.001$) when compared to malignant lymphadenopathy ($0.95\pm0.29\times10^{-3}$ mm^2/s). The differences between the mean ADC values obtained with different scan parameters were insignificant ($p>0.05$) within all types of the lesions. According to the ROC-analysis the cut-off value of 1.36×10^{-3} mm^2/s can be used for differentiation of benign from malignant lymphadenopathy with a sensitivity of 80% and a specificity of 92%. The area under the curve was 0.947.
Conclusion: Quantitative analysis of ADC maps is a promising tool which can be used for noninvasive differentiation of malignant from benign mediastinal lymphadenopathy regardless of scan parameters and type of data acquisition of DWI.

B-1577 14:48

Value of computed tomography perfusion and diffusion-weighted imaging inpredicting the efficacy of non-small cell lung cancer chemoradiotherapy

L. Cui; *Nantong/CN (cuigeleili@126.com)*

Purpose: To evaluate computed tomography perfusion(CTP) and diffusion-weighted imaging(DWI) parameters in estimating the efficacy of non-small cell lung cancer(NSCLC) chemoradiotherapy in terms of two-year progression-free survival (PFS) and overall survival (OS).
Methods and Materials: This prospective study was approved by our institutional review board. All 23 pathologically-confirmed NSCLC patients underwent CTP and DWI scans before the standard concurrent chemoradiotherapy. A serial of pseudo-color perfusion images were produced, such as BF(blood flow), BV(blood volume) and PMB(permeability). DWI scan used three b values and generated three ADC images, i.e., ADC_1(b=0, 300s/mm^2), ADC_2(b=0, 800s/mm^2), and ADC_3(b=300, 800s/mm^2). Fixed area of ROI_f and maximum area of ROI_m were drawn. Kaplan-Meier survival curves were used to estimate PFS and OS while Cox regression with multiple variables was applied to identify independent predictors, significant level being 0.05.

Results: No significant correlation was found between clinical stages and two-year PFS and OS(*P*=0.223 and 0.112). The regression analysis showed that parameters with independent predictive value for PFS and OS were $BF(ROI_m)$, $PMB(ROI_m)$, and $ADC_2(ROI_m)$. A prediction scoring model was established accordingly: 0 for $BF(ROI_m)\geq 46.10ml/100ml/min$, $PMB(ROI_m)\geq 30.95ml/100ml/min$ or $ADC_2(ROI_m)\leq 1.52\times 10^{-3}mm^2/s$ whereas 1 for the otherwise. Three groups were yielded and the differences in two-year PFS and OS between them had statistical significance (Hazard Ratio=6.712 to 19.921,*P*<0.001).
Conclusion: CTP parameters $BF(ROI_m)$, $PMB(ROI_m)$ and ADC(b=0, 800 s/mm^2, ROI_m) had independent predictive value for PFS and OS, and the prediction scoring model based on which had higher value in estimating treatment efficacy.

B-1578 14:56

Multiparametric approach by dynamic contrast-enhanced perfusion MRI with FDG-PET/CT: capability for conservative therapeutic response prediction in NSCLC patients

Y. Ohno[1], Y. Kishida[1], S. Seki[1], M. Yui[2], S. Ohyu[2], T. Yoshikawa[1]; [1]*Kobe/JP*, [2]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To directly compare the capability for quantitative therapeutic response prediction among dynamic CE-perfusion MRI, FDG-PET/CT and multiparametric approach by both modalities in non-small cell lung cancer (NSCLC) patients treated with chemoradiotherapy.
Methods and Materials: 43 consecutive Stage IIIB NSCLC patients (25 men, 18 women; mean age 67 years) underwent PET/CT, dynamic CE-perfusion MRI, chemoradiotherapy, and follow-up examination. Then, all patients were divided into two groups by RECIST guideline as follows: 1) responders (CR+PR cases: n=23) and 2) non-responders (SD+PD cases: n=20). In each patient, total perfusion (TP) and tumour perfusions from pulmonary (TPP) and systemic (TPS) circulations calculated from dynamic CE-perfusion MR data and SUV_{max} on PET/CT were assessed at each targeted lesion, and averaged to determine final values. Multivariate logistic regression analysis was performed to investigate the discriminating factors of responders. In addition, ROC analysis was performed to compare diagnostic performance among all methods. Finally, sensitivity, specificity and accuracy were compared among all methods by McNemar's test.
Results: Multivariate regression analysis identified SUV_{max} (odds ratio [OR]: 2.56) and TP (OR: 0.68) as significant differentiator of responder. ROC analysis showed area under the curve (Az) of multiparametric approach (Az=0.95) was significantly larger than that of TPP (Az=0.72, p=0.001). Sensitivity (95.7%) of multiparametric approach was significantly higher than that of TP (69.6%, p=0.03) and TPP (65.2%, p=0.02).
Conclusion: Multiparametric approach by dynamic CE-perfusion MRI and PET/CT can improve the capability for therapeutic response prediction as compared with each modality alone in NSCLC patients after conservative therapy.

Blood volume-based MR imaging with ultra-short TE: capability for prediction of postoperative lung function in NSCLC patients as compared with CT and perfusion SPECT

Y. Ohno[1], M. Yui[2], Y. Chen[3], S. Ohyu[2], Y. Kishida[1], S. Seki[1], T. Yoshikawa[1]; [1]*Kobe/JP*, [2]*Otawara/JP*, [3]*Beijing/CN (yosirad@kobe-u.ac.jp)*

Purpose: To directly compare the capability of semi-quantitatively assessed blood volume-based pulmonary MR imaging with ultra-short TE (BV-MRI with UTE) for prediction of postoperative lung function in non-small cell lung cancer (NSCLC) patients as compared with CT and perfusion SPECT.
Methods and Materials: 29 NSCLC patients underwent unenhanced and contrast-enhanced pulmonary MR imaging with UTE at a 3T system, CT, perfusion SPECT, and measurements of FEV_1% before and after lung resection. In each patient, BV MRI was generated as percent signal change between unenhanced and CE-MR imaging. On BV-MRI with UTE and perfusion SPECT, postoperative FEV_1% ($poFEV_1$%) was predicted from semi-quantitatively assessed blood volumes within total and resected lungs. Quantitatively predicted $poFEV_1$% using CT was determined from the functional lung volumes within total and resected lungs. Qualitatively predicted $poFEV_1$% using CT was determined from the number of segments of total and resected lungs. On each method, correlation with actual $poFEV_1$% and the limits of agreement between actual and each predicted $poFEV_1$% were statistically evaluated.
Results: BV-MRI with UTE (r=0.82, p<0.0001) and quantitative CT (r=0.86, p<0.0001) showed better correlation than qualitatively assessed CT (r=0.79, p<0.0001) and SPECT (r=0.78, p<0.0001). The limits of agreement by BV-MRI with UTE (4.3±12.7%) and quantitatively assessed CT (3.5±10.8%) were smaller than those by qualitatively assessed CT (5.1±13.9%) and SPECT (4.2±14.5%).
Conclusion: BV-MRI with UTE can more accurately predict postoperative lung function than qualitatively assessed CT and perfusion SPECT, and is at least as valuable as quantitatively assessed CT in NSCLC patients.

A 3T MRI with radial T1-weighted 3D spoiled gradient echo sequence can clarify pleural invasion classification of primary lung cancer

H. Lee, W. Kwon, Y. Zhang; *Wonju/KR (jeenylee@yonsei.ac.kr)*

Purpose: To clarify the pleural invasion of primary lung cancer by a 3T MRI with free-breathing radial T1-weighted 3D spoiled gradient echo sequence.
Methods and Materials: The study was approved by the institutional review board and the local ethics committee. All subjects provided written informed consent. Twelve patients (7 men and 5 women, average 73.0 years old) with primary non-small cell lung cancer had suspicion for pleural invasion on CT. Cases were reviewed by retrospective interpretation of prospectively acquired data from January 2016 to August 2017 and confirmed by pathology. A 3T MRI was performed with fat suppression and contrast enhancement with 0.9 mm slice thickness, TR=3.36 msec, and TE=1.66 msec. It was compared with 64 MDCT and conventional MRI sequence. Pleural invasion (PL) was graded as smooth and irregular margin of pleural enhancement.
Results: Six adenocarcinoma and six squamous cell carcinoma cases were enrolled. Five T3 stage (5 PL0) and six T4 stage (5 PL1 and 1 PL2) were involved. All cases with proven PL0 and PL1 had smooth and curvilinear high signal intensity of pleura. One case with PL2 had irregular signal intensity of tumour interface of pleura against the chest wall suggesting tumour invasion beyond the visceral pleural surface. Well-enhancing high signal intensity of pleural adhesion is well visible on enhanced radial T1-weighted spoiled gradient echo sequence by MRI and can estimate resectable visceral pleural invasion of primary lung cancer.
Conclusion: MRI with radial T1-weighted 3D spoiled gradient echo sequence can assess pleural invasion for T classification of lung cancer in routine clinical practice.

B-1581 15:20

MRI with DWI vs FDG-PET/MRI vs FDG-PET/CT vs conventional radiological examination: capability for TNM staging in patients with malignant pleural mesothelioma

Y. Ohno[1], Y. Kishida[1], S. Seki[1], M. Yui[2], K. Aoyagi[2], S. Kaminaga[2], T. Yoshikawa[1]; [1]*Kobe/JP*, [2]*Otawara/JP (yosirad@kobe-u.ac.jp)*

Purpose: To compare the TNM staging capability among MRI with diffusion-weighted imaging (DWI), FDG-PET/MRI, FDG-PET/CT and conventional radiological examination in patients with malignant pleural mesothelioma (MPM).
Methods and Materials: 23 consecutive and pathologically diagnosed MPM patients underwent whole-body MRI including DWI, PET/CT, conventional radiological and pathological examinations and surgical reports as well as follow-up examinations. TNM staging was evaluated by three different reader groups. Kappa statistics were determined for evaluations of agreements of each factor and the clinical stage between each method and final diagnosis. Finally, the diagnostic accuracy of each factor and of determination of the clinical stage was statistically compared with each other using McNemar's test.
Results: T factor agreements were determined as substantial (PET/CT and conventional examination: kappa value=0.61) or almost perfect (PET/MRI and MRI: kappa value=0.86). N factor agreements were also determined as substantial (PET/CT: kappa value=0.73, conventional examination: kappa value=0.61) or almost perfect (PET/MRI and MRI: kappa value=1.00). M factor assessment, agreements were also determined as moderate (conventional examination: kappa value=0.47), substantial (MRI: kappa value=0.78) or almost perfect (PET/MRI and PET/CT: kappa value=1.00). In addition, clinical stage agreements were determined as substantial (PET/CT and conventional examination: kappa value=0.70) or almost perfect (PET/MRI and MRI: kappa value=0.87). Finally, accuracies of N factor evaluation on PET/MRI and MRI were significantly higher than that of conventional examination (p=0.03).
Conclusion: Whole-body MRI with DWI and PET/MRI are potentially more useful than conventional radiological examination, and can be considered at least as effective as PET/CT in this setting.

Structured reporting supports junior readers and improves PI-RADS conformity of multi-parametric MRI reports of the prostate-based on cross-lingual RADLEX annotations

M.E. Maros[1], B. Kämpgen[2], A. Förster[1], C. Groden[1], W.H. Sommer[3], S.O. Schönberg[1], T. Henzler[3], H. Wenz[1]; [1]*Mannheim/DE*, [2]*Rimpar/DE*, [3]*Munich/DE (matt.maros@gmail.com)*

Purpose: Prostate cancer (PC) represents an enormous burden as the second most common cancer in men. Therefore, the Prostate Imaging Reporting and Data System (PI-RADS v2) was developed to provide imaging and reporting standards of multi-parametric prostate MRI (mpMRI) in accordance with terminologies of RSNA's Radiologic Lexicon (RADLEX). We present a proof of concept study to assess the effect of (1) structured reporting (SR) and (2) to use automatic RADLEX content annotation as a quality measure for prostate MRI-reports.
Methods and Materials: A cohort of 294 consecutive patients (02/2017-08/2017; mean age 66.6, range 34-89yrs) with suspected PC and mpMRI were retrieved from local RIS archives and reassessed by two independent blinded readers. All reports were generated using an online SR tool (www.smart-radiology.com). An automatic, cross-lingual annotation of German reports and English PI-RADS guideline with RADLEX terms was performed using a proprietary information extraction software (www.empolis.com). Structured reports of junior (n=110;37.4%) and senior (n=184;62.6%) radiologists were compared with the extracted PI-RADS RADLEX terms as a query using a free web-tool (radreport-query.com) and Wilcoxon rank-sum test.
Results: Annotation of PI-RADS guideline identified 394 RADLEX terms. Reports of junior and senior radiologists had similar number of key terms (W=10700, p=0.416). Comparing PI-RADS guideline confirm RADLEX content of both findings (W=10266, p=0.837) and impressions (W=11103, p=0.164) sections showed that junior readers achieved comparable scores as senior ones.
Conclusion: Automatic guideline-based RADLEX content extraction could serve as an important quality measure of reports of PC MRIs. SR templates support junior readers to produce high-quality PI-RADS conform mpMRI reports.

Opportunities in automatically annotating radiology reports with RadLex terms

B. Kämpgen[1], M.E. Maros[2], T. Stening[1], W.H. Sommer[3], A. Klüter[4]; [1]*Rimpar/DE*, [2]*Mannheim/DE*, [3]*Munich/DE*, [4]*Kaiserslautern/DE (benedikt.kaempgen@empolis.com)*

Purpose: With the development, subsequent refinement and translation of RadLex, there is a trend in radiology towards the use of standardised terms for all information resources. As a result, there will be greater opportunities for Natural Language Processing (NLP) to automatically collect data with a high degree of accuracy. This work investigates the gap in coverage between the vocabulary used in non-English radiology reports and the controlled vocabulary of RadLex.
Methods and Materials: 300 MR prostate cancer, 280 CT haemorrhage, and 75 MR stroke suspected cases were randomly selected from two radiological institutions. Findings sections of anonymised German reports were annotated with RadLex terms using a proprietary web service that includes stemming, compounds, abbreviations and automatic inference of more general terms (average no of annotations=71). An ID3 decision tree with (pre-)pruning (criterion=gain ratio; maximal depth=20; minimal leaf size=2) was trained, 10-fold cross-validated, and tested on subsets of the data to automatically classify case type (300/280/75) and level of reader experience (unexperienced: yrs>2, no=149; experienced: yrs>6,no=225).
Results: For case type, there is a macro-averaged f-score of 98% (precision: 97%, recall: 98%). For experience level, there is an f-score of 75% (precision: 65%, recall: 96%). Each test shows a 95% binomial confidence Wilson score interval no wider than 5%.
Conclusion: Radlex annotations of reports are sufficiently specific for basic data analysis and decision support. The more complex the information extraction task, the more additional information (e.g., beyond localised synonyms) need to be considered, e.g., negation detection, disambiguation and relation extraction.

Quality assurance in CT: using automated CT dose monitoring software to implement updated national diagnostic reference levels

E. Appel, P. Kröpil, C. Thomas, J. Aissa, Y. Klosterkemper, N. Heinzler, J. Boos; *Düsseldorf/DE (elisabeth.appel@med.uni-duesseldorf.de)*

Purpose: To evaluate the implementation of the updated computed tomography (CT) diagnostic reference levels (DRLs) from the German Federal Office for Radiation Protection into clinical routine using an automatic CT dose monitoring system.
Methods and Materials: CT radiation exposure was analysed before and after implementing the updated national DRLs into clinical routine in 2016. After the implementation process, institutional CT protocols were mapped to the anatomic regions for which DRLs were provided. Systematically exceeded protocols were optimised and analysed in detail. Analysed CT radiation output parameters were volumetric computed tomography dose index (CTDIvol) and dose length product (DLP). Three radiologists evaluated subjective image quality using a 3-Point-Likert-Scale.
Results: 94258 CT series (from 27103 CT examinations) in adult patients performed in 2016 were included. Averaged over all body regions with available DRL, institutional CTDIvol/DLP were always below the DRLs (65.2 ± 32.9 %/67.3 ± 41.5 % initially; 59.4 ± 32.0 %/60.5 ± 39.9 % after optimisation). Thus, incipiently exceeding protocols were seen for pelvis (CTDIvol 107.7 ± 65.7 %/DLP 106.3 ± 79.3 %), lumbar spine (160.8 ± 74.7 %/175.2 ± 104.1 %) and viscerocranium (108.0 ± 39.0%/152.7 ± 75.7%). After optimisation, radiation dose was 87.9 ± 73.0 %/87.8 ± 80.8 % for the pelvis, 67.8 ± 33.2 %/74.5 ± 50.6 % for the lumbar spine and 95.1 ± 45.8 %/133.3 ± 74.6 % for the viscerocranium.
Conclusion: An automatic CT dose monitoring system enabled not only comprehensive monitoring of a DRL implementation process but can also help optimising radiation exposure.

B-1585 14:24

Investigating potential gadolinium toxicity to gadoterate meglumine (Dotarem) in local renally insufficient adult and paediatric populations using bioinformatics data linkage

L.K. Young, S. Matthew, G. Houston; *Dundee/UK (lkyoung@dundee.ac.uk)*

Purpose: Although current guidelines restrict the use of some gadolinium-based contrast agents in patients with renal insufficiency (RI) (eGFR<60ml/min/1.73m^2), they may be administered when the clinical benefit-risk ratio is favourable. This study uses routine electronic health records to investigate the incidence of potential gadolinium toxicity to the agent gadoterate meglumine within a local RI population.
Methods and Materials: Adult and paediatric patients who underwent contrast-enhanced MRI were identified, stratified by renal function and followed using health data. The following were identified: confirmed cases of NSF; onset of chronic pain, a symptom of NSF and potentially gadolinium deposition disease (GDD) (identified by new, regular pain medication prescriptions within 7 days post-MRI) and contrast-induced nephropathy (CIN) (>25% increase in creatinine within 3 days post-MRI). Comparisons were made via chi-square tests to non-RI and non-contrast MRI populations.
Results: From 2004 to 2016, 22,325 and 572 contrast-enhanced scans were performed on adult and paediatric patients, respectively. 14% of scans were undertaken while the patient had RI (30≤eGFR<60, n=2,622; 15≤eGFR<30, n=464; eGFR<15, n=123). Zero resulted in NSF diagnosis with an average follow-up time of 6.0 ± 2.5years (range, 8months - 15years). For all scans, there was no statistically higher rate of chronic pain onset post-MRI (adults: p=0.777, paediatrics: p=0.578), nor rate of CIN (adults: p=0.566, paediatrics: p=0.841), regardless of renal function or whether contrast was administered.
Conclusion: These data indicate that gadoterate meglumine administered to adult and paediatric RI patients does not result in a higher rate of potential gadolinium toxicity symptoms.

Machine learning in radiology operations management

O. Pianykh; *Newton Highlands, MA/US (opiany@gmail.com)*

Purpose: Radiology workflow presents a complex mixture of planned events and random deviations. The old management approach was to set certain expectations and hope that they would be met. Instead, we propose to employ machine learning algorithms for predicting and managing Radiology workflow.
Methods and Materials: To optimize radiology workflow at Massachusetts General Hospital, we developed an event-tracking system ("Tempus Fugit", or TF for short), entirely based on RIS, PACS, and reporting data. The system was implemented as a real-time process (3-minute updates), querying radiology databases for the most recent year of data (nearly 1,000,000 records per query), to identify each study status in the current processing chain. Capturing this complex data enabled us to build machine-learning models for predicting and analyzing radiology operations.
Results: We applied machine learning algorithms to several major operational problems such as predicting patient wait times, predicting facility delays, and identifying operational bottlenecks. Decision-based models such as regression trees proved efficient for identifying bottlenecking logic - Predictive models such as elastic nets achieved high accuracy in forecasting wait/delay times. As a result, we achieved: - Accurate prediction of wait/delay times: 80% within a 5-min error. Ability to objectively identify the real sources of our operational bottlenecks.
Conclusion: Machine learning is only a tool, but it can help when applied to a right problem. Large, noisy radiology workflow data, too complex to be analyzed manually, presents a perfect target for such applications, and can lead to visible improvements in operations management.

Automated assessment of Sarcopenia on CT studies

J.E. Burns[1], J. Yao[2], J. Chen[1], R.M. Summers[2]; [1]*Orange, CA/US*, [2]*Bethesda, MD/US (jburns@uci.edu)*

Purpose: Central sarcopenia is an adverse risk factor for mortality in cancer, liver transplantation, cirrhosis, and older trauma patients. The purpose is to validate a fully-automated system to opportunistically analyze lumbar paraspinous muscles for sarcopenia on CT.
Methods and Materials: Watershed, graph cut, and level set algorithms obtain initial segmentation of lumbar vertebrae. Paraspinous muscles are localized and segmented by holistically nested neural networks through image-to-image training and classification. The system is tested on two data sets, CTs from PET/CT examinations of 40 patients with metastatic cancer and abdominal CTs from an elder cohort of 25 patients, to assess performance variation and generalizability of results. Manually segmented paraspinous muscles served as reference standard. Sarcopenia is defined through meta-analysis of publications as normalized L3 total psoas muscle index (L3TPI) of < 3.62 cm^2/m^2 for women and <4.92 cm^2/m^2 for men. Segmentation accuracy is assessed via Dice Similarity Coefficient.
Results: Dice coefficients for detecting psoas and posterior paraspinous muscle groups were 0.877+/-0.073 and 0.919+/-0.031 for PET/CT, and 0.886+/-0.089 and 0.948+/-0.018 for abdominal CT, respectively. L3TPI was 5.6 +/- 2.5 and 4.9 +/- 2.1 cm^2/m^2 (women) and 8.6 +/- 3.2 and 7.9 +/- 3.6 cm^2/m^2 (men) for automatic and manual measurement respectively. Sarcopenia was present in 21.2% (7/33) and 24.2% (8/33) of women, and 9.3% (3/32) and 15.6% (5/32) of men from automatic and manual measurement respectively.
Conclusion: This fully-automated system accurately determines paraspinous muscle volume on CT for sarcopenia detection and monitoring, with potential to predict prognosis and guide patient management.

B-1588 14:48

COPD phenotyping with parameter response maps based on paired inspiratory/expiratory low-dose computed tomography

O. Weinheimer[1], C.J. Galban[2], T.E. Robinson[3], M. Wielpütz[1], C. Heussel[1], H.-U. Kauczor[1], B.J. Jobst[1]; [1]*Heidelberg/DE*, [2]*Ann Arbor, MI/US*, [3]*Palo Alto, CA/US (weinheimer@uni-heidelberg.de)*

Purpose: Patients suffering from chronic obstructive pulmonary disease (COPD) can be subdivided using computed tomography (CT) into an airway-dominant or emphysema-dominant phenotype. The parametric response map (PRM) method, a voxel-wise image analysis technique may detect distinct functional differences between these phenotypes.
Methods and Materials: 169 paired inspiratory/expiratory low-dose CT scans (120 kV, 30-35 mAs, ~3.5 mSv) from the multicentre COSYCONET study were visually classified as airway-dominant (67%) and emphysema-dominant (33%). PRM was computed fully automatically employing a deformable volumetric registration and lung segmentation, classifying lung voxels as normal parenchyma (PRM^{Normal}), functional small-airway disease (PRM^{fSAD}) and emphysema (PRM^{Emph}). For comparison the emphysema index (EI) was calculated on the inspiratory scans.
Results: Average PRM^{Normal}, PRM^{fSAD}, PRM^{Emph} and EI were 66.9%, 26.4%, 6.9% and 9.2% in the airway-dominant group and 46.9%, 32.3%, 19.8% and 23.1% in the emphysema-dominant group, respectively. The differences were significant between the groups with p=1.8e-07, p=0.006, p=3.6e-08 and p=2.8e-08. The Pearson correlation coefficient r between PRM^{Normal} and forced expiratory volume in 1s (FEV_1) was 0.63 (p<2.2e-16), for PRM^{fSAD} -0.54 (p=3.1e-14), for PRM^{Emph} -0.55 (p=5.1e-15) and for EI -0.55 (p<2.2e-16) across all patients, which was similar for airway-dominant and emphysema-dominant phenotypes.
Conclusion: PRM identified fSAD regions, which would have been missed by emphysema quantification just on inspiratory CT scans. The results show that in emphysema-dominant COPD there is a large fraction of fSAD besides irreversible emphysema, which may be addressed by therapy. Additionally, the combination of PRM^{fSAD} and PRM^{Emph} leads to a higher correlation with FEV_1.

B-1589 14:56

Model for improved correlation of BMD values between abdominal routine dual-energy CT data and DXA scans

M. Woisetschlager, A. Spångeus; *Linköping/SE*

Purpose: In this study, we evaluated a new software solution to calculate volume bone mass densities (vBMD) from dual-energy CT studies (DECT) and correlated them to DXA. We constructed a model where influencing factors for differences between vBMD and aBMD were taken into account.
Methods and Materials: A total of 20 patients, i.e. 80 vertebrae, were examined with abdominal DECT (in three contrast phases) where the L1-L4 were analysed with a software delivering vBMD. Within 1 months after the DECT, a DXA scan was performed. The amount of calcifications in the abdominal aorta (ACS) and of spondylarthritis (SAS) was evaluated.
Results: The median age was 70.5 years (43 - 85) where 60% were women and 40% men. A significant correlation was found between DXA BMD and vBMD from DECT without contrast (WNC), and with venous contrast (WVC), but no significant correlation was found with arterial contrast. After combining DECT WNC, ACS and SAS in Model 1, a correlation is achieved with an R2 = 0.616. The Pearson correlation between Model 1 predictive value and DXA is 0.785 (p=0.001). The respective values in Model 2 for the DECT WVC are R2 = 0.612 and predictive value of 0.782 (p=0.001).
Conclusion: The shortcomings of DXA in predicting true BMD values compared to DECT, as being susceptible for confounding factors like calcifications in the abdominal aorta and osteoarthritis changes can be overcome by quantifying the amount of confounding factors and taking these into account in an explanatory model.

Computer-aided detection of sonographic features for thyroid nodules and its effects on readers' performance

A. Chen, C.-N. Chen, H.-C. Tai, M.-H. Wu, K.-Y. Chen, M.-C. Ho, K.-J. Chang; *Taipei/TW (achen@ntu.edu.tw)*

Purpose: This study is to evaluate the performance of an FDA-cleared computer-aided detection (CADe) device for thyroid nodules and its effects on readers' performance.
Methods and Materials: A total of 130 images of thyroid nodules were randomly selected from a case pool of 372 patients with 472 thyroid nodules. The ground truth for the presence of each sonographic feature was determined by a panel of three specialists. Detection of feature presence was evaluated by AUROC's and t-test *p*-values. For assessment of the effects on readers' performance, diagnostic decisions were compared to the pathology results (74 benign and 56 malignant). Seven physicians were recruited to read the 130 ultrasound images. The reader performance was then evaluated by the multiple reader multiple case (MRMC) study design and Dorfman-Berbaum-Metz method.
Results: The study first showed that the computed values of the anechoic area, echogenic foci, hypoechogenicity, heterogeneity, and ill-defined margin were all tested significant in detecting their presence with *p*-values <0.0001 for the first three features, 0.033 and 0.0014 for the last two and the AUC=0.882, 0.788, 0.817, 0.71 and 0.686, respectively. The MRMC study showed that the average AUC (=0.796) with CADe was significantly larger (*p*-value=0.0077) than the average AUC (=0.724) without CADe.
Conclusion: The tested CADe device was shown significant in detecting presence of the five sonographic characteristics. The diagnostic interpretations by physicians reading the ultrasound images with the CADe device were also shown significantly improved when compared to interpretations without the device.

Newly developed curvelet-based noise reduction algorithm for volume CT data

M.S. Usanov, N.S. Kulberg, A.V. Petraikin, S.P. Morozov; *Moscow/RU (m.usanov@npcmr.ru)*

Purpose: Estimate the effectiveness of newly developed noise reduction algorithm by means of analysis of acquired volume CT data, obtained from phantoms and patient studies of various anatomical areas.
Methods and Materials: A new 3D noise reduction algorithm was developed based on wavelet curvlet transformation and bilateral filter. Estimation of noise reduction quality was made based on volume CT data, obtained from various CT scanners and study objects, including phantoms, brain, chest, abdominal area. 30 % of analysed studies are low dose CT. Overall, 113 studies were analysed. After data processing the results were assessed by radiologists, who made valuable notices in the algorithm presets. The following parameters were taken into consideration: standard deviation (SD), determination coefficient. Special attention was paid to speed of data processing.
Results: SD is improved in phantom study by 58.08%, and in patient study by 76.89%. Confidence interval for SD value difference = 0.0003. Determination coefficient between mean native and processed values = 0.99 for phantom study and = 0.97-0.99 for patient study, which means the data remains unspoiled, without any value loss or border deformation. Estimated processing time of 500 slices is around 20 seconds.
Conclusion: Proposed algorithm has shown its effectiveness in the field of various CT data processing without data spoilage, comparing to standard methods. This method requires only DICOM files, without manipulating raw data. High speed processing allows the algorithm to be used both on workstations and PC. This new technology will enhance quality of CT diagnostic, as well as lowering x ray dose for patients during the study. The work is supported by RFBR, project 17-01-00601.

Multiparametric magnetic resonance imaging of the prostate with computer-aided detection: non-experienced observer performance study

G. Cappello, V. Giannini, S. Mazzetti, F. Russo, L. Vassallo, V. Doronzio, D. Regge; *Turin/IT (giovanni.cappello@ircc.it)*

Purpose: To understand how non-experienced readers interacts with likelihood map generated by a computer-aided detection (CAD) for prostate cancer (PCa) detection and to compare their sensitivity, specificity and reading time obtained with and without the color-coded map.
Methods and Materials: 90 multiparametric magnetic resonance imaging (mp-MRI) prostate cases (45 negatives and 45 with at least one significant PCa) were reviewed twice by three radiology residents. First, suspected PCa were detected on the basis of CAD marks observed on a likelihood map superimposed to the T2w image, as anatomical reference. After 6 weeks, readers reviewed the same cases analyzing mp-MRI unassisted. Sensitivity, specificity, and reading time were compared for the two reading paradigms.
Results: The stand-alone CAD sensitivity was equal to 94.3%. Considering all readers, sensitivity was 66.7% (95% CI 58.0-74.5%) and 70.4% (95% CI 61.9-77.9; p=0.236) for unassisted and CAD paradigm, respectively. Sensitivity was higher with CAD for lesions with GS>6 (79.6% vs
71.0%; p=0.0287), but not for lesion with diameter ≥10 mm (76.5% vs 79.0%; p=0.395). Specificity was not affected by CAD (94.8% for CAD vs 89.6%; p=0.071).The average reading time was significantly lower (170s vs 66s; p<0.001) when using the CAD system.
Conclusion: Using the CAD system, non-experienced readers can detect more patients with GS>6 PCa than unassisted MRI interpretation; overall reporting time is shorter. However, CAD stand-alone sensitivity was significantly higher, demonstrating that operators were somewhat uncomfortable when using CAD systems. However, other reading paradigms should be tested to evaluate the clinical usability of CAD systems.

Saliently alteration of hub profiles following acute mTBI

X. Wang[1], C. Sun[1], S. Wang[1], J. Cao[1], H. Xu[1], S. Gan[1], B. Yin[2], G. Bai[2], L. Bai[1]; [1]*Xi'an/CN*, [2]*Whenzhou/CN (lemon124w@outlook.com)*

Purpose: To investigate altered network hubs following acute mild traumatic brain injury (mTBI) in a large homogenous sample compared with healthy controls.
Methods and Materials: 74 mTBI patients (46 males, ages of 36.3 ± 12.7 years) within 7 days post-injury and 51 matched healthy controls (26 males, ages of 36.7 ± 12.2 years) were enrolled in this study. Functional brain networks were constructed using resting state fMRI. Hub disruption index κ was also calculated across the whole network and for each functional network. SVM was applied to test whether participation coefficient can be used as a neurobiomarker to identify mTBI patients from controls.
Results: Our results indicated evidence for a radical reorganization of highly efficient hub nodes following mTBI. Specially, hubs for mTBI patients distributed in more extensive networks such as the default mode network (DMN), ventral attention network (VAN) and frontoparietal network (FPN), somatomotor network (SMN) and the visual network (VN), compared with healthy controls limited to the first three. Hubs in healthy controls typically became non-hubs in patients and vice versa defined by a novel hub disruption index. Participation coefficients for mTBI presented significantly decreased in the DMN (P=0.015) and FPN (P=0.02), while increased in the VN (P=0.035). Additionally, SVM trained with participation coefficient metrics identified mTBI patients from controls with 78% accuracy, providing for its diagnostic potential in clinical settings.
Conclusion: These evidence suggested a saliently spatial transition of hub profiles even in the very early stage of mTBI, associated with functional network reorganization in these patients.

B-1594 14:08

Automatic vs human detection of traumatic cerebral microbleeds on susceptibility-weighted imaging

A.W. van der Eerden[1,2], T.L.A. van den Heuvel[1], B.H. Geurts[1], B. Platel[1], T. Vande Vyvere[3,4], L. van den Hauwe[3,4], T.M.J.C. Andriessen[5], B.M. Góraj[1,6], R. Manniesing[1]; [1]*Nijmegen/NL*, [2]*Venlo/NL*, [3]*Edegem/BE*, [4]*Leuven/BE*, [5]*Gorinchem/NL*, [6]*Warsaw/PL (ankevandereerden@gmail.com)*

Purpose: To evaluate the performance of computer-aided traumatic cerebral microbleed detection (CAD) with and without human interference.
Methods and Materials: 33 adult patients admitted to our emergency department with moderate or severe TBI (mean age 33 years, 21 males) underwent a standardised trauma 3T MRI-protocol at 28 weeks. The microbleeds in their SWI-scans were annotated by an expert. A CAD system was developed, based on this training set. Six experts, blind to the CAD-results, annotated a subset of ten patients. In two experiments, we compared the performance of the CAD system to each of these six experts, using the majority voting results of the other five experts as the reference standard for the calculation of performance characteristics (paired *t*-test). In the first experiment, the performance of fully automatic microbleed detection was assessed. In the second experiment, one expert removed CAD-annotations she considered false positives from the automatically detected microbleeds, and briefly screened the CAD-annotated SWI-scans to complete the dataset with missed definite microbleeds.
Results: Fully manual evaluation took one hour per patient with an average sensitivity of 77% (SD 12.4%). The sensitivity of fully automatic detection of candidate microbleeds was 89% (SD 0.8%). Evaluation of the CAD results by an expert took 13 minutes per patient with a sensitivity of 93% (SD 1.0%) ($p < 0.05$ versus fully manual evaluation).
Conclusion: This CAD system allows detecting more microbleeds in a reduced reading time. This may facilitate the execution of otherwise too time-consuming large studies on the clinical relevance of microbleeds.

Looking for association between blood pressure, imaging severity and complications - MR imaging study in posterior reversible encephalopathy syndrome

S.B. Hiremath, A.A. Gautam, G. Benjamin; *Thiruvalla/IN (shivaprakashbh@gmail.com)*

Purpose: To evaluate for significance of association between blood pressure and imaging severity with hemorrhage and cytotoxic edema in PRES.
Methods and Materials: This retro - prospective study included the medical records and imaging involving 35 consecutive patients with PRES from 2010 - 2016. The clinical data was analyzed for blood pressure recorded at the ictus with MR imaging including a spin-echo echo planar diffusion weighted imaging (DWI) and susceptibility weighted angiography (SWAN) with conventional sequences. The presence of haemorrhage and cytotoxic edema was assessed for significance of correlation and association with each other and with BP and imaging severity (IS).
Results: Hemorrhage was found in 25.7 % of patients and cytotoxic edema was in 20 % of patients. There was no statistically significant association of hemorrhage ($p = 0.403$) and cytotoxic edema ($p = 0.162$) with BP. There was statistically significant association of hemorrhage ($p < 0.001$) and cytotoxic edema ($p = 0.011$) with IS and with each other ($p = 0.002$). There was significant correlation of hemorrhage (Cramer's V - 0.672) and cytotoxic edema (Cramer's V - 0.506) with IS and with each other (Cramer's V - 0.523).
Conclusion: There is significant association of hemorrhage and cytotoxic edema with imaging severity and among each other. The endothelial injury secondary to hyperperfusion or hypoperfusion is the basic mechanism of changes in PRES. Vasculopathy and decreased perfusion results in ischemia and restricted diffusion; rupture of pial vessels due to impaired autoregulation causes subarachnoid hemorrhage and post-ischemic reperfusion leads to microhemorrhages.

B-1596 14:24

Atypical inter-hemispheric communication following subacute mild traumatic brain injury

Z. Wang[1], S. Wang[1], C. Sun[1], B. Yin[2], G. Bai[2], X. Niu[1], Y. Sun[1], M. Zhang[1], L. Bai[1]; [1]*Xi'an/CN*, [2]*Wenzhou/CN (wangzhuonan424@stu.xjtu.edu.cn)*

Purpose: To examine the structural integrity of the corpus callosum (CC) in subacute phase of mild traumatic brain injury (mTBI) patients and its related inter-hemispheric functional connectivity changes.
Methods and Materials: Forty two patients with mTBI (29 male, ages of 37.8 ± 11.9 years) and 42 matched healthy controls (male 22, 36.2 ± 9.9 years) underwent comprehensive neuropsychological evaluations as well as both diffusion tensor imaging (DTI) and resting state scanning. The specific division of the CC was conducted by using DTI in combination with a tract-tracing algorithm. Fractional anisotropy (FA) for each subsection of the CC was generated by the Tract-Based Spatial Statistics (TBSS) and inter-hemispheric functional connectivity (FC) was analyzed by using voxel-mirrored homotopic connectivity (VMHC) approach. These analysis were also compared between patients with mTBI and controls, covarying for age, sex, and education with multiple comparison corrections.
Results: MTBI patients showed significantly decreased FA in the splenium and marginally reductions in the mid anterior body part of CC compared with controls (P <0.01, corrected for multiple comparisons). The increased FC were shown in the pre-supplementary motor area and supplementary motor area, while decreased in the default-mode network (DMN) (precuneus/ posterior cingulate and inferior parietal lobule), salience network (SN) (fronto-insular cortex) and orbitofrontal cortex (OFC) ($P < 0.05$, FDR corrected).
Conclusion: As a conduit in mediating inter-hemispheric communications, the structural loss in the specific section of the CC may, therefore, influence the corresponding projection fibers and its related inter-hemispheric functional connectivity following mTBI.

B-1599 14:32

Subcortical nuclei and cognitive impairment in sub-acute mild traumatic brain injury: a diffusion kurtosis imaging and volumetric study

M.-L. Wang, W. Li; *Shanghai/CN (doctor-mingliang@sjtu.edu.cn)*

Purpose: To investigate the volumetric and diffusional kurtosis imaging (DKI) changes of subcortical nuclei in sub-acute mTBI, and to assess the relationship between subcortical nuclei volume, DKI parameters and cognitive function.
Methods and Materials: A total of 23 mTBI patients and 24 control participants underwent examinations of neuropsychological tests, MRI-based morphological and DKI scans. Volume, mean kurtosis (MK), mean diffusivity (MD), and fractional anisotropy (FA) were measured in bilateral hippocampus, thalamus, caudate, putamen, pallidum, and amygdala. Neuropsychological tests and MRI parameters were compared between mTBI and control group. Correlation analysis was performed to examine the relationship between subcortical nuclei volume, DKI parameters and cognitive function.
Results: There were no significant differences in the volume of any subcortical nuclei between mTBI and control group. The mTBI group had higher MK value in right hippocampus, left thalamus, left caudate, right putamen, and right pallidum ($P<0.05$), and lower MD value in right pallidum ($P<0.05$).mTBI participants had worse performance in the domains of verbal memory, attention and executive function. In the mTBI group, the declined verbal memory function was correlated with higher MD value in left thalamus ($r=-0.678$, $P=0.022$) and lower FA value in left amygdala ($r=0.611$, $P=0.016$). The attention deficit was correlated with lower MK value in left amygdala ($r=0.625$, $P=0.010$), right thalamus ($r=0.634$, $P=0.008$), right putamen ($r=0.582$, $P=0.018$), right hippocampus ($r=0.576$, $P=0.020$) and right amygdala ($r=0.503$, $P=0.047$).
Conclusion: DKI is more sensitive than conventional DTI for detecting subcortical nuclei microstructural changes that might underlie the pathology of cognitive impairment in sub-acute mTBI.

B-1600 14:40

Resting-state functional connectivity in the visual network: a possible predictor of treatment response in chronic migraine

D. Kies, J.A. Pijpers, M.D. Ferrari, M.C. Kruit, G.M. Terwindt; *Leiden/NL (d.a.kies@lumc.nl)*

Purpose: Up to 25% of episodic migraine patients progress to chronic migraine (headache on more than 15 days per month). The mechanisms behind chronification and reversion are still uncertain, although overuse of acute headache medication plays an important role. We investigated whether resting-state functional connectivity (RS-fc) can predict favourable outcome of treatment.
Methods and Materials: RS-fMRI was conducted in 112 participants with chronic migraine and medication overuse before and 3 months after treatment. Responders to treatment (greater than 50% reduction in headache days) were compared with non-responders, using RS-fc within ten functional networks. Data were preprocessed using a standard FSL pipeline with addition of the AROMA motion correction tool. Results were corrected for multiple comparisons.
Results: Data of 99 participants was complete and useable for analysis. The mean number of headache days at baseline was 21.2 per month. At baseline, the lateral visual network showed a higher connectivity in areas in the bilateral occipital cortex in responders vs non-responders ($p= .015$). Only in responders this higher functional connectivity decreased after treatment ($p= .001$). No differences in connectivity were detected at baseline or during follow-up in any of the other 9 evaluated networks.
Conclusion: Chronic migraineurs who responded to treatment showed a significantly higher RS-fc within the lateral visual network as compared to non-responders at baseline, as well as a significant decrease of RS-fc in this area after treatment. RS-fc might serve as a prognostic tool in selecting responsive patients for treatment.

Prognostic role of CT imaging in coup and contre coup injuries of brain

M. Jayakumar, A. Rangari, M.J. Rodriguez; *Vaniamkulam/IN (meghpsbb@gmail.com)*

Purpose: Coup and contrecoup contusions are a set of focal brain injuries. Since the pathogenesis of the two are different, the outcome in the two also would be expected to be different. Present study aims to evaluate role of CT in predicting prognosis in coup-contrecoup injuries.
Methods and Materials: 103 consecutive cases presenting with coup and contrecoup injuries over a 1-year period were retrospectively analyzed. They were divided into three groups: Coup injuries with intraparenchymal injury ($n = 53$), contrecoup injuries ($n = 25$) and coup-contrecoup injuries ($n = 25$). The groups were comparable with respect to age and GCS. Site of primary imapact was detrmined clinically.All patients underwent CT scan of brain. The mortality rates in each group were compared with respect to age, GCS and CT pattern. Significance was calculated using the chi -square test.
Results: Fractures,extraxial hemorrhage and intraparenchymal hemorrhage were the common findings identified on CT brain scan. There was a statistically significant difference in mortality between patients with coup injuries and patients with contrecoup ($p< 0.005$) and coup-contrecoup injuries ($p<0.001$). There was no significant difference in mortality between contrecoup and coup-contrecoup injuries
Conclusion: CT is able to identify coup and contre coup injuries effectively.Presence of a contrecoup component on CT scan predicts a worse outcome in head injuries and warrants aggressive management and thus can help in deciding couse of management.

B-1603 14:56

Vision-related structural and functional reorganisation after incomplete acute cervical cord injury

Q. Chen, N. Chen, W. Zheng, X. Chen, X. Li, K. Li, C. Zhang; *Beijing/CN (chaozhang0328@hotmail.com)*

Purpose: The aim of this study was to explore possible vision-related structural and functional reorganisation of the brain after acute incomplete cervical cord injury (ICCI), which often leads to motor dysfunction, using multi-modal MR imaging study, and to further study their associations with motor and other clinical variables.
Methods and Materials: Eleven patients with ICCI and eleven matched healthy controls (HCs) were recruited. All participants underwent structural and functional MRI scans. Voxel-based morphometry analysis was carried out to investigate the differences in brain structure between ICCI and HCs, the fractional amplitude of low-frequency fluctuations (fALFF) was used to characterise changes in regional neural activities, and the independent component analyses (ICA) were used to explore alterations in resting-state network after spinal cord injury (SCI). Finally, we also investigate the correlations between brain imaging metrics and clinical variables.
Results: Compared with HCs, patients with ICCI showed significant grey matter (GM) atrophy in the left hippocampus and parahippocampal gyrus, and right superior frontal gyrus (SFG) and right middle frontal gyrus (MFG), and decreased fALFF in the left OFC. Moreover, ICCI patients exhibited decreased intra-network functional connectivity (FC) in the medial vision network (mVN). Finally, the mean fALFF value was correlated with the clinic motor scores.
Conclusion: Our findings provide evidence that acute ICCI can induce significant structural and functional alterations in vision-related regions of the brain. These reorganisations may suggest a potentially vital role for vision-related rehabilitation training in SCI patients with sensorimotor dysfunction, such as virtual reality (VR)-augmented training, brain-computer interfaces (BCI).

Risk-based strategies for supplemental breast cancer screening

D.L. Miglioretti[1], B. Sprague[2], C. Gard[3], G. Rauscher[4], J. Tice[5], K. Kerlikowske[5]; [1]*Davis, CA/US*, [2]*Burlington, VT/US*, [3]*Las Cruces, NM/US*, [4]*Chicago, IL/US*, [5]*San Francisco, CA/US (dmiglioretti@ucdavis.edu)*

Purpose: Supplemental screening of women with dense breasts has been promoted given the low sensitivity of mammography in these women; however, screening ultrasound and MRI are limited by high false-positive rates. We evaluated the efficiency of basing supplemental screening decisions on a risk model for screening failures versus breast density.
Methods and Materials: We included 1,808,514 million screening mammograms on women 40-74 years in the U.S. Breast Cancer Surveillance Consortium. Risk factors were collected at the screen. Screening failures were defined as interval invasive cancers (<12 months after a normal mammogram) and screen-detected cancers AJCC stage IIb or higher. We used logistic regression to develop a risk model to predict the probability of a screening failure given a woman's age, BI-RADS breast density, family history, race/ethnicity, and history of benign breast disease.
Results: Screening failures occurred in 1.36/1000 and 1.71/1,000 screens performed on women with heterogeneously and extremely dense breasts, respectively. Supplemental screening of women with dense breasts (46% of population) would potentially avert 64% of screening failures. To potentially avert 64% of failures based on our risk model, only the 41% of women with failure risk >1.05/1000 would receive supplemental screening, resulting in fewer supplemental screens per failure (601 vs. 705). Supplemental screening of the 23% of women with failure risk >1.36/1000 would to potentially avert 46% of failures, further lowering the supplemental screens per failure to 476.
Conclusion: A risk model for screening failures more efficiently identifies women who might benefit from supplemental imaging than breast density.

B-1605 14:08

Feasibility of risk assessment and personalised breast screening recommendations delivery in community radiology practice: a national prospective study (NCT02997384)

C.S. Balleyguier[1], E. Bayou[1], B. Boyer[2], S. Canale[1], I. Ewenczyk-Bitton[2], R. Gilles[3], L. Rotenberg[4], J. Viala[5], S. Delaloge[1]; [1]*Villejuif/FR*, [2]*Paris/FR*, [3]*Bordeaux/FR*, [4]*Neuilly-Sur-Seine/FR*, [5]*Antony/FR*

Purpose: Stratified breast cancer (BC) prevention is a major option for the future but requires adapted and relevant tools to assess BC risk and communicate with the women. The prospective "Riviera" trial (NCT02997384) aimed to evaluate the feasibility of a BC prevention consultation using a dedicated software, in private community practices in France. We report results obtained among participating radiologists.
Methods and Materials: Riviera was conducted from December 2016 to July 2017 and involved 8 community radiologists. Women aged 40-74 were proposed to have their BC risk assessed and a personalized screening program (PSP) provided using the Mammorisk™ software. Primary end point was the % of women accepting to participate. Secondary objectives were women's awareness, anxiety and satisfaction, and physicians' satisfaction. The participants filled questionnaires at accrual and 48h later. The radiologists' point of view was evaluated with a standardized questionnaire.
Results: 189 women were included. Median age was 51 (41% between 40 and 49). The BC risk assessment acceptance rate was 100%. 31 % of women were reclassified at high risk. 70% of women returned the H48 questionnaires. 93% found that the information and the PSP were clear or very clear. Anxiety levels after the consultation were low. The mean score for radiologists' satisfaction was good.
Conclusion: A BC prevention consultation with risk assessment and delivery of a PSP is feasible in community radiology practices. The next step is to evaluate the feasibility at a European level taking into consideration the different BC screening organizations.

B-1606 14:16

Mammographic density, age and family history: a minimally sufficient set of parameters to risk stratify average-risk women for follow-up screening

M. Abdolell, K. Tsuruda, J.I. Payne, P. Brown, J. Caines, P. Barnes, M. Rivers-Bowerman, S.E. Iles; *Halifax, NS/CA (Sian.Iles@nshealth.ca)*

Purpose: This study evaluated the consistency and discriminatory power of several short-term breast cancer risk models within a general screening population.
Methods and Materials: This 3:1 age- and screen-matched case-control study sampled all breast cancer cases diagnosed among digitally screened women aged 40-75 years (2009-2015) within a provincial breast screening programme. Clinical risk factor data and fully automated percent mammographic density assessments were obtained for 2,347 cases and 7,041 controls. The data were partitioned such that risk models were developed using a training dataset and validated using a test dataset. Patient-specific risk estimates were derived from models that included density and clinical risk factors alone and in combination. Agreement between models was assessed using intraclass correlation coefficient (ICC) and kappa; the predictive performance was assessed using the area under the receiver operating curve (AUROC).
Results: The agreement between risk estimates was highly variable (ICC=0.016-0.962, kappa=0.025-0.823). The risk model performance varied highly (AUROC=0.485-0.602). Agreement was almost perfect between a model including density, family history and age versus a model that additionally included menopausal status, HRT use and parity (ICC=0.962, kappa=0.823); the predictive performance was similar (AUROC =0.594,0.598).
Conclusion: Risk models can generate significantly different risk estimates for the same woman depending on the risk factors included, thus altering follow-up recommendations, especially for higher-risk women. A short-term risk model incorporating mammographic density, family history and age provides a practical solution for risk stratification of the average-risk population.

Mammographic breast density analysis with automated volumetric breast density in a single centre of Taiwan women

H.-K. Wu, W.-P. Wu; *Changhua/TW (139496@cch.org.tw)*

Purpose: Women with increased mammographic breast density are known to be at higher risk of developing breast cancer. The changes of breast density among diverse age groups in Asian women is still elusive. We aimed to investigate the distribution of breast density in Taiwanese women.
Methods and Materials: A retrospective review of data collected from 130,237 women who underwent digital mammography from 2011 to 2016 was conducted. On the basis of ACR BI-RADS 5th edition breast composition, breast density analysis based on fully-automated volumetric breast density

estimates (Volpara) were determined on four density grades (a, b, c, d) and a binary classification of fatty (a-b) vs. dense (c-d) breast.
Results: In Taiwan women, the frequency of dense breast was 94.0% (30-39 years old), 93.4% (40-49), 82.8% (50-59), 67.5% (60-69), 63.1% (70-79), and 63.5% (80-89), *p*-trend <0.001. Taiwanese women has a higher frequency of dense breast, but this frequency decreased abruptly between the ages of 50 and 69. Even in 70-89-year-old women, dense breasts are majority.
Conclusion: Our results indicate the higher frequency of dense breast among Taiwanese women.

B-1608 14:32

Assessing the diagnostic accuracy of a 3D functional infrared imaging as adjunct screening for women at high risk for breast cancer
M. Sklair-Levy[1], E. Friedman[1], O. Halshtok Neiman[1], A. Shalmon[1], M. Gotlieb[1], R. Faermann[1], J. Oaknin[2], D. Izhaky[2]; [1]*Ramat Gan/IL*, [2]*Airport City/IL (david@realimaging.com)*

Purpose: Three-dimensional functional infrared imaging (3DIRI) has been shown before to provide high-accuracy risk assessment for the likelihood of breast cancer based on multiparametric evaluation of metabolic imaging biomarkers. In this prospective one-arm clinical study, 3DIRI is added twice yearly to a screening program which includes annual breast MRI and breast ultrasound or mammography surveillance. The aim of this study was to determine diagnostic accuracy of 3DIRI.
Methods and Materials: Following Ethics Approval, 230 females at high risk for breast cancer due to genetic predisposition, mainly known carriers of BRCA 1/2 mutation, signed informed consent for this study. They underwent 465 screening rounds between January 2015 and June 2016. Screening included 3DIRI scan (prototype Real Imager 8) and MRI or breast ultrasound or mammography. Accuracy of 3DIRI was determined by ROC curve using histopathological confirmation for cancer cases and one-year follow-up for non-cancer.
Results: Of 230 women who underwent 465 standard care screening procedures, 63 women underwent biopsy of which, 55 proved to be benign while 8 were malignant on histopathology. In addition, one interval cancer was observed during the follow-up. AUC of 3DIRI was 82.32%.
Conclusion: Three-dimensional functional infrared imaging can provide risk assessment for the likelihood of breast cancer with high accuracy in a population of women that are at high risk for breast cancer. Additional studies are necessary to evaluate its clinical utilisation as adjunct to mammography in screening population.

Correlation of breast MRI screening with 3D functional infrared imaging
U. Fischer[1], F. Baum[1], J. Oaknin[2], D. Izhaky[2]; [1]*Göttingen/DE*, [2]*Air Port City/IL (david@realimaging.com)*

Purpose: Three-dimensional functional infrared imaging (3DIRI) has been shown before to provide high-accuracy risk assessment for the likelihood of breast cancer in women based on multiparametric evaluation of metabolic imaging biomarkers. The aim of this study was to investigate the relationship between risk assessment score derived from 3DIRI and BI-RADS classification result derived from breast MRI.
Methods and Materials: In this prospective, ethically approved study, written informed consent was obtained from 120 women who underwent 3DIRI exam and breast MRI between September 2016 and September 2017. 3DIRI risk assessment score (on a scale of -100 to 100, with positive score indicating likelihood for malignancy) was used to determine area under the receiving operating characteristics in which MRI assessment (BI-RADS lexicon classification) was used as the gold standard. We used a Fisher's exact test to further compare association of MRI BI-RADS classification with 3DIRI scores.
Results: Seventy-three women (mean age, 58) were enrolled, recruited and had bilateral contrast-enhanced MRI screening and valid 3DIRI (Real Imager 8) imaging scan at day of analysis. Of 73 women, 32 women (44%) had positive MRI (BI-RADS>=3). AUC for 3DIRI was 0.70 (U test p<0.005). A Fisher's exact test of association between positive/negative MRI and positive/negative 3DIRI risk assessment score further corroborated this association ($p<0.01$).
Conclusion: Three-dimensional functional infrared imaging risk assessment score may serve as a predictor of positive breast screening MRI and may be utilized for selection of women for breast MRI screening.

Interest of breast MRI surveillance in women with a personal history of breast invasive lobular carcinoma
J. Sanchez, C. de Bazelaire; *Paris/FR*

Purpose: Our purpose was to evaluate if breast MRI (BMRI) had an interest in the follow-up of patients after pure invasive lobular carcinoma (ILC).
Methods and Materials: From a retrospective review from Jannuary 2006 to February 2016, we recorded patients' and tumours' characteristics at the initial and second breast cancer (BC): systemic recurrence, disease-free survival (DFS) and overall survival (OS).
Results: 308 of 727 patients were included with a mean follow-up of 75.5 months: 217 with a conventional follow-up (mammography and ultrasound) and 91 with additional BMRI. There was no difference between the groups in locoregional recurrence (LR) (13 vs 22, p = 0.561). 306 BMRI were performed to detect 12 LR with 4 occult BC. BMRI had 4.2% cancer detection rate, 100% sensitivity, 88.7% specificity and 11.8% false positives. The DFS after exclusion of patients with distant recurrence was not significantly different: 184.7 months (IC 95% : 145.6-223.8) without MRI and 156.3 months (125.5-187.2) with MRI (p = 0.132). The mean OS did not differ significantly between the groups, being 318 months with MRI and 301.8 months without MRI (IC 95% = 275.5 - 328; log rank = 0.087).
Conclusion: BMRI surveillance did not increase the detection of LR and appeared not to be associated with an improvement in OS.

B-1611 14:56

How early can MRI diagnosis of breast cancer be in BRCA mutated women?
A. Pecchi, G. Musacchia, M. Verrusio, R. Battista, B. Canossi, L. Cortesi, P. Torricelli; *Modena/IT (pecchi.annarita@policlinico.mo.it)*

Purpose: Genes mutations increase the risk of developing breast cancer in women by approx. 50%. In the literature, evidence has consistently reported the importance of MRI screening for early diagnosis of breast cancer in these patients. Primary endpoint was to describe morphological and dynamic patterns of breast cancer diagnosed by MRI during an intensive surveillance multi-imaging protocol. Secondary endpoint was to retrospectively analyse the MRI examination obtained during the round prior to diagnosis to identify the early signs of cancer.
Methods and Materials: Our study involves 224 high-risk women studied with a multi-imaging screening protocol that includes mammography, ultrasound and MRI, differently matched according to woman's age.
Results: 25/224 women developed breast cancer: 4/25 diagnosed in the interval between a round and the next; 21/25 during multi-imaging follow-up. Among these, MRI enhancement pattern was non mass-like in 4 cases, mass-like in 17 cases, 4 of which showed a typical ring enhancement. In 9/21 of tumours detected during MRI screening, at the MRI performed one year before the diagnosis can be detected 3-6 millimetre neoangiogenetic foci, early sign of cancer not visible with the other imaging modality.
Conclusion: In high-risk women, MRI showed a higher sensibility than mammography and ultrasound, confirming as the more efficient screening method. Repeated annually, MRI offers the advantage of comparing with previous exams from which you can detect the appearance of small enhancement foci that may be an early sign of tumour and, therefore, must be considered suspicious.

B-1612 15:04

Single-centre experience with breast MRI maximum intensity projection (MIP) views: sensitivity, specificity and accuracy of the stand-alone evaluation
M. Orsi, M. Cellina, C. Floridi, F. Leone, E. Battaglia, F. Barmettler, G. Oliva; *Milan/IT (marcello.orsi@asst-fbf-sacco.it)*

Purpose: Breast MRI has been proposed as a reliable screening tool for young high-risk patients for breast cancer. MIP reconstruction is a simple, reproducible and comparable view. The aim of our study was to test MIP views as a stand-alone tool for the detection of suspicious findings.
Methods and Materials: From September 2013 to February 2017, 159 consecutive breast MRI scans, performed in a single centre with a 1.5 Tesla scanner, were retrospectively evaluated by an expert radiologist that analysed the MIP coronal and axial views to assess the presence of suspicious findings (SF+ or SF-). The diagnostic accuracy of the MIP views was tested taking as gold standard of the complete radiologic evaluation (breast MRI, US and mammography), considering BI-RADS 1-2 as true negative and BI-RADS 3-5 as true positive.
Results: We analysed 159 breast MRI scans performed in women of a median age of 51(+/-24) years. 11 exams were excluded from the study for motion artefacts. In 89/148 MIP evaluation result was SF+; in 59/148 SF-. MIP evaluation showed sensitivity and specificity of 90.5% and 94.3%, respectively, and accuracy of 0.92. False-negative results were 9: 4 BI-RADS3, 2 BI-RADS4 and 3 BI-RADS5; mean diameter of non-depicted lesions was 8mm (+/-4mm).

Conclusion: MIP reconstruction view showed high sensitivity and specificity in assessing the presence of suspicious findings. Single image comparison with previous analogues helps the readers to notice the appearance or growing of the suspicious findings in the screening setting.

B-1613 15:12

Assessment of background parenchymal enhancement on breast MRI: which sequence shows the best agreement?

B. Bignotti[1], M. Calabrese[1], S. Tosto[1], F. Valdora[1], M. Durando[2], A. Tagliafico[1,1], G. Mariscotti[2]; [1]*Genoa/IT*, [2]*Turin/IT (bignottibianca@gmail.com)*

Purpose: To evaluate inter- and intrareader agreement among different sequences for assessment of background parenchymal enhancement (BPE) on breast MRI.
Methods and Materials: Two independent readers qualitatively categorized BPE on ninety-eight breast MRI using a four-point scale (minimal, mild, moderate or marked) in accordance with the BI-RADS category system. According to MR sequence used for the assessment of BPE categorization, interreader and intrareader agreement across four reading strategies were performed: (1) initial contrast-enhanced fat-suppressed T1-weighted; (2) initial contrast-enhanced subtracted images; (3) MIP images; (4) combination of the initial contrast-enhanced fat-suppressed T1-weighted, initial contrast-enhanced subtracted and MIP images. Readers repeated BPE assessment of twenty-eight breast MRI four weeks after the initial assessment. K statistics was used to calculate the agreement.
Results: Interreader agreement was moderate (k=0.44) using initial contrast-enhanced fat-suppressed T1-weighted, substantial (k=0.69) using initial contrast-enhanced subtracted images, substantial (k=0.67) using MIP images, substantial (k=0.71) using a combination of the initial contrast-enhanced fat-suppressed T1-weighted, initial contrast-enhanced subtracted and MIP images. Mean intra-reader agreement among the two readers was moderate (k=0.55) using a combination of contrast-enhanced fat-suppressed T1-weighted, initial contrast-enhanced subtracted and MIP images.
Conclusion: Overall, the combination of the initial contrast-enhanced fat-suppressed T1-weighted, initial contrast-enhanced subtracted and MIP images showed the highest inter- and intrareader agreement.

B-1614 15:20

Background parenchymal enhancement in MRI, mammographic density and risk of breast cancer

F. Amato[1], A. Orlando[1], M. Di Vittorio[1], M. Safina[2], T.V. Bartolotta[1], R. Ienzi[1]; [1]*Palermo/IT*, [2]*Castellammare del Golfo/IT (amaciccio89@gmail.com)*

Purpose: Evaluate the relationship between "background parenchymal enhancement" (BPE) on magnetic resonance imaging (MRI), mammographic density (MD) and breast cancer (BC).
Methods and Materials: According to BIRADS, two radiologists have classified BPE on MRI (minimal/mild/moderate/marked) and mammographic density (A/B/C/D) of 231 patients (age: 29-91 aa)underwent MR and Mammography examination. Patients with (111/231; 48 %) and without (120/231 ; 52 %) family history of BC were included, and patients with BRCA positivity were excluded. Patients were divided into four groups: Group I:BPE minimal/mild and DM A-B; Group II:BPE minimal/mild and DM C-D; Group III:BPE moderate/marked and DM A-B; Group IV:BPE moderate/marked DM and C-D.Using the chi-square test was calculated the Relative Risk (RR) of BC in the various groups.
Results: 75/231 (32,5%) patients were in Group I, 131/231 (56,7%) in the second, 11/231 (4,8%) in the third and 14/231 (6,1%) in the fourth. Diagnosis of BC was made in 35/75 (46,7% %) of cases in group I, in 60/131 (45,8%) in Group II, in 8/11 (72,7%) in Group III and in 5/14 (35,7%) in group IV. Prevalence of BC was significantly greater among the patients of group III, who had a moderate/marked BPE and DM Grade A-B (p = 0.0181; RR = 1.60; 95% CI: 1.08-2.36), regardless of familiarity and age.
Conclusion: The degree of BPE isn't directly related to the degree of mammographic density or to the relative risk of BC. The association between high BPE and low DM was significantly correlated with a higher prevalence of BC.

Detection of osteitis at the sacroiliac joint in patients with chronic low back pain by STIR and T2-weighted fat-suppressed turbo spin echo sequences: results from the SIMACT study

J. Greese, T. Diekhoff, J. Sieper, C. Schwenke, M.R. Makowski, D. Poddubnyy, B. Hamm, K.-G. Hermann; *Berlin/DE (juliane.greese@charite.de)*

Purpose: To compare short tau inversion recovery (STIR) and T2-weighted fat-suppressed turbo spin echo (T2-FS) sequences to detect osteitis lesions at sacroiliac joints (SIJ) in patients with chronic low back pain (CLBP).
Methods and Materials: This prospective study included 110 patients with CLBP and suspicion of spondyloarthritis and 18 healthy volunteers. All 128 participants (age range 19 to 57 years) underwent 3.0 Tesla MRI of the SIJ including STIR and T2-FS. Two readers independently evaluated osteitis in STIR and T2-FS in separate scoring sessions. Sum score values, signal-to-noise (SNR) and contrast-to-noise (CNR) ratios were calculated. Images were further analysed whether they fulfilled the Assessment of SpondyloArthritis international Society (ASAS) criterion of a "positive MRI" (MRI+). Inter-reader agreement was calculated by intra-class correlation coefficients (ICC).
Results: Overall, sum score values for osteitis lesions were significantly higher (p=0.02) for T2-FS (reader 1: 3.90±5.67; reader 2: 7.10±8.69) compared to STIR (reader 1: 2.55±4.41; reader 2: 3.95±5.79). Mean SNR was measured 16.54 for STIR and 37.30 for T2-FS (p=0.03). Likewise, mean CNR was 4.14 for STIR and 20.20 for T2-FS (p=0.02). ASAS MRI+ definition was significantly more often fulfilled for T2-FS compared to STIR (p=0.0003) by both readers. Inter-reader ICC values were very good both for STIR (0.91) and T2-FS (0.86).
Conclusion: T2-FS sequences detect more MRI+ patients with superior image quality in cohorts with CLBP compared to STIR. Therefore, we recommend T2-FS as addition to STIR for MRI protocols of the SIJ.

B-1616 14:08

T2-mapping of the sacroiliac joints at 1.5T: a reproducibility study

D. Albano[1], V. Chianca[2], M. Galia[1], R. Cuocolo[2], R. Bignone[1], C. Messina[3], L.M. Sconfienza[3], A. Brunetti[2], R. Lagalla[1]; [1]*Palermo/IT*, [2]*Naples/IT*, [3]*Milan/IT (vitochianca@gmail.com)*

Purpose: T2-mapping of the sacroiliac joints has shown to be feasible at 3T, but feasibility at 1.5T has never been tested. We evaluated the reproducibility of T2 relaxation time measurements of the sacroiliac joints at 1.5T.
Methods and Materials: Healthy volunteers underwent an oblique axial multislice multiecho spin-echo T2-weighted sequence of the sacroiliac joints at 1.5 T. The regions of interest were manually drawn with Olea Sphere® 3.0 software (Olea Medical®, La Ciotat, France) by two musculoskeletal radiologists to include the cartilaginous part of the sacroiliac joints. Intra- and inter-observer reproducibility was tested using the Bland-Altman method. Association between sex and T2 relaxation times was tested using the Mann-Whitney U test. Correlation between T2 relaxation times and body mass index (BMI) was tested using the Spearman's rho.
Results: Eighty sacroiliac joints of 40 subjects (mean age: 28±4.8 years, range: 20-43; mean BMI: 23.3±3.1, range: 18.9-30) were imaged. The mean T2 value calculated by the senior radiologist in the first series of measurements was 42±4.4ms, whereas in the second series was 40.7±4.5ms. The mean T2 value obtained by the radiology resident was 41.1±4.2ms. Intra-observer reproducibility was 88% (coefficient of repeatability=3.8; bias=1.28; p<0.001), while inter-observer reproducibility was 86% (4.7; -0.88; p<0.001). There was significant association between sex and T2 relaxation times (p=0.024) and significant inverse correlation between T2 relaxation times and BMI (r=-.340, p=0.002).
Conclusion: The assessment of T2 relaxation time measurements of sacroiliac joints seems reproducible to be performed at 1.5T. Further studies could investigate the potential clinical application of this tool.

B-1617 14:16

MRI findings of sacroiliac joint disorders in SAPHO syndrome

X. Shao, W. Xu, C. Li, X. Zhao, W. Zhang; *Beijing/CN (sxl669594@sina.com)*

Purpose: To retrospectively evaluate the MRI features of sacroiliac joint disorders in 38 SAPHO patients, thus increasing the awareness of SAPHO syndrome among clinicians.
Methods and Materials: 38 SAPHO patients (female: male, 26:12; mean±SD age, 46.3±10.1 years) were enrolled. The frequency of sacroiliac joint disorders was calculated and MRI features were evaluated.
Results: 23 patients (41 joints) were involved, with a frequency of 60.5%(23/38). 52.2% (12/23) of these patients were bilaterally involved. Among the involved 41 joints, lesions distributed with a predilection on the sacrum in 58.5% (24/41). 87.8% (36/41) of the involved sacroiliac joints were affected by the cartilaginous portion, and 90.2%(37/41) by the ligamentous portion. Inflammatory changes including bone marrow oedema, capsulitis, effusion and enthesitis were observed in 80.5% (33/41), 29.3%(12/41), 24.4%(10/41) and 80.5%(33/41) of the involved sacroiliac joints, respectively. While chronic changes including post-inflammatory fatty deposition, erosion and sclerosis were observed in 92.7% (38/41), 70.7% (29/41) and 70.7% (29/41) of the involved sacroiliac joints, respectively. Joint space was widened in 19.5% (8/41) joints, narrowed in 17.1% (7/41) and ankylosis in 14.6% (6/41). Soft tissue involvement was observed in 14.6% (6/41) of the involved sacroiliac joints.
Conclusion: Sacroiliac joints were more bilaterally involved in SAPHO patients, with predilection on the sacrum. Active lesions and chronic lesions usually coexist, with a lower prevalence of ankylosing and soft tissue involvement. These MRI features could provide certain information of SAPHO syndrome. Consultation of skin lesions should be taken into consideration for a comprehensive evaluation and definite diagnosis.

B-1618 14:24

Sacroiliitis due to early ankylosing spondylitis, inflammatory bowel disease and Behçet's disease: could sacroiliac MRI play a role in differentiation?

Z. Akkaya, E. Peker, F.S. Ozalp Ates, G. Sahin; *Ankara/TR (zehraakkaya@gmail.com)*

Purpose: The purpose of this study was to investigate whether sacroiliitis due to early ankylosing spondylitis (AS), inflammatory bowel disease (IBD)-related spondyloarthropathy and Behçet's disease (BD) were distinguishable by MRI.
Methods and Materials: Sacroiliac MR images of 88 patients (52 with AS, 17 with BD, 12 with Crohn's disease (CD) and 7 with ulcerative colitis (UC) including 65 females and 23 males (mean age: 41.8 ±11.3) were retrospectively evaluated by two radiologists who were blind to the diagnoses. The evaluation parameters consisted of soft tissue-related changes (thickness of perirectal fat, presence of perirectal lymph node or submucosal fatty infiltration) and sacroiliac joint changes (joint surface irregularities-erosions, bone marrow edema, subchondral sclerosis-fatty change and laterality of involvement). Statistical analyses were performed to search for distinguishing parameters between the AS and IBD-Behçet's disease combined group. Additionally, the findings for the Behçet's disease group were compared to those of the IBD group.
Results: Marrow edema, chronic subchondral marrow changes, surface irregularities-erosions and bilateral involvement of the sacroiliac joints were significantly more common in the AS group ($p < 0.05$). No statistically significant results were found for either parameter between the IBD and Behçet's disease groups.
Conclusion: Both active and chronic joint changes were more pronounced in the AS group. Behçet's disease is a multisystem disorder but not an IBD-associated spondyloarthropathy. However, the analyzed Behçet's disease group displayed bowel and joint changes similar to those of the IBD group.

B-1619 14:32

Osteitis distribution on MRI of the sacroiliac joints in patients with osteitis condensans compared to axial spondyloarthritis

K.-G. Hermann[1], S. Mercan[1], K. Ziegeler[1], T. Diekhoff[1], J. Greese[1], B. Hamm[1], M. Bollow[2]; [1]*Berlin/DE*, [2]*Bochum/DE (kghermann@gmail.com)*

Purpose: Osteitis condensans (OC) is a non-inflammatory disorder affecting the sacroiliac joints (SIJ) and is attributed mainly to mechanical stress, such as pregnancy and delivery or frequent sports activities. In later stages, it can be readily diagnosed on conventional X-rays. However, frequently MRI is the sole imaging modality and confusion exists whether the distribution and frequency of MRI findings.
Methods and Materials: 119 MRI examinations of the SIJ from a single center specialized in MSK imaging were retrospectively analyzed independently by two experienced readers. Clinical data was collected prior to MRI acquisition via standardized patient questionnaires. A third reader (senior MSK expert) made a decision between either OC or SpA as the leading diagnosis, taking all available imaging data and clinical data into account. Scoring of osteitis was done in a quadrantic scheme and in addition, the predominant site of findings in the anterior-posterior orientation was recorded (anterior, middle, and posterior positions).
Results: 71 patients with OC and 48 with SpA were identified. Osteitis was evident in 73% and 79% of patients, respectively, with mean osteitis sum scores of 1.75±2.55 and 4.13±4.62 ($p<0.001$). While the distribution of osteitis was in the anterior position in 94% of OC patients only 38% of SpA patients demonstrated osteitis in the anterior position and 52% in the middle position.
Conclusion: Different osteitis distribution patterns can be identified to distinguish OC and SpA at SIJ, with OC demonstrating the lesser amount of osteitis compared to SpA, but most frequently located in the anterior inferior position.

B-1620 14:40

Relative maximum apparent diffusion coefficient: a potential biomarker of disease activity in axial spondyloarthritis

K. Lee, W. Lau, H. Tsang, C. Lau, H. Chung; *Hong Kong/HK (viclkh88@gmail.com)*

Purpose: To evaluate the correlation between diffusion-weighted imaging (DWI)-derived parameters of disco-vertebral lesions and clinical parameters in axial spondyloarthritis (SpA).
Methods and Materials: Two hundred and seventy-five patients with expert diagnosed axial SpA were recruited from 3 rheumatology centres. Clinical, biochemical and radiological parameters were collected. All patients underwent whole spine and sacroiliac (SI) joints MRI using short tau inversion recovery (STIR) sequence and diffusion weighted imaging (DWI). The presence of disco-vertebral lesions was defined by positive identification by two independent readers. Apparent diffusion coefficients (ADC) of disco-vertebral lesions and normal marrow were measured for determination of relative mean ADC ($rADC_{mean}$) and relative maximum ADC ($rADC_{max}$) of the disco-vertebral lesions. These were then compared with clinical parameters using Spearman and Pearson correlation coefficients.
Results: Twenty-six (9.5%) patients had disco-vertebral lesions. Forty-two (23 thoracic, 17 lumbar) lesions were identified. Inter-observer agreement was excellent (kappa = 0.895). $rADC_{max}$ correlated positively with intensity of back pain (CC=0.46; p=0.02), morning stiffness (CC=0.47; p=0.02), duration of stiffness (CC=0.44; p=0.03), and stiffness score (CC=0.49; p=0.01). No significant correlations were found between the number of lesions, ADC_{mean}, $rADC_{mean}$, CRP, ESR, and BASDAI score. There were no significant differences in the BASDAI score, CRP, and ESR in patients with or without disco-vertebral lesions.
Conclusion: In axial SpA, $rADC_{max}$ of disco-vertebral lesions correlates significantly with degree of back pain and intensity of morning stiffness. This parameter could be a potential imaging biomarker.

B-1621 14:48

Examination of association of inflammatory activity in psoriatic arthritis and vascular calcification metabolism based on integrated ^{18}F PET/MRI

N. Guberina, A. Körber, M. Forsting, L. Umutlu, A. Bockisch, K. Herrmann, T.D. Poeppel; *Essen/DE*

Purpose: To examine the association between vascular calcification metabolism and musculoskeletal manifestations in patients with active psoriatic arthritis.
Methods and Materials: In a prospective clinical trial 21 patients with psoriatic arthritis were included in the study. Participants were examined according to a standardized whole-body protocol on the PET/MRI-scanner MagnetomBiograph_mMR (Siemens Healthcare, Germany) within a single session. Joint inflammation based on ^{18}F-NaF PET/MRI images was assessed according to 8 different variables (SUV_{max}, tenosynovitis, bone and soft tissue oedema, bone erosions, joint-space narrowing, joint-subluxation, and interphalangeal ankylosis). Vascular calcification metabolism was evaluated based on ^{18}F-NaF-PET/MRI images in terms of ^{18}F-NaF-uptake in large (aorta ascendens, aortic arch, thoracal and abdominal aorta descendens) and medium vessels (supraaortic arteries, a. mesenterica superior, iliac arteries, a. femoralis superficialis). SUV_{max} was normalized for the mediastinal blood pool. Furthermore, association with laboratory parameters (CRP, CCP, leukocytes, rheuma factor, triglycerides and cholesterol) was examined.
Results: A total of 21 subjects (71.4% men, 28.6% women, age range 23 - 77 years) were evaluated. Vascular calcification metabolism of large and medium vessels showed a significant positive correlation with changes observed in advanced stage of psoriatic joint manifestation ($p<0.05$). Moreover, arthritic changes were not associated and showed no correlation with laboratory markers of inflammation ($p>0.05$).
Conclusion: The severity of psoriatic joint manifestations in advanced stage of psoriatic arthritis does significantly correlate with vascular calcification metabolism. Patients with psoriatic arthritis with clinical mild arthritic changes may present severe atherosclerotic changes. Both psoriatic changes and vascular inflammation may precede the actual onset of clinical symptoms.

B-1622 14:56

Subclinical psoriatic arthritis detection in patients with psoriatic onychopathy

V. Linovs, M. Radzina, T. Linova, A. Rubins, S. Rubins; *Riga/LV (dr.viktors.linovs@gmail.com)*

Purpose: Find correlation between psoriatic onychopathy and subclinical enthesitis.
Methods and Materials: The prospective study included 97 patients: 25 patients with nail psoriasis (clinically confirmed) with no history of previous rheumatological disease, 47 patients with psoriasis without onychopathy with no history of previous rheumatological disease and 25 control cases (healthy individuals). Clinical evaluation and ultrasonographic assessment was performed in 12 entheses and 8 nails in each patient by a dermatologist and a radiologist (ultrasonographic assessment using modified Madrid Sonographic Enthesis Index (MASEI) protocol). Inflammatory activity in enthesis (active enthesitis) was defined as the presence of power Doppler signal, tendon thickening and/or hypoechogenicity.
Results: There was correlation between enthesitis and psoriatic nail involvement ($p<0.05$), as well as correlation between psoriasis and enthesitis ($p<0.05$). No correlation between clinical evaluation of the enthesis and enthesitis was observed ($p>0.05$). Nail matrix thickness was significantly increased in patients with nail disease (1.89 mm vs. 1.75 mm; $p<0.05$). The loss of the trilaminar nail plate appearance and increased Power Doppler signal in the matrix were also significantly associated with nail psoriasis ($p< 0.05$). There is correlation between clinical evaluation of the nail and ultrasound findings in the nail organ ($p<0.05$). No pathological findings were seen in control group.
Conclusion: Ultrasound could be a valuable diagnostic tool for detection of subclinical enthesitis in patients with psoriatic onychopathy, which is proved to be predisposing factor of psoriatic arthritis. Ultrasound screening in psoriatic onychopathy patients may be considered as early stratification method for early treatment initiation.

B-1623 15:04

Hypodermal adipose tissue sonoelastography for monitoring different treatment responses in patients with plaque psoriasis

M. Guazzaroni, S. Altobelli, S. Marsico, A.U. Cavallo, A. Bozzi, R. Floris; *Rome/IT (salvatore.marsico@hotmail.it)*

Purpose: To evaluate hypodermal adipose tissue inflammation underneath psoriasis plaques quantifying tissue elasticity with sonoelastography before and after treatment with topic therapy, systemic therapy or with biologic drugs.
Methods and Materials: From September 2015 to September 2017, we enrolled 120 patients with plaque psoriasis with a mean age of 51 years (range 18-80) (38F, 22M) with plaque psoriasis and a PASI score of >5. They were divided into 3 groups of treatment depending on the prescribed drug: topic therapy (Group A), systemic therapy with DMARDS (Group B) and biologic drugs therapy (Group C). A baseline (T0) ultrasound examination with sonoelastography was performed before the beginning of drugs assumption. At this time the mean strain ratio was recorded on normal and pathologic skin. A follow-up clinical and ultrasonographic examination (T1) was performed after one month of treatment to evaluate therapy response.
Results: At T0 lesional mean strain ratio was significantly higher than non-lesional one, thus documenting an high grade of stiffness of the hypodermal fat underneath psoriasis evaluated plaques. T1 examination data obtained from the 3 selected groups of patients documented a significant decrease in stiffness when comparing groups B and C together with groups A and group C with both groups A and B. Mean strain ratio decrease correlated with clinical PASI improvement in all the responder patients in the considered groups.
Conclusion: Sonoelastography is able to identify hypodermal adipose tissue involvement in plaque psoriasis and it represents a valid method to assess early therapy response.

B-1625 15:12

Correlation between central adiposity distribution measured by DXA and inflammatory markers in the Italian cohort of the NU-AGE project

D. Mercatelli[1], A. Santoro[1], G. Guidarelli[1], M. Aparisi Gomez[2], G. Guglielmi[3], C. Franceschi[1], G. Battista[1], A. Bazzocchi[1]; [1]*Bologna/IT*, [2]*Valencia/ES*, [3]*Andria/IT (abazzo@inwind.it)*

Purpose: Adipose tissue is a source of hormones and cytokines, in particular visceral adipose tissue(VAT) and subcutaneous adipose tissue(SAT) have been linked to systemic inflammation.Both modifications in body composition(BC) and a low-grade chronic inflammation characterise human ageing.This study evaluates the changes of fat distribution, measured by dual-energy X-ray absorptiometry(DXA), and the correlation with some inflammatory markers in a group of Italian elderly people that increased BMI but reduced fat and vice-versa after one-year.
Methods and Materials: 271 sex-balanced volunteers free of major overt diseases, aged 65-79 years, were enrolled in the Italian cohort of the NU-AGE study, a one year randomised, single-blind, controlled trial with two parallel groups (control vs. diet).Whole-body DXA scans to assess BC, and blood samples were taken at T0 and T1. Comparison of variables was performed using Wilcoxon rank-sum test.
Results: In 42 patients showing reduction of SAT but increase or no change in BMI, significantly lower levels of pro-inflammatory cytokines leptin($p=0.02801$) and TGF-β($p=0.04676$) were found, compared to 28 patients who gained SAT with no changes or reduced BMI. In 47 patients showing a reduction of VAT but an increase or no changes in BMI, significantly lower levels of leptin ($p=0.02736$) were found compared to 23 patients who gained VAT but reduced their BMI.
Conclusion: DXA scans are useful to monitor BC changes over time, especially in patients where changes in BMIdo not reflect changes in central adiposity distribution.Both VAT and SAT reduction were positively correlated with a decreased inflammatory status, despite an increase or no change in BMI.

Determination of breast parenchymal enhancement (BPE) in breast MRI using a deep convolutional neural network

N. Berger, C. Rossi, A. Ciritsis, M. Marcon, A.S. Becker, A. Boss; *Zurich/CH (Nicole.Berger@usz.ch)*

Purpose: Breast parenchymal enhancement (BPE) is rated in each breast MRI in the categories minimal, mild, moderate and marked. If elevated, BPE may hamper the evaluation of the acquired images. The aim of this study was to train a deep convolutional neural network (dCNN) for automatic classification of BPE according to the American College of Radiology Breast Imaging Reporting and Data System (ACR BI-RADS) Atlas.
Methods and Materials: In this IRB-approved retrospective study, breast-MRI data (1200 images) from 106 different patients were downloaded from the picture archiving and communications system (PACS) and labelled by a board certified radiologist according to the enhancement category. A dCNN with 13 convolutional layers followed by 4 dense layers and one fully connected layer implemented in Keras 2.08 was trained with 70% of the data, whereas 30% were used for validation. Minimal, mild and moderate BPE were compared in a one-vs-one fashion computing the probability for the suitability of each category. The classification was determined from the highest probability.
Results: Validation accuracy for BPE category minimal vs. mild was 0.63 and minimal vs. moderate was 0.69.
Conclusion: Even with limited training data, dCNN shows promising results for distinguishing the first three categories of the BPE in breast-MRI based on the ACR BI-RADS system. The proposed technique may in future be useful for accurate, standardized, and observer-independent BPE rating.

B-1628 14:08

Can the breast cancer screening case-load be reduced by deep-learning based identification of normal cases? An international multi-centre retrospective analysis

A. Rodriguez Ruiz[1], A. Gubern-Mérida[1], G. Gennaro[2], M. Chevalier[3], S. Zackrisson[4], I. Andersson[4], I. Sechopoulos[1], R.M. Mann[1]; [1]*Nijmegen/NL*, [2]*Padua/IT*, [3]*Madrid/ES*, [4]*Malmö/SE (alejandrorzrz@gmail.com)*

Purpose: To study the feasibility of reducing the screening case load by automatically identifying digital mammography (DM) exams without abnormalities.
Methods and Materials: Three datasets used in previously published multi-reader studies, performed across four countries and using systems from three vendors, were collected. Each dataset consisted of DM exams, radiologists' BI-RADS© scores and ground truth, yielding 1122 exams (257 malignant) interpreted by 15 readers. A deep learning based computer system (Transpara 1.3.0, ScreenPoint Medical) automatically analyzed each exam, providing a cancer suspiciousness score (1-10). For each dataset, a modified set was created in which pre-selection was simulated by setting the radiologists' scores to BI-RADS 1 for all cases with cancer suspiciousness score ≤5. The area under the reader-averaged receiver operating characteristic curve (AUC) was calculated for the original and modified sets, and compared using bootstrapping.

Results: After pre-selection, we observed only non-significant AUC changes; a slight increase in two sets: 0.785 (95% CI: 0.671-0.865) to 0.807 (0.696-0.887) [P=0.095], and 0.870 (0.819-0.912) to 0.883 (0.836-0.921) [P=0.197]; and a slight decrease in one: 0.821 (0.752-0.877) to 0.804 (0.723-0.871) [P=0.473]. Averaging among readers on each dataset, 27%, 20%, 8% of false positives were excluded; and 1%, 1%, 5% of true positives. Across datasets, pre-selection discarded 44%, 40%, 51% of non-malignant cases and 8%, 6%, 17% of malignant cases.
Conclusion: Automated identification of mammograms that are most likely normal, and therefore might not need to be read, is feasible without significantly affecting the reading performance. This may nearly halve the workload for screening radiologists.

B-1629 14:16

A novel open-access neural network to evaluate suspicious mass lesions detected in breast MRI for direct integration into clinical workflows
S. Ellmann, E. Wenkel, M. Hammon, R. Janka, P.A. Fasching, R. Schulz-Wendtland, A. Maier, M. Uder, T. Bäuerle; *Erlangen/DE (stephan.ellmann@uk-erlangen.de)*

Purpose: To develop a novel machine learning algorithm for classification of suspicious mass lesions detected in breast MRI that can be readily integrated into clinical workflows and is based on objective image features only.
Methods and Materials: This retrospective study included 176 BIRADS 4 and 5 mass lesions in breast MRI with available histopathology as gold standard. 138 lesions were used to train a neural network for classification (benign vs malignant) using different objective parameters (lesion diameter, diffusion restriction, T2w-fs signal intensity, patient age, dynamic contrast enhancement curve type and washout ratio and number of lesions in the affected breast). 38 lesions were randomly selected and retained as a test set. Receiver operating characteristic analyses were used to determine the predictive abilities of the single predictors, and compared to the diagnostic accuracy of the neural network with McNemar tests. The neural network was made available as an open-access internet application using Shiny for R.
Results: The neural network achieved a sensitivity of 90.1% (95% CI 87.8-92.4) and a specificity of 82.6% (78.8-86.4) during training and validation, featuring significantly higher diagnostic accuracy compared to all single parameters alone ($p < .0001$). Regarding the test set lesions, sensitivity and specificity of the neural network were within the 95% confidence intervals (92.0% and 84.6%, respectively).
Conclusion: Here we present a machine learning algorithm for evaluation of suspicious mass lesions in breast MRI based on objective parameters that can only be directly applied in clinical workflows using an open-access online form.

B-1630 14:24

Advancements in computer-aided BI-RADS US characterisation of focal breast lesions: clinical assessment of a new software release of S-Detect
M.L. Di Vittorio, A. Orlando, F. Amato, L. Spatafora, M. Safina, A. Taibbi, F. Ienzi, R. Ienzi, T.V. Bartolotta; *Palermo/IT (marialaura.divittorio@gmail.com)*

Purpose: To compare version 2.0 (V2) to 1.0 (V1) of a computer-guided decision-making software (S-Detect) in the sonographic characterisation of focal breast lesions (FBLs).
Methods and Materials: 73 FBLs (mean size 15.9 mm) in 73 women detected by high frequency US (RS80A with Prestige, Samsung, Seoul) were retrospectively assessed by five independent reviewers with different years of experience (YOE) in breast sonography: one experienced radiologist (ER, >20 YOE), two general radiologists (GR#1 and GR#2, 5-10 YOE) and two radiology residents (RR#1 and RR#2). FBLs were randomly evaluated twice according to BI-RADS US lexicon with V1 and V2. US-guided core-biopsy was the standard of reference for BI-RADS category 4 or 5 FBLs. US follow-up at 6 and 12 months has been available for BI-RADS 3 category lesions both before and after S-detect assessment.
Results: 33/73 were malignant and 40/73 were benignant. Diagnostic accurancy, sensitivity, specificity values for the ER were 0.90, 1.00, 0.83 with V1 and 0.89, 1.00, 0.80 with V2 ($p>0.05$). Corresponding values were: 0.71, 0.83, 0.64 with V1 and 0.71, 0.79, 0.65 with V2 ($p>0.05$) for GR#1; 0.74, 0.76, 0.72 with V1 and 0.74, 0.76, 0.72 with V2 ($p>0.05$) for GR#2; 0.70, 0.95, 0.60 with V1 and 0.75, 0.87, 0.67 with V2 ($p>0.05$) for RR#1; 0.67, 0.77, 0.60 with V1 and 0.73, 0.76, 0.69 with V2 ($p=0.009$) for RR#2.
Conclusion: S-Detect V2 showed a better performance than V1 in lesion boundary segmentation, offering a more accurate tool for decision-making in the characterisation of FBLs, especially for less experienced physicians.

Selection of parameters for computer model of breast anatomy through human observer experiments
D. Pokrajac[1], Z. Radovanovic[2,2], T. Milosavljevic[2], V. Stokanovic[2], S. Weinstein[3], A. Imran Al-Zubaer[1], A.D.A. Maidment[3], P.R. Bakic[3]; [1]*Dover, DE/US*, [2]*Niš/RS*, [3]*Philadelphia, PA/US (dpokrajac@desu.edu)*

Purpose: Human observers have evaluated the influence of software breast phantom parameters on the realism of synthetic mammography and tomosynthesis images.
Methods and Materials: Previously, we developed a recursive partitioning algorithm to simulate breast anatomy. The simulation parameters were selected using a volumetric analysis of reconstructed CT images of a mastectomy specimen. To validate selected parameters, we performed an observer study with clinical radiologists. Mammography and reconstructed tomosynthesis images of phantoms with various simulation parameters were synthesised, and used in 2-alternative forced choice experiments. The varied parameters included the number of simulated tissue compartments and the relative size and shape of compartments. In a preliminary study, we presented 16 synthetic image pairs (8 mammographic and 8 tomosynthesis) to a clinical radiologist. The observer was asked to indicate a more realistic image in each pair. We compared the observers' preference with parameters selected from the mastectomy specimen images.
Results: In the preliminary study, consistently for both mammography and tomosynthesis images, the observer preferred images of phantoms with the larger number of compartments, and with a wider variation in the compartment shape and size. While the number of compartments may be relatively easy to notice, the visual difference in parenchymal pattern due to the range of speed parameters is more subtle.
Conclusion: Our preliminary study supported the anatomy simulation parameters selected from the analysis of mastectomy specimen CT images. A full observer study with two additional radiologists and a larger image set is ongoing.

B-1633 14:40

S-detect as a teaching tool in the characterisation of breast lesions: a preliminary study
M. Di Segni, V. De Soccio, G. Bonito, A. Rubini, V. Magri, V. Cantisani, C. De Felice, F. D'Ambrosio, C. Catalano, G. Alagna; *Rome/IT (gralagna@gmail.com)*

Purpose: To assess the value of S-detect as a teaching tool in the characterisation of breast lesions.
Methods and Materials: One hundred twenty two female patients, aged 21 to 84 years, with 135 breast lesions were prospectively imaged with baseline US by a 32 years experienced radiologist and analysed with S-detect; 4 residents with different experience in breast imaging, blinded to clinical and pathological results, completed the exam with elastography. Then, the residents retrospectively described and categorised lesions according to BIRADS 2013 lexicon and to the scheme proposed by Jales et al. When lesions were categorised as BIRADS 4a by the residents, their readings were compared to the readings of S-detect and in case of disagreement, priority was given to S-detect (Samsung Healthcare, Seoul, South Korea). Diagnostic performance was analysed with 2x2 contingency tables and differences were assessed with Pearson's χ^2 test.
Results: Residents' sensitivity values varied from 95.5% to 100%, whereas specificity values varied from 54.2% to 70.8%; S-detect showed 91.1% sensitivity and 70.8% specificity. In case of BIRADS 4a lesions, using S-detect for 2 of the residents significantly increased from 54 to 75% and from 50% to 75%, whereas it was not significant for the most experienced one (from 70.8% to 75%, $p<0.005$) and for the remaining resident with weak performance ($p>0.05$).
Conclusion: S-detect has a potential as a teaching tool for the less experienced operators.

Evaluation of a CAD (computer-aided detection)-enhanced 2D synthetic mammogram: comparison with a standard synthetic 2D mammogram and conventional 2D digital mammography
J. James[1], E. Giannotti[1], Y. Chen[2]; [1]*Nottingham/UK*, [2]*Loughborough/UK (jonathan.james@nuh.nhs.uk)*

Purpose: CAD-enhanced mammograms utilise an algorithm identifying potential abnormalities on tomosynthesis slices blending them onto a synthetic image. The aim was to evaluate the diagnostic performance of CAD enhanced 2D synthetic mammograms in comparison with standard 2D synthetic mammograms generated from a tomosynthesis data set and conventional 2D digital mammography.

Methods and Materials: A CAD-enhanced synthetic 2D mammogram, a standard synthetic 2D mammogram and 2D digital mammogram were available in 68 breast screening recall cases. Two radiologists, blinded to image type and final assessment outcome, retrospectively read a single-side oblique and cranio-caudal projection for each of the three conditions. The resulting 204 pairs of 2D images were presented in random order and scored on a 1-5 scale (1: normal to 5: malignant) without access to the DBT slices. ROC analysis was performed with area under the curve (AUC) compared using Hanley's two-tailed test.
Results: There were 34 biopsy-proven malignancies and 34 normal/benign cases. Diagnostic accuracy was significantly improved for the CAD enhanced synthetic mammogram compared to the standard synthetic mammogram (AUC=0.846 and AUC=0.683, respectively, p=0.004) and compared to the conventional 2D digital mammogram (AUC=0.724, p=0.027). For all 68 cases, there was an average of 3.2 areas enhanced per image. For the 34 cancer cases, 97.4% of lesions were correctly enhanced, with 2.1 false areas enhanced per image.
Conclusion: CAD enhancement significantly improves performance of synthetic 2D mammograms and also exhibits improved diagnostic accuracy compared to conventional 2D digital mammography.

The impact of shift work on life, psychological and physical health of radiographers: a comparison between fixed and rotating shifts
A.F.V. Cardoso[1], A.F. Abrantes[1], L.P. Ribeiro[1], S. Rodrigues[1], R.P. Almeida[1,1], C.A. da Silva[2]; [1]*Faro/PT*, [2]*Evora/PT (ana.fv.cardoso@hotmail.com)*

Purpose: Shift work is necessary to ensure continuity of care in healthcare facilities where radiographers play an increasingly key role in patient care and patient safety. The aim of this study was to analyse the influence of rotating shift work on social and domestic life and on the health of radiographers as compared to the fixed shift.
Methods and Materials: This cross-sectional and correlational study was conducted in several public and private imaging departments using a combination of four instruments (Sleep Questionnaire, General Health Questionnaire, Physical Health Questionnaire and Scale of Social and Domestic life) consisting of 183 questions. A total sample of 102 radiographers was included and the questionnaires were interpreted and statistically analysed through descriptive statistics and correlation tests.
Results: Using *Mann-Whitney* test it was observed statistically significant differences between fixed and rotating shifts regarding the psychological disorders, social and domestic life (p<0.05). The rotating shifts have a moderate influence on psychological disturbances (X=26,6; p=0,016) as well on the social and domestic life (X=9,5; p=0,005). Moderate sleep disturbances were found for both groups and no statistically significant differences were found regarding the sleep disturbances, gastrointestinal and cardiovascular disorders.
Conclusion: Rotating shifts have consequences on the psychological health and social and domestic life of the radiographer. It is important to regulate and implement strategies to minimise biological, physical and social impact in the radiographer life to allow that these professionals keep working without significant health impairment.

B-1638 14:08
Patient perceptions of radiographer communication skills in general radiology
L. Soares[1], L.P. Ribeiro[1], A.F. Abrantes[1], A.M. Ribeiro[1], K.B. Azevedo[1], R.P. Almeida[1], O. Lesyuk[2], C.A. da Silva[3]; [1]*Faro/PT*, [2]*São Brás de Alportel/PT*, [3]*Evora/PT (oksanalesyuk@gmail.com)*

Purpose: The improvement of results in healthcare through the transmission of information to the patient within a relation of empathy and trust is already a verified hypothesis. Healthcare professionals should base themselves on interpersonal competences throughout their daily work routine, to promote quality in medical imaging, patient safety and technical excellence. The aim of this study was the exploration of patient's perceptions regarding the performance of radiographer in terms of interpersonal communication skills during general radiology procedures.
Methods and Materials: The instrument used was the questionnaire "communication Assessment Tool" (Makoul et al. 2007) adapted to the professional reality of the radiographers. A total of 225 valid questionnaires (including 14 questions with a five-point Likert scale) from patients aged between 24 to 85 years old. The paper-based instrument was delivered and filled by the patients after the performance of general radiology procedures in two public hospitals
Results: The internal consistency of the questionnaire was excellent (Cronbach's alpha = 0.98). Highest ratings were for radiographer behaviour items, such as "greet the patients" (3.88), "respect for the patients" (4.04) and "time available to patient-centred care" (3.80). Lowest ratings were "encouraged to make questions," (3.65), "involved patients in decision-making process" (3.34) and "talk with patients about the next following steps" (3.49).
Conclusion: Radiographers communication skills were evaluated with good levels of patient confidence with the radiological examinations. Despite the overall positive results, this area of health service delivery must be accorded the attention it deserves to continually improve on patient satisfaction through improved communication.

B-1639 14:16
An account of silences in diagnostic radiography: a cultural quilt stitched together with the threads of social defences
T.J. O'Regan[1,2], L. Robinsion[2], A. Newton-Hughes[2], R. Strudwick[3]; [1]*London/UK*, [2]*Salford/UK*, [3]*Ipswich/UK (Tracyo@sor.org)*

Purpose: Multi-professional disciplines contribute typologies of silence that theorize approximately 50-70 different forms, functions and motives for silence. This study provides an account of cultures of silence that present at three UK clinical imaging departments.
Methods and Materials: A qualitative methodology of visual ethnography produced an account of silence in radiography practice. Main methods of creative collage workshops and twelve interviews were supplemented with observations of twenty five staff working in accident and emergency and general practice radiography.
Results: Thematic analysis demonstrates five overarching themes grounded in the data. Silence in radiography clinical practice is related to 1) Emotional labour and social defences; 2) Workload; 3) Avoidance of conflict; 4) Legal and ethical dilemma and dichotomy; 5) Hierarchy. Silence strategies were used to facilitate the smooth every day running of the imaging departments. Silence functioned to reflect and enact empathy towards patients and colleagues, it facilitated staff and patient well being and was also a strategy used to keep waiting times to the minimum. Silence reduced threats of litigation, promoted harmonious teamwork, decreased emotional anxiety and diminished the demands of emotional labour.
Conclusion: The study results in knowledge of silence and silencing strategies used in radiography. In particular data in the form of images and words raise awareness of the emotional labour and social defences employed within radiography. The conclusion is that silence is both help and hindrance to services in a clinical setting. The results should be used to inform health service development and change in cultures of practice.

B-1640 14:24
Job satisfaction of radiographers
S. Souto[1], A.F. Abrantes[1], C.A. da Silva[2], L.P.V. Ribeiro[1], R.P. Almeida[1], K.B. Azevedo[1]; [1]*Faro/PT*, [2]*Evora/PT (lpribeiro@ualg.pt)*

Purpose: The main objective of this study was to determine the relationship between job characteristics and job satisfaction among radiographers to determine which of the dimensions of the job characteristics model contribute most to job satisfaction among radiographers.
Methods and Materials: A self-applied questionnaire was used based in the basic task dimensions tool developed primarily by Hackman e Oldham. This paper-based survey was made available to the radiographers (n=63) working in two local public hospitals to assess the work content (variety of skills (VS), identity (I), Task Meaning (TM), Autonomy (A), Intrinsic feedback (IF), extrinsic feedback (EF), interrelationship (IR)) and the work context (satisfaction with the social environment (SE), satisfaction with supervision (SS), satisfaction with the possibilities of growth (SPG), satisfaction with the physical environment (SPE), satisfaction with payment and compensation (SPC), Satisfaction with Work Organization (SWO) and Satisfaction with Safety at Work (SSW)).
Results: The internal consistency of the questionnaire was good (Cronbach's alpha = 0.88). The lowest satisfaction scores were identified in IR (61.9%), EF (59%), SSW (71%), SPC (31.7%), SS (74.6%) and (77.8%). All the other dimensions scored higher than 80%.
Conclusion: In general, it is possible to say that radiographers are professionally satisfied. However, it is of major importance to show to the managers that human resources policies and management related problems still need major attention and improvement. In order to further strengthen and validate the findings of the study, interviews can be carried out in addition to the distribution of questionnaires.

B-1641 14:32

Evaluation of burnout syndrome in radiographers

V.R. Luiz, L.P.V. Ribeiro, A.F. Abrantes, K.B. Azevedo, R.P. Almeida, S. Rodrigues, N.F. Pinto; *Faro/PT (lpribeiro@ualg.pt)*

Purpose: Evidence demonstrates that health care professionals are more prone to burnout than other professionals due to the emotionally taxing interactions they have with their patients on a daily basis. The aim of this study was to measure occupational burnout levels among radiographers.
Methods and Materials: This research used a sample characterisation survey in addition to the *Maslach Burnout Inventory* (MBI), translated and validated to the professional's native language. The evaluated dimensions were emotional exhaustion (EE), depersonalisation (D) and reduced personal accomplishment (RPA). The MBI survey is composed by 22 questions where the professional should mark the answer in a 0 (never) to 6 (daily) Likert scale. A total of 119 radiographers from 9 different healthcare facilities agreed to participate.
Results: In this study, 99.2% of radiographers worked in a facility with emergency department. The EE, D and RPA dimensions revealed moderate levels of burnout. Statistically significant differences were found between dimension D and the hospital and between dimension RPA and the work in rotational shifts ($p<0.05$). The variable job satisfaction interferes significantly with the three dimensions of the MBI.
Conclusion: This research allow us to conclude that the burnout may reach disturbing levels, since professionals often do not recognise this phenomenon and do not seek for help, thus becoming a chronic problem. Therefore, it is vital to develop further research in this area to strengthen the demonstration that healthcare may be endangered by health professionals in burnout.

B-1642 14:40

A survey on the attitude towards research among radiographers

I. Conceição, A.F. Abrantes, L.P. Ribeiro, S.I. Rodrigues, R.P. Almeida; *Faro/PT (inesconceicao.ic@gmail.com)*

Purpose: Research is a key component of evidence-based medical imaging and good knowledge and attitude towards research is important in implementing the paradigm shift from traditional model of practice to evidence-based practice. Therefore, the aim of this study was to assess the radiographers attitudes towards scientific research.
Methods and Materials: A cross-sectional, non-experimental research design was adopted, using a self-applied questionnaire and assigned to 115 radiographers from public and private imaging departments in order to verify important barriers and attitudes regarding research in clinical practice. The questionnaire includes 5 main sections with a total of 43 items. Data were interpreted and statistically analysed through descriptive statistics. Chi-square, Spearman and Mann-Whitney tests were also performed.
Results: Currently, most radiographers (78,3%) are not involved in research activities, but 80% presented interest in this field. It were observed statistically significant correlations between the radiographer involvement in research activities and the academic degree ($p=0.027$) as well with the participation in research training programs ($p=0.046$). Also, it were observed statistically significant differences between the radiographers involved and not involved in research activities, namely in the items: "Radiographer role includes the promotion of research activities" ($p=0.019$), "Radiographer uses the research findings in clinical practice" ($p=0.016$), "The need for research training programs" ($p=0.001$) and all the items related to research competences ($p<0.05$).
Conclusion: The data suggest positive attitudes among radiographers. However, some barriers to participation were identified and institutional support and provision of research related courses are needed to increase radiographers involvement in research activities.

B-1643 14:48

A comparative study about motivations, expectations and professional development in four European radiography programmes

C.S. Reis[1], J. Pires Jorge[2], S. Mæhle[3], H. York[4], L. Flaction[2], S. Johansen[3]; [1]*Perth/AU*, [2]*Lausanne/CH*, [3]*Oslo/NO*, [4]*Herts/UK (Jose.JORGE@hesav.ch)*

Purpose: To compare motivations, expectations and work plans of recent graduated students and teaching-staff from different European radiography programmes.
Methods and Materials: A survey was performed to collect data about motivations, expectations, challenges, potentials of radiography education and plans for further professional development addressing students and teaching-staff. The questions were closed ended and answers were dichotomous, multiple choice, five- or nine-point Likert Scale. To explore further perspectives, open questions were introduced into the questionnaires. Content analysis was performed to analyse the data.
Results: Response rate varied between 16% to 93%. The motivations referred by students to pursue radiography education were the opportunity to work in a health-care organisation helping those that need help, performing different tasks and combining different areas of knowledge such as physics, patient care, physiology and anatomy. 75% of students did not reach all of their own expectations for radiography, mainly due to the content and poor specialisation. An enlargement of radiographers' role was expected for the future by the teaching-staff. As further professional developments, the participants identified also the extension of studies (postgraduations, masters), more research and international collaborations.
Conclusion: In general, the participants have similar motivations, expectations and plans for the future even having different curricula. There is a need for improvements in education due to the permanent technological developments, changes and demands observed in the workplace/job markets. Further studies need to be perform to identify an approach that considers, at the same time, the specificities of each country and proving strategies to harmonise radiography in Europe.

B-1644 14:56

Where is the radiography profession heading? Plausible scenarios for the profession in Sweden in 2025

B. Bjorkman[1], K. Fridell[2], P. Tavakol Olofsson[3]; [1]*Jönköping/SE*, [2]*Huddinge/SE*, [3]*Stockholm/SE (berit.bjorkman@ju.se)*

Purpose: The aim of the study was to analyse and describe plausible scenarios for the radiography profession in 2025.
Methods and Materials: The study has a qualitative design with an inductive approach. Data collection is based on eleven focus group interviews, with 48 registered radiographers, working in eleven different diagnostic radiology departments throughout Sweden. The study builds on the scenario-planning method, which has the potential to predict four plausible scenarios for the radiography profession in the future.
Results: Two trends were considered as the most uncertain scenarios for the future, hence having the greatest impact on the radiography profession if they should occur. These trends were labelled: "Access to career advancement" and "A sufficient number of radiographers". Following four plausible scenarios unfolded: "The happy radiographer", "The specialist radiographer", "The dying profession" and "The assembly line".
Conclusion: The direction of the radiography profession within the Swedish context can probably be changed in a positive way. Hence, future opportunities and threats should be identified and incorporated into the strategic planning. Following, appropriate actions should be taken. It is suggested, that "The dying profession" scenario could be turned in the opposite direction by facilitating career development opportunities for radiographers. This direction would probably lead to a profession composed of "happy radiographers", who are specialists and competent to carry out advanced tasks. Heading towards this scenario, may as well lead to a more visible profession and consequently, radiographers being proud of their profession.

B-1645 15:04

Radiographers and non-accidental injury in children

A.F. Abrantes[1], D.M. Sobral[2], L.P.V. Ribeiro[1], K.B. Azevedo[1], R.P. Almeida[1], O. Lesyuk[1]; [1]*Faro/PT*, [2]*Cercal do Alentejo/PT (lpribeiro@ualg.pt)*

Purpose: The purpose of this research was to evaluate the capabilities and competences of radiographers with regard to situations of non-accidental injury in children.
Methods and Materials: On the medical environment, particularly in two public radiology departments from two hospitals, a self-applied questionnaire was applied to a total of 42 radiographers in order to study their capabilities and competences within the non-accidental injury in children.
Results: The internal reliability of the questionnaire was good (Cronbach's alpha = 0.84). Most of the radiographers (78.6%) referred to have had formal formation in paediatrics, during the academic training. The remaining have had post-graduated formation. Despite this fact, there was no statistical significance correlation ($p>0.05$). 42.5% of the radiographers declared to have an acceptable level of competence to recognise the radiological signs of non-accidental trauma in children, although 47.6% referred to not know exactly the national guidelines on this matter. Most of the radiographers said to have excellent capacity to do these examinations, but most of them do not feel comfortable in give testimony in the court.
Conclusion: This research allowed to conclude that during the procedure of imaging examinations in cases of non-accidental injury in children, radiographers attribute a more significant valuation to clinical practice and direct contact with this type of situation, compared to specific training, as a means of attain the skills to engage in this area. Further education and training for radiographers dealing with children and non-accidental trauma is recommended.

B-1646 15:12

Evaluating the use of detector dose indicators in digital x-ray imaging systems

S. Lewis[1], T. Pieterse[2], L.A. Rainford[3], H. Lawrence[1]; [1]*Johannesburg/ZA*, [2]*Doornfontein, Johannesburg/ZA*, [3]*Dublin/IE (shantell@uj.ac.za)*

Purpose: Detector dose indicators (DDI) are the only indicator of correct exposure technique in digital x-ray imaging systems but the use of such indicators remains largely unexplored in a South African setting. The study investigated radiographers' familiarity and use of DDI and compared the actual DDI obtained in practice to the manufacturer's recommended standards which provided insight into current exposure technique practices in this setting.
Methods and Materials: An explorative and descriptive quantitative study was conducted in two phases at randomly selected radiography clinical training facilities (n=10). Phase one of the study investigated the radiographers familiarity with and use of DDI (n=105) at selected sites by means of a questionnaire. In phase two of the study, actual DDI values were collected retrospectively from the same sites and compared to the manufacturer's recommended standards (n= 1422).
Results: 54.3% of respondents had a correct understanding of DDI and 55.7% of respondents used the DDI correctly. Of the 1422 retrospectively collected actual DDI values only 50% of DDI evaluated were within the manufacturer's recommended range and 27% of DDI evaluated indicated overexposure.
Conclusion: An observable lack of familiarity and the questionable use of DDI by radiographers coupled with some evidence of overexposure in the clinical setting suggest that improvements could be made to the training radiographers' receive on digital imaging systems. Moreover, retrospective auditing of DDI is advocated as a dose optimisation, radiation protection and quality improvement strategy in clinical departments in a South African setting.

B-1647 15:20

Evaluation of radiation protection knowledge among hospital employees

T.Ø. Holter[1], S. Torp[2], A. Martinsen[1]; [1]*Oslo/NO*, [2]*Kongsberg/NO (uxtaho@ous-hf.no)*

Purpose: Radiation protection regulations emphasize the importance of knowledge as a preventive factor in radiation safety. Employees occupationally exposed to ionizing radiation in hospitals are required to possess adequate competence regarding radiation protection and possible health hazards from radiation exposure. Besides, knowledge may prevent unnecessary concern. In this study, the reliability of self-assessment was compared to quantitative tests to evaluate the different methods for measuring the level of employees' knowledge on radiation protection.
Methods and Materials: A quantitative cross-sectional survey was performed to evaluate self-reported competence compared to quantitative test results. The results from the survey were tested for correlations using Cohen's Kappa. All staff members in the hospital carrying dosimeters were invited to participate. 528 respondents (52% of the invited respondents) answered the electronic questionnaire.
Results: Findings from this study demonstrate that there were discrepancies between the respondents tested and self-reported radiation protection knowledge (kappa = 0.27). Personnel with a high tested score tended to underestimate their knowledge, while personnel with a lower level of tested knowledge, tended to overrate themselves.
Conclusion: To evaluate the level of radiation protection knowledge among hospital workers, it is not sufficient to map their personal perception, as a large proportion of the informants either overrate or underestimate their level of knowledge. Supplementary analyses are needed to give an accurate impression of the level of competence, and should be implemented in further competence-raising efforts.

Performance of native T1 and T2 mapping cardiovascular magnetic resonance to detect myocardial oedema in patients with dilated cardiomyopathy

W. Peng, Z.-L. Li, C. Xia; *Chengdu/CN (yimaerlin@163.com)*

Purpose: To evaluate the performance of nativeT1 and T2 mapping techniques to identify myocardial oedema in patients with dilated cardiomyopathy (DCM).
Methods and Materials: Twenty DCM patients and 10 healthy volunteers were enrolled in and underwent CMR examination. Modified Look-Locker Inversion recovery T1 maps and Balanced Steady-State Free Precession (bSSFP) T2 maps were acquired on matching short axis of basal, middle and apex segments. The native T1 values of T1 maps and T2 values of T2maps were measured and compared. Receiver operating characteristic analysis was performed to determine whether T2 values could be used in discriminating myocardial oedema between DCM patients and normal subjects.
Results: In DCM patients, T2 values were significantly increased in comparison with normal controls (45.61 ± 4.30 vs. 39.57 ± 5.01, $p < 0.05$). T1 values of DCM subjects were increased(1095.21 ± 266.73 vs. 991.99 ± 229.90), but no statistical significance (P=0.458). For the segmental heterogeneity, T2 values of basal, middle and apical segments in DCM patients were higher comparing with normal ones(all P<0.05). A cutoff value for global myocardial T2 of ≥ 42.91 ms provided a sensitivity, specificity, accuracy, negative and positive predictive value of 71% (42%-92%), 80% (30%-95%), 81.4% (57%-95%), 91% (59%-100%), and 50% (16%-84%) for DCM, respectively.
Conclusion: T2 mapping seems to be superior when compared with native myocardial T1 values for assessing myocardial oedema in patients with DCM. The threshold values of global T2 values may be used as indicators for differentiating myocardial oedema between DCM patients and normal subjects.

B-1649 14:08

The multidisciplinary "endocarditis team": results on imaging utilisation and diagnostic and therapeutic changes in the first 100 patients

L.E. Swart, M.M. Henneman, T.W. Galema, J.A. Bekkers, R. Valkema, C.A.M. Schurink, N.J. Verkaik, J.W. Roos-Hesselink, R.P.J. Budde; *Rotterdam/NL (r.budde@erasmusmc.nl)*

Purpose: The most recent European Society of Cardiology guidelines on endocarditis strongly advise to set-up a multidisciplinary "endocarditis team" including imaging specialists to guide diagnostic and therapeutic decisions. These guidelines now also include Cardiac CTA and PET-CT as major diagnostic criteria next to blood cultures and echocardiography. We present the first 100 patients discussed in our "endocarditis team".
Methods and Materials: Starting January 1st 2016, patients with suspected endocarditis were discussed in our "endocarditis team". At least one radiologist, nuclear medicine physician, cardiologist, cardiac surgeon and infectious diseases specialist/medical microbiologist were present every meeting. Data of patients were retrieved from the structured reports of these meetings and electronic patient files, including imaging technique utilization as well as diagnostic and therapeutic changes.
Results: One hundred patients (66 males; age 64±19y) with (suspicion of) native (n=43) or prosthetic (n=48) heart valve endocarditis or cardiac implantable device infection (n=9) were discussed (total amount of discussions: 143). At the time of initial discussion, the following diagnostics had been performed: TTE (n=82), TEE (n=76), cardiac CT (n=22), PET-CT (n=35) and MRI (n=10). Additional imaging was advised in 19 patients (19%) (16 cardiac CT, 7 PET-CT). During the "endocarditis-team" meetings, diagnosis changed in 13 patients (13%), and therapy in 53 (53%; surgical intervention recommended in 34, change in antimicrobial therapy recommended in 42).
Conclusion: A multidisciplinary "endocarditis team"-approach to patients with (suspected) endocarditis results in increased utilization of additional imaging techniques and a change in both diagnosis and treatment in a substantial numbers of patients.

B-1650 14:16

Six months follow-up after triple rule-out using second-generation dual-source CT in patients with acute chest pain

M. Fusaro[1], G. Balestriero[1], A. Dorigo[2], G. Battistella[1], C. Bortolanza[1], G. Tessarin[1], L. Doni[1], A. De Leo[1], G. Morana[1]; [1]*Treviso/IT*, [2]*Santa Maria di Sala/IT (fusaro341@gmail.com)*

Purpose: To determine the prognostic value at six months of a low-dose protocol triple-rule-out CT using second-generation dual-source CT vs standard evaluation in acute chest pain.
Methods and Materials: A blinded prospective observational cohort study was conducted. We enrolled patients with acute chest pain, negative ECG, negative troponin test and low-intermediate cardiovascular risk, arriving at ED from March 7, 2016 to December 31, 2016. CT was performed in all patients with a standardized low-dose prospective ECG-trigger triple rule-out. Patients were classified with CAD >50%, <50% or without: all patients were treated by a standard protocol of our hospital without knowledge of the CT results. A follow-up phone call was conducted after 6 months to determine the occurrence of MACE (death, ACS, and coronary revascularization). Total DLP and contrast-enhanced phase DLP were assessed.The analysis of the data was performed with SPSSv13 and WinPEPI v11.5.
Results: 125 consecutive patients (53.2 yo ± 9.7), 83 (66.4%) males, were enrolled: 76 (60.8%) were free of CAD, 40 (32%) had <50% CAD and 9 (7.2%) had a >50% CAD. No pulmonary embolism or aortic dissection was observed. At 6 months, no MACE was observed. 4 patients were not traceable during follow-up. The total and the single contrast-enahnced phase DLP were, respectively, 250.7±90.8 and 195.2 ±82.5.
Conclusion: The triple-rule-out protocol with second-generation dual-source CT in properly stratified acute chest pain patients allows safe discharge and may be an ideal diagnostic tool in all hospitals with the necessary technology and experience.

B-1651 14:24

The prognostic value of late gadolinium enhancement in non-ischaemic dilated cardiomyopathy

P.M. Cannao', F. Secchi, M. Scarabello, M. Alì, F. Sardanelli; *Milan/IT (paola.m.cannao@gmail.com)*

Purpose: To evaluate the prognostic value of late gadolinium enhancement (LGE) amount for the stratification risk in patients with non-ischaemic dilated cardiomyopathy (DCM).
Methods and Materials: We retrospectively evaluated 58 DCM patients who underwent 1.5-T CMR at our Institution from July 2008 to April 2016. Of these, only 30 patients followed up for at least 10 months (median follow-up was 46 months). For each patient, segmentation and volume analysis were performed. LGE images were processed, after a semi-automated endocardial and epicardial segmentation of the slices, choosing 6 standard deviation threshold. Spearman's correlation was used to correlate the EDVi, ESVi, EF and SV of both ventricles with the amount of LGE. The ROC analysis was performed between the amount of LGE and the ICD implantation.
Results: There was a positively significant correlation between LV EDVi and LGE (r=0.550, P<.001), LV ESVi and LGE (r =0.590, P<.001) and LGE and LV SV (r=0.379, P=.004), while there was a negatively significant correlation between LVEF and LGE (r =-0.479, P=.002). In 10 patients implanted ICD or PM, a receiver-operator characteristic (ROC) curve analysis revealed a cutoff value of 20.4 g for the LGE amount and this cutoff was determined to have 80% sensitivity and 100% specificity.
Conclusion: An association between myocardial LGE and ICD implantation may be possible to identify high-risk patients. The cutoff found of 20.4 g could be an innovative method to guide the selection of patients eligible for device therapy with a sensitivity 80% and specificity 100%.

B-1652 14:32

The feasibility of dual-energy-computed tomography in cardiac contusion imaging for mildest blunt cardiac injury

M. Kantarci, A. Levent, S. Eren; *Erzurum/TR (akkanrad@hotmail.com)*

Purpose: The purpose of this study was to evaluate the efficiency and feasibility of DECT used in the diagnosis of cardiac contusion with the mildest blunt cardiac injury (BCI).
Methods and Materials: This study was performed between February 2014 and September 2015, a total of 17 consecutive patients (10 men and 7 women; median age 51 years [range: 20-78]) were enrolled in the study. DECT was performed within 48 hours of the trauma and a subsequent follow-up DECT was performed a little less than one year after the first examination. All examinations were analysed on iodine map images by two experienced radiologists. Interobserver and intraobserver agreement was calculated. The correlation of initial troponin level, age and gender with number of contusion areas in the left ventricle and complete recovery of contusion were measured.
Results: The contusion areas were amorphous, with considerable variation in their size, shape, and density. Contusions were primarily located in the left free wall of ventricle, the ventricular septum, and the apex, respectively. In 10 patients, contusion areas disappeared upon follow-up examination. In four patients, the contusion areas decreased but were still present in the follow-up examination. The interobserver agreements were almost perfect with respect to the presence of cardiac contusion, the anatomic location of contusions, and the contusion areas.
Conclusion: DECT can show cardiac contusion and could be useful and feasible for the diagnosis and follow-up of BCIs. DECT is a new, user-independent and valuable imaging technique.

B-1653 14:40

Morbus Fabry: new insights from CMR strain imaging

M.C. Halfmann, S. Benz, J. Eichstädt, A. Lollert, C. Düber, K.-F. Kreitner, T. Emrich; *Mainz/DE (Moritz.Halfmann@gmx.de)*

Purpose: Although Morbus Fabry is widely acknowledged as a systemic disease, the focus of research concerning myocardial involvement has been focused on the left ventricle. Through the measurement of strains, we want to encourage the close examination of right ventricle (RV) as well.
Methods and Materials: In our study, 62 healthy volunteers and 10 patients with a diagnosis of Morbus Fabry and proven cardiac involvement underwent cardiac magnetic resonance (CMR) imaging at 3T. Using a semi-automatic tissue tracking software (CVI Circle®), we measured global strains for both ventricles from multiple axes.
Results: The left ventricular strain parameters (radial, circumferential and longitudinal strains) showed statistically significant differences between Morbus Fabry patients and healthy volunteers (p = .027 and .003). There were also significant differences concerning right ventricular strains (p = .012) with mean of RV global radial strains for Fabry patients of 19.13% (±6.35) and healthy volunteers of 13.47% (±6.46).
Conclusion: Despite the still limited patient number, we found significant evidence for right ventricular involvement of Fabry's disease. This should be the motivation to take a closer look and expand research also on the right ventricle in Fabry patients.

B-1654 14:48

Late gadolinium enhancement patterns in patients with hypereosinophilia: can CMR help identifying the aetiology?

D. Morgan[1], J. Pagniez[1], G. Lefevre[1], L. Averlant[1], J.-E. Kahn[2], B. Longere[1], V. Silvestri[1], F. Pontana[1]; [1]*Lille/FR*, [2]*Suresnes/FR (dubois.morgan.59@gmail.com)*

Purpose: The aim of this study was to assess the prevalence and patterns of cardiac abnormalities detected by cardiac magnetic resonance (CMR) in patients with hypereosinophilia according to the underlying disease.
Methods and Materials: Thirty consecutive patients without history of coronary artery disease (15 males; mean age = 47.7 ± 21) referred for hypereosinophilia were prospectively included. Hypereosinophilia was related to: idiopathic hypereosinophilic syndrome (HES) n=13; eosinophilic granulomatosis with polyangiitis (EGPA) n=6; parasitic infection n=3; hemopathy n=4; and allergy n=4. Cine functional parameters, T1 and T2 values on parametric mapping and late gadolinium enhancement (LGE) were independently assessed by two readers.
Results: Left ventricle (LV) and right ventricle (RV) ejection fractions were impaired in 19 patients (63%) and 7 patients (23%) respectively. LV and RV dilatation was observed in 7 patients (23%) and 2 patients (7%) respectively. Increased myocardial T1 and T2 values were found respectively in 10/21 patients (48%) and 4/21 patients (19%). LGE was detected in 13 patients (43%). Among them, 5 patients presented a myocarditis enhancement pattern (HES n=2, EGPA n=2, parasitic infection n=1), 5 patients presented a vasculitis enhancement pattern (EGPA n=3, parasitic infection n=1, hemopathy n=1) and 3 patients presented an endomyocardial fibrosis pattern (HES n=2, EGPA n=1); p = 0.59.
Conclusion: LGE was observed in almost half of the patients with hypereosinophilia with three different patterns (myocarditis, vasculitis and endomyocardial fibrosis) independently of the etiological diagnosis, suggesting a non-specific myocardial toxicity of the eosinophils.

The effect of myocardial bridge on the presence and extent of coronary artery disease: case-control study

S. Papp, J. Karady, M. Kolossvary, Z. Drobni, B. Szilveszter, G. Barczi, B. Merkely, P. Maurovich-Horvat; *Budapest/HU (papp.sara94@gmail.com)*

Purpose: Previous studies have suggested that the presence of myocardial bridge (MB) increases the risk of atherosclerosis proximal to the MB. Our aim was to assess the effect of MB on the quantity and composition of plaques proximal to MBs.
Methods and Materials: Patients who underwent coronary CT-angiography due to suspected coronary artery disease were enrolled into this retrospective case-control study. We selected patients with MB on their left anterior

descending (LAD) coronary artery and a control group matched to age, sex, BMI and cardiovascular risk factors such as smoking, hypertension, diabetes mellitus and dyslipidaemia. Using semiautomated plaque quantification software we segmented the LAD segment proximal to the bridge in the cases and an identical length segment of the LAD in each control patient. We compared the plaque volume and plaque composition between the case and control groups (Wilcoxon signed-rank test).
Results: In total, we assessed 25 case-control pairs (mean age: 59.0±10.9 versus 59.0±10.9 years, p=0.946; males: 88%). The average length of the analysed segments proximal to MBs were 43.5±9.3mm in the case and 43.3±9.3mm in the control group (p=0.412). The total plaque volume did not differ between the groups (178mm^2 [IQR:146.9-198.9] versus 154mm^2 [IQR:124.4-204.9], p=0.638). We found no significant difference in the calcified plaque volume (19mm^2 [IQR:7.3-37.4] versus 12mm^2 [IQR:5.1-24.8], p=0.861), and in the non-calcified plaque volume (109mm^2 [IQR:66.3-131.7] versus 107mm^2 [IQR:79.0-139.1], p=0.527) between the groups.
Conclusion: Our results suggest that the MB has no effect on plaque volume and composition in coronary segment proximal to the MB.

B-1656 15:04

Atrial dysfunction in arrhythmogenic right ventricular cardiomyopathy: value of quantitative MR analysis in predicting atrial arrhythmias
M. Bourfiss[1], T. Zghaib[2], R.N.W. Hauer[1], H. Tandri[2], H. Calkins[2], S. Nazarian[3], A.S.J.M. te Riele[1], B.K. Velthuis[1], S.L. Zimmerman[2]; [1]*Utrecht/NL*, [2]*Baltimore, MD/US*, [3]*Philadelphia, PA/US (m.bourfiss-2@umcutrecht.nl)*

Purpose: Arrhythmogenic Right Ventricular Cardiomyopathy (ARVC) is an inherited cardiomyopathy that predominantly affects the ventricles. Evidence for direct atrial involvement remains limited and few studies have characterized atrial arrhythmias (AA) in ARVC. We aimed to characterize atrial involvement in ARVC using Cardiac Magnetic Resonance (CMR) and to identify CMR-based predictors of AA in ARVC.
Methods and Materials: We analyzed cine-CMR images of 66 definite ARVC patients without a history of AA or severe heart failure (NYHA≥3) and 24 healthy controls. Using tissue-tracking, we evaluated phasic bi-atrial volumes, ejection fractions (EF), peak longitudinal-strain (PLAS) and strain rates (SR). The primary outcome was the occurrence of AA during 6.8 [3.0-10.8] years of follow-up.
Results: Compared to controls, ARVC patients had higher bi-atrial volumes and lower right atrial (RA) passive-EF, RA-PLAS, systolic and early RA-diastolic SR and systolic left atrial (LA)-SR (p<0.05). Although worsening in ventricular size and function was associated with increased bi-atrial volumes and decreased function, variation in atrial parameters was only partially explained by ventricular changes (r^2 5-29%). Using multivariable analysis, predictors of increased risk of AA during follow-up were higher atrial volumes (10% increased risk of AA per mL, p<0.05), decreased LA reservoir function (total LA-EF and LA-PLAS) and decreased RA conduit function (passive RA-EF and RA early diastolic SR).
Conclusion: ARVC is characterized by enlarged atria with decreased function, which is only partially explained by ventricular changes. Bi-atrial parameters predict incident AA after adjusting for clinical and ventricular characteristics, which suggests primary atrial involvement in ARVC.

B-1657 15:12

The role of cardiac magnetic resonance imaging (MRI) in the diagnostic work-up after aborted sudden cardiac death
L. Szabó, C.L. Czimbalmos, I. Csécs, A. Tóth, F.I. Suhai, K. Heltai, E. Zima, L. Gellér, D. Becker, B. Merkely, H. Vágó; *Budapest/HU*
(sz.liliana.e@gmail.com)

Purpose: The aim of our study was to assess the added value of cardiac magnetic resonance (CMR) imaging in the diagnostic work-up of aborted SCD in absence of coronary artery disease and to determine commonness to the myocardial abnormalities in this patient population.
Methods and Materials: During a 7.5-year period (between 2010 and 2017) at the Heart and Vascular Center of the Semmelweis University we performed CMR examinations in 78 patients (37.9±13.8 y, 37 male) after aborted SCD with normal coronary angiography. Among them, 10 were athletes (28.4±10.3 y, 8 male). We measured the left and right ventricular parameters and the presence of myocardial scar/necrosis. We assessed whether CMR changed the provisional diagnosis.
Results: In 65% of the cases (n=51) the CMR proved structural myocardial abnormality as follows: dilated (DCM n=12), arrhythmogenic right ventricular (ARVC n=4), hypertrophic (HCM n=4), Tako-tsubo (n=1) and noncompaction cardiomyopathy (n=1); myocarditis (n=4), acute myocardial infarction (n=3), mitral valve prolapse (n=4), endomyocardial fibrosis (n=1) and aspecific structural alterations (n=16). In the last group, myocardial fibrosis with nonischaemic pattern could be identified in 7 patients. Age group specific incidence rates show that the most common structural heart disease over 35 years was DCM (n=9), while ARVC occurred more frequently under 35 years in our patient population, and was the most common structural disorder in athletes (n=3). CMR examination changed the provisional diagnosis in 50% of the patients.
Conclusion: CMR provides an advanced diagnostic yield in the diagnostic work-up of the excessively variable aetiology of SCD.

B-1658 15:20

Cardiac MRI for a better identification of structural heart disease in patients with ventricular arrhythmia
D. Andreini, S. Mushtaq, G. Pontone, A.D. Annoni, A. Formenti, M.E. Mancini, E. Conte, M. Guglielmo, M. Pepi; *Milan/IT (daniele.andreini@ccfm.it)*

Purpose: Aim of this study is to evaluate whether in patients with ventricular arrhythmia and normal echocardiography, cardiac MRI may identify patients with structural heart disease whose risk has been underestimated by transthoracic echocardiography
Methods and Materials: We enrolled a cohort of consecutive patients with VA who underwent to cardiac MRI after a negative echocardiography. For every patient the presence of cardiovascular symptoms were evaluated. Ventricular ectopic beats (VEBs) was graded as follow: >1000 VEBs/24h; >10000 VEBs/24h; non-sustained ventricular tachycardia (NSVT); sustained ventricular tachycardia (SVT) and history of resuscitated cardiac arrest. End-point of the study was the presence of structural heart disease at MRI.
Results: We enrolled 946 patients (age 41±16 years; 609 male 64.4%). Among them, 241 patients (25.5%) were found to have structural heart disease at cardiac MRI. More specifically, 91 (37.7%) patients had a diagnosis of previous myocarditis, 50 (20.7%) of arrhythmogenic right ventricular cardiomyopathy, 39 (16.2%) of dilated cardiomyopathy, 22 (9.1%) of previous myocardial infarction, 11 (4.6 %) of congenital heart disease, 13 (5.4%) of hypertrophic cardiomyopathy, 5 (2.1%) of left-dominant arrhythmogenic cardiomyopathy, 5 (2.1%) pericarditis and 5 (2.1%) of left ventricular non-compaction cardiomyopathy. Among clinical variable at multivariate analysis only previous SVT (OR 2.23 95%CI 1.26-3.9) and reported chest pain (OR 2.38 95%CI 1.55-3.64) are associated with MRI positive for structural heart disease.
Conclusion: Among patient with ventricular arrhythmia and normal transthoracic echocardiogram almost 25% had cardiac MRI positive for structural heart disease. Among clinical variable previous chest pain and SVT were associated to positive cardiac MRI.

"Avascular" hypoechoic testicular lesions on colour Doppler ultrasound: can they be considered benign? what is the added value of contrast-enhanced ultrasound?
D. Huang, M.R. Alsadiq, M. Sellars, R. Eckersley, P. Sidhu; *London/UK*
(m.alsadiq@nhs.net)

Purpose: Although most avascular hypoechoic testicular lesions on colour Doppler US (CDUS) are often considered benign, the diagnosis may be unreliable due to inherent limitation of CDUS. The purpose of this study is to determine the added value of contrast-enhanced US (CEUS) to conventional CDUS in assessing hypoechoic testicular pathology in differentiating benign from malignant aetiology detected at scrotal US.
Methods and Materials: This retrospective study included 102 avascular hypoechoic testicular lesions detected at colour Doppler testicular ultrasound. The sonographic features recorded include lesion size and presence of vascularity on CEUS and CDUS. The reference standard was pathologic results or at least 6 months stability documented with serial follow-up ultrasound studies.
Results: 102 lesions with no vascular signal on CDUS were identified. 18 of these lesions (17.6%) showed enhancement on CEUS despite lack of signal on CDUS. 6 of lesions with CEUS enhancement were malignant (6/18, 33.3%). The remaining lesions (12) include pathology such as sarcoidosis, post biopsy change, intra-testicular adenomatoid tumour, focal scarring with history of previous orchiopexy, and focal atrophy in patient with klinefelter syndrome. All lesions with no enhancement on CEUS (84) were of benign nature.
Conclusion: Although most avascular hypoechoic testicular lesions on CDUS are benign, a proportion of these lesions are malignant and demonstrate CEUS enhancement. CEUS provides a more definitive characterisation of vascularity

of a focal testicular lesion and would therefore add value to conventional CDUS in differentiating malignant from benign lesions.

A comparison of testicular tissue stiffness using shear wave elastography

M.R.V. Pedersen[1], H. Møller[2], P. Osther[1], P. Vedsted[3], R. Holst[4], S.R. Rafaelsen[1]; [1]*Vejle/DK*, [2]*London/UK*, [3]*Aarhus/DK*, [4]*Oslo/NO (Malene.Roland.Vils.Pedersen@rsyd.dk)*

Purpose: To compare elastography measurements in different testis tissues.
Methods and Materials: A total of 248 consecutive patients were included during the period between 2013 and 2016 from our department of radiology. All patients were outpatients referred by their general practitioner to a clinical US scrotal examination due to symptoms such as pain, discomfort, lump or testicular mass. Exclusion criteria were patients with torsion, inflammation, previously diagnosed with testicular cancer or any linguistic difficulties to understand the informed consent. All men provided written informed consent. Testicular stiffness was assessed using shear wave elastography (SWE). Three SWE velocity measurements were assessed in each testicle. All patients underwent B-mode US investigation followed by SWE. The patients were divided into three groups: men with normal testicular tissue, men with testicular microlithiasis and men with testicular cancer.
Results: We found a higher mean velocity in the group of patients with testicular cancer (1.92 m/s (95% CI 1.82-2.03)) compared to both the group with normal tissue (0.76 m/s (95% CI: 0.75-0.78)) ($p<0.001$) and the group with testicular microlithiasis 0.79 m/s (95% CI: 0.77-0.81) ($p<0.001$).
Conclusion: The presence of testicular microlithiasis increased stiffness slightly, but within the range of variation in normal testicles. Increased stiffness may indicate testicular malignancy in testicular lesions. Ultrasound elastography may be a very useful tool when investigating scrotum.

B-1661 14:16

Diffusion-weighted imaging combined with ADC in the diagnosis of testicular lesions

M. Huang; *Zhengzhou/CN (huangmengna1127@163.com)*

Purpose: The purpose of this study is to identify the diagnostic value of ADC combined with DWI in benign lesions and malignant lesions of testis.
Methods and Materials: 35 patients with testicular lesions confirmed by operation and pathological examination in our hospital were retrospectively analysed, including 18 benign lesions and 17 malignant lesions. The mean ADC values of normal tissue and parenchyma of testicular lesions were measured and statistically analysed by Kruskal-Wallis test and receiver operating characteristic (ROC) curve was delineated. The optimum ADC value for differential diagnosis of malignant testicular lesions was analysed and determined.
Results: In 33 cases of normal testicular tissue, DWI showed homogeneous high signal, mean ADC was (1.137±0.119)×10-3 mm^2/s. 18 cases of benign lesions mostly showed unrestricted diffusion, mean ADC was (1.104±0.463)×10-3 mm^2/s. In 17 cases of malignant lesions, DWI showed high signal, mean ADC was (0.778±0.198)×10-3 mm^2/s. The comparison of ADC mean values between malignant testicular lesions and normal tissue as well as benign lesions of testis showed significant difference ($P<0.05$). The optimum ADC to distinguish malignant testicular lesions from benign testicular lesions was 0.911×10-3 mm^2/s (82.4% sensitivity and 82.4% specificity).
Conclusion: DWI combined with ADC value is beneficial to the preoperative diagnosis and differential diagnosis between malignant testicular lesions and benign lesions of testis.

B-1662 14:24

Diffusion tensor imaging parameters in the identification of spermatogenesis in men with non-obstructive azoospermia

A. Tsili[1], A. Ntorkou[1,2], L.G. Astrakas[1], A. Goussia[1], E. Panopoulou[1], N. Sofikitis[1], M. Argyropoulou[1]; [1]*Ioannina/GR*, [2]*Paris/FR (atsili@cc.uoi.gr)*

Purpose: To assess possible differences of testicular apparent diffusion coefficient (ADC) and fractional anisotropy (FA) values in different histological states of spermatogenesis in men with non-obstructive azoospermia (NOA).
Methods and Materials: Twenty infertile men with NOA and 21 age-matched controls were retrospectively evaluated. All subjects underwent 1.5 T MRI of the scrotum, including diffusion tensor imaging (DTI). ADC and FA in NOA and normal testes were measured. NOA testes were classified as NOA with highest Johnsen score (JS) ≥8 (group 1) and JS <8 (group 2), based on the presence of tubules with spermatozoa at histologic analysis. The same classification was used for mean JS (mJS). Parametric and non-parametric statistical tests were used to compare ADC and FA between NOA groups and normal testes (group 3).
Results: Statistical analysis showed differences in ADC and FA between groups 1 and 3 ($P=0.047$ and $P<0.001$, respectively) and between groups 2 and 3 ($P=0.003$ and $P<0.001$), but not between groups 1 and 2 ($P=0.241$ and $P=0.976$), when using the highest JS. When classification was based on mJS, ADC ($P=0.014$) and not FA ($P=0.849$) enabled the discrimination between groups 1 and 2.
Conclusion: Our preliminary data show promising results in the identification of spermatogenesis in NOA testes using DTI parameters. Both ADC and FA are increased in NOA testes compared to controls. However, ADC and not FA proved useful in differentiating NOA testes, based on histology.

B-1663 14:32

High-resolution MR imaging with small surface coil in diagnosis of slight penile lesions after penile injury

J. Guan, Y. Peng, H. Wang, Y. Guo; *Guangzhou/CN (py9165@163.com)*

Purpose: To investigate the diagnostic value for micro-penile lesions after penile injury using high-resolution MR imaging with small surface coil.
Methods and Materials: There were 13 patients with history of penile injury including intense intercourse or masturbation recently without clinical manifestations of penile fracture. In all patients, the complaints were mild and the sonographic results were negative. MR scan with both small surface coil (loop coil, diameter 11 cm) and body coil was performed in all 13 cases, respectively. MR findings were analysed by two experienced radiologists.
Results: Only 2 cases with suspected lesions were found by MR scan with body coil. 10 cases with slight lesions of penis were detected by MR scan with small surface coil. 8 out of 10 cases with slight albuginea tear presented as focal interruption (about 1~2mm) of the hypointensity tunica albuginea and a small amount overlying effusion. Tiny haematomas with diameter 2-3mm between tunica albuginea and the buck fascia were seen in the remaining 2 cases, presenting as a small nodule with hyperintensity on T2WI, hypo- or iso-intensity on T1WI without enhancement. MR scan with small surface coil detected more tiny lesions of penis than routine scan with body coil ($P<0.05$), and showed the MR imaging features for diagnosis.
Conclusion: MR scan with small surface coil can provide higher diagnostic sensitivity for slight penile lesions after penile injury, and avoid misdiagnosis.

B-1664 14:40

Neoclitoris size and location: a preliminary pelvic MRI study

E. Serena, F. Vedovo, S. Bucci, C. Trombetta, M. Bertolotto, M.A. Cova; *Trieste/IT (elena.serena1986@libero.it)*

Purpose: To evaluate whether MR investigation of neoclitoris size and location can help predict sexual function after male-to-female sex reassignment surgery (MtF-SRS).
Methods and Materials: The Female Sexual Function Index (FSFI) was calculated in 40 consecutive transsexual women who had postoperative MRI after MtF-SRS. An investigator blinded to sexual function data measured the distance between the neoclitoris and the neovagina and calculated the coronal and sagittal area of the neoclitoris and the volume from the three axes using the ellipsoid formula.
Results: 22 patients completed the study. The mean age was 34±7.44 years. The majority were Caucasians (n=20, 91%) and in a relationship (n=13, 51%). The volume of the neoclitoris was 1.18±0.43 cm3. Coronal and sagittal areas were 6.80±2.4 cm2 and 5.33±1.34 cm2, respectively. There was an inverse relationship between the distance of the neoclitoris from the neovagina and the FSFI total score ($p < 0.0001$). Neoclitoris size did not significantly correlate with FSFI total score ($p=0.76$).
Conclusion: In patients with MtF-SRS MRI allows evaluation of the neoclitoris. Our data suggest that neoclitoris localisation affects sexual function, with reduction of the distance between the neovagina and the neoclitoris associated with greater sexual satisfaction. Conversely, neoclitoris size does not to affect sexual function.

B-1665 14:48

US-guided sclerotisation of the cavernosal stumps following male-to-female sex reassignment surgery

M. Muca, M. Bertolotto, I. Zorzenon, M. Iannelli, C. Sachs, M.A. Cova; *Trieste/IT (bertolot@units.it)*

Purpose: In early male-to-female sex reassignment surgery (MtF-SRS) operations a variable portion of the cavernosal crura was preserved. This residual erectile tissue undergoes engorgement during sexual arousal, causing dyspareunia and limiting patient's life. Surgical removal is the most commonly used treatment. It consists in a wide dissection of the perineum with significant morbidity and a high risk of complications. Development of mini-invasive techniques is therefore necessary. The aim of this study is to describe US-guided sclerotherapy of the cavernosal stumps as an alternative to surgery, and to illustrate the results obtained in a series of 3 consecutive patients treated with this technique.

Methods and Materials: US-guided sclerotherapy was performed in 3 patients (mean age 29-38 years) with severe dyspareunia after MtF-SRS caused by residual cavernosal stumps. 2.5 micrograms of PGE1 were injected in each stump under US guidance to achieve erection. A 3% sodium tetradecyl sulphate (Fibrovein®) solution diluted 1/5 with saline was injected bilaterally. A variable amount (max.3.5 cc) was injected depending on the volume of the erectile tissue. In 2 patients, the treatment was repeated monthly for 7 and 8 sessions, respectively. The 3rd patient developed an abscess after the 5th session with prompt resolution of clinical symptoms after drainage.
Results: A good aesthetic and functional result was achieved in all patients with disappearance of the erections during sexual arousal and improvement of the sexual quality of life.
Conclusion: In patients with MtF-SRS US guided sclerotisation is a suitable mini-invasive alternative to surgical excision of the cavernosal stumps.

B-1666 14:56

Role of diffusion MR imaging and 3D/4D ultrasound in the assessment of placental insufficiency in gestational hypertension

S.A. Mansour, S.T. Hamed, S. Hosny, S.B. Elsayed; *Cairo/EG (sohathamed@yahoo.com)*

Purpose: To assess the role of diffusion-weighted MRI and 3D/4D ultrasound and power Doppler scanning in the detection of placental insufficiency in high-risk pregnancies with hypertension.
Methods and Materials: This prospective analysis included 50 pregnant females; 40 hypertensive and 10 control with the gestational age range from 20 to 34 weeks. All cases had undergone 3D/4D transabdominal ultrasound aided by power Doppler scanning and diffusion-weighted MR imaging. No contrast administration was used.
Results: There was a significant relation between right uterine artery RI (mean) of both cases and control groups when measured by power Doppler ultrasound (P=0.014). There was also a positive correlation between the presence of diastolic notch and RI value (P value= 0.012). There was also a significant difference between patients with normal and those with the abnormal placental signal in diffusion images as P value is significant (0.047). The mean of placental volume by MRI was 500.5+223.12 with median (IQR) 507.08 (311.22-721.85) and by 3D ultrasound was 374.11+251.52 with median (IQR) 329.02 (162.66-596.75). There was a significant difference between the measurement of placental volume by MRI and US among both cases and control groups where P value<0.001 and 0.017, respectively. There was significant relation between results of both US and diffusion imaging in cases group (P value=0.006 and kappa value=0.318).
Conclusion: Diffusion-weighted imaging can detect early subtle findings of placental dysfunction more than detected with 3D/4D ultrasound, so it can add to the diagnostic accuracy of imaging in pregnancies at high risk of placental insufficiency.

B-1667 15:04

Placenta accreta index: what a radiologist should know about an imaging update in detection of morbidly adherent placenta

A. Agarwal, S. Agarwal, S. Sharma, S. Chandak; *Moradabad/IN (drarjit26@gmail.com)*

Purpose: To study the role of placenta accreta index (PAI) in detection of morbidly adherent placenta and to analyse the inter-observer reliability in its calculation.
Methods and Materials: 42 pregnant females with sonographically confirmed placenta previa in their third trimester and history of ≥1 caesarean section were subjected to ultrasonography for calculation of placenta accreta index (PAI). The index was calculated on the basis of placental morphology, retro-placental zone, uterine-bladder interface, myometrial thickness, bridging vessels and previous history of caesarean sections. Each parameter was weighted to produce a 9-point score (PAI) which predicted the probability of adherent placenta. PAI score of <5 was considered unfavourable and ≥5 as favourable for accreta. Statistical analysis was done to find the sensitivity, specificity and predictive values of PAI. The PAI was calculated by two radiologists separately, to determine the reproducibility of the technique. Cohen's Kappa and intra-class correlation co-efficient (ICC) were calculated for categorical and scale variables, respectively, to determine the inter-rater agreement in calculation of scores.
Results: Among 42 patients, 15 were placenta accreta on caesarean section. PAI ≥5 (favourable for accreta) was found in 17 and 14 patients by the two radiologists, respectively. The index showed highest sensitivity of 93.3% and specificity of 92.6% with negative predictive value of 96%. A perfect agreement was also found in calculation of PAI by the two radiologists with ICC of 0.959; p value<0.001.
Conclusion: PAI can be utilised as a standard criterion for prediction of adherent placenta and thus decreasing maternal and foetal morbidity.

B-1668 15:12

Implementing strategies for a better quality fetal MRI by technologist training and the effect on radiologist satisfaction

S. Sefidbakht, L. Mina, R. Ravanfar Haghighi, B. Zeinali, M. Saeedi-Moghadam, F. Zarei, S. Haseli; *Shiraz/IR (sarahaseli@gmail.com)*

Purpose: To simplify and implement limited strategies for a improving quality of performing fetal MRI and to evaluate the effect on exam time and radiologist satisfaction
Methods and Materials: We designed a limited extra education strategy for MRI technicians which included a limited fetal brain MRI a±natomy, practical solutions for obtaining perfect orthogonal images using a knowledge of the anatomy of the corpus callosum and vermis as key sagittal landmarks. We also included an extra orientation to motion insensitive MRI protocols tailored to our 1.5 Seimens Avanto and 8channel body coil. We measured the duration of the study with retrospective evaluation of the metadata on our PACS database. In addition we measured radiologist satisfaction of the quality of the images on a scale of 1 to 10 and recorded the time spent by the radiologist at the scanner before and after implementing the strategies. Independent samples T test was used to compare results.
Results: Last 100 patients before implementing the quality measures and first 100 patients with fetal MRI's performed immediately after implementing the qualities entered the study. Mean exam duration time changed from 36.57±9.69 minutes to 24.86±5.39 minutes (p=0.002). Mean radiologist supervision time was reduced from 9.58±5.76 minutes to 5.43±2.74 minutes (p=0.020). Radiologist satisfaction score with the quality of the images increased significantly from 7.35±2.65 to 8.98±2.31.
Conclusion: Implementing a limited extra education strategy for technologists involved in fetal MRI can significantly improve the quality of the images and in the meantime reduce the exam time.

B-1669 15:20

Added value of foetal MRI in evaluation of lung anomalies

S. Sefidbakht, S. Bagheri, Z. Etemadi, B. Zeinali, M. Saeedi-Moghadam, N. Asadi, H. Vafaee; *Shiraz/IR (SepidehSefidbakht@yahoo.com)*

Purpose: To retrospectively correlate all foetal MRI's performed over the last 5 years in our center with lung anomalies detected either primarily in ultrasound or unexpectedly in MRI with post-delivery results.
Methods and Materials: From a total of 456 foetal MRI's performed 53 studies (GA=30+/-8 wks) were performed either for evaluation of a lung finding detected in ultrasound or had an incidental lung finding detected in MRI. In 36 patients post delivery confirmation in form of phone calls, national registry search results or post-delivery CT scans, operation notes or pathology results was available.
Results: Patients included 11 cases of pure CPAM, 3 patients with hybrid lesions (two of which were correctly identified by MRI as such), 3 cases of bronchopulmonary sequestration (correctly diagnosed both by ultrasound and MRI, one fetus with pulmonary blastoma, one case of CHAOS, one case of LAM, 3 cases of pleural effusion, including one proven chylothorax. MRI ruled out focal lung abnormality suspected in ultrasound in 3 suspected cases, all asymptomatic after birth, showed two unsuspected cases of possible CO, both of which subsequently resolved spontaneously. Other patients had some form of uni or bilateral pulmonary hypoplasia.
Conclusion: Foetal MRI detected unsuspected non-significant foetal lung pathology in a small number of cases and also more accurately characterized two lesions. This detailed characterization however did not alter patient management or course.

Evaluation of pituitary micro-lesions using 3D space: the large sample analysis

H. Zhang, Y. Tang; *Shanghai/CN (wozhanghua@126.com)*

Purpose: To evaluate the diagnostic yield of the 3D-T2 SPACE sequences compared to a standard MR protocol concerning the pituitary micro-lesions at 3.0T with large sample analysis.
Methods and Materials: Magnetic resonance imaging (MRI) findings of 664 patients with clinically suspected pituitary lesions were retrospectively analysed in this study, some of them confirmed by pathology. Of all patients, post-contrast coronal 3D-SPACE sequence was performed, besides conventional scanning sequences (coronal T1 weighted image (T_1WI) and post-contrast enhanced T_1WI). The images were evaluated by two-experienced neuroradiologists independently in a retrospective fashion. The inter-observer agreement was analysed with kappa statistics.
Results: Compared to conventional sequences, there was an increase of 60.3% in confidence level on diagnosing pituitary micro-lesions with addition of 3D-SPACE sequence. The scores of combined conventional and 3D-SPACE sequences were significantly higher than that of conventional ($z=-6.403$, $P<0.01$) and 3D-SPACE ($z=-4.243$, $P<0.01$) alone. In addition, there was good inter-observer agreement for 3D-SPACE sequence ($k=0.826$).
Conclusion: Combined with routine sequence, 3D-SPACE sequence is reliable in improving the diagnostic confidence for evaluation of pituitary micro-lesions.

Fully automated meningioma detection and segmentation using deep learning on routine multiparametric MRI

K.R. Laukamp, F. Thiele, G. Shakirin, M. Perkuhn, D. Zopfs, A. Faymonville, M. Timmer, J. Borggrefe; *Cologne/DE (kai.laukamp@uk-koeln.de)*

Purpose: MRI is a key method for meningioma imaging. Clear indications regarding detection and tumour volume are needed for primary assessment, resection planning and monitoring along therapy. Monitoring meningioma volumetrically is superior to conventional diameter methods. We used a multiparametric deep learning model (DLM) on routine MR data including images from referring institutions to investigate performance in automated detection and segmentation.
Methods and Materials: MRI data (T1-/T2-weighted, T1-weighted contrast-enhanced [T1CE], FLAIR) of n=38 grade I and n=18 grade II non-treated meningioma were available. Nine patients had been excluded earlier due to leucoencephalopathy, prevalent secondary tumours or strong artefacts. Tumour grade was determined by histopathology. The DLM was trained on an independent dataset of 249 cases of glioma and segments different tumour classes as defined in the BRATS-benchmark. Preprocessing included registration, skull stripping, resampling to isotropic resolution, and normalisation. The DLM was based on the DeepMedic-architecture (Kamnitsas2016) using a 3D-convolutional neural network for segmentation and a 3D-post-processing step to remove false positives. Results were compared to manual segmentation by an experienced radiologist in FLAIR and T1CE tumour.
Results: The DLM detected meningioma in 55 of 56 cases. Further, automated segmentation correlated strongly with manual segmentation: average dice coefficients were 0.81±0.10 (range, 0.46-0.93) for the total tumour volume (union of tumour volume in FLAIR and T1CE) and 0.78±0.19 (range, 0.27-0.95) for contrast-enhancing tumour volume in T1CE.
Conclusion: The DLM yielded accurate automated detection and segmentation of meningioma tissue despite diverse scanner data and thereby may improve and facilitate future clinical management of this highly frequent tumour entity.

^{23}Na-MRI demonstrates a sodium gradient within gliomas as a biomarker of tumour heterogeneity

F. Zaccagna[1], F. Riemer[1], M.A. McLean[1], J.T. Grist[1], R. Schulte[2], C. Watts[1], S.J. Price[1], M.J. Graves[1], F.A. Gallagher[1]; [1]*Cambridge/UK*, [2]*Munich/DE (f.zaccagna@gmail.com)*

Purpose: The increase in mitotic activity within gliomas is associated with a decrease in Na^+/K^+-ATPase activity and gain in concentration of these ions. ^{23}Na-MRI quantifies sodium concentration and can probe cell morphology and membrane function within the tumour microenvironment, as well as heterogeneity. The purpose of this study was to evaluate sodium distribution within glioma and in the surrounding tissue.
Methods and Materials: 33 patients were imaged on a 3T clinical scanner (GE Discovery MR750) using a Rapid Biomedical (Rimpar) dual-tuned ^{23}Na/^{1}H birdcage head coil. Sodium imaging was performed using an UTE sequence with 3D-cones readout (nominal isotropic resolution = 3mm). Intracellular-weighted sodium imaging was obtained using fluid suppression by inversion recovery (adiabatic inversion, TI = 30ms). Differences between tumour, grey matter (NAGM) and white matter (NAWM) in total sodium concentration (TSC) and intracellular sodium concentration (IW-SC) were tested using the paired samples t-test ($p<0.05$).
Results: All the patients completed the examination (age 57.8±17.5 yrs). TSC in the lesion was 50.2±16.9mM in the high grade gliomas (HGG), 43.1±28.6mM in the low grade gliomas (LGG) and 52.3±0.5mM in the metastases. The IW-SC was 22.4±17.4mM in the HGGs; 12.9±8.8mM in the LGGs and 7.5±2.3mM in the metastases. TSC was significantly higher in tumours when compared to NAGM ($p=0.0001$) and NAWM ($p=0.0001$).
Conclusion: In all cases, TSC was higher in the entire lesion and in the enhancing tumour compared to the NAGM and NAWM. In conclusion, we demonstrated a sodium concentration gradient across gliomas that is consistent with the expected underlying histopathology.

Brain aging in chronic HIV infection: a comparative multivoxel MR spectroscopy study

J. Boban[1,2], S. Brkic[1,1], D. Lendak[1,1], J. Ostojic[1], M. Bjelan[2], D. Kozic[2]; [1]*Novi Sad/RS*, [2]*Sremska Kamenica/RS (jasmina.konstantinovic@gmail.com)*

Purpose: Studies of cognitive changes during the course of HIV infection resulted in hypothesis of accelerated brain aging. The aim of this study was to compare age-related changes in chronic neuroasymptomatic HIV+ patients, with age-related changes in age, gender and education-level-matched healthy subjects using magnetic-resonance spectroscopy (MRS).
Methods and Materials: Study included 60 chronically-infected HIV+ patients on combination antiretroviral therapy and 60 age- and education-matched healthy male subjects, who underwent standard magnetic resonance imaging and long-echo time multivoxel MRS protocol on 3T unit (Trio Tim, Siemens, Germany). Voxels were placed in grey matter of frontal and parietal cortices, and in posterior cingulate gyrus. We analyzed N-acetyl aspartate and creatine (Cr) peaks, expressed as NAA/Cr ratios. Statistical analysis included stratification of the sample according to age (in decades) and comparison of correspondent groups of HIV+ and healthy subjects using ANOVA. Significance was set at value $p<0.05$.
Results: ANOVA with stratified sample revealed significant differences in all locations when youngest groups were compared (20-29 years), while there were no significant differences between the youngest HIV+ subjects (20-29) and the oldest controls (50-59).
Conclusion: Our results imply an initial rapid decrease in NAA/Cr level early in the course of HIV infection, followed by relatively stable level of NAA/Cr over time. However, levels of NAA/Cr in healthy subjects were stable at younger age, with progressive descrease in the oldest group. Brain aging process in chronic, stable HIV infection shows signs of accentuation compared to healthy, with early and rapid decrease in neuron marker.

B-1674 14:32

Empty sella and inferior sella impression are frequently associated and characteristic in patients with growth hormone-secreting pituitary adenomas

G. Bier, J.-M. Hempel, U. Ernemann, B. Bender, J. Honegger; *Tübingen/DE (georg.bier@med.uni-tuebingen.de)*

Purpose: To assess the prevalence of a sellar floor lowering and empty sella phenomenon in patients with GH (growth hormone)-secreting pituitary adenoma in comparison to an age-matched control cohort.
Methods and Materials: 159 acromegalic patients were included in this study and compared to a control group (150 patients with non-GH-secreting adenomas and 50 patients without pituitary pathology). Magnetic resonance images of all patients were evaluated for the presence of an empty sella,

downward tumour extension and maximum superoinferior diameter of the mass.
Results: The empty sella phenomenon was detected significantly more often in patients with a GH-secreting adenoma (22% vs 7%; p=0.003). Moreover, GH-secreting adenomas presented with a significant rate of downward tumour extension (74.8% vs 35.5%; p<0.0001). A comparably decreased superoinferior diameter and higher ratio of intrasellar to suprasellar extension are predictive for the presence of a GH-secreting adenoma (AUC, 0.712).
Conclusion: The association of GH-secreting pituitary adenomas and an empty sella phenomenon is frequent. Moreover, GH-secreting adenomas are frequently accompanied by an enhanced impression of the sellar floor. Hypothetically, this is caused by tumour-induced bone remodelling processes.

B-1675 14:40

Role of phase contrast MR CSF flowmetry study in the evaluation of normal pressure hydrocephalus

S. Kumari[1], M. Mohammad Zakir[2], Y. Kirubha[1], K. Sudhakar[1], P. Chatterjee[1], R. Ranjan[3], J. Kumari[4], S. Kumari[5], S. Khan[2]; [1]*Chennai/IN*, [2]*Nagpur/IN*, [3]*Rohtak/IN*, [4]*New Delhi/IN*, [5]*Patna/IN (surbhinmch@gmail.com)*

Purpose: To study role of cerebrospinal fluid (CSF) flowmetry indices in patients with symptoms of normal pressure hydrocephalus (NPH) and to establish its diagnostic value.
Methods and Materials: In this prospective case-control study, 44 patients (age range = 45-83 years) were evaluated by phase contrast (PC) MR CSF flowmetry in a 3T MRI equipment. 22 patients of NPH (with clinical and MRI diagnosis) and 22 age-matched control were evaluated. The CSF flow parameters studied include aqueductal stroke volume (ASV), peak systolic velocity (PSV), mean systolic velocity (MSV), forward flow (FF) and backward flow (BF). Statistical significance of these parameters was studied and comparisons were made between the parameters.
Results: CSF flow parameters reliably differentiated NPH patients from controls in this study. Cerebral aqueduct in patients with NPH showed increased ASV. ASV parameters also showed marked difference in the values between NPH and controls. In patients with NPH above 45 years of age, mean values of ASV, PSV, MSV, FF and BF flow were 0.190(ml), 9.0(cm/s), 4.8cm/s,0.098(ml) and 0.091(ml), respectively. In the control group above 45 years of age, mean values of ASV, PSV, MSV, FF and BF were 0.032(ml), 5.0(cm/s), 3.3 cm/s, 0.022(ml) and 0.020 (ml). CSF flow parameters including ASV, PSV, MSV, FF and BF reliably differentiated NPH patients from controls in the above 45 years age group (p values were 0.0001, 0.0001, 0.003, 0.0001 and 0.0001 ml, respectively).
Conclusion: Phase-contrast MR CSF flowmetry is a non-invasive means of calculating CSF flow in patients with NPH. In patients with clinical and MRI evidence of NPH, CSF flow parameters including ASV, PSV, MSV, FF and BF can be reliably used as an additional diagnostic tool.

B-1676 14:48

Cognitive decline in ageing and cerebrovascular reactivity assessed by ASL fMRI of perfusion

N. Boudiaf, A. Krainik, J. Warnking, J. Pietras, O. Moreaud, M. Baciu; *Grenoble/FR (akrainik@chu-grenoble.fr)*

Purpose: Cerebral blood flow (CBF) and cerebral vascular reactivity (CVR) decrease with age and might affect cognitive functions. This study aimed at investigating their correlations with cognitive abilities during normal and pathological ageing.
Methods and Materials: We performed neuropsychological assessments on 13 healthy younger subjects (44.1±9.5yo), 10 older subjects without cognitive complaint (72.1±5.7yo), 11 older subjects with cognitive complaint (73.4±7.9yo). We tested cognitive functions (attention, short-term and working memories, executive functions, language). We measured basal CBF and CVR elicited by hypercapnic challenge (7%CO_2) using pCASL (3T Achieva TX, Philip, post-label delay=1525ms; voxel=3x3x6mm3; 20 slices; TE 12 ms; TR=4s for a total of 180 control and tag volumes acquired in 12 min during block-designed hypercapnia; s). Individual end-tidal CO_2 pressure was used as physiological regressor to conduct linear regression analysis. Post-processing was performed using AMIGOv0.9, an in-house software (Python3.6, Matlab8.6, SPM12), giving whole-brain and regional basal CBF, CBV, MTT, CVR. We tested correlations between global and regional CBF and CVR with cognitive scores.
Results: We found a decrease in attention and inhibition in older participants. Impaired-old subjects showed specific decreases in global cognitive functioning, executive functions, short-term and working memory. Global CBF decreased with age, only. Regional CBF decreased with attention and inhibition processes in anterior regions. Global CVR decreased with age and executive functions. Regional CVR decreased with lower performances in all cognitive tests, especially in posterior regions.
Conclusion: CBF and CVR decrease with ageing. Unlike CBF, regional CVR decrease is specifically associated with cognitive impairment during ageing.

Comparative study of activation during color-word Stroop test and new suggested counting test performance

S. Morozova, E.I. Kremneva, Z. Gadzhieva, A.N. Sergeeva, B. Akhmetzianov, M. Zabitova, E. Kashina, M. Krotenkova, L. Dobrynina; *Moscow/RU (kulikovasn@gmail.com)*

Purpose: To explore fMRI-based activation in healthy subjects performing the Stroop color-word test, widely used for executive functions mapping, and new suggested counting test, which is simpler to explain and perform.
Methods and Materials: Data were acquired from 12 healthy subjects age ranged 45-63. MRI was performed on Siemens Verio 3.0 T scanner, scanning protocol included conventional T2-weighted sequence, T1 multiplanar sequence and simple block task-fMRI sequences using the Stroop color-word test and new suggested counting test as paradigms. Statistical analysis was performed using SPM8.
Results: FMRI-based analysis using modified Stroop test paradigm showed activation of constituent regions of executive network (anterior insular and anterior cingulate cortex, dorsolateral prefrontal cortex, premotor cortex, supplementary motor area and inferior parietal lobules) and also of medial parts of lenticular nuclei, of regions in occipital cortex and cerebellar hemispheres. FMRI analysis using new suggested counting test paradigm also showed activation of constituent regions of executive network, including angular gyri, and also activation of cerebellar hemispheres but without activation of occipital cortex. Significant differences between the series were found in occipital cortex.
Conclusion: Similar areas of activation during examination with Stroop test and counting test allow using new suggested counting test as an alternative paradigm for executive functions mapping, especially in patients with vision problems.

Comparing normative subcortical volume distributions across cohorts

E.J. Vinke[1], W. Huizinga[1], M. Bergtholdt[2], M.A. Ikram[1], W.J. Niessen[1], F. Wenzel[2], M.W. Vernooij[1]; [1]*Rotterdam/NL*, [2]*Hamburg/DE (e.vinke@erasmusmc.nl)*

Purpose: More and more brain imaging data are publicly accessible and may serve as normative data for individual patient comparison. However, different normative cohorts differ in field strength, sequence parameters, and population. We assessed the differences in subcortical structure volumes between population and case-control studies, and the effects of using different cohorts for individual patient assessment.
Methods and Materials: Segmentation of subcortical structures was performed using a shape-constrained deformable surface model. Then, percentile curves were fitted on the volume distributions using the LMS method on healthy subjects from three different studies: (1.) the population-based Rotterdam Study (n=1000), (2.) the case-control study, Alzheimer's Disease Neuroimaging Initiative (ADNI) (n=430), and (3.) the United Kingdom Biobank population study (UKBB) (n=904), with an overall age range of 40 to 95 years. The percentiles for 50 AD and 50 MCI patients (from ADNI) based on the distributions of the three datasets served for assessing the impact on individual patient classification. Here, differences between these percentiles were tested using a Welch's two-sample T test.
Results: Overall, LMS percentile curves were highly overlapping between the three different datasets: for AD and MCI patients, there were no significant differences between percentiles for the putamen, thalamus, hippocampus and the nucleus caudate. Globus pallidus and amygdala revealed small differences, with mainly the Rotterdam Study data showing slightly lower normative values.
Conclusion: Overall, we found that the subcortical volume normative data from these three cohorts is interchangeable, suggesting more flexibility in clinical implementation.

Are cerebral DTI changes correlated with degree of disability and cognitive dysfunction in patients with multiple sclerosis?

J. Bladowska, A. Pokryszko-Dragan, A. Banaszek, A. Zacharzewska-Gondek, M. Nowakowska-Kotas, E. Gruszka, M. Sasiadek; *Wroclaw/PL (asia.bladowska@gmail.com)*

Purpose: The aim of the study was to evaluate the microstructural changes within normal-appearing brain regions in multiple sclerosis (MS) patients using diffusion tensor imaging (DTI) as well as their association with disability and cognitive dysfunction.
Methods and Materials: Fifty patients with clinically definite, relapsing-remitting MS, according to McDonald's criteria (mean age 36.4 yrs) and 40 age- and sex-matched control subjects were enrolled in the study. DTI examinations were performed on a 1.5T MR scanner. Fractional anisotropy (FA) and apparent diffusion coefficient (ADC) values were obtained with a small ROI method within: genu (GCC) and splenium of the corpus callosum

(SCC) as well as within right and left thalami. There were no demyelinating lesions within the ROIs in any of the patients included in the study. Degree of disability was assessed using Expanded Disability Status Scale (EDSS) and cognitive function using Paced Auditory Serial Addition Test (PASAT) and Symbol Digit Modalities Test (SDMT).
Results: Significant decrease of FA ($p<0.05$) and significant increase of ADC ($p<0.05$) values were found in MS patients in GCC, SCC and both thalami compared to the normal subjects. There were significant correlations between FA values in GCC, SCC and SDMT results in MS subjects. ADC values in SCC and right thalamus were also significantly correlated with SDMT score. No correlations were found between FA or ADC values and EDSS.
Conclusion: Microstructural tissue damage assessed with DTI measurements within normal-appearing corpus callosum and thalamus shows significant relationship with cognitive dysfunction in MS patients.

Optimising pre-surgical fMRI language mapping using knowledge derived from intrinsic connectivity brain networks for personalised therapy planning

L.R. Kozák[1], G. Gyebnár[1], A.G. Szabo[1], A.L. van Graan[2,3], P. Barsi[1], L. Lemieux[2,3], G. Rudas[1]; [1]*Budapest/HU*, [2]*London/UK*, [3]*Chalfont St. Peter/UK (lrkozak@gmail.com)*

Purpose: Blood-oxygenation level dependent functional MRI (fMRI) became an important tool of pre-surgical workup of tumors and/or other epileptogenic lesions within or near eloquent brain areas. Still, there are almost as many paradigms in use as MRI centers using them. We aimed to investigate whether language mapping paradigms can be fine-tuned in a neuropsychologically meaningful way using inference based on intrinsic connectivity (also referred as resting-state) brain networks (ICNs).
Methods and Materials: fMRI language mapping results of 40 consecutive patients scanned using picture naming, synonym matching, speech comprehension, and word/non-word decision tasks in 2016-2017 on a Philips Ingenia 3T scanner were re-evaluated using our recently published ICN_Atlas framework[1]. Correspondence information between ICNs and pertinent cognitive/behavioral domains derived from BrainMap[2,3] were used to infer the specific cognitive processes involved by the different paradigms based on the fMRI activation maps.
Results: There were paradigm-dependent differences both in the categorical label output of ICN_atlas toolbox (e.g. 'Perception.Vision.Shape' and 'Naming (Overt)' for picture naming; 'Perception.Audition', 'Passive Listening' and 'Pitch Monitor/Discrimination' for word/non-word decision), and in the weights associated with labels; within-task effects being smaller than between-tasks effects (Friedman's test, $p<0.05$). These labeling differences reflected those expected for paradigms and patients based on prior neuropsychology.
Conclusion: fMRI-based inference may be used to fine-tune mapping paradigms for specific symptoms, lesion loci and/or specific sub-functions deemed necessary by neuropsychological evaluation, thus opening personalized ways for paradigm optimization and therapy planning.

High-risk screening with breast MRI: today and in the future

Moderator:
C. Van Ongeval; Leuven/BE

Phenotype-genotype correlation and radiological screening for breast cancer in gene mutation carriers
C. Van Ongeval; *Leuven/BE*

Approximately 5%-10% of breast cancers (BC) are hereditary; the most common mutation is BRCA 1, BRCA 2 and CHEK2. It has been shown that breast cancer gene mutation carriers (BCGM) have different clinical, histological and immune-phenotypic features. In BRCA1 BC presents at younger age (<40y) compared to BRCA2 and CHEK2 and is often more aggressive, presenting as medullary-like, triple negative breast cancers. Notwithstanding some studies reporting different mammographical characteristics of BC in BCGM, a study on imaging characteristics of BC in BRCA 1/ 2 and CHEK2 performed in University Hospitals Leuven (poster EUSOBI 2016) did not prove any difference compared to BC in non-mutation carriers. Breast tumour recurrence (first, second and contralateral) risk is significantly higher in BCGM carriers compared to non-mutation carriers, with CHEK2 most frequently showing an early and contralateral recurrence. Age at first breast cancer is also a strong risk factor for cumulative contralateral BC in BRCA1/2 carriers. Annual MRI alternating mammography and/or ultrasound is probably the most effective screening strategy in BCGM. Screening benefits, associated risks, and acceptance of false-positive results should be discussed.
Learning Objectives:
1. To learn about the immunohistochemical and radiological characteristics of breast cancer in BRCA 1, BRCA 2 and CHEK2 gene mutation carriers.
2. To understand the radiological follow-up program for breast cancer detection in gene mutation carriers.

Ten-year experience of population-based dynamic breast MR Imaging: the Study of Health in Pomerania (SHIP)
R. Bülow; *Greifswald/DE*

Purpose: To present 10-year results of dynamic breast MRI in the population-based Study of Health in Pomerania (SHIP).
Methods and Materials: Between 2008 and 2012, 774 women (51±12.9 years (range 20 to 83 years) participated in dynamic breast MRI with T1-weighted three-dimensional MR images (repetition time msec/echo time msec, 8.86/4.51; flip angle, 25°) acquired with a 1.5-T MR unit before and 1 to 5 minutes after a gadobutrol bolus injection of 0.1 mmol per kilogram of body weight. Images were analysed by two radiologists independently using the American College of Radiology BI-RADS-MRI Classification Form. In case of disagreement a consensus reading was performed. BI-RADS IV and V breast lesions were disclosed to the women with individual recommendations for follow-up. Between 2013 and 2017, MRI follow-up was realised in 275 (35.5%) women and 228 women participated additionally.
Results: At baseline 113/774 women (recall rate 14.6%) had breast lesions of category BI-RADS IV (n=106) or BI-RADS V (n=7): 84 mass lesions, 15 foci and 29 non-mass lesions. Diagnostic follow-up was completed in 111/113 (97.3%) women. In 21/113 (18.6%) women breast biopsy was performed confirming malignancy in 7/774 (0.9%) women. In the 5-year-follow-up group 3/275 women with new mass lesions (BI-RADS IV) have been detected (recall rate 1.1%) and malignancy was confirmed in 2/275 (0.73%).
Conclusion: Population-based dynamic breast MRI is feasible and has a recall rate of 14.6% at baseline and 1.1% during 5-year-follow-up. Mass lesion was the most detected lesion type. Malignancy was confirmed in 0.9% women at baseline.

Gadolinium retention: impact on breast MRI?
J. Barkhausen; *Lübeck/DE*

More than 30 years ago, contrast-enhanced MRI emerged as a new technique in clinical breast imaging and over the last three decades numerous clinical studies have shown excellent results for the detection and characterisation of breast lesions. Despite the most recent improvement of high-resolution and diffusion-weighted MRI, dynamic contrast-enhanced sequences are still considered as the key component of any breast MRI examination. The applied gadolinium-based contrast agents (GBCAs) were considered as very safe compounds until the association between nephrogenic systemic fibrosis and GBCAs was suspected in 2006. Additionally, in late 2013 Kanda and colleagues described increased signal intensity in the dentate nucleus on unenhanced T1-weighted MR images as a consequence of repetitive previous GBCA administrations. Although no clinically relevant adverse events have yet been associated with the detection of gadolinium in the brain, the results of these studies must be taken seriously. With respect to breast MRI, these issues are especially important for repetitive breast cancer screening in high-risk patients for example with BRCA mutations. In this lecture the results of the most recent clinical trials addressing this topic and the regulatory recommendations will be presented and discussed in a comprehensive manner.
Learning Objectives:
1. To gain knowledge of the pharmacokinetics of different MR contrast agents.
2. To discuss the potential risks of gadolinium based contrast agents.
3. To learn about the most recent recommendations and guidelines.

ABVS and personalised breast cancer screening
A.-R. Grivegnée; *Brussels/BE*

Dense fibroglandular tissue has an important impact on breast cancer screening. While mammography remains the gold standard in breast cancer screening (BCS), the approach has evolved and more personalised programs are now emerging. We will present our experience in BCS including ultrasound (Hand Held (HH) and/or Automated 3D) for patients having heterogeneously and extremely dense breasts. The conclusions of this study conducted in the ASSURE PROJECT (EU funded) show a higher cancer detection with an acceptable recall rate. The personalised workflow for BCS in our clinic has been defined as: Mammography (including DBT) followed by ABVS decided on the basis of volumetric density evaluation; then rapid overview by the radiologist of the examinations. If any positive or doubtful finding is seen, HHUS or dedicated mammogram is immediately performed. In addition, the use of CAD for mammography and ABVS is programmed as an evaluation process in our clinic.
Learning Objectives:
1. Ultrasound examination increases breast cancer detection rate with an acceptable recall rate.
2. ABVS is at least equivalent to HHUS in this application; furthermore it allows a quality assurance which is mandatory in BCS.
3. ABVS can be utilised in personalised breast cancer screening workflow in a reasonable cost-effective approach.

Approaches to accelerating and standardising DBT reading in screening: what's new? Final results of the Malmö Breast Tomosynthesis Screening Trial
S. Zackrisson; *Malmö/SE*

The superiority of digital breast tomosynthesis (DBT) compared to digital mammography (DM) for cancer detection in screening is undoubted, as indicated by the results from several large, prospective screening trials. One of the challenges for implementation of DBT in screening is that longer reading times are reported for DBT, up to twice as long as for DM. In high-volume screen reading, ways to improve reading times with sustained sensitivity and specificity are warranted. The image protocols vary between trials, from two-view DM+DBT, two-view synthetic DM+DBT and one-view DBT, although with quite similar results on detection and somewhat mixed effects on recalls. This presentation will include a discussion on what is the optimal image protocol. Further, does the use of narrow- versus wide-angle DBT make a difference? Do we need double reading with DBT? Will artificial intelligence systems replace one reader? Are thicker slices, slabbing, a way forward? How much

does experience add? Finally, some of the final results from the Malmö Breast Tomosynthesis Screening Trial will be presented.
Learning Objectives:
1. To be familiar with the different image protocols used in prospective trials.
2. To acknowledge ways to accelerate and standardise DBT screen-reading.

Breast elastography: examination protocol and imaging interpretation
C. Gkali; *Athens/GR*

In recent years the use of elastography in addition to sonography has become a routine clinical tool for the characterisation of breast masses. Studies have investigated the improvement of specificity in differentiating benign from malignant breast masses. Therefore, additional use of elastography could help to reduce the number of unnecessary biopsies in benign breast lesions especially in category IV lesions of the ultrasound breast imaging reporting data system (US-BI-RADS). Ultrasound elastography is a cheap, readily available, useful, quick, non-invasive method in the diagnosis of breast lesions but it needs specific training as well as acknowledging the technical and pathological factors which may influence it. Both Strain and ARFI (Shear Wave Elastography) methods have been evaluated. Whereas Strain elastography results in qualitative imaging of tissue stiffness due to induced compression, ARFI (SWE) elastography displays quantitative and qualitative information of tissue displacement. A standardised protocol is essential for an adequate and effective examination, also helping reducing the dependence from operators. Furthermore, knowledge of pitfalls that can be encountered when ultrasound elastography is performed may help to avoid erroneous images interpretation. Interesting and rare cases will be presented and interpreted.

Progress on whole-body MRI use for advanced breast cancer
A.R. Padhani; *London/UK*

Learning Objectives:
1. To learn how WB-MRI addresses limitations of current imaging for bone metastatic detection and response.
2. To understand how the biology of metastatic bone disease affects imaging findings.
3. To enumerate patient care.

MRI-US fusion for diagnostic assessment of the prostate and treatment guidance
T. Fischer; *Berlin/DE*

Published data on TRUS-guided repeat biopsy reveal markedly declining detection rates. The combination of high-resolution 3T magnetic resonance imaging (MRI) with multi- parametric ultrasound (B-mode, elastography, Doppler, CEUS) can be implemented in the form of MRI/US fusion biopsy of the prostate. Our studies show this approach to be able to increase the detection rate of PCa in general and also of significant PCa (≥ cT2b and/or ≥ Gleason score of 7). Since mainly patients with clinically significant PCa benefit from prostatectomy, the foremost diagnostic aim should be to identify these patients and separate them from patients with non-significant PCa. Our working group focuses on prostate cancer treatment by irreversible electroporation (IRE) which spares not only the nerves but also the large blood vessels and the urethra.
Learning Objectives:
1. Understand the basic technique of TRUS-guided prostate biopsy.
2. Understand the basics of MRI/US image fusion using clinical examples.
3. Understand the advantages of multi-parametric ultrasound compared with MRI.
4. Understand the benefits of focal treatment of prostate cancer using IRE.

Improving clinical pathways with angio CT in abdominal IR
B. Guiu; *Daix/FR*

Minimally invasive techniques, such as liver ablation, are recommended for almost 50% of primary liver cancer cases. Thermoablation of tumours of the liver using multi-modality imaging, combining CT, ultrasound and angiography is a promising technique being developed. Almost 40% of liver tumours are not detectable with ultrasound and 20% are not identified in CT scanning. The combination of these imaging modalities, however, as well as the ability to mark the tumours endovascularly, has enabled us to perform three times more thermoablation treatments over the last three years with interventional follow-up.
Learning Objectives:
1. Understand the components of a modern Angio CT system.
2. Learn how Angio CT can change practice in abdominal IR.
3. Appreciate the benefit of Angio CT in terms of radiation exposure.
4. Learn about 4D imaging.

Interventional oncology in a state-of-the-art angio CT environment
A. Gangi; *Strasbourg/FR*

The combination of CT scan and C-arm fluoroscopy has been used since the 1990s. Expanding this set-up with high-end CT and angiography, a milestone in interventional radiology (IR) and oncology, has been shown to provide the most precise imaging in liver tumour management. In this presentation we will explore further applications in oncology and IR that might benefit from the combination of the high-end imaging modalities. We will furthermore discuss the minimal requirements for the installation of such a system, including technical and financial challenges.
Learning Objectives:
1. Identify the best indications for an Angio CT set-up.
2. Recognise the advantages of Angio CT.
3. Plan the installation of such a combination, transparency and accuracy in treatment decisions.

L.J. Pina Insausti; Pamplona/ES

Impact of tomosynthesis angular range on mass conspicuity in patients with dense breasts: experiences from a radiologist's view
P.R. Fisher; *Stony Brook, NY/US*

Purpose: Recent studies have suggested that cancer detection rates for digital breast tomosynthesis (DBT) are poor for patients with heterogeneously to extremely dense breasts. These studies have been predominantly conducted on narrow-angle DBT. Increasing angular range (AR) reduces breast structural noise and increases image contrast for masses, potentially improving mass detection in dense breasts. We investigate the effect of AR on mass detectability using a previously validated cascaded linear system model (CLSM) for DBT, and compare theoretical results with clinical findings in an IRB-approved study.
Materials and Methods: Mass conspicuity in DBT was modelled as a function of AR using a normalised detectability index d', incorporating breast structural noise and image contrast. DBT images were acquired for 6 patients with heterogeneously or extremely dense breasts on both the Hologic Selenia Dimensions (AR = 15°) and the Siemens MAMMOMAT Inspiration (AR = 50°). Two breast radiologists were presented with both sets of images for each patient and compared lesion conspicuity on a five-point scale (-2: lesion much more conspicuous on narrow-angle DBT, to +2: lesion much more conspicuous on wide-angle DBT).
Results: Mass detectability was predicted to increase with increasing AR due to reduced structural noise and increased contrast in the reconstructed image slices. Increasing AR from 15° to 50° would increase detectability of 2, 5 and 10 mm masses by 85.3%, 87.5% and 87.9%, respectively. Clinical findings corroborated simulation results, with mass conspicuity shown to be superior for wider-angle DBT, with a mean score of 0.89 (95% CI: 0.44, 1.44). Importantly, masses found in areas with high masking risk (defined as high local density as characterised by the radiologist) were more conspicuous on wider-angle DBT.
Conclusion: Using a normalised detectability index d', mass conspicuity was shown to increase with increasing AR. These results were corroborated by a pilot clinical study, and motivate an ongoing larger scale study to demonstrate whether DBT with wider AR provides superior mass conspicuity for patients with heterogeneously to extremely dense breasts.
Learning Objectives:
1. To understand the imaging science of the impact of AR in DBT image quality.
2. To compare the mass conspicuity in DBT with wide and narrow AR for patients with dense breast.

Impact of tomosynthesis angular range on mass conspicuity in patients with dense breasts: experiences from a physicist's view
W. Zhao; *Stony Brook, NY/US*

Purpose: Recent studies have suggested that cancer detection rates for digital breast tomosynthesis (DBT) are poor for patients with heterogeneously to extremely dense breasts. These studies have been predominantly conducted on narrow-angle DBT. Increasing angular range (AR) reduces breast structural noise and increases image contrast for masses, potentially improving mass detection in dense breasts. We investigate the effect of AR on mass detectability using a previously validated cascaded linear system model (CLSM) for DBT, and compare theoretical results with clinical findings in an IRB-approved study.
Materials and Methods: Mass conspicuity in DBT was modelled as a function of AR using a normalised detectability index d', incorporating breast structural noise and image contrast. Conclusion: Using a normalised detectability index d', mass conspicuity was shown to increase with increasing AR. These results were corroborated by a pilot clinical study, and motivate an ongoing larger scale study to demonstrate whether DBT with wider AR provides superior mass conspicuity for patients with heterogeneously to extremely dense breasts.
Learning Objectives:
1. To understand the imaging science of the impact of AR in DBT image quality.
2. To compare the mass conspicuity in DBT with wide and narrow AR for patients with dense breast.

Synthetic 2D mammography with digital breast tomosynthesis: the new mammography
P. Clauser; *Vienna/AT*

The introduction of digital breast tomosynthesis (DBT) in conjunction with digital mammography (DM) is rapidly changing clinical practice. DBT is becoming the new mammography, and therefore the new first-line examination - in conjunction with DM - for women in the screening and assessment setting. The need to perform two examinations (DM and DBT) has raised concerns regarding the increased radiation exposure. Synthetic 2D mammography (SM) is a 2D image reconstructed from the DBT projections. SM is similar to DM and it could be used instead of DM to avoid the need for two examinations.
Learning Objectives:
1. Radiation dose of DM and DBT.
2. What is synthetic 2D mammography?
3. Current evidence in favor of the introduction of SM mammography to replace DM as an adjunct to DBT in clinical practice.

Clinical utility of contrast-enhanced dual energy mammography (CEDEM)
L.J. Pina-Insausti; *Pamplona/ES*

Contrast-enhanced dual energy mammography (CEDEM) is a development of digital mammography. By using dual energy (conventional low energy mammography plus high energy mammography) after the administration of a bolus of intravenous iodinated contrast medium, a morpho-functional image of the breast is acquired. This technique joins the high spatial resolution of conventional digital mammography with functional information based on neoangiogenesis. The indications of this technique for clinical use include: Problem-solving technique after inconclusive mammography, preoperative assessment of breast cancer, follow-up of scars after conservative treatment, follow-up of intermediate risk patients (borderline histological lesions, such as lobular carcinoma in situ, atypical ductal or lobular hyperplasia, as well as positive family history of breast cancer). In fact, the majority of indications are those of MRI, including the contraindications for MRI (pacemakers, claustrophobic patients, etc.). Furthermore, CEDEM has fewer false negative results than MRI. Nevertheless CEDEM has some limitations: The sensitivity is lower for ductal carcinomas in situ, lesions out of the field of view of the detector are missed and some benign lesions can enhance after contrast administration. CEDEM is contraindicated for patients allergic to iodine as well as for patients with renal insufficiency.
Learning Objectives:
1. To become familiar with contrast-enhanced dual energy mammography (CEDEM).
2. To learn the main indications for this technique.
3. To learn the main limitations of CEDEM.

Comparison of contrast-enhanced dual energy mammography and contrast-enhanced digital breast tomosynthesis for lesion assessment and radiation dose
P.R. Fisher; *Stony Brook, NY/US*

Purpose: Digital breast tomosynthesis combined with contrast-enhanced dual energy mammography (DBT+CEDEM) is being investigated for diagnostic accuracy. Contrast-enhanced digital breast tomosynthesis (CEDBT) provides coregistered low energy DBT and 3D contrast enhancement map. Synthetic CEDEM may also be generated and paired with synthetic mammogram. This study compares CEDBT with CEDEM for lesion assessment and dose efficiency.
Method and materials: A Siemens MAMMOMAT Inspiration DBT system modified for dual energy contrast-enhanced imaging is used. Patients with BIRAD 4 and 5 lesions and scheduled for biopsy were recruited for an IRB-approved CE imaging study. CEDEM images were acquired 120 seconds after injection of iodine contrast agent, followed by CEDBT acquisition under the same breast compression. Eleven malignant lesions from 12 patients were confirmed by pathology result. A reader study of side-by-side comparison between CEDEM and CEDBT is performed to assess lesions on 1) Contrast

enhancement level and 2) Margin identification, using a 5-point scale from -2 (CEDEM much better) to 2 (CEDBT much better). The radiation dose recorded by the DBT system is reviewed for DBT+CEDEM and CEDBT.
Synthetic CEDEM is created with dual-energy subtracted projections from CEDBT using software developed by Siemens Healthineers.
Results: For malignant lesions, CEDEM shows higher enhancement level than CEDBT slices (mean score=-0.64; 95% CI: -1.09, -0.18). CEDBT shows lesion margin better than CEDEM (mean score=0.78; 95% CI: 0.11, 1.44). In CEDBT slices, background parenchymal enhancement is less intense, and motion artifact is less severe than that in CEDEM. On average, CEDBT reduces dose by 32.8% ± 9.9% compared to DBT+CEDEM (average dose 1.91 ± 0.74 mGy vs. 2.86 ± 1.04 mGy). Synthetic CEDEM has similar mammographic appearance to CEDEM, and shows the same enhanced lesions.
Conclusion: CEDBT provides better lesion margin identification and reduces structural noise due to background parenchymal enhancement and motion compared to CEDEM, while the intensity of lesion enhancement is lower. CEDBT uses lower dose than DBT+CEDEM. Synthetic CEDEM can be created from CEDBT to quickly identify lesion enhancement. Clinical relevance/application: With the advent of DBT replacing FFDM, contrast imaging can potentially be done in full 3D setting (CEDBT) facilitated by synthetic 2D images (synthetic mammogram and synthetic CEDEM).

Integrated decision support for improved patient outcome
T. Manoharan; *Forchheim/DE*

In this segment we'll focus on value-based healthcare, exploring how Integrated Decision Support (IDS) can help make more precise diagnosis and therapy decisions in multi-disciplinary teams, improving patient health outcome, while keeping the clinical pathway cost-efficient. Emphasis will be placed on multi-modal data integration, including imaging, pathology, lab, genomics and other relevant clinical information.

Improving the clinical utility of digital breast tomosynthesis using novel software applications
R.M. Mann; *Nijmegen/NL*

Digital breast tomosynthesis (DBT) is rapidly replacing mammography as standard of care due to its higher sensitivity and specificity. In clinical practice, in contrast to the screening situation, images are scrutinised in depth. Furthermore, the availability of ultrasound and MRI, if needed, require the DBT findings to be appreciated in a multimodality context. To deal with the large amount of data and the demanding requirements, software applications are indispensable to aid reading. To ensure detection of all lesions within the DBT dataset, novel CAD applications may help, not only localising abnormalities on synthetic 2D slices, but also navigating directly to the most relevant slice in the tomosynthesis volume. For the rapid evaluation of findings within the tomo dataset, synthetic 3D images offer unique possibilities; showing tissue composition of possibly abnormal areas and clearly locating suspicious lesions in the breast. Novel tools that automatically segment and measure relevant findings further aid in reporting and in addition may reduce inter-reader variability. Finally, coupling studies from one modality to the next integrates the findings and allows for multimodal assessment of lesions. Consequently, current software developments have a powerful impact on the usefulness of DBT and multimodality imaging.

The future of MR mammography: radiomics?
C.G.N. Kaiser; *Mannheim/DE*

Recently, terms like big data, radiogenomics and radiomics as a basis for precision-based medicine are an increasingly common topic for discussion. In MR mammography there is also more information to be retrieved from the images than the sole question of whether invasive carcinoma is present. However, MR mammography presents more challenges than the "optimisation of the diagnostic return on investment" as the indications for MR mammography are still limited.

Personalised therapy through optimisation of diagnostic data in multi-disciplinary team decisions
R.M. Mann; *Nijmegen/NL*

How can the use of diagnostic data in multi-disciplinary team decisions be optimised to enable more personalised therapy? A paediatric cost and safety analysis of contrast-enhanced ultrasound
G.T. Yusuf; *London/UK*

Because of concern over medical ionising radiation exposure of children, contrast-enhanced ultrasound (CEUS) has generated interest as an inexpensive, ionising radiation-free alternative to CT and MRI. CEUS has received approval for paediatric hepatic use but remains off-label for a range of other applications. A retrospective study was performed to analyse adverse incidents encountered in paediatric CEUS and to assess the financial benefits of reducing the number of CT and MRI examinations performed. The records of 305 paediatric patients (187 boys, 118 girls; age range, 1 month-18 years) undergoing CEUS were reviewed. Most of the studies were for characterising liver lesions (147/305 [48.2%]) and trauma (113/305 [37.1%]); the others were for renal, vascular, and intracavitary assessment (45/305 [14.8%]). No immediate adverse reactions occurred. Delayed adverse reactions occurred in two patients (2/305 [0.7%]). These reactions were transient hypertension and transient tachycardia. Neither was symptomatic, and both were deemed not due to the underlying disorder. The potential cost savings of CEUS were $74 per examination over CT and $180 over MRI. Paediatric CEUS is a safe and potentially cost-effective imaging modality. Using it allows reduction in the ionising radiation associated with CT and in the gadolinium contrast administration, sedation, and anesthesia sometimes required for MRI.
Learning Objectives:
1. To acknowledge that paediatric CEUS is off label, but safe and useful in a wide variety of scenarios without exposure to radiation, iodinated contrast or the need for anaesthetic drugs.
2. To understand that the use of paediatric CEUS over conventional imaging pathways can result in significant cost reduction.
3. To learn about the characterisation of focal liver lesions and follow up post trauma represent two of the commonest reasons for paediatric CEUS usage.

The benefits of Shear Wave elastography in the liver
N.N.

The clinical advantages of advanced applications in the abdomen
M. D'Onofrio; *Verona/IT*

Shear Wave Elastography (SWE/ARFI) allows the assessment of the tissue stiffness. It is very important to consider that ARFI is implemented in the ultrasound scanner. Strength of the ARFI Virtual Touch Quantification technique relies in obtaining a number (meter/second or kilopascals) for the shear wave velocity generated in the explored tissue: the stiffer a tissue, the greater the numeric value. Several non-invasive methods are used for assessing liver fibrosis in order to avoid biopsy. Liver function tests and transient elastography are other non-invasive, sensitive and accurate tools. Many published studies analyse ARFI performance and feasibility in studying diffuse liver diseases and compare them to other diagnostic imaging modalities such as conventional US and transient elastography. Fewer papers describe the application of ARFI technology in the study of solid focal liver or pancreatic lesions, with different results. Contrast enhanced ultrasound can enhance the diagnosis of lesions and the use of SWE/ARFI can then improve the characterisation of these ultrasound detected pancreatic masses. Image fusion (CT/MRI & US) using eSieFusion can then be used in follow up and treatment to aid in more successful interventional exams, such as ablation procedures and response to therapies.
Learning Objectives:
1. To understand where using SWE can help in assessing tissue stiffness.
2. To understand the benefits of contrast enhanced ultrasound imaging and where it is useful in clinical practice.
3. To understand how the combination of SWE, CEUS and CT/MRI image fusion can be used to improve both detection and ablation of abdominal malignancies.

SY 12

Advances in iterative reconstruction and spectral CT: transforming the use of CT in routine practice

Moderator:
A. Vlassenbroek; Anderlecht/BE

Iterative model-based reconstruction: basis of new imaging era
D. Ippolito; *Monza/IT*

Model-based iterative reconstruction is a new image reconstruction method which models the acquisition process, leading to image optimisation acting not only in the image domain but also in the projection domain (i.e. during the acquisition process). As a result, this algorithm can better deal with low signal levels in the setting of modern low dose acquisitions; in fact IMR can provide a significant reduction in image noise and streak artifacts, an increment of contrast-to-noise ratio and a significant improvement in spatial resolution, creating virtual “noise free” diagnostic images. Therefore the use of IMR may further improve the sensitivity and specificity of lesion’s detection also in follow-up CT studies in different clinical setting (i.e. angiographic study, oncologic fields, emergency examinations), due to the increase of small details evidence. In summary, the main advantages of IMR in clinical practice are represented by high contrast resolution, subtle attenuation differences, applications in no compliant patients or patients with limited IV access or suboptimal acquisition timing, use of reduced radiation and contrast dose.

Spectral CT for emergency imaging: luxury or necessity
E. Danse; *Brussels/BE*

This lecture is focused on the interest of dual layer spectral scanner detectors for its routine use in the visceral emergency spectrum, including severe traumatised patient, bowel obstruction and ischemic disorders, genitourinary, pancreatic and hepatobiliary situations. Spectral CT for acute aortic and peripheral arteries disorders will be also presented. Additionally, we propose to share our way of process for the analysis and the report of CT examinations done with the spectral system, compared to the conventional CT.

The clinical validation of spectral benefits
D. Maintz; *Cologne/DE*

Spectral Detector CT offers new possibilities regarding image quality, dose reduction and diagnostic performance in clinical computed tomography. Using virtual monoenergetic images the contrast-to-noise ratio can be significantly increased and using material decomposition maps, such as e.g. iodine-maps, quantitative measurements of tissue components can be obtained. Over the last years systematic studies have been performed to evaluate the benefits in image quality, lesion detection and lesion characterisation. This lecture presents the scientific state-of-the-art and also gives an outlook on future spectral benefits.

Innovations in Samsung's Digital Radiography Technologies

Experiences with Samsung's Digital Radiography at Freiburg University Hospital
E. Kotter; *Freiburg/DE*

Initial experiences with Samsung's Digital Radiography (DR) technology at Freiburg University Hospital will be presented. Two specific DR technology utilising the deep-learning (DL) algorithms and their preliminary results will be introduced - bone suppression imaging (BS) and computer-aided detection (CAD) for lung cancer nodules. First, application of bone suppression imaging (BS) for various subtle lung lesions will be shown. Second, computer-aided detection (CAD) technology for lung cancer nodule detection will be introduced. The detection accuracies of CAD system, radiologists, and radiologists with CAD assistance in reading chest PA digital radiography images will be compared.

Value of x-ray in the diagnosis and follow-up of rheumatic diseases
K.-G.A. Hermann; *Berlin/DE*

Initial experiences with Samsung's low-dose Digital Radiography technology will be presented. The speaker will share preliminary impressions from applying S-vue (TM) technology to diagnosis and follow-up of patients with rheumatic diseases of hands and feet.

Innovations in digital radiography dose reduction by Samsung

Post-treatment evaluation: what every radiologist should know: A. Thoracic aorta (RC 815), A-357

Leiner T.
How can radiologists expand their role in peripheral vascular intervention?: How to improve your diagnostic skills (PC 9), A-430

Leiser P., Schoettler J., Centner F.S., Kirschning T., Krebs J., Hagmann M., Weiß C., Schönberg S.O., Haubenreisser H.
Quantitative CT as a one-stop shop to describe status and outcome of patients with acute respiratory distress syndrome (ARDS) (SS 304), B-0243

Leithner D., Wengert G.J., Weber M., Helbich T.H., Kapetas P., Baltzer P.A.T., Morris E.A., Karanikas G., Pinker K.
Implementation of imaging biomarkers of healthy breast tissue with multiparametric [18F]FDG-PET/MRI may aid breast cancer diagnosis (SS 602), B-0506

Leithner D., Helbich T.H., Bernard-Davila B., Wengert G.J., Kapetas P., Baltzer P.A.T., Haug A., Morris E.A., Pinker K.
Are there differences in multiparametric breast [18F]FDG-PET/MR imaging biomarkers of contralateral healthy tissue in patients with and without breast cancer? (SS 602), B-0507

Leithner D., Kaltenbach B., Park C., Pinker K., Hoedl P., Stephan F., Moebus V., Vogl T.J., Müller-Schimpfle M.P.
Intraductal papilloma without atypia in breast biopsies: rate of upgrades to carcinoma at excision and radiological features predictive of an upgrade (SS 1402a), B-1091

Lell M.
Pathways for tumour spread: B. Pathways for nasopharyngeal tumour spread including perineural spread (RC 408), A-111

Lenga L., Leithner D., Albrecht M.H., Booz C., Wichmann J.L., Vogl T.J., Martin S.S.
Dual-energy CT in patients with abdominal malignant lymphoma: impact of noise-optimised virtual monoenergetic imaging on objective and subjective image quality (SS 1901a), B-1515

Lenkinski R.
Gd retention: back to basics (SY 17)

Lennartz S., Le Blanc M., Abdullayev N., Grosse Hokamp N., Maintz D., Borggrefe J., Persigehl T.
Improved detection of skeletal muscle metastases in iodine-density overlay maps and virtual monoenergetic reconstructions provided by spectral detector CT (MY 3), B-0377

Lennartz S., Le Blanc M., Grosse Hokamp N., Maintz D., Persigehl T.
Iodine density obtained with spectral detector CT is a predictor for lesion dignity of pleural thickening (SS 616), B-0587

Leonardi A., Napoli A., Scipione R., Anzidei M., Dababou S., Catalano C.
Lung adenocarcinoma radiogenomics predicts clinical outcome (SS 1004), B-0875

Leone F., Orsi M., Presazzi A., Mariani D., Cellina M., Oliva G.
Screening mammography's pitfalls: a retrospective review of false positive recall (SS 702), B-0683

Lerchbaumer M.H., Rübenthaler J., Putz F.J., Slowinski T., Clevert D.A., Jung E., Fischer T.
Value of contrast enhanced ultrasound in evaluation of cystic renal lesions compared to computed tomography and magnetic resonance Imaging (SS 207), B-0055

Lesyuk O., Ribeiro L.P., Abrantes A.F., Sousa P., Rodrigues S., Almeida R.P., Azevedo K.B., Pinheiro J.P.
Study of scattered radiation during fluoroscopy in hip surgery (SS 1814), B-1445

Lev Cohain N., Leichter I., Sosna J.
Are there suboptimal CTPE studies in the DECT era: low mono-energetic images for pulmonary artery assessment (SS 604), B-0457

Lewis S., Pieterse T., Rainford L.A., Lawrence H.
Evaluating the use of detector dose indicators in digital x-ray imaging systems (SS 1914), B-1646

Li C., Li M., Jin L.
Application of high-pitch scanning mode in low-dose lung-computed tomography screening for patients with chronic obstructive pulmonary disease: a pilot study (MY 5), B-0408

Li H., Hu X., Zhang L., Lu L., Bu X., Tang S., Huang X.
Investigating direction of effective connectivity in obsessive compulsive disorder with resting state fMRI (SS 711a), B-0653

Li H., Chen G.W., Chen X.L.
Diffusion-weighted MR-volumetry and high-resolution MR-volumetry association with lymphovascular invasion and N-stages in resectable rectal cancer (SS 1001b), B-0846

Li J., Song Y., Wu Y., Cai H., Li L.
Characterising mammographic calcification as a prognostic biomarker for breast tumour phenotypes (MY 16), B-1279

Li J., Zhang C., Liu H., Yang S., Wang Y., Chen W., Wang D.
Diagnostic performance in the stage of liver fibrosis: comparison of magnetic resonance T1 rho and acoustic radiation force impulse (SS 1801), B-1323

Li T., Yang L.
Cardiac CT for demonstrating non-calcified coronary atherosclerotic plaque: effect of knowledge-based iterative model reconstruction on image quality (SS 703), B-0756

Li T., Han X.
Analysis of remodeling in abdomial aortic branch perfusion patterns complicated by type B aortic dissection after thoracic endovascular aortic repair (SS 309), B-0225

Li T., Li K., Xiong Y.
A comparative study of the DKI model and the traditional DWI model in the diagnosis of breast cancer (SS 1402b), B-1110

Li T., Xiong Y., Li K.
Preoperative diagnostic value of DKI combined with quantitative dynamic contrast-enhanced MRI in breast lesions (SS 1402b), B-1111

Li X.
A glance of China through images: Interventional therapy for hepatocellular carcinoma: Chinese experiences (EM 3), A-949

Li X., Huang S., Fang Z., Li Z.
Magnetisation transfer MRI can characterise the degree of intestinal fibrosis in patients with Crohn's disease: comparing with contrast-enhanced and diffusion-weighted MRI (SS 1901c), B-1531

Li Y., Dai Y., Guo Y.
Morphological study of blood vessels near lung tumour by the 3D quantitative CT technique (MY 5), B-0409

Authors' Index

Li Y., Beiderwellen K.J., Nensa F., Herrmann K., Jost L., Umutlu L.
Detection of inflammatory bowel segments with [18F]-FDG PET/MR enterography by Crohn's disease: which surrogate marker is better? MaRIA, Clermont score or PET?
(SS 1901c), B-1534

Li Y., Zhang F., Zhao S., Jin G., Zhao L., Zhou Y., Li P., Yang X.
Radiofrequency hyperthermia-enhanced intratumoral herpes simplex virus-thymidine kinase (HSV-TK) gene therapy of ovarian cancer: monitored by ultrasound and optical imaging (SS 1406), B-1172

Li Y., Ren C., Cheng J.
Feasibility study of intra-voxel incoherent motion MR imaging for the differentiation of benign and malignant soft tissue tumours (SS 210), B-0111

Li Y., Fan F., Feng Z., Liang W., Tan S., Yang F.
Structural magnetic resonance imaging study on schizophrenic patients with violence risk
(SS 711a), B-0654

Yadav A., Bagarhatta M., Jaipal U.
PI-RADS version 2-based assessment of prostate in patients with borderline-elevated prostate-specific antigen levels: a prospective study (SS 1807a), B-1362

Yagami K., Miyoshi T., Shigeyama S., Okada H., Suzuki S., Foley S.J.
Effective dose calculations of trunk CT scans in single-energy CT (SECT) and fast kVp switching dual-energy CT (FKS-CT) (SS 314), B-0324

Yamada A., Nonaka T., Nakamura M., Suzuki T., Komatsu D., Fujita S., Fujinaga Y., Kadoya M.
Evaluation of T1 measurement methods of the liver in chronic liver disease (SS 1801), B-1315

Yamamura J., Aigner A., Schramm C., Zenouzi R., Adam G., Keller S.
Assessment of histological stage of fibrosis using relative liver enhancement in patients with primary sclerosing cholangitis (SS 1801), B-1317

Yamamura J., Sedlacik J., Schuler T., Buchert R., Kooijman-Kurfuerst H., Schramm C., Fiehler J., Adam G., Keller S.
The potential role of Gadoxetate disodium (Gd-EOB-DTPA) and diffusion-weighted magnetic resonance imaging in primary sclerosing cholangitis (SS 1801), B-1319

Yan F.
A glance of China through images: Multiparameteric analysis in imaging liver disease (EM 3), A-947

Yang I., Wu B.
Locally advanced rectal cancer: the value of whole-tumour histogram-based texture analysis of baseline ADC map in predicting tumour response to neoadjuvant chemoradiotherapy (SS 1001b), B-0849

Yang L.
The concentration of iodine in perigastric adipose tissue: a novel index for assessment of serosal invasion in patients with gastric cancer after neoadjuvant chemotherapy (SS 701b), B-0709

Yang L., Zeng M., Rao S.
Assessing liver fibrosis with diffusion-weighted MRI: comparison between conventional and kurtosis models (SS 1801), B-1318

Yang L., Hou Y., Ma Y., Jia Z., Lu X.
Study on the optimum keV and different contrast agent concentration in coronary stent imaging using spectral CT: in vitro study (SS 703), B-0759

Yang Q., Yu T., Huang J., Su Y., Li J., Liang B.
Application of T1rho in evaluating liver fibrosis and correlation with liver function (SS 201a), B-0004

Yang S., Lu F., Zhan S.
USPIO-enhanced MRI study on electroacupuncture alleviating inflammatory response of permanent focal subacute-stage cerebral ischaemia in rats (SS 1011b), B-0999

Yang X., Miller E., Subramanian P., Williams T.M., Knopp M.V.
Multi-parametric MRI assessment of acute response to stereotactic body radiation therapy in patients with hepatocellular carcinoma or non-small cell lung cancer (SS 1416), B-1079

Yang Z., Jin H., Kim J.
A noise-robust and accurate measurement method for the wall thickness of small airways in low-dose CT scans (SS 713), B-0735

Yazicioglu Y., Pinker K., Tahmassebi A., Meyer-Baese A.
Determining leader nodes in dementia networks (SS 1411a), B-1036

Yilmaz P., Ikram M., Niessen W.J., Ikram M., Vernooij M.W.
Sum score of cerebral small vessel disease relates to risk of stroke, dementia and mortality in the Rotterdam study (MY 8), B-0797

Yim J., Kim Y.
Diagnostic efficacy of conventional gadolinium-enhanced MRI in the detection of recurrent hepatocellular carcinoma: intra-individual comparison with gadoxetic acid-enhanced MRI (SS 301a), B-0197

Yim Y., Kim J.Y., Jung S.C., Lee B.E., Kim S.J., Kim H.S., Lee D.H., Choi C.G., Park J.E.
Diagnosticperformance of three-dimensional high resolution magnetic resonanceimaging for intracranial aneurysms: comparison with digital subtractionangiography (SS 711b), B-0693

Authors' Index

Yin X., Gao F., Wang G.
Altered hippocampal GABA and glutamate levels and functional connectivity in multiple sclerosis (SS 311), B-0279

Ying T.M., Li Y., Wu W.C.V., Yuan C., Kwong L.W.D., Yip S.P., Law K.W.H., Lee W.Y.S.
Are there any differences in radiation-induced and non-radiation-induced carotid atherosclerosis? (SS 315), B-0217

Ying T.M., Cheng S., Ahuja A.
Computer-aided quantification of intranodal vascularity enhanced the accuracy of ultrasound in distinguishing metastatic and tuberculous cervical lymph nodes (SS 1508), B-1214

Yiqun S., Tong T.T., Gu Y.J.
Radiomic features from pretreatment MRI are associated with prognosis in rectal cancer patients: preliminary findings (SS 216), B-0163

Yoneda T., Iwata M., Indo H., Kurehana N., Yoshinaga S., Takeda M., Terasawa H.
ROI-based phase analysis for neuronal current MRI (SS 713), B-0738

Yoon D., Moon S.
Subtalar instability and lateral ankle instability: the difference with emphasis on subtalar ligaments using 3-D isotropic MRI (SS 710b), B-0724

Yoon J., Kim E., Okuaki T., Lee J.
Liver function estimation using gadoxetic acid-enhanced liver MRI (SS 1801), B-1321

Yoon S., Na D., Gwon H.
Diagnostic performance of US-based fine-needle aspiration criteria for thyroid malignancy: comparison of three international society thyroid imaging reporting and data systems (SS 708), B-0672

Yoshida M., Enokido K., Nishiyama T.
The diagnostic performance of automated breast ultrasound (ABUS) compared with handheld ultrasound (HHUS) (SS 202b), B-0106

Young L.K., Matthew S., Houston G.
Investigating potential gadolinium toxicity to gadoterate meglumine (Dotarem) in local renally insufficient adult and paediatric populations using bioinformatics data linkage (SS 1905), B-1585

Yousry T.A.
Radiologic anatomy: neuro: Cortical anatomy and primary functional areas (ESR/ESOR 3), A-561

Yousry T.A.
My three top tips for neuroimaging: Movement disorders (SF 15c), A-761

Yu Q., Quan X., Lu X.
Correlation analysis of quantitative CT parameters and pulmonary function in COPD patients (SS 304), B-0233

Yu Y., Ren Y., Pang H., Yao Z.
Quantitative T1rho-weighted magnetic resonance imaging in gliomas: a preliminary study of its biochemical mechanism (SS 1811b), B-1482

Yuan B., Zhang W., Lu X., Jia Z.
Evaluation of diagnostic value of iodine base material of dual-detector spectral CT for pulmonary aspergillosis invasion by ROC (SS 604), B-0456

Yuan Q.Q.
Study of image quality in chest CT using prospective ASIR-V (SS 704), B-0636

Yue Y., Lu X., Guo Q.
Oligaemia of tumour-involved lung displayed by Z-effect of dual-detector spectral CT (SS 604), B-0454

Yue Y., Lu X., Zhang W., Guo Q.
Segmental and sub-segmental pulmonary embolism displayed by dual-detector spectral CT (SS 604), B-0464

Yuekao L.
Early residual tumour differentiation from benign periablational thermal injury after radiofrequency ablation by spectral analysis with dual-energy computed tomography (MY 5), B-0418

Yun G., Kim Y., Lee Y.
Tumour heterogeneity of pancreas head cancer assessed by CT texture analysis: association with survival outcomes after curative resection (SS 201b), B-0020

Yun G., Yoon C., Seong N., Byeon J., Lee H., Kim Y.
Percutaneous treatment of postoperative benign hepaticojejunostomy strictures: temporary placement of covered metallic stents versus balloon dilation (SS 209), B-0032

Yun G., Kim Y., Choi S.
Sonographic features of medullary thyroid carcinoma: application of Thyroid Imaging Reporting and Data System (TIRADS) classification (SS 708), B-0664

Yusuf G.T.
A paediatric cost and safety analysis of contrast-enhanced ultrasound (SY 11)

Z

Zaccagna F., Riemer F., McLean M.A., Grist J.T., Schulte R., Watts C., Price S.J., Graves M.J., Gallagher F.A.
^{23}Na-MRI demonstrates a sodium gradient within gliomas as a biomarker of tumour heterogeneity (SS 1911b), B-1672
